LEXICON—Part 2, M-Z

Mabb amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan (Keweenaw Point).

L. L. Hubbard, 1898 (Mich. Geol. Surv., vol. 6, pt. 2, pp. 132, 135, 136). Cgl. No. 3 can be traced for only a short distance back of Houghton, beyond the old workings of *Mabbs vein* in sec. 1, T. 54, R. 34. The cgl. lies upwards of 100 ft. E. of Mabbs vein. [*Mabbs vein* was used by A. R. Marvine (in Mich. Geol. Surv. vol. 1, pt. 2, 1873, pp. 17, 63) and probably other early writers.]

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 34, 58, 190, 229, 472, pl. X, fig. 44). The *Mabb ophite* of Isle Royale section is over 200 ft. thick and lies just above Lac la Belle cgl. Is exposed in old Mabb workings [Houghton Co.] and dump and along N. line of sec. 6–55–33. [This rock has for many years been called *Mabb amygdaloid.*]

Belongs to Bohemian Range group. Is younger than Baltic West amygdaloid. The mineralized part is the Mabb lode.

Mabb flow.

Includes Mabb amygdaloid and the underlying trap.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Mabou formation.

Carboniferous: Nova Scotia (Cape Breton Island).

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 323).

P. D. Trask, 1929 (Nova Scotia Rept. on Mines 1928, p. 285).

McAdam formation.

Silurian: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 203). [Assigned to Sil.]

Many later repts, by other geologists, assign this fm. to Sil.

McAlester formation. (Also **McAlester shale.**)

Pennsylvanian (Allegheny): Eastern Oklahoma and western Arkansas coal field.

J. A. Taff, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 437). *McAlester sh.*—Consists of (ascending): (1) 800 ft. of sh. with thin ss. and coal, the Hartshorne or Grady coal at or just above base; (2) three or four beds of ss. separated by sh. beds, 100 to 200 ft. thick, aggregating 500 ft.; and (3) 700 ft. of blue, gray, or black sh., with McAlester coal about 50 ft. above base and several thin coals higher up. Overlies Hartshorne ss. and underlies Savanna ss.

In 1907 (U. S. G. S. Bull. 326) the McAlester sh. was raised to rank of a *group* in Ark. coal field, where its supposed equivalents were named (descending) *Paris sh., Fort Smith fm.,* and *Spadra sh.,* the ss. overlying Paris sh. being supposed to correspond to true *Savanna ss.* of Okla. Later work (by T. A. Hendricks and C. B. Read) led to opinion that true Savanna ss. of Okla. corresponded to lower part of Savanna ss., the Paris sh., and upper part of Fort Smith fm. of Ark. (See A. A. P. G. Bull. vol. 18, No. 8, 1934, pp. 1050–1058.) Subsequent work (by B. Parks and T. A. Hendricks) led to (1) identification of Boggy sh. of Okla. with so-called Savanna ss. and upper part of Paris sh. of Ark. coal field; (2) identification of true Savanna ss. of Okla. with lower part of Paris sh. and upper part of Fort Smith fm. of Ark.; and (3) identification of lower part of Fort Smith fm. and Spadra sh. of Ark. with true McAlester sh. of Okla. They therefore extended the Okla. names (descending) Boggy sh., Savanna ss., and McAlester sh. into Ark. coal field, to replace so-called Savanna ss., Paris sh., Fort Smith fm., and Spadra sh. of that area, all of which names were discarded, as was McAlester *group* as used in Ark.

The base of McAlester sh. in Okla. is drawn at top of 1st ss. below Upper Hartshorne coal, and in Ark. at top of 1st ss. below Lower Hartshorne coal.

Named for exposures around McAlester, Pittsburg Co., Okla.

McAras Brook formation.

Mississippian: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 244).

McArthur member. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio (Vinton and Jackson Counties).

H. Morningstar, 1922 (Ohio Geol. Surv., 4th ser., Bull. 25, p. 116). *McArthur memb.*—Consists of (1) 4 ft. of sh., in places sparingly fossiliferous, and shaly calc. sss., underlain by (2) 1½ ft. of impure ls. or calc. sh., not persistent but very fossiliferous. Is of marine origin. Overlain by Homewood sh. and ss. and underlain by Tionesta or No. 33 coal. Named by Stout in 1919 [where?] McArthur ls., from typical exposures in vicinity of McArthur, central part of Vinton Co., where the memb. consists of massive bluish gray ls., very fossiliferous. Thickness 2 to 14 ft. Best developed in Vinton and Jackson Counties, but pinches out and disappears S. of Monroe Furnace in S. part of Jackson Co.

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, p. 170, footnote). Putnam Hill ls. of central Ohio is correlative with McArthur memb. of Morningstar (Bull. 25) of Vinton Co., and in this (Vinton Co.) rept is called Putnam Hill ls.

W. Stout, 1930 (Letter dated Feb. 25). *McArthur ls.* is only a shaly phase of the Putnam Hill of central Ohio, being very dissimilar, however, in fossils and lithologically. The name has been dropped, and the fossils should be credited to Putnam Hill.

Macastey black shale.

Macasty black shales.

A. F. Foerste, 1924 (Canada Geol. Surv. Mem. 138, p. 2), mentioned (but did not describe) that *Macastey black sh.* of Anticosti Island is certainly of Utica (Upper Ord.) age.

W. H. Twenhofel, 1928 (Canada Geol. Surv. Mem. 154, p. 22), described (under heading) *Macasty black sh.*, and in the description (pp. 22, 23) referred to Makasti Cliff, Makasti Bay, and Makasti Hill.

McBean formation.

Eocene (Claiborne): Eastern Georgia and western and central South Carolina.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, pp. 60, 237–284). *McBean fm.*—Mainly clays, in nature of fullers earth, shell marls, sandy lss., and calc. glauconitic sands; the marls are for most part massive bedded and friable, but hard, compact, and even partially silicified beds were noted on Savannah River. Basal bed of McBean fm. consists principally of fullers earth and drab or greenish sandy clays, here called *Congaree clay memb.* [p. 268]. Thickness of fm. 100 to 400 ft. Underlies Barnwell sand and overlies Wilcox fm. Is a shallow-water marine deposit included in Claiborne group, along with Barnwell sand. *Ostrea georgiana* zone at Shell Bluff, on Savannah River, Ga., is top memb. of McBean fm.

C. W. Cooke and H. K. Shearer, 1918 (U. S. G. S. P. P. 120C), showed that the faunas of Barnwell sand and of *Ostrea georgiana* zone are of Jackson age, and restricted Claiborne group of Ga. and McBean fm. to the beds beneath *Ostrea georgiana* zone and above Wilcox fm., including the *Ostrea georgiana* zone in Barnwell fm. They also showed that Congaree clay memb. of Veatch and Stephenson does not lie at base of Claiborne group and of McBean fm., but that it is of Jackson age and much younger than Congaree shales of Sloan, to which it was supposed to be equiv. They therefore discarded Congaree clay, renamed the beds *Twiggs clay memb.*, and included them in Barnwell fm. They showed (p. 53) *Ostrea georgiana* zone to be contemp. with lower part of Twiggs clay memb., and that Twiggs memb. thins out in Ga. near Savannah River and is absent in S. C. These are the definitions of McBean and Barnwell fms. at present used by U. S. Geol. Survey.

Named for exposures at McBean and on McBean Creek, in Richmond Co., eastern Ga.

McCann sandstone.

Permian: Central northern Oklahoma (Kay County).

C. N. Gould, 1900 (Kans. Univ. Quart., vol. 9, pp. 175–177). *McCann ss.*—Dark-red or mottled ss., 2 to 5 ft. thick, forming basal ledge of Harper fm. Not known to have any counterpart in Kans. It forms dividing line from blue to red shales, or from the Wellington to the Harper. Named for McCann's quarry, on Deer Creek, 20 mi. SW. of Blackwell, Kay Co.

C. N. Gould, 1927 (Obsolete Okla. names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, p. 235). *McCann ss.* died a natural death.

McCarthy shale (also **formation**).

Upper Triassic: Alaska (Nizina-Tanana region).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 426). *McCarthy Creek shales.*—A series of soft black, highly fissile shales and slates, typically exposed on McCarthy Creek. Rest on Chitistone ls. Underlie (uncon.?) Kennicott series. Contain Triassic fossils.

The simplified name *McCarthy sh.* has been in use many years. The underlying fm. is now known as *Nizina ls.*, a name introduced many years ago for the upper thin-bedded lss. composing top part of Chitistone ls. as originally defined, Chitistone now being restricted to the massive lss. forming lower part of the original Chitistone.

†McCarthy Creek shale.

See under *McCarthy sh.*

McCartys basalt flow.

See under *Laguna basalt flow.*

McCaulley dolomite.

Permian: Central northern Texas (Fisher County).

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, p. 26, pl. 1). *McCaulley dol.*—A series of white, chalky dolomites comprising a thickness of 3 to 20 ft., consisting of 1-in. to 1-ft. dolomites separated by 6-in. to 1-ft. partings of red and blue shales. Part of town of McCaulley, Fisher Co., rests on this dol. Is older than Aspermont dol. and younger than Guthrie dol. Included in Double Mtn group.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, p. 951, pl. 9). Acme dol., which lies 64 ft. above Mangum dol. and 90 ft. below Guthrie dol., can be correlated with reasonable certainty with McCaulley beds of Fisher Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). Acme dol. is probably same as McCaulley dol., and McCaulley dol. is discarded, as Acme is in more general use.

McClearys Bluff formation.

Pennsylvanian: Indiana.

See 1935 entry under *St. Wendell ss.*

McClesky sand.

A subsurface sand, 10 to 50 ft. thick, in Marble Falls ls. (Penn.) of Ranger and other fields of central northern Tex. Lies 170 to 230 ft. below top of Black lime, which is also in Marble Falls ls.

McClosky sand.

Name that has been applied to subsurface sands in Ste. Genevieve ls. and overlying rocks of Chester group (Miss.) of Ind. and Ill. (See Ill. Geol. Surv. Bull. 54, index.) In western Ky. (see Ky. Geol. Surv. ser. 6, vol. 42, 1931, frontispiece) the name has been applied to a sand that is said to lie 150 ft. below top of Ste. Genevieve ls.

McCloud limestone.

Permian (?): Northern California (Redding region).

H. W. Fairbanks, July 1894 (Am. Geol., vol. 14, pp. 29–30). The ls. peaks along E. side of the McCloud extend in N.-S. direction, but strike of strata is about N. 30° W. The repetition of the ls. bodies in N.-S. direction, as well as that of the fossiliferous beds along the river, is undoubtedy due to sharp folding or faulting. If this were not so the thickness of the ls. would be immense. The *McCloud lss.* are considered by Mr. [J. P.] Smith as belonging to Upper Carbf.

J. P. Smith, October 1894 (Jour. Geol., vol. 2, pp. 592, 599–601). Immediately above Baird shales, and probably conformably with them, lies *McCloud ls.*, consisting of about 2,000 ft. of massive lss. and marbles of McCloud river, rich in corals and brachiopods. Underlies McCloud shales [Nosoni fm.]. Form upper div. of McCloud fm.

Later treated as distinct fm., overlying Baird sh. and underlying Nosoni fm. (†McCloud shales).

N. E. A. Hinds, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 274, and Calif. Univ. Dept. Geol. Sci. Bull. 20, p. 403), assigned McCloud ls. to Perm., as did H. E. Wheeler, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 218). The U. S. Geol. Survey at present classifies this fm. as *Perm. (?)*.

†McCloud shales.

Permian: Northern California (Redding region).

H. W. Fairbanks, July 1894 (Am. Geol., vol. 14, p. 30). The uppermost horizon of fossiliferous strata on the McCloud occurs about 20 mi. above the Fisheries on E. side of the river. Here is found a calc. argillite rich in several species of *Productus*, besides other forms, which according to Mr. Smith belong in upper part of Carbf. These argillitic lss. and associated shales are embraced under designation *McCloud shales*.

J. P. Smith, October 1894 (Jour. Geol., vol. 2, pp. 592, 601–602). *McCloud shales.*—Siliceous and calc. shales and cgls., with Upper Carbf. fauna at base. Occurs on E. bank of McCloud River, about 20 mi. N. of U. S. Fisheries. Thickness 1,000 ft. Basal fm. of Pitt fm. Underlies Pitt shales and overlies McCloud ls.

Same as Nosoni fm., which is now classified as Perm.

†McCloud formation.

Permian (?) and Mississippian: Northern California (Redding region).

J. P. Smith, 1894 (Jour. Geol., vol. 2, pp. 592–593). *McCloud fm.* (H. W. Fairbanks ms.) is especially well developed in region of McCloud River in Shasta Co., and from this it receives its name. Divided into Baird shales (Lower Carbf.), 500 ft. thick, overlain by McCloud ls. (Upper Carbf.), 2,000 ft. thick. Is overlain by McCloud shales [Nosoni fm.], basal fm. of Pitt fm., and underlain by Sacramento fm. (Kennett lss. and shales).

Unnecessary name, with conflicting usages. Includes Baird sh. (Miss.) and McCloud ls. (Perm. ?).

McClure sandstone member (of Norton formation).

Pennsylvanian: Southwestern Virginia.

J. B. Eby, 1923 (Va. Geol. Surv. Bull. 24, pp. 63, 67). *McClure ss. memb.*—Lies near middle of Norton fm., just below Kennedy coal. Consists of coarse ss. 50 to 200 ft. thick. On Pine Mtn it is sparingly conglomeratic.

Named for McClure River, Dickinson Co.

McCoy formation.

Pennsylvanian: Northwestern Colorado (northern part of Eagle County).

R. Roth, 1930 (A. A. P. G. Bull., vol. 14, No. 9, pp. 1265–1267). The Penn. sediments at McCoy, Eagle Co., Colo., are here given name *McCoy fm.* for following reasons: The beds form lower part of so-called "Undifferentiated Carboniferous" on Colo. State geol. map. The contained fauna is a unit and cannot be divided into zones. Correlation with Mid-Continent Cherokee sh. can be made precisely. The fm. is unique. It is very fossiliferous, fossils occurring in thin beds of ls. and black sh., which are separated from each other by beds of red shales and massive arkosic cgls. 50 ft. or more thick. Thickness of the cgls. above the measured section is unknown. Includes at base 200± ft. of thin-bedded pink qtzites, interbedded with maroon and red micaceous shales, which are separated from rest of fm. by seeming uncon., probably due to deltaic nature of sediments. General aspect of all fossils seems to be lower Cherokee. Thickness of measured section of fm. at McCoy aggregates 1,011 ft. It rests on undiff. Camb. or Ord. and granite.

R. Roth, 1934 (A. A. P. G. Bull., vol. 18, No. 7, p. 947). A comparison of fauna of Hermosa fm. with that of McCoy fm. shows them to be identical and therefore equiv. in age.

McCoytown sandstone.

Silurian: Central Pennsylvania.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, p. xxvii). *McCoytown ss.*—Near middle of the lower red shales of Clinton fm. of Juniata dist., occur layers of soft brown ss. from 6 in. to 2 ft. thick, which break with square fracture. Near McCoytown, in Tuscarora Valley, these layers become very hard and siliceous and exhibit on the surface numerous quartz crystals.

Maccrady shale.

Mississippian (Osage): Southwestern Virginia.

G. W. Stose, 1913 (U. S. G. S. Bull. 530, pp. 233, 234). *Maccrady fm.*—Underlies Newman ls. and overlies Price ss. Replaces "Pulaski sh.," preoccupied. Thickness 1,025 ft. Consists of (descending): (1) Earthy ls. and sh., abundantly fossiliferous, dark gray, weathering lighter and crumbly, 470± ft.; (2) gray ss., mostly calc. and crumbly, and shaly argill. or earthy ls., fossils at top, 240 ft.; (3) soft rocks, including shaly ls. and probably earthy ss. and red sh., 225 ft.; (4) upper part red sh. and shaly ss. with some gray shaly ss.; lower part soft light-buff sh. with thin black carbonaceous sh. and coal seamlets, 90 ft. Best section measured at Maccrady [Smyth Co.], for which the fm. is named.

C. Butts, 1927 (Va. Geol. Surv. Bull. 27). It is doubtful if typical "Pulaski sh." includes any representative of ls. of Warsaw age, as does typical Maccrady. In author's opinion *Maccrady* should be *restricted* to the red beds of pre-Warsaw age, and the beds of Warsaw age should be called *Warsaw ls.* [This *restricted definition* of *Maccrady sh.* was adopted by U. S. Geol. Survey in Dec. 1931.]

C. Butts, 1933 (Va. Geol. Surv. Bull. 42, pp. 37–38). In his original definition Stose included in the Maccrady the overlying ls. of Warsaw age, here separated as a distinct fm. *Maccrady sh.* as here *restricted* is a red sh. or mudrock with less red argill. ss. Stose believes that the salt and gyp. at Saltville are in the Maccrady. In Greendale syncline the Maccrady is 50 to 60 ft. thick, where its top is defined by overlying ls. of Warsaw age, and as much as 500 ft. thick in Pulaski-Blacksburg region, where even with this thickness it is not known to be all present, owing to overthrust faulting.

McCum limestone.

Misprint for *McCune ls.*, U. S. G. S. Bull. 191, p. 247.

McCune limestone.

Middle Ordovician: Central eastern Missouri.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 61). *McCune ls.*—Very fossiliferous massive buff dolomitic ls., 25 or 30 ft. thick, forming upper part of what has heretofore been called *Trenton* in NE. Mo. Overlies Bryant ls. and underlies Buffalo sh. in Pike and Lincoln Counties. [In later repts Keyes gave thickness as 50 ft.]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), showed *McCune dol.* as of Trenton age, as uncon. underlying Fernvale ls., and as overlying Prosser ls. (of basal Trenton age); and he defined Kimmswick ls. as consisting wholly of beds of late Black River age. This definition was repeated by R. S. Bassler, 1915.

A. F. Foerste, 1920 (Denison Univ. Bull. Jour. Sci. Lab., vol. 19, pp. 175+). Kimmswick ls. (broad sense) is=McCune ls. of Keyes (1898). [This same statement was made by Keyes, 1923 (Pan-Am. Geol., vol. 39, pp. 67–70).]

J. H. Bradley, Jr., 1925 (Jour. Geol. vol. 33, pp. 53–54, 65, 69). [See 1925 entry under *Kimmswick ls.*]

The Kimmswick ls. is now considered to be of Trenton age, possibly including some beds of Black River age at base.

Named for exposures near McCune Station, Pike Co.

McCurtain shale member (of McAlester shale).

Pennsylvanian: Eastern Oklahoma (Muskogee, Haskell, McIntosh, and adjacent Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *McCurtain sh. memb. of McAlester sh.*—Almost wholly dark-blue fissile sh., containing several layers of iron concretions, and (10 in. to 4 ft. above base) the Upper Hartshorne coal. Thickness in Muskogee-Porum area 144± ft. Basal memb. of McAlester sh. Is overlain by Warner ss. memb. Named for fact McCurtain, Haskell Co., is built on this sh.

McDermott formation.

Upper Cretaceous: Northwestern New Mexico (San Juan Basin) and southwestern Colorado.

J. B. Reeside, Jr. 1924 (U. S. G. S. P. P. 134, pp. 22–25). *McDermott fm.*—A series of lenticular sss., shales, and cgls. containing much andesitic debris and usually in part of purple color. Thickness at most places in Colo. 200 to 400 ft.; in northern San Juan Co., N. Mex. 150 to 200 ft.; to S. of San Juan River 30 to 50 ft. Except near Durango, Colo., the McDermott seems to be conformable with underlying Kirtland sh. restricted and bdy to be arbitrary. In Durango region it appears to be uncon. with Kirtland. In Colo. it is in places uncon. overlain by Animas fm. (restricted) and in other places the younger Torrejon fm. uncon. overlies it. In N. Mex. it is uncon. overlain by Ojo Alamo ss. restricted. The McDermott fm. in Colo. was included in lower part of "Animas River beds" of Cross (1896) and Animas fm. of Gardner (1909). It is same as Animas fm. of Shaler (1907). In N. Mex. it was included in upper part of Ojo Alamo beds of Brown (1910), in uppermost part of Kirtland sh. of Bauer (1916), and in Ojo Alamo ss. in part and in Kirtland sh. in part of Bauer and Reeside (1921). It is here tentatively assigned to Cret. (?), because of somewhat conflicting paleontologic evidence, which, however, on the whole seems to favor Cret. age. Named for McDermott Arroyo, SW. part of La Plata Co., Colo.

This fm. is now classified as Upper Cret., since it underlies Ojo Alamo ss., which is demonstrably of that age.

MacDonald formation.

Pre-Cambrian: Southern British Columbia and northwestern Montana (Galton Range).

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 2, 3). *MacDonald fm.*—Thin- to thick-bedded gray metargillite with rare lenses of dol. [MacDonald Range, B. C., is on this sheet and MacDonald fm. is mapped there.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 101, 178). Chiefly metargillite. Top 700 ft. weathers light brown or buff, a few gray beds; middle 1,100 ft. weathers light gray; lower 550 ft. weathers light brown or brownish gray. Underlies Wigwam fm. and rests, with some abruptness, on Hefty fm. Named for fact it underlies extensive surface in MacDonald Range, B. C.

McDonald sand.

A subsurface sand, of probable late Upper Dev. age, in western Pa. and W. Va. Younger than Bayard or Sixth sand and probably=Fifth sand. Is older than Gordon or Third sand. Named for McDonald oil field, Washington Co., Pa.

†McElmo formation.

Jurassic (Upper): Southwestern Colorado, northwestern New Mexico, and southeastern Utah.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). *McElmo fm.*, the name here proposed for upper div. of Gunnison fm., the lower div. being here named *La Plata ss.* As developed in this quad. consists of a variable complex of shales and sss., the latter much more prominent here than elsewhere. The sss. are fine-grained, quartzose, of yellowish or gray color, and usually soft and crumbling. Some beds are locally massive, cross-bedded, and 50 ft. thick, but sh. partings of variable importance subdivide most of ss. members. The shales are either reddish or greenish or variegated by a mixture of these 2 colors; they are seldom pure clay shales, but are commonly both calc. and sandy; ss. layers appear in the shales. Basal memb. is a usually highly colored sh. and upper stratum is also a marked sh. beneath a massive ss., commonly conglomeratic, which is assumed as base of Dakota Cret. No fossils in Telluride quad. but is assigned to Juratrias.

Later work showed that the names "McElmo fm." and "La Plata ss." had been variously used in repts. The McElmo fm. of some areas is exactly the same as Morrison fm.; the McElmo fm. of other areas is only upper part of Morrison fm., the so-called "Upper La Plata" being the lower part of the Morrison; the McElmo fm. of still other areas included Morrison fm. and Upper Jurassic deposits down to top of Entrada ss., the Entrada alone in those areas having been called "La Plata ss." The names "McElmo fm." and "La Plata ss." have therefore been replaced by *Morrison fm.* and the other recently adopted subdivisions of SE. Utah, which can also be discriminated in SW. Colo. See U. S. G. S. P. P. 183, 1936 (especially chart opp. p. 39), by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.

Named for exposures on McElmo Creek, Montezuma Co., Colo., and SE. Utah.

McElroy member (of Fayette sandstone).

Eocene (upper): Eastern Texas.

O. L. Brace, 1931 (A. A. P. G. Bull., vol. 15, No. 7, pp. 779–781). *McElroy beds.*—Local. Thickness 500± ft. Overlain by Fayette and separated from underlying Cockfield by 100± ft. of beds [not described] called *Dibollensis* zone. Includes in upper part Simms, Holzmark, and Nichols sands. [Derivation of name and lithology of beds not stated.]

L. P. Teas, 1931 (p. 788 of book cited above). *McElroy zone* is 500 or more ft. thick at Pettus. It is bentonitic, grayish brown to brownish, and consists almost entirely of sh. The peculiar McElroy lithology has not been reported in any exposures in Karnes Co. [Derivation of name not stated.]

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 680–681, 685–687, 693, 696). *McElroy memb. (of Fayette fm.)* was named by Miss Ellisor (ms. read at meeting Soc. Econ. Pal. and Min., San Antonio, March 1931) for McElroy, a small town in Sabine Co. Previously the basal ss. beds of this div. had been named *Wellborn* by Kennedy, and the clays above named *Manning beds* by Dumble. Dumble did not define his div. clearly nor designate a type section, and consequently geologists have had difficulty in distinguishing the limits of Manning beds. Cushman and Applin (1926) referred to the middle div. of the Fayette as *"Textularia hockleyensis* zone." Most other geologists have preferred the new name *McElroy*. The memb. consists of brownish-gray gypsiferous plastic clays containing fossiliferous, limonitic concretions and layers of thin-bedded fossiliferous sand or ss. Thickness averages 200 ft. along outcrop. It is limited at top by a more or less persistent ss. (Alva Ellisor, personal communication, 1932), which passes through town of Groveton, Trinity Co., and caps Lipan Hills near Campbellton, Atascosa Co. [On p. 687 he says top is limited by base of Whitsett memb.] It is limited at base by Caddell clays, the dividing line being drawn at base of Wellborn ss. Type loc. is the R. R. cut just N. of station of McElroy, a small town N. of Brookeland, on Santa Fe R. R., in Sabine Co. [NE. Tex.] Fossils listed.

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11). *McElroy fm.* of Jackson group, underlies Whitsett fm., overlies Caddell fm., and is divided into (descending) Manning beds, Wellborn sands, and Wooley's Bluff clays.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

McEwin sand.

A subsurface sand, of Penn. age and 30 ft. thick, in NE. Okla., which lies 125± ft. above Big lime, and probably corresponds to part of Nowata sh.

MacFarlane red beds.

Carboniferous (Pennsylvanian?): Nova Scotia (Cape Breton Island).

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 323).

McGee glacial stage.

Pleistocene: Sierra Nevada, California.

E. Blackwelder, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 91-92) and 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 865-922). *McGee stage.*—Oldest glacial stage on E. slope of Sierra Nevada. Represented by several thick patches of a deposit strongly resembling till and consisting largely of granite debris resting on Paleozoic ls. and marble. Best exposed on high ridge W. of McGee Peak, Mount Morrison quad. Correlated with Nebraskan stage.

McGraw bed.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *McGraw bed.*—Ferruginous ss. with oolitic hematite. Overlain by Beach fm., and underlain by Lance Cove fm. Included in Bell Island series. [Derivation of name not stated.]

McGregor member (of Platteville limestone).

Middle Ordovician (Black River): Northeastern Iowa, northwestern Illinois, southeastern Minnesota, and southwestern Wisconsin.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 64, 70, 71, fig. 1). *McGregor ls. memb. of Platteville fm.*—Shaly ls., 22 to 30 ft. thick, underlying Spechts Ferry memb. and overlying Pecatonica memb. of the Platteville. [Section 1 mi. W. of McGregor gives thickness of 22 ft.; at Guttenberg, 30 ft.; near Dubuque, 25 ft.]

G. M. Kay, 1935 (pp. 286-295 of book cited above). *McGregor memb. of Platteville fm. (new name).*—*McGregor ls.* is here defined as consisting of the ls. succeeding Pecatonica (Lower Buff) memb. of Platteville fm. and underlying Spechts Ferry memb. Includes Blue Beds and Upper Buff Beds of older Wis. classification. Type section is in a ravine S. of highway 1½ mi. W. of McGregor, Clayton Co., Iowa, where the beds consist of 21½ ft. of gray-blue, rather fine-textured fossiliferous ls. with greenish sh. partings and interbeds. Thickness normally 20 to 25 ft.; about 27 ft. in type section of Platteville fm., where it includes at top the "Glass Rock," 3 ft. 4 in. thick, underlain by 27 ft. of the gray ls. In southern Minn. the Pecatonica memb. is absent and the McGregor memb. lies on Glenwood memb. of Platteville.

C. A. Bays and G. O. Raasch, 1935 (pp. 297-298 of 1935 Conf. Rept. cited above), restricted McGregor memb. to Lower Blue memb. of Chamberlin, and introduced a new name (*Magnolia memb.*) for upper part of McGregor memb. of Kay.

McGregor lime.

A term applied to subsurface beds correlated with Platteville ls. of NE. Iowa. (See A. Folger, A. A. P. G. Bull., vol. 12, p. 206, 1928.)

Machapoorie formation.

Miocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol., No. 7, p. 59).

McHenry formation.

Pleistocene and Recent: Northeastern Maryland (Baltimore County).

P. R. Uhler, 1901 (Md. Acad. Sci. Trans., n. s., vol. 1, pp. 395-400). *McHenry fm.*—A series of marshes and beds constituting one of latest fms. of Modern Period. Extends over parts of recent beaches of Patapsco River and Chesapeake Bay, and near Baltimore composes upper part of Fort McHenry Plateau, in marsh of which many trees grew, as evidenced by the many stumps in the black mud.

Varies greatly in thickness, and where complete continues up from the black marsh, or marshy sand, deposited in the depressions of the Cret. clays. Probably thickest section of this fm. is where the sewer was dug beneath Eutaw St., S. of West St. Omitting the 5-8 ft. of gravel, sand, and soil of the surface the total thickness is 23 ft.

Probably includes deposits of Recent and Pleist. age.

Machias moraine.

Pleistocene (Wisconsin): Southeastern Maine.

G. H. Stone, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 381). *Machias moraine.*—The western part at least is a terminal moraine. Named for occurrence about 5 mi. S. of Machias, Washington Co., near first fork of the road.

Machias shale.

Upper Devonian: Western New York (Cattaraugus County).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). Beds of Chemung age in Cattaraugus Co. divided as follows (descending): Cuba ss.; *Machias* (=Northeast sh. of Chautauqua Co.); unnamed ss.; Gowanda beds; and Dunkirk sh.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 152). Northeast sh. is nearly barren to W., but to E. it contains an easily recognized fauna, best exhibited in Pierce quarry, W. of Machias. The *Machias fauna* is present in road hill S. of Persia turnout and at least as far W. as S. of Wango. It is fully developed in railway cut at Cattaraugus. In all these localities it involves the Northeast beds from top downward, and the change is lithologic as well as faunal. Apparently the Northeast (*Machias*) embraces those beds which on Genesee River intervene btw. the heavy sss. of Caneadea and the Cuba ss. and which become the main mass of Wellsburg ss. Farther E. the Cuba ss. goes above Machias-Northeast series.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 3, p. 200), shows *Machias* as overlain by Cuba ss., underlain by Rushford ss., and as=Northeast sh. On p. 202 he states that the Machias is a fossiliferous phase of Northeast sh. containing many bryozoans.

Machuca formation.

Tertiary (Oligocene?): Nicaragua.

C. W. Hayes, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 285, 313).

McIntire Upper Conglomerate.

See under *Scranton ss.*

McIntyre series.

Pre-Cambrian: Ontario.

L. C. Graton and H. E. McKinstry, 1933 (Canadian Min. and Met. Bull. 250, also Trans., pp. 3, 7).

McKay group.

Upper Cambrian and Ordovician: British Columbia.

C. S. Evans, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. A_2, p. 126).

McKean group.

A term that has been applied to 600 or 700 ft. of subsurface beds, of probable Chemung and Portage age, lying about 500 ft. below Venango oil group in McKean Co., western Pa. Includes (descending) Cherry Grove-Balltown sand, Darling sand, Cooper sand, and Bradford Third sand. (See J. F. Carll, 2d Pa. Geol. Surv. Rept. I_5, p. 135, 1890.)

McKenzie formation (also **McKenzie limestone**). (In Cayuga group.)

Silurian: Central Pennsylvania to northeastern West Virginia, northern Virginia, and western Maryland.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 522, 545, 591, pl. 28). *McKenzie fm.*—Basal fm. of Cayugan series in Pa., Md., and Va. Uncon. underlies Bloomsburg ss. and uncon. overlies Clinton group. The *Kiefer* [Keefer] *ss.* of Md. has hitherto been referred to [but not named] as top memb. of the

Clinton. On investigation it was established that it is a locally developed deposit, that it passes without break into overlying sandy shales of *McKenzie fm.*, and that it is bounded below by an uncon. which in places cuts out Rochester memb. or fm. of Clinton group. On these grounds, which are supplemented by good faunal evidence, the Kiefer ss. is now classified as a local basal memb. or facies of McKenzie fm.

G. W. Stose, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179, p. 5). *McKenzie fm.*—Thin beds of gray crystalline ls. in gray sh., with 40 ft. of hard white ss. (*Keefer ss. memb.*) at base. Thickness 170 to 300 ft. Overlies Clinton sh. and underlies Bloomsburg red ss. memb. of Wills Creek sh. Basal fm. of Cayuga group. In Cumberland area, to W., the Keefer ss. is not recognizable and ls. and shales of the Clinton pass into those of the Cayuga without marked lithologic break, a faunal change only being observed.

G. W. Stose, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 89). The stratigraphy presented by Mr. Swartz in the diagrams [not published] is no doubt more accurate and final than that in my rept on E. part of area about Hancock, Md. In regard to faunal relations of *Kiefer ss.*, I do not feel competent to speak, but Mr. Ulrich, who was responsible for having it made a memb. of McKenzie fm. in my rept, has, in recent table [not published] placed it as a memb. of Clinton fm., thus agreeing with Mr. Swartz.

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 536). *Keefer ss. memb.* included in Clinton fm. [This is present generally accepted definition.]

C. K. Swartz, 1923 (Md. Geol. Surv. Sil. vol.), identified 20 to 45 ft. of beds as composing Rochester fm. of Clinton group of Md., consisting of (ascending) *Keefer ss. memb.* (11 to 35 ft. thick), Roberts iron ore, and a few ft. of interbedded calc. sh. and thin gray crystalline ls.

The McKenzie is lower fm. of Cayuga group, as generally classified, but F. M. Swartz (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1165–1194, 1935) believes lower part is=Lockport dol. of Niagara group.

Named for McKenzie Station, Allegany Co., Md.

McKenzie Hill limestone.

Ordovician (Lower): Central southern Oklahoma (Murray County).

J. Bridge, 1936 (A. A. P. G. Bull., vol. 20, No. 7, pp. 982–983). C. E. Decker has recently subdivided Arbuckle ls. into several units, but the published digest of his paper (Tulsa Geol. Soc. Digest, 1933, pp. 55–57) does not give much idea of boundaries of his subdivisions. The Honey Creek, Fort Sill, Royer, and Signal Mtn fms. had previously been described by Ulrich. The names *Chapman Ranch* and *McKenzie Hill* (the former from Chapman's Ranch on Highway 77 and the latter from a small hill S. of Signal Mtn, near Fort Sill, Okla.) have never been defined, although Ulrich has used them repeatedly in correspondence and ms. The following is sequence and approx. position of these units (descending): (1) Undiff. Arbuckle ls.; (2) *McKenzie Hill*, bdy indefinite to (3) *Chapman Ranch;* (4) unnamed unit, bdy indefinite to (5) Signal Mtn; (6) Royer; (7) Ft. Sill; and (8) Honey Creek, which rests on Reagan ss. In describing fossils from Mo., Ulrich and I (Mo. Geol. Surv. Bull. 24, 1930, p. 195) stated that some of sp. also occur in Ulrich's proposed Chapman Ranch fm., and also that the Chapman Ranch is in part=the Van Buren. Ulrich now considers Chapman Ranch fm. to be exact equiv. of the Van Buren. This would restrict it to the 144 ft. of beds in Decker's unit 184 and possibly some of unit 183. Ulrich has always used *McKenzie Hill* to denote lss. in Arbuckle and Wichita Mtns which carry Gasconade fauna, and in this section the name should be applied to Decker's units 181, 182, and possibly 183. The contact btw. the two has not been satisfactorily established in the section.

See also under *Arbuckle group*, Decker, 1933.

McKerney limestone member (of Hannibal shale).

Mississippian: Southeastern Iowa (Des Moines County) and central western Illinois (Pike County).

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 20, 21, 22, 49, 58–59). *McKerney ls. memb. of Hannibal fm.*—Bluish-drab "fragmental" ls., fine-grained, very hard, compact, with sharply conchoidal fracture, slightly irregular bedding and partially altered to brown mag. ls. Thickness at Kinderhook, Ill., 6 ft.; at Burlington, Iowa, 10 ft. 8 in. At Burlington, Iowa, it underlies Prospect Hill ss. memb. of Hannibal fm. and overlies English River ss. memb. of the Hannibal. At Kinderhook, Ill., is discon. overlain by Lower Burlington ls., and rests on a ss. tentatively correlated with English River ss. Only 7 fossil sp. found, not one of which is present in typical Louisiana ls. fauna of Mo., with which this ls. has hitherto been correlated, and its strat. position appears certainly to be distinctly higher than the Louisiana. Judged by fauna and lithology there is nothing in Hannibal fm. of Mo. corresponding to McKerney ls. Exposed in small deep ravine in Miss. bluffs just S. of McKerney Creek, at Kinderhook, Ill.

McKim graywacke.

Pre-Cambrian: Ontario.

A. P. Coleman, 1905 (Ont. Bur. Mines Rept. 1905, vol. 14, pt. 3, p. 14).

Mackinac limestone.

Middle Devonian: Northern Michigan.

C. C. Douglass, 1839? (Mich. Leg. House Doc. 27, btw. pp. 97 and 111). *Mackinac ls.*—Very porous and much shattered ls. of Mackinac Island.

C. Whittlesey, 1851 (rept. of J. W. Foster and J. D. Whitney on geol. Lake Superior land dist., pt. 2, S. Ex. Doc. 4, special sess., March 1851, pp. 177–183). *Mackinac ls.*, 350 ft. thick, is=in part Onondaga salt group and upper Helderberg ls. Overlies Coralline and marly beds 200 to 250 ft. thick near Mackinac.

Mackinaw limestone.

Same as *Mackinac ls.*

McKinney basalt.

Pleistocene: Southern Idaho (Gooding County region).

H. T. Stearns, 1932 (Correlation chart of Idaho, compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *McKinney basalt.*—Decidedly porphyritic grayish-black pahoehoe basalt containing phenocrysts of fresh green olivine and long laths of plagioclase. Thickness 20 ft. on plains and 500 ft. in Snake River Canyon. Issued from McKinney Butte, NW. of Gooding, and displaced part of Big Wood River and Snake River btw. King Hill and Bliss. Older than Sand Springs basalt and may be older than Bliss basalt, or latter may be a subaqueous facies of the McKinney.

McKissick shale formation.

See following entries under *McKissick Grove fm.*: VerWiebe and Vickery, 1932, and Condra, 1935.

McKissick Grove shale. (In Wabaunsee group.)

Pennsylvanian: Southwestern Iowa and southeastern Nebraska.

G. L. Smith, 1909 (Iowa Geol. Surv. vol. 19, pp. 617, 631, 638, 645). *McKissicks Grove sh.*—Blue and gray shales, 75 ft. thick, with two or three thin ls. beds and a thin ss., forming top part of Atchison shales. Overlies Tarkio ls. (25 ft. thick) and represents close of Carbf. in Iowa. Included in Missouri stage.

J. L. Tilton, 1924 (Iowa Geol. Surv. vol. 29, p. 239). *McKissick Grove sh.* is here applied to all the strata that are found in Iowa above Tarkio ls. Thickness 91 to 93 ft.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 73, 74, 80).—*McKissick Grove sh. memb. of Wabaunsee fm.*—As originally defined by Smith it included all Penn. beds above Tarkio ls. in Iowa. This definition is objectionable, because topmost bed of Penn. of Iowa probably is covered somewhere in Missouri River bluffs or in uplands, awaiting discovery, and therefore is not a fixed horizon. Highest known exposed Penn. horizon of Iowa is in lower part of Aspinwall sh., but highest well-defined marker would be Brownville ls. or the better-shown Dover ls., which outcrops at McKissick Grove, below which Tarkio ls. is exposed. If McKissick Grove is to be retained it should have definite upper and lower boundaries. This has been taken up with Iowa Geol. Surv. in field and decided that top of McKissick Grove memb. should be at base of Brownville ls. As thus defined the memb. is 63 ft. thick, and is divided into (descending) Pony Creek sh., Dover ls., Table Creek sh., Maple Hill ls., and Pierson Point sh.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, p. 96). *McKissick Grove sh.* includes (descending) Pony Creek sh., Jim Creek ls., Table Creek sh., Dover ls., Frenck sh., Maple Hill ls., and Pierson Pt. sh. Underlies Brownville ls. and overlies Tarkio ls.

W. A. VerWiebe and W. R. Vickery, 1932 (p. 110 of book last cited above), used *McKissick sh. fm.* for beds below Brownville ls. and above Tarkio ls.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised chart). *McKissick Grove sh.* includes (descending) Pony Creek sh., Nebraska City ls., Frenck sh., Dover ls., Table Creek sh., Maple Hill ls., and Pierson Point sh. Underlies Brownville ls. and overlies Tarkio ls.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 9–10). *McKissick sh. fm.* [restricted] underlies *Dover ls. fm.* and overlies Tarkio ls. Includes (descending) Table Creek sh., Maple Hill ls., and Pierson Point sh. [The beds btw. Brownville ls. and his Dover ls. fm. he called *Pony Creek sh. fm.*]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 232), discarded McKissick Grove sh. and treated its subdivisions as fms. in Wabaunsee group.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for McKissick's Grove, 2 mi. NE. of Hamburg, Fremont Co., Iowa.

McKittrick formation.

Pliocene and lower Pleistocene (?): Southern California (McKittrick-Sunset district).

R. Arnold, 1909 (U. S. G. S. Bull. 396, p. 22). At most localities along flanks of Diablo and Temblor Ranges S. of Coalinga dist. it is impossible to separate the post-Santa Margarita (?) Tert. fms., and to these beds—the equiv. of Jacalitos, Etchegoin, and possibly Tulare fms. of Coalinga dist.—the name *McKittrick fm.* has been given in McKittrick dist. (R. Arnold and H. R. Johnson, U. S. G. S. Bull. 406 [1910]). This name was chosen because of importance of the beds in that dist., the basal members yielding the petroleum found in the productive McKittrick field.

R. Arnold and R. Anderson, 1910 (U. S. G. S. Bull. 398, p. 79). To S. of Coalinga dist. the *McKittrick fm.* is distributed over both sides of Temblor Range along most of its length and forms whole of Buena Vista and Elk Hills. On E. side of Temblor Range it consists of coarse to fine cgls. and coarse sands near its base, then a zone of bluish sandy clay, then medium to coarse sands and sandy shales, and at top a succession of alternating coarse gravel and clay beds. Thickness ranges from 1,300 to possibly 2,500 ft. Uncon. overlies Monterey and Santa Margarita (?) fms. and is uncon. overlain by Quat. deposits. Is=Jacalitos, Etchegoin, and Tulare fms. of Coalinga dist.

R. Arnold and H. R. Johnson, 1910 (U. S. G. S. Bull. 406, pp. 74–90). [Same definition as above.] Named for exposures ½ mi. S. of McKittrick, Kern Co.

Macksburg sandstone.

Pennsylvanian: Southeastern Ohio.

E. Lovejoy, 1888 (Ohio Geol. Surv. vol. 6, pp. 628, 635). *Macksburg ss.*, 60 ft. thick, lies at top of Upper Coal Measures in Athens and Morgan Counties. Underlain by Macksburg coal.

Probably named for Macksburg, Washington Co.

Macksburg sands.

Pennsylvanian: Southeastern Ohio.

J. A. Bownocker, 1903 (Ohio Geol. Surv. Bull. 1). *Macksburg 500-foot sand*, 22 ft. thick, is top memb. of Pottsville group in Ohio.

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21). *Macksburg 500-foot sand* appears=Clarion ss. of Allegheny fm.

J. R. Lockett, 1927 (A. A. P. G. Bull., vol. 11, No. 10). *Macksburg sand* of eastern Ohio lies 125 ft. below Peeker sand and 50 ft. above Second Cow Run sand.

K. Cottingham, 1927 (A. A. P. G. Bull., vol. 11, p. 951). *Macksburg (500-foot) sand* is basal part of Allegheny fm.

W. Stout et al., 1935 (Geol. of nat. gas, A. A. P. G., pp. 901–902). *Macksburg 300-foot sand* is Mahoning ss. memb. of Conemaugh fm.; *Macksburg 500-foot sand* seems to be same as Clarion ss. memb. of Allegheny fm.

Mackworth slate. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Washington Acad. Sci. Jour., vol. 7, p. 198). [*Mackworth sl.* mentioned as a fm. of Casco Bay group. Not defined.]

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 172). *Mackworth sl.*—Qtzite and quartz-chlorite-mica sl., in beds less than an inch to 2 or 3 ft. thick. Rocks dominantly siliceous and laminated and characterized by abrupt alternations from flinty to chloritic slate. Range from white through drabs and light grays to dark grays and browns. Estimated thickness 100 ft. Top of fm. unknown. Is uppermost fm. of Casco Bay group. Probably overlies Jewell phyllite conformably. Assigned to Penn. (?). Named for development on Mackworth Island, Casco Bay.

McLeansboro formation.

Pennsylvanian: Illinois and western Kentucky.

F. W. DeWolf, 1910 (Ill. Geol. Surv. Bull. 16, p. 181). *McLeansboro fm.*—Uppermost Penn. fm. in Ill. Conspicuously shaly, but locally contains sss., lss., and thin coals. Base defined by top of coal No. 6 [Herrin coal]. Thickness 919 to 1,155 ft.

Overlies Carbondale fm. In western Ky. and SE. Ill. underlies Henshaw fm. Is correlated by D. White with upper part of Allegheny fm. and with Conemaugh fm.

Named for McLeansboro, Hamilton Co., Ill.

McLeod member (of Kootenai formation).

Lower Cretaceous: Alberta.

J. A. Allan and R. L. Rutherford, 1924 (Alberta Sci. and Indus. Research Council Rept. No. 9, p. 23).

McLish formation.

Lower Ordovician (Chazy): Central southern Oklahoma (Arbuckle and Wichita Mountains).

E. O. Ulrich. [See under *Falls fm.*]

C. E. Decker, 1930 (A. A. P. G. Bull., vol. 14, No. 12, pp. 1498–1505). *McLish fm.*—Chiefly lss.; some sh.; with ss. (8 to 200 ft. thick) at base and some sss. higher up. Contains limited but very distinctive fauna. Thickness 300 to 500+ ft. Underlies Tulip Creek fm. and overlies Oil Creek fm. Same as Falls fm., and latter name abandoned.

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 12, 98). A 7-partite div. of Simpson group has been used during part of this study, and the 2 additional fm. names used temporarily are *Falls Creek* and *Criner*. Briefly these 2 fm. names were used and later discarded for the following reasons: The McLish has a distinctive though rather limited fauna the major part of which has been traced to the region a short distance S. of Sulphur, and it was then thought the McLish was not represented in W. part of mtns, and *Falls Creek* was used for the fm. in this western region, btw. the Oil Creek and Tulip Creek fms. But, because the marked lower cystid zone, which occurs a short distance above the second ss. called "Burgen" along Highway 77, extends E. and ties in with McLish fauna at Roff, in region E. of Sulphur, and at Bell school house 2½ mi. NW. of Connerville, it is thought the body of rocks temporarily named *Falls Creek* is approx. = the McLish to E. Further confirmation of this view is found at N. edge of Criner Hills.

E. O. Ulrich, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 105). Falls fm. is an older unit than McLish. It is confined mainly to SW. half of Arbuckle uplift and McLish to NE. half, the two fms. occurring one above the other in a few intermediate localities. *Simpson group* divided into 8 fms. [See this entry under *Simpson fm.*]

C. E. Decker, 1933. [See this entry under *Simpson fm.*]

Named for McLish ranch, T. 1 S., R. 7 E., Johnston Co.

McLure shale member (of Monterey shale).

Miocene (upper): Southern California (Fresno and Kings Counties).

G. Henny, 1930 (A. A. P. G. Bull., vol. 14, No. 4, p. 403). *McLure sh.* is name given by writer to the brown sh. of southern Coalinga region, Fresno and Kings

Counties, previously termed *Santa Margarita (?) sh.* on geol. maps of U. S. Geol. Survey. It is found, however, that this sh. lies with angular uncon. on Santa Margarita ss. (Mio.), and that the Etchegoin (Plio.) lies uncon. on the sh. Whether it is upper Mio. or lowest Plio. in age has not been determined. Average thickness 800± ft. Base consists of 30± ft. of light-gray coarse ss. with concretions. Borders McLure Valley on nearly all sides. Type loc. is a canyon crossing Tent Hills S. of Avenal Creek near W. line of sec. 6, T. 24 S., R. 17 E. In Zapata Canyon it overlies Temblor ss. In Devils Den it rests uncon. on Monterey sh.

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, pp. 1175–1177, 1180). Because Reef Ridge sh. weathers brown it is not certain whether Henny intended to include in his McLure sh. both the Reef Ridge sh. and the underlying siliceous shales, or merely the latter. The ambiguity is increased by fact that Arnold and Anderson were inconsistent in mapping of Reef Ridge sh., sometimes including it as upper part of Santa Margarita (?) fm. and sometimes in "Transition zone mapped as Jacalitos." Writers are tentatively using *McLure sh.* to designate that body of brown sh. recognized in Kettleman Hills wells as lying uncon. below the blue sh. of the Reef Ridge and uncon. above Temblor fm. The term is thus restricted to lower memb. of Santa Margarita (?) of Arnold and Anderson in their mapping in SE. end of Reef Ridge and to Santa Margarita (?) of same authors in NW. end of Reef Ridge. Upper members are chocolate-brown but weather white. The McLure sh. is unquestionably a part of Maricopa sh. Thickness in Kettleman Hills 1,200–1,600 ft. In the outcrops along Reef Ridge there is a thin cgl. at base of McLure sh. containing pebbles derived from Franciscan fm.

W. F. Barbat and F. L. Johnson, 1934 (Jour. Pal., vol. 8, No. 1, p. 4). Henny defined "McLure sh." as replacing Santa Margarita (?) of Arnold and Anderson. But as Arnold and Anderson were inconsistent in their mapping of "Santa Margarita (?)," Henny's definition of "McClure sh." is ambiguous. Whether "McLure" is applicable to present Reef Ridge sh. and lower div. of Arnold and Anderson's "Santa Margarita (?)," or only to Arnold and Anderson's lower div., is a matter of opinion; but it is believed Henny had in mind only the lower div. of "Santa Margarita (?)" when he proposed "McLure." To avoid confusion, the "McLure sh." is to be regarded as former "Santa Margarita" exclusive of Reef Ridge sh. None of the Reef Ridge is exposed at type loc. of "McLure." The "McLure" is of Santa Margarita age. [See also under *Reef Ridge sh.*]

The U. S. Geol. Survey now treats this sh. as a memb. of Monterey sh., and assigns it to upper Mio. (See 1934 entry under *Reef Ridge sh.*)

†Maclurea limestone.

†Maclurea limestone series.

Lower Ordovician: Eastern Tennessee and Alabama.

Paleontologic names used in early Tenn. and Ala. repts for rocks of Chazy age, containing sp. of *Maclurea*.

McMicken member. (In Latonia shale.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 10). *McMicken.*—Highly calc. and extremely fossiliferous shales and lss., 60 ft. thick, holding the bryozoan *Dekayella ulrichi* in great abundance, and comprising upper third of Eden fm.

Now treated as upper memb. of Latonia sh., of Eden group.

Named for McMicken Avenue, Cincinnati, Ohio.

McMillan formation. (In Maysville group.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 10). *McMillan fm.*—The Bellevue, Corryville, and Mount Auburn members are closely related and not of sufficient importance to be mapped separately. The three are here recognized as members of the new fm., the *McMillan,* from the street of that name at Cincinnati along which the 85 ft. of strata comprising this fm. are fairly well exposed. Overlies Fairview fm. and underlies Richmond group.

Now treated as upper fm. of Maysville group.

McMillan sand.

A subsurface sand, of Penn. age, in Runnels Co., north-central Tex., lying at 2,600 ft. depth.

McMurray formation.

Lower Cretaceous: Alberta.

F. H. McLearn, 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 147). [Assigned to Cret.]

J. A. Allan and R. L. Rutherford, 1934 (Alberta Sci. and Indus. Research Council Rept. No. 30, p. 13), assigned this fm. to Lower Cret.

†McNairy shell bed.

Upper Cretaceous: Western Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 156). *McNairy Shell-bed (Green sand).*—Sometimes called rotten ls., because it has appearance, especially in Ala. and Miss., of a soft chalky ls. Consists of fine quartzose sand mixed with clay and much calc. matter. Contains also green grains of glauconite, which give greenish color to the stratum, hence the name green sand. Abundance of fossil shells of many varieties. Overlies Coffee sand and underlies Ripley fm. Occupies belt through E. part of McNairy and Henderson Counties and extreme W. part of Hardin and Decatur Counties. Max. thickness of 350 ft. is in McNairy Co.

Same as Selma chalk, older name.

Named for McNairy Co.

McNairy sand member (of Ripley formation).

Upper Cretaceous: Western Tennessee and Kentucky, southwestern and southeastern Illinois, and northern Mississippi.

L. W. Stephenson, 1914 (U. S. G. S. P. P. 81, pp. 18, 22). *McNairy sand memb. of Ripley fm.*—In vicinity of [southern] Tenn. State line and northward in Tenn. all but basal beds of Ripley fm. appear to merge along the strike into shallow-water equivalents consisting of irregularly bedded, largely nonglauconitic sands and subordinate clays, probably in part marine, in part estuarine, and in part fresh water. Since time of Safford these beds have been correlated with Ripley fm. Their lithologic dissimilarity to typical Ripley materials seems to justify use of a memb. name to designate them. Type section is in cut of Southern Ry. 1¼ mi. W. of Cypress Station, McNairy Co., where the railroad passes through a ridge known as "Big Hill." Max. thickness probably 400 to 500 ft. Uncon. overlain by Eocene. [As thus defined included Owl Creek fm. at top and as mapped included at base the ferruginous clays, 100 ft. thick, of Wade's 1917 rept.]

B. Wade, 1917 (Johns Hopkins Univ. Circ., n. s., No. 3, pp. 73–100), divided Ripley fm. of SW. Tenn. into (descending): (1) *Owl Creek horizon;* (2) McNairy sand memb. [restricted]; (3) ferruginous clay horizon, 100 ft. thick; and (4) Coon Creek horizon, 30 ft.

B. Wade, 1926 (U. S. G. S. P. P. 137), divided Ripley fm. of Tenn. into (descending): (1) *Owl Creek tongue;* (2) McNairy sand memb.; and (3) Coon Creek horizon, including at top the 100 ft. of ferruginous clay described in his 1917 rept.

According to L. W. Stephenson, 1936 (personal communication July 17), McNairy sand memb. is present in Pulaski Co., SW. Ill., and in Massac Co., SE. Ill. The Owl Creek is now treated as a distinct fm. by U. S. Geol. Survey.

McNamara formation.

Pre-Cambrian (Belt series): Central western Montana (Missoula to Helena region).

C. H. Clapp and C. F. Deiss, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 680, figs. 2, 3). *McNamara fm.*—Upper memb., 1,780 ft. thick, chiefly argillites, some qtzite and some ss.; middle memb. 810 ft. thick, almost wholly qtzites; lower memb., 410 ft. thick, purple to green-gray micaceous sandy argillite, with thin sandy qtzite beds in upper part. Rests conformably on Hellgate fm. 2 mi. N. of McNamaras Landing. Overlain by Garnet Range fm. [Gives details of type section, along Blackfoot River, in vicinity of McNamaras Landing.] Included in Missoula group.

McNaughton sandstones.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll. vol. 57, No. 12, pp. 335, 339).

McNulty rhyolite.

Eocene: Western central Colorado (Tenmile district).

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48). *McNulty rhyolite* cuts both Lincoln and Quail porphyry. Occurs in small irregular masses in McNulty Gulch and extends to S.

Called *McNulty Gulch rhyolite* by W. Cross, 1886.

McNulty Gulch rhyolite.

Eocene: Western central Colorado (Tenmile district).

W. Cross, 1886 (U. S. G. S. Mon. 12, p. 350). *McNulty Gulch rhyolite.*—Light colored; numerous slightly pinkish quartz crystals, white glassy feldspars, and brown biotite leaves, with subordinate ashen gray groundmass btw. them.

Called *McNulty rhyolite* by S. F. Emmons, 1898.

Named for occurrence in one large and several small bodies at head of McNulty Gulch, which runs N. and enters Tenmile River at Carbonateville, Summit Co.

Macoma sands.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 224).

Macomb granite.

Pre-Cambrian: Northern New York (St. Lawrence County).

H. P. Cushing, 1916 (N. Y. State Mus. Bull. 191, pp. 13, 17, 18, 19, 25, 26). *Macomb granite.*—In large part a fine-grained red orthogneiss, composed chiefly of feldspar and quartz, but with a variable amount of black mica. Occurs at Macomb [St. Lawrence Co.]. Is pre-Camb., but uncertain whether it belongs to the older Laurentian intrusives or to the younger "Algoman" intrusives. We are disposed to class it as Laurentian.

Macomb's Dam gneiss.

R. P. Stevens, 1867 (N. Y. Lyc. Nat. Hist. Annals, vol. 8, pp. 116–120). [On his "Section across New York [Manhattan] Island along southern shore of Spuyten-Duyvel Creek and Harlem River" the name *Macomb's Dam gneiss* is applied to one of the bodies of gneiss shown. In U. S. G. S. New York City folio (No. 83) the gneiss of this region is mapped as Fordham gneiss.]

Macon City shale.

Pennsylvanian: Northern Missouri.

C. H. Gordon, 1893 (Mo. Geol. Surv. Sheet Rept. No. 2 (vol. 9), p. 60). *Macon City sh.*—Soft plastic fine-grained olive-green sh., 5 to 15 ft. thick, overlying Macon City coal in Bevier quad. (parts of Macon, Randolph, and Chariton Counties).

Is a part of Cherokee sh. and is separated from underlying Macon City (Mulky) coal by a cap of ls.

Named for Macon, Macon Co.

Macoupin limestone. (In McLeansboro formation.)

Pennsylvanian: Southwestern Illinois (Macoupin County) and central western Illinois (Sangamon County).

H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 804), showed *Macoupin ls.* lying a few ft. above coal No. 9, about 30 ft. below Shoal Creek ls., and 35± ft. above Carlinville ls., but he did not describe it.

J. R. Ball, 1934 (Ill. Acad. Sci. Trans., vol. 26, No. 3, p. 97). *Macoupin ls.* of Carlinville quad. [type region] resembles Centralia ls. but lies 17± ft. higher, and lies 40± ft. above Shoal Creek ls., which has also been called "Carlinville ls."

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, pp. 129–138). Macoupin ls. is 4 to 7 ft. thick locally in Sangamon Co. and is known as *Crows Mill ls.*

Apparently named for Macoupin, Macoupin Co., which adjoins Sangamon Co. on S.

Macoupin cyclical formation.

A name applied by H. R. Wanless (Geol. Soc. Am. Bull., vol. 42, 1931, pp. 801–812) to a middle portion of McLeansboro fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 9 and Macoupin ls. Derivation of name not stated.

McPherson marble.

Middle Ordovician: Central eastern Missouri.

B. F. Shumard, 1873 (Mo. Geol. Surv. Rept. 1855–1871, p. 307). Light-drab brittle ls., 2½ ft. thick, with bluish cloudings, forming handsome and durable building rock (*McPherson marble*). Included in lower part of Bird's-Eye ls. Underlies compact even-bedded light-bluish ls. with dark-bluish cloudings and containing chert nodules and crystalline bands, also included in Bird's-Eye ls. Lies 30 ft. above First Mag. ls.

Is a bed in Plattin ls.

Named for McPherson's marble quarry, Jefferson Co.

McPherson formation.

Pleistocene (pre-glacial): Central Kansas.

E. Haworth and J. W. Beede, 1897 (Kans. Univ. Geol. Surv. vol. 2, pp. 287–296). *McPherson Equus beds.*—Alternating layers of fossiliferous sand and clay, with stratum of volcanic ash in part of northern area and in places heavy gravel stratum near bottom. Thickness 65 ft. Overlies Dakota ss.

Named for exposures in McPherson Co. Kans. Geol. Surv. Bull. 6, pt. 2, 1920, pl. xiii, on p. 92, mapped the distribution of this fm. in Kans.

Macquereau series.

Ordovician or Cambrian: Quebec.

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 39).

McRoberts sand.

A subsurface sand in Mansfield ss. (Penn.) of Ind.

Madame Joie formation.

Miocene: Haiti.

W. P. Woodring, 1922 (Haiti Geol. Surv., Stratigraphy, structure [etc.], of central plain, p. 6).

†Madder dirt.

See †*Kimball or* †*Madder dirt.*

Maddox limestone.

Silurian: West-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 565, 579). At base of Sil. section at Swallow Bluff, Maddox mill, and W. D. Helton's, also at New Era and Kelley Landing, there is a considerable section of ls., usually whitish in color, massive at base and more distinctly bedded near top. Occurs below the beds referred to Osgood horizon. Thins out toward Riverside and Iron City. Base of section at least is equal to the [so-called] Clinton; top may belong to Osgood horizon; position of intermediate part is doubtful. It is evident the plane of div. btw. Clinton and Osgood beds is rising southward and that the lithological divisions here do not correspond strictly to those farther N. and NE. For present the name *Maddox ls.* may prove convenient for the massive ls. in question.

Named for Maddox mill, Hardin Co.

Madera diorite.

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Madera diorite.*—Quartz mica diorite; usually a gray rock of granitic texture and habit, consisting essentially of plagioclase, feldspar (usually andesine) with quartz and biotite. Named for Mount Madera, one of the peaks of Pinal Range (in Globe quad.), of which it occupies the crest. Intrudes Pinal schist, which is overlain by Apache group.

Madera limestone. (Of Magdalena group.)

Pennsylvanian: Central New Mexico.

C. R. Keyes, 1903 (Ores and Met., vol. 12, p. 48). The upper Carbf. blue to gray beds, the superior part of the great ls. fm., are called *Madera ls.* in Sandia Mtns. They overlie middle Carbf. lss.

C. R. Keyes, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 360–362). *Madera fm.* consists of 300 ft. of lss. underlying Bernalillo shales and overlying Sandia lss., 300 ft. thick, which rest on Lake Valley ls.

C. H. Gordon, 1907 (Jour. Geol., vol. 15, pp. 810–816). *Madera ls.*—Dark-blue ls., 300 to 700 ft. thick. Top fm. of Magdalena group. Overlies Sandia fm. and uncon. underlies Manzano group.

Maderan series.

A time term introduced by C. R. Keyes to cover part of the Carbf. (Penn.?) rocks of N. Mex.

†Madison water limestone. (In Richmond group.)

Upper Ordovician: Southeastern Indiana.

D. D. Owen, 1859 (Rept. geol. reconn. Ind. made in 1837, p. 28). *Madison water ls.*—Dark-gray fossiliferous ls. 13 ft. thick. Overlain by 93 ft. of mag. lss. and underlain by 40 feet of thin-bedded blue lss. alternating with dark marlite.

Conflicts with better-established name of Miss. ls. in Rocky Mtns. Probably forms lower part of †Madison beds (Saluda) of later repts, according to Cumings (1922).

Named for Madison, Jefferson Co.

†Madison beds. (In Richmond group.)

Upper Ordovician: Indiana, southwestern Ohio, and north-central Kentucky.

W. W. Borden, 1874 (Ind. Geol. Surv. 5th Ann. Rept., p. 139). *Madison rocks.*—Thin stratified dark-blue crystalline lss. with intermediate layers of lighter-colored coarse-grained ls. Top fm. of Cincinnati group.

A. F. Foerste, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., pp. 218, 220). *Madison beds.*—Argill. lss., 30 to 60 ft. thick, consisting of white ls. layer at top, *Murchisonia hammelli* beds in middle, and typical Madison beds (argill. or very impure ls.) at base. Form topmost part of Cincinnati group. Underlain by 80 ft. of richly fossiliferous interbedded shales and lss.

A. F. Foerste, 1902 (Am. Geol., vol. 30, p. 369). "Madison bed" replaced with *Saluda bed*, because of conflict of Madison.

J. M. Nickles, 1903 (Am. Geol., vol. 32, pp. 202–218). *Madison fm.* preferred by writer to *Saluda*. Top fm. of Richmond group in Cincinnati area. Writer includes at top the Belfast bed of Foerste, which Foerste excluded from Madison.

Named for Madison, Jefferson Co., Ind.

Madison sandstone.

Cambrian (Upper): Southern Wisconsin.

R. D. Irving, 1875 (Am. Jour. Sci., 3d, vol. 9, p. 442). *Madison ss.*, 35 ft. thick in south-central Wis., underlies ls. correlated with Shakopee ls. [as here used includes Oneota dol.] of Minn. and overlies Mendota ls.

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, p. 260). *Madison ss.*—Rather coarse-grained, thick-bedded, compact, soft, slightly calc., light-colored ss. 35 ft. thick. Top subdivision of Potsdam ss. Grades into underlying Mendota ls. Named by Prof. Irving from its occurrence in vicinity of Madison, where it is quarried. He regards it as a memb. of Calciferous group above, but I differ with him.

R. D. Irving, 1877 (Geol. Wis., vol. 2, pp. 525, 577, 584, 590, 591, 592, 602, 603). *Madison ss.*—Larger part nearly pure white quartz sand, or sand turned brown by oxide of iron; toward top generally becomes somewhat dolomitic, the upper limit being frequently marked by layers of greensand and oolitic chert. Quarried at Madison. Thickness 35 to 60 ft. Overlies Mendota ls. and grades into overlying Lower Mag. ls. Only intended as local name in central Wis.

In subsequent repts this ss. was correlated with Jordan ss. by several authors, including E. O. Ulrich. Later work, however, led Ulrich to belief that it is younger than Jordan ss. He later stated (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93, 1924) that it lies stratigraphically below Oneota dol., and is younger than Jordan ss., and he assigned the Madison, Mendota, and underlying Devils Lake ss. of eastern Wis. to his Lower Ozarkian and the Jordan ss. to underlying Upper Camb.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 63, 64). Unless we are mistaken the 39 ft. of Madison ss. at Madison, Wis., is = whole of Jordan fm. elsewhere.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 6, 8, 25–26). *Madison fm.* overlies Trempealeau fm. (the top memb. of which is Jordan ss.) and is uncon. overlain by Oneota fm. It is composed of sss. The Mendota dol. is now considered to be same as Black Earth dol. memb. of St. Lawrence (†Trempealeau fm. of some authors). [See under *Mendota dol.*]

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 61). *Madison memb of Trempealeau fm.* (*Madison fm.* of Raasch, p. 302) is introduced at Victory, Wis. The Madison has not been recognized in Iowa and Minn. as a separate memb. or fm., but these beds occur in sections at McGregor [Iowa] and Lansing. Being unable to find a plane of separation btw. these beds and underlying Jordan ss. that can be recognized in more than a few sections, the stratigraphers of Minn. and Iowa classify the Madison of Wis. merely as upper beds of the Jordan. [In this Field Conf. rept many geologic sections are given in Wis., and one in Minn., showing Madison ss. overlying Jordan ss. Page 21 (also pp. 313–315) states Raasch objects to including Madison in Trempealeau fm. Fig. 1, however, includes the Madison in † Trempealeau fm., but excludes it from Jordan ss. Page 442 gives a section at city quarry at Madison, Wis., and restricts *Madison* to upper 10 ft. of sss. present there, or to "Madison building stone." Page 445 gives a "general section" at Madison, Wis., in which the 39 ft. of ss. present at top of section is all assigned to Jordan ss.]

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1687–1743). *Madison memb.* is here treated as top div. of Trempealeau fm., overlying the Jordan memb., although Twenhofel and Thwaites think Madison represents a lithic phase, succeeding, and perhaps in part lateral to, the sss. of Jordan aspect. If long sections could be seen, possibly this gradation could be traced. At type exposures the base of the Madison is concealed. The ss. has been quarried at type loc. (Madison, Wis.) for over 90 years. It overlies Jordan memb. of the Trempealeau, which is not seen in the quarries, and which differs from the quarry stone in less evenness of bedding, more cross lamination, and poorer cementation. The Jordan memb. can be seen in South Madison railroad cut, where the quarry stone is not present, and in the Mendota cut N. of Madison, where a few ft. of quarry stone are present. So far as known to writers the Madison is absent in Chippewa River country and northwestward. In some districts sand-pebble cgls. occur at different levels in the Jordan. Raasch is strongly inclined to concur with bulk of published accounts of last quarter century in regarding the Madison as separate fm., younger than Jordan. He bases his opinion primarily on sedimentary and lithologic criteria. The other authors place little weight on criteria used by Raasch and prefer to follow Trowbridge and Atwater in considering the Madison as top memb. of Trempealeau fm. In places it is difficult to locate top of Trempealeau fm., because overlying Oneota fm. not infrequently begins with sss. not greatly unlike the Madison and Jordan. But in places there is well-developed cgl. at base of Oneota, and not uncommonly an erosion surface.

F. W. Sardeson, 1936 (Pan-Am. Geol., vol. 65, p. 344). *Madison ss.* is synonym of Jordan ss.

E. O. Ulrich, 1936 (Geol. Soc. Am. Proc. 1935, p. 113). There are 3 sss. in Wis. that previously have been regarded as constituting an indivisible strat. unit. The Norwalk ss. is top memb. of Trempealeau fm., the Jordan is a separate final deposit of the Camb. of upper Miss. Valley, and the Madison is first deposit of Ozarkian of the region.

The U. S. Geol. Survey at present treats Madison ss. as a distinct fm., overlying Jordan ss. and underlying Oneota dol., and classifies it as Upper Camb.

Madison limestone.

Mississippian (lower): Montana (widespread), Wyoming (rather widespread), Idaho, northern Utah.

A. C. Peale, 1893 (U. S. G. S. Bull. 110). *Madison ls.*—Consists of (descending): Massive jaspery lss., 575 ft.; light bluish gray massive lss., 350 ft.; dark-colored compact laminated lss., 325 ft. Fossils listed. Rests on Dev. Threeforks sh. and is overlain by Quadrant fm.

Named for Madison Range, central part of Threefords quad., Mont., where it is conspicuously developed.

Madison coral reef. (In Richmond group.)

Upper Ordovician: Southwestern Ohio and southeastern Indiana.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull., vol. 14, p. 290). *Madison coral reef* lies at base of Saluda bed in Ind. and Ohio.

Probably named for Madison, Jefferson Co., Ind.

†Madison sand. (In Vicksburg group.)

Oligocene (lower): Southwestern Mississippi.

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, p. 82). *Madison sands.*—Distinctly stratified, non-fossiliferous, prevailingly gray sands, sometimes varying from gray to yellow and white. Thickness 50 to 75 ft. First noted in Madison Co., hence the name. Also exposed near Madison, Madison Co. May belong to either Jackson or Vicksburg group.

Name preoccupied and replaced by Forest Hill sand. More recent studies (by C. W. Cooke) have shown this sand to be basal fm. of Vicksburg group, and the nonmarine equivalent of Red Bluff clay (marine). (See also *Forest Hill sand* and *Red Bluff clay*.)

Named for Madison Co. and for exposures near Madison in that county.

Madison Hill sand.

A subsurface sand, of probable Dev. age, in western N. Y., lying higher than Bradford and Richburg sands.

Madisonic period.

Pre-Cambrian: Montana.

See under *Bitterroot period.*

†Madison Valley beds.

Tertiary (upper Miocene or lower Pliocene): Central southern Montana (Three Forks region).

E. Douglass, 1903 (Carnegie Mus. Annals, vol. 2, pp. 151–155). *Madison Valley beds*, a phase of Loup Fork Mio. in lower Madison Valley. Overlie White River Olig.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 65, 115), assigned †*Madison Valley beds* of Mont., 1,200 ft. thick, to upper Mio.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 9, 25, 27), assigned these beds to upper Mio. or lower Plio.

Madisonville limestone. (In McLeansboro formation.)

Pennsylvanian: Western Kentucky.

C. J. Norwood, 1878 (Ky. Geol. Surv. n. s., vol. 4, pp. 319–320). *Madisonville ls.*—Massive fossiliferous ls., 4 ft. thick, usually drab and dove-colored, some parts blue, exposed at spring at Madisonville. Overlain by sh. and underlain by 1 ft. of nodular ls. succeeded below by shales and interbedded nodular and other lss. Lies about 80 ft. above coals A and B. [Later rept (Ky. Geol. Surv. Bull. 19, p. 13) states this ls. lies almost midway btw. coals Nos. 14 and 15, or about 300 ft. above coal No. 9.]

F. M. Hutchinson, 1912 (Ky. Geol. Surv. Bull. 19, p. 94), applied *Upper Madisonville ls.* to a ls. 4½ ft. thick, lying 32 ft. above Madisonville ls.

Named for Madisonville, Hopkins Co.

Madras formation.

Pleistocene and late Tertiary: Central northern Oregon (Cascade Mountains).

E. T. Hodge, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 163). [See under *Crooked River fm.*]

E. T. Hodge, 1928 (Pan-Am. Geol., vol. 49, pp. 350–356). *Madras fm.*—Composed of at least 6 flows of basaltic and andesitic lavas separated by torrential and lacustrine deposits. The torrential deposits are chiefly pumice, aggl., and arkosic and obsidian sands. Rests uncon. on Clarno, John Day, and Columbia basalt fms. West of Deschutes River contains fragments of Black Crater and all older fms. Includes part of Satsop fm. and all of Dalles beds, Deschutes sands, and Deschutes fm. The latter name is objectionable because Deschutes River exposes at least 8 fms., several of which occupy larger sections than Madras fm., and it leads to impression several much older fms. may belong to it. Entire fm. is exposed in vicinity of Madras [Jefferson Co.]. Is late Pleist. or post-Pleist.

E. T. Hodge, 1930 (Mon. Weather Rev., vol. 58, pp. 405–411). *Madras fm.* closely resembles The Dalles fm., but does not furnish direct proof that glaciers extended more than a few mi. to E. of Cascade Divide. Lies S. of Mutton Mtns. Extends S. almost to Bend, Oreg., and lies W. of Deschutes River and W. of Crooked River. Fills structural and erosional depressions that are younger than Columbia River basalt. Contains no glacial erratics. If Madras and The Dalles fms. are equiv. in time, both may represent aggradational activity during first glacial stage.

E. T. Hodge, 1932 (Univ. Oreg. Pub., Suppl. to Geol. ser., vol. 1, No. 5). *Madras fm.* was suggested in 1928 as a substitute for Russell's Deschutes sands, so as to give a specific location and truly formational name to a fm. that, except along Deschutes River, has been mistaken for Columbia River basalt, and because near town of Madras all the various features of this fm. are excellently displayed. Includes beds that farther N. have been variously known as *The Dalles beds* and *Satsop fm.* Accumulated rapidly. Not older than Plio. and may be Pleist. Rests uncon. on Columbia River basalt and older fms. Overlain by Cascade fm., which tentatively includes all lavas younger than Madras fm. and older than Recent.

†Madrid formation.

Upper Cretaceous: Central northern New Mexico (Santa Fe County).

D. W. Johnson, 1903 (School Mines Quart., vol. 24, p. 338). *Madrid coal group.*—Coal series, of Fox Hills age, 1,000 ft. thick in Cerrillos Hills, N. Mex. Upper 25 ft. consists of massive yellow and white ss.; lower 300 ft. contains several coal seams and some sh. beds. Underlies Galisteo sand group of Hayden and overlies Fort Pierre group.

Same or approx. same as Mesaverde fm., the older name.

Named for Madrid, Santa Fe Co.

Madruga chalk.

Cretaceous: Cuba.

J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, No. 6, p. 539).

Madson basalt.

Pleistocene: Southern Idaho (Gooding County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Madson basalt.*—Diabasic black basalt, in most places regularly jointed, and filling a former canyon of Snake River carved in Hagerman lake beds. Exposed thickness 200 ft. Older than Malad basalt and younger than American Falls lake beds. Madson Spring, Gooding Co., issues from this basalt.

Magallanes rhyolite.

Age (?): Mexico (Sonora).

N. L. Taliaferro, 1933 (Jour. Geol., vol. 41, No. 1, p. 34).

Magdalena group (also **Magdalena limestone**).

Pennsylvanian (lower): New Mexico (widespread) and western Texas.

C. H. Gordon, 1907 (Jour. Geol., vol. 15, pp. 807–816). *Magdalena group.*—Divided into (descending) Madera ls. (300 to 700 ft. of dark-blue ls.) and Sandia fm. (500 to 700 ft. of alternating beds of blue and black clay sh., compact earthy ls. and cgl., vitreous ss. or qtzite; sh. and ls. predominate). In Magdalena Mtns overlies Kelly ls. (Miss.).

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–798), extended *Magdalena ls.* into Tex. (where he identified the fm. in Hueco and Franklin Mtns and in a small area in Sierra Diablo) and restricted Hueco ls. to beds, of Perm.(?) age, uncon. overlying the Magdalena.

Named for development in Magdalena Mtns, N. Mex.

Magnolia member (of Platteville limestone).

Middle Ordovician (Black River): Southwestern Wisconsin, southeastern Minnesota, northeastern Iowa and northwestern Illinois.

C. A. Bays and G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 297–300). Kay's definition of McGregor memb. includes Lower Blue beds of Chamberlin and overlying beds which authors here name *Magnolia memb.*, *restricting McGregor memb.* to Lower Blue beds alone. Introduction of *Magnolia* is necessary because of somewhat inconsistent use of "Upper Buff," although in the main the Magnolia memb. is coincident with latter. However, in south-central Wis. (type area of Upper Buff) the Spechts Ferry and Magnolia are included in "Upper Buff," but in Lead Region the Magnolia is rather generally included in underlying "Blue Beds." There is extant no term which universally and specifically refers to the dolomites for which we are proposing *Magnolia*. Type exposure is on and near highways 13 and 14, 1 mi. S. of Magnolia, in NW¼ sec. 26, T. 3 N., R. 10 E., Rock Co., Wis., where the beds are 39 ft. thick. The beds are light-buff, moderately thick-bedded dol., with conspicuous fucoidal markings on bedding planes, at least in upper part of the memb. Lower down the bedding planes in many places bear great numbers of ostracod *Leperditia fabulites*. The Magnolia rests on dolomitic facies of Blue memb. and is overlain by 8 ft. of cherty Spechts Ferry beds with Hounsfield metabentonite [type in N. Y.] 17 inches above base. Fauna remarkably similar to that of Lower Buff or Pecatonica memb. In W. Wis.

Magnolia memb. is thinner and less conspicuous. In Lead Region it is more limy and more thinly bedded. Fossils listed. The *Vanuxemia* bed of Minn. is clearly = Magnolia memb.

Magoffin beds.

Pennsylvanian: Eastern Kentucky (Magoffin, Knott, and Breathitt Counties).

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 296, 301). *Magoffin beds* proposed for the shales and lss. so extensively developed in southern Magoffin Co.; not limited to that county, but probably have their most typical development there. In section at head of Sycamore Branch of Oakley Creek at home of Mrs. Sarah Salyers they consist of (descending): (1) Shales, blue, black, clayey, and carbonaceous, 3½ ft.; (2) dove-colored ls., 1 ft.; (3) shales, upper part calc. and very fossiliferous, 1½ ft.; (4) impure sandy ls., fossiliferous, 0.4 ft.; (5) shales, soft, blue, clayey, filled with plant fossils, 3 ft. This is perhaps an average section. Overlie Middle, "Taylor," or Copland coal; lie 35 ft. below Saltlick beds and 220 or 230 ft. above Kendrick shales. Can be traced from type loc. through Knott and Breathitt Counties to North Fork of Kentucky River at Copland, where they form roof of coal mined there.

Magog formation.

Ordovician: Quebec.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 200). *Magog fm.*, Ord., Canada.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11). *Magog slates*, Ord., Quebec.

Magog conglomerate.

Lower Ordovician: Quebec and northeastern Vermont.

J. A. Dresser, 1925 (Roy. Soc. Canada Proc. and Trans., 3d ser., vol. 19, sec. 4, p. 116). *Magog cgl.*, Ord., Quebec. Included in Quebec group.

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 107–110). *Magog phase of Irasburg cgl.* was discovered by Dresser, 1925. Its pebbles are pre-Ord. and its matrix is Ord. It lies at base of my Memphremagog slates. In this respect it conforms to Northfield phase of the Irasburg, which is more than 100 mi. farther S.

Magothy formation.

Upper Cretaceous: Maryland, New Jersey, Delaware, Long Island and other islands of New England coast.

N. H. Darton, 1893 (Am. Jour. Sci., 3d, vol. 45, pp. 407–419). *Magothy fm.*—Mainly white and buff sands with local beds of brown ss. and limonitic streaking in plates and discolorations. To SW. becomes gravelly for some distance, and some portions are locally lithified into loose cgls. or more or less pebbly brown sss. I formerly supposed these beds to be a local upper memb. of Potomac fm., but find they are separated from Potomac by a continuous erosion plane and that they constitute a distinct fm. 0 to 30 ft. thick in upper Chesapeake Bay region. Uncon. underlies Severn fm. Excellently exposed on Magothy River [Anne Arundel Co., Md.].

For further explanation of *Magothy fm.* see under *Raritan fm.*, 1904 and subsequent entries.

Magpie dolomite member (of Blaine gypsum).

Permian: Western Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 48). *Magpie dol. memb. of Blaine div.*—Hard fossiliferous aren. dol., 1 to 12 ft. thick, overlain by Medicine Lodge gyp. memb. and separated from underlying Ferguson gyp. memb. by a stratum of red sh. All included in Blaine div.

Later abandoned by Gould. See 1906 and 1927 entries under *Altona dol. memb.*

Creek, Blaine Co., just below the ledge.

Named for permanent camp of an Arapahoe chief of that name on Bitter

Magrath sandstone. (In Bearpaw shale.)

Upper Cretaceous: Southern Alberta (near Lethbridge).

T. A. Link and A. J. Childerhose, 1931 (A. A. P. G. Bull., vol. 15, No. 10, pp. 1232, 1235). *Magrath ss.* (*Arctica zone*).—A distinctly sandy zone, consisting of several members having aggregate thickness of 62 ft., present in top part of lower third of Bearpaw sh. Top lies 272 ft. above base of Bearpaw and 100± ft. below Kipp ss. Type section is on S. bank of St. Mary River ½ mi. downstream from mouth of Magrath Coulee, Lethbridge area.

Mahanoy black shale member.

Middle Devonian: Central Pennsylvania (Northumberland County).

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, Proc. Pal. Soc. Feb. 28, pp. 202–203). *Mahanoy black sh. memb.*—Top memb. of Marcellus fm. in central Pa. Is fissile, nearly barren, black sh.; 200 ft. thick SW. of Mexico, Juniata Co. Named for Mahanoy Twp, SW. Northumberland Co., where well exposed. Overlies Mexico ss. memb.

Mahantango formation.

Middle Devonian: Central Pennsylvania (Allegheny Front).

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, Proc. Pal. Soc., Feb. 28, pp. 202, 205–223). *Mahantango fm.*—Introduced to include all beds btw. Marcellus black sh. and base of Portage. It is=Hamilton as formerly in general use. As Hamilton is now rated in N. Y. and Pa. as a group term, and because the post-Marcellus beds in central Pa. are lithologically inseparable into fms., it is necessary to employ some new title for these strata. Named for North Branch of Mahantango Creek, in whose valley and in adjacent parts of Snyder and Juniata Counties are excellent exposures. The fm. is exposed throughout central Pa. except in a few sections in south-central Juniata Co. Thickness varies from max. of 1,100 ft. in Northumberland Co. to minimum of 500 ft. in western Juniata. With exception of the prominent Montebello ss. the fm. throughout is of nearly uniform lithology. In south-central Pa. contains coarse heavy ss. lenses. The fm. is chiefly uniformly dark gray or brown, usually clayey or finely aren. sh. to fine-grained, dark, shaly ss. that may become platy or flaggy locally. Very fossiliferous. Fossils listed. In central Pa. it is divided into (descending) Moscow faunal facies, Ludlowville faunal facies, and Skaneateles faunal facies. In eastern Pa. it is represented by Moscow fm., Ludlowville fm., and Skaneateles fm.

B. Willard, 1935 (Geol. Soc. Am. Proc. 1934, June 1935, p. 361). Hamilton group along Allegheny Front divided into *Mahantango fm.* above (including, descending order, Frame sh. memb., Cheneysville ss. memb., and Gander Run sh. memb.), and Marcellus fm. below.

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, Aug. 31, pp. 1276–1290). Hamilton group of eastern Pa. divided into 4 fms. (Moscow, Ludlowville, Skaneateles, and Marcellus), which maintain their identity btw. Susquehanna and Delaware Valleys. In more easterly sections the characters are obscured except for the Marcellus, which is the one fm. of the group recognizable throughout the Hamilton in Pa. In central Pa. Hamilton group is divided into Mahantango fm. (including Moscow faunal facies, Ludlowville faunal facies, and Skaneateles faunal facies) and Marcellus fm. (divided into, descending, Mahanoy black sh. memb., Mexico ss. memb., Turkey Ridge ss. memb., and Shamokin black sh. memb.). In Bedford Co., near Chaneysville, Mahantango fm. is divided into (descending) Frame sh. memb., Chaneysville ss. memb., and Gander Run sh. memb., aggregating 1,375 ft. In Huntingdon Co. the thickness is 1,065 ft. [Long description.]

Mahaska till.

Mahaskan glacial epoch.

Terms employed by C. [R.] Keyes to designate the Pleist. deposits in Iowa now called *Kansan*. (In his opinion the deposits called *Kansan* in Iowa are in truth pre-Kansan and correspond to the Nebraskan or oldest Pleist. stage. See Pan-Am. Geol., vol. 55, p. 145, 1931, and vol. 58, p. 203, 1932.)

Mahomet beds.

Pleistocene: Central eastern Illinois (Champaign County).

E. J. Cable, 1921 (Iowa Univ., Some phases of Pleistocene in Iowa, pp. 59–60). *Mahomet beds* are located near Mahomet [Champaign Co.], Ill., and belong to Sangamon interglacial epoch. [Discusses fossils—insects.]

Mahoning sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania, eastern Ohio, West Virginia, and western Maryland and Virginia.

J. P. Lesley, 1856 (Manual of Coal, pp. 94, 97–98). *Mahoning ss.*—Underlies coal F of Barren Measures and overlies the Lower series, which includes coal E (Upper Freeport) about 50 ft. beneath top. The Mahoning consists of 2 sss., each 35 ft. thick, separated by 25 ft. of sh. Rests on 2 to 50 ft. of brown and blackish sh.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 477, 493). *Mahoning massive bed of ss.*, 50 to 75 ft. thick, underlies Lower Barren Measures and overlies Freeport group. Becomes a true cgl. along the Mahoning Creeks.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 33). The *Mahoning ss. of Rogers* extended from top of Buffalo ss. to base of Lower Mahoning ss. Name here restricted to lower ss., which is 40 to 80 ft. thick, and consists of (descending): Flaggy ss., 28 ft.; fire clay and argill. sh., 35 ft.; ls., 5 ft.; shaly ss., 10 ft. When massive it is usually a coarse-grained yellowish white rock and frequently contains small pebbles of quartz. The term Mahoning has always been applied to this lower ss. The Buffalo ss. and Mahoning ss. never merge. Both sss. are present on Mahoning Creek [Indiana and Jefferson Counties, Pa.]. Lies lower than Brush Creek coal and rests on Upper Freeport coal.

W. G. Platt, 1880 (2d Pa. Geol. Surv. Rept. H_5), recognized in Armstrong Co., Pa.: (1) An Upper Mahoning ss. 160 ft. thick (which J. P. Lesley on p. 312 proposed to change to *Saltsburg ss.*); (2) a *Middle Mahoning ss.*, 15 ft. thick [probably Buffalo ss.], overlying the Gallitzin coal; and (3) a *Lower Mahoning ss.*, 20 ft. thick, separated by a short interval from underlying Upper Freeport coal.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 95–98). *Mahoning ss.*—In places one rock; in other places it subdivides, is complex, and 100 to 150 ft. thick, consisting of (descending): Upper Mahoning sss., 40 to 50 ft.; Mahoning coal, 0 to 17 ft.; *Mahoning ls.*, 0 to 20 ft. (in Beaver Co., Pa., locally termed "Summit" ls.); Upper Cannelton coal, 0 to 5 ft.; thin red or variegated sh.; Middle Cannelton coal, 0 to 3 ft.; thin red or variegated sh.; Lower Mahoning ss., 30 to 100 ft. (generally bluish-gray sss. and shales).

C. Butts, 1906 (U. S. G. S. Bull. 279, pp. 39–40). For reasons fully stated in Kittanning folio (No. 115, 1904) writer has decided to apply *Mahoning ss.* to only sss. lying btw. Upper Freeport and Brush Creek coals, an interval of 70 to 100 ft. This ss. usually lies at base of Conemaugh fm. and closely overlies Upper Freeport coal. It may, however, occupy a higher position and be separated from the coal by a sh. bed of variable thickness. [This is definition followed by U. S. Geol. Survey.]

Mahoning limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 477, 489). *Mahoning ls.*, 2 ft. thick, is top memb. of Tionesta group and in neighborhood of Newcastle, Pa., it immediately underlies Tionesta [Homewood] ss.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). The Mahoning ls. of Rogers is here renamed *Upper Mercer ls.* [See quotation under *Upper Mercer ls.*]

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3). The Mahoning ss. having been named during the First Survey from Mahoning Creek, in Indiana and Jefferson Counties, it was confusing to have a Mahoning ls. much lower in the series, named from Mahoning River in Lawrence Co., and it is therefore replaced by *Upper Mercer ls.*

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 95–98), recognized *Mahoning ls.* as a bed in midst of Mahoning ss. memb. (See quotation under *Mahoning ss. memb.*) The application of the name to this ls. bed has had considerable usage.

Mahoning red bed. (In Conemaugh formation.)

Pennsylvanian: Western Maryland, western Pennsylvania, and northern West Virginia.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 57, pl. 6), applied *Mahoning red bed* and *Mahoning red sh.* to beds both overlying and underlying Mahoning ls. in Pa. and western Md. On p. 57 he stated: A bed of red sh. has been observed at several localities in Upper Potomac Basin beneath Brush Creek coal, for which the name *Mahoning red sh.* is here proposed. Red sh. appears at this horizon in Conemaugh fm. at widely separated points, having been observed in well at Glenova, W. Va., in various wells in vicinity of Pittsburgh, and more recently by Dr. Harvey Bassler and writer at Freeport, Pa. This bed may be divided into 2 benches btw. which the Gallitzin coal may lie. [The chart, pl. 6, applied *Mahoning red bed* and *Mahoning red sh.* to beds both overlying and underlying Mahoning ls. in Pa. and western Md., and also to beds both overlying and underlying Gallitzin coal.]

Mahoning fire clay. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia, western Pennsylvania, and western Maryland.

See under *Thornton fire clay*. In Pa. the name *Mahoning flint clay* has been applied to 0 to 15 ft. of clay underlying Mahoning coal and overlying Mahoning ls.

Mahoning formation.

Pennsylvanian: Southwestern Pennsylvania.

G. H. Ashley, 1926 (Pa. Topog. and Geol. Atlas No. 65, Punxsutawney quad., pl. 4, pp. 25–26). *Mahoning fm.* includes beds btw. top of Upper Freeport coal and top of Brush Creek coal.

Includes Mahoning ss. memb. of Conemaugh fm. and some overlying and underlying beds.

Mahopac granite.

Pre-Cambrian: West Point quadrangle, southeastern New York.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225–226, pp. 54–56). *Mahopac granite*.—Medium-grained pinkish gneissoid granite, distinctly but not strongly foliated. Composed of colorless quartz, slightly pink feldspar, and dark biotite. Mapped with Reservoir granite, but it can be mapped separately. Is an intrusive rock. Type loc. along road running from Kent Cliffs to Mahopac mines, especially on fault scarp N. of latter mines, in Putnam Co.

Mahto sandstones.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll. vol. 57, No. 12, pp. 335, 339).

Maidment formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Maidment fm.*—Shales carrying *Niobe howelli*; underlying Riders Brook fm. and overlying Apsey fm. Included in Clarenville series. [Derivation of name not stated.]

Main Street limestone member (of Denison formation).

Lower Cretaceous (Comanche series): Northeastern Texas and central southern Oklahoma.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 302, 303, 317, 328–331). *Main Street ls.*—Fossiliferous coarse-grained ls., of irregular hardness, composed of minute shell fragments, and separated by thin beds of clay. Of dull yellow color on weathering, white on fracture. Thickness not over 30 ft. Top memb. of Denison beds and of Washita div. Overlies Pawpaw clays and uncon. underlies Dakota ss. [As thus defined included Grayson marl memb.]

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 114–115, 121–124, 245, 246–249, 266–271, pls. 7, 18). *Main Street ls.*—Impure, hard, yellow or yellowish white ls. with marl layers, underlying Main St. at Denison, Tex. Thickness 15 to 22 ft. Underlies Grayson marl (grayish marl, lighter colored than Main Street ls., and 60 ft. thick) and overlies Pawpaw fm., all of which are included in Denison beds. [This is generally approved definition, and it displaces "Choctaw ls."]

Maissade tongue (of Thomonde formation).

Miocene: Haiti.

W. F. Jones, 1918 (Jour. Geol., vol. 26, p. 739). [Assigned to Tert., and called *Maissade beds.*]

W. P. Woodring, 1922 (Haiti Geol. Surv., Stratigraphy, structure [etc.], of central plain, p. 7). *Maissade tongue of Thomonde fm.* assigned to Mio.

Major sand.

A subsurface sand in St. Louis ls. of western Ky.

Makalapa tuff.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Makalapa tuff.*—Erupted from Makalapa Crater. Included in middle part of Honolulu volcanic series [q. v.].

Makanda sandstone member. (In Pottsville formation.)

Pennsylvanian: Southwestern Illinois.

S. St. Clair, 1917 (Ill. Geol. Surv. Bull. 35, p. 48, pl. 4). *Makanda ss. memb.*—Heavy cliff-making ss., 100+ ft. thick, exposed near Makanda. Lies 100 to 150 ft. above base of Pottsville fm. and top lies 400 to 460 ft. below top of Pottsville fm. (base of No. 2 coal) of Williamson, Union, and Jackson Counties, Ill.

J. E. Lamar, 1925 (Ill. Geol. Surv. Bull. 48, pp. 23, 95–100, and map). In general *Makanda ss. memb.* may be divided into a basal massive ss. 80 to 120 ft. thick and an upper part, of about same thickness, composed of medium and thin bedded sss. interbedded with sh. Cross bedding and ripple marks are common. Lenses of coal occur at many horizons. Locally its upper part includes beds of massive ss. and two beds of black sh., which may or may not be same. Thickness 250 ft. in E. part of Carbondale quad. and 300 ft. in W. part. Is top memb. of Pottsville fm. Rests conformably on Drury sh. and ss. memb., and is overlain conformably by Murphysboro (No. 2) coal, the basal memb. of Carbondale fm. Named for town of Makanda, Jackson Co., near which it forms prominent bluffs.

Makasin Hill zone. (In Negaunee formation.)

Pre-Cambrian (middle Huronian): Northern Michigan (Marquette County).

J. L. Adler, 1935 (Jour. Geol., vol. 43, No. 2, pp. 113–132). *Makasin Hill zone of Negaunee fm.*—Chiefly straight, medium to thin bedded, dense chert, hematite, and limonite. Grades laterally into ore bodies. Martitic portion near base grades down into Siamo sl. The Makasin Hill zone grades up into North Lake zone. Thickness 310 ft. Type area, Makasin Hills.

Makawao breccia.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Makawao breccia.*—Included in lower part of Honolulu volcanic series [q. v.]. Exposed 2½ mi. S. and a little W. of Olomana Peak, in Maunawili ranch, also at an altitude of 600± ft. in the bed of Makawao Stream.

Malad basalt.

Pleistocene: Southern Idaho (Gooding County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Malad basalt.*—Black feldspar pahoehoe basalt filling a deep ancient canyon of Snake River N. of present canyon. In places well covered with loess. Thickness 400+ ft. Older than Thousand Springs basalt and younger than Madson basalt. Exposed in Malad Canyon, Gooding Co. Near Malad power plant it forms cliff 400+ ft. high.

Malade Valley group.

Pliocene (?): Northeastern Utah and southeastern Idaho (Malade River valley).

A. C. Peale, 1879 (U. S. Geol. and Geog. Surv. Terr. 11th Ann. Rept., p. 641). *Malade Valley group.*—The soft sss. and marls of Malade Valley containing forms of fresh-water shells are probably more modern than same beds in Cache Valley.

Now considered probably of same age as beds in Cache Valley (NE. Utah and SE. Idaho) and as Salt Lake fm.

Malaga mudstone member (of Monterey shale).

Miocene (upper): Southern California (Palos Verdes Hills).

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 146). *Malaga mudstone memb.*—Radiolarian mudstone forming top memb. of Monterey sh. in Palos Verdes Hills. Thickness 300 to 600 ft. Overlies Valmonte diatomite memb. and underlies Repetto siltstone (Plio.). Is upper Mio. Type region at Malaga Cove, Palos Verdes region [Los Angeles Co.].

Malahat volcanics.

Carboniferous (?): British Columbia.

C. H. Clapp, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 46; Canada Geol. Surv. Summ. Rept. 1913, p. 90); and 1917 (Canada Geol. Surv. Mem. 96, p. 72). *Malahat volcanics*, Carbf. (?), B. C.

Malbaie conglomerate.

Devonian: Quebec (Gaspe Peninsula).

C. H. Kindle, 1936 (Eastern Geol., No. 1, April 1936, pp. 3–5). Gaspe ss. may be divided into a lower memb. (called by Williams *York River ss.*), 7,000 ft. thick, and an upper memb. (consisting of 3,000 ft. of ls. cgls. and sss.), which may be called *Malbaie cgl.* Assigned to Dev. The fossils of York River beds are probably Middle Dev. [Mapped along shores of Mal Baie.]

Malden sandstones. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A, pp. 271, 425). *Malden ss.*—Dull gray or dove-colored, micaceous, sometimes massive but usually flaggy, always making steep bluffs. Thickness 200 to 350 ft. Overlies Cedar Grove coal and underlies fire clay beneath Chilton coal. Is conspicuous on both banks of Great Kanawha River in vicinity of Malden, Kanawha Co.

R. V. Hennen, 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., pp. xxvi–xxviii). *Malden ss.*, 15 to 25 ft. thick, underlies fire clay beneath Little Alma coal and lies 0 to 5 ft. above Campbells Creek ls.

C. E. Krebs and D. D. Teets, Jr., 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., p. 279). *Malden ss.*, gray, dove-colored, micaceous, and often flaggy ss., 60 ft. thick; lies 5 to 10 ft. above Cedar Grove coal and lies lower than Thacker coal.

C. E. Krebs and D. D. Teets, Jr., 1915 (W. Va. Geol. Surv. Rept. Boone Co., p. 46). *Malden ss.*, 5 to 50 ft. of massive grayish-blue micaceous ss., often with layers of slate; underlies Little Alma coal and lies 1 to 5 ft. above Campbell Creek ls. *Lower Malden ss.*, 8 to 30 ft. of massive ss., lies 1 to 3 ft. below upper bench Campbell Creek (No. 2 Gas) coal and 1 to 5 ft. above lower bench of Campbell Creek (No. 2 Gas) coal.

Malheur formation.

Recent: Northeastern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Review, vol. 8, pp. 207–214). *Malheur fm.*—Loose sands, 10 to 200 ft. thick, occurring as dunes. Type loc., Malheur, Harney Co.

Malignant Cove formation.

Ordovician: Nova Scotia.

M. Y. Williams, 1912 (Am. Jour. Sci., 4th, vol. 34, pp. 245, 246).

Mallett dolomite.

Lower Cambrian: Northwestern Vermont (Chittenden County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 110). *Mallett dol.*—Practically all of fm. is massive light- and dark-gray dol. Beginning 100 ft. above base there are 2 or 3 beds of fine white qtzite, cross-bedded and ripple-marked, and sandy dolomites are numerous, in many places grading into dolomitic ss. Between St. Albans and Canada border a few beds of sh. occur btw. the dolomites. Bedding is usually plain and even; most layers are less than 1 ft. thick. Secondary quartz in geodes is common in the dolomites. A few beds of pink dol. occur here and there, apparently in lower part of fm., but these may be repetitions of underlying Winooski marble by faulting. The beds are hard and tough and make ridges. Lower Camb. fossils in upper part in towns of Georgia and Highgate. Thickness 50 to 800 ft. Named for fine exposures on shores of Mallett Bay [Milton quad.], 5 mi. N. of Burlington. Grades into overlying Colchester fm. [Parker sl.], and overlies Winooski marble with abrupt change.

Mallorytown granite.

Pre-Cambrian: Ontario.

J. F. Wright, 1923 (Canada Geol. Surv. Mem. 134, p. 26).

Malone formation.

Upper Jurassic: Western Texas (Hudspeth County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 720–721, 736). *Malone bed.*—In descending order: Gyp., 110 ft.; massive blue granular ls., 170 ft.; white fissile granular gyp., 45 ft.; pale-yellow flaggy ls., 25 ft. Underlies Etholen bed. Included in Washita div. of Cret.

F. W. Cragin, 1897 (Jour. Geol., vol. 5, pp. 817–819). *Malone beds or Malone fm.*—Fossiliferous sss. and lss., gypsums, massive calcite-seamed lss., and any other rocks included among these of Malone Mtn and hills N. and E. of Malone Station. The Malone fm. thus assumes wider limits, a different age significance, and far greater importance than were assigned to it by Mr. Taff. Contains Jurassic fossils. [These fossils are now considered to be Upper Jurassic.]

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 254–257). *Malone fm.* of Cragin included rocks of both upper Jurassic and lowermost Cret. age, which outcrop near Malone (now Torcer) Station on Southern Pacific Ry, SW. of Hudspeth Co. The name *Malone*, in accordance with Cragin's apparent intention, is here restricted to that portion of these rocks which is of Jurassic age. These beds are only a small terminal residue of Jurassic strata of much greater extent which were deposited in a northwardly narrowing arm of Kimmeridge sea in north-central Mexico. They are mostly of Kimmeridge age. The Malone beds rest uncon. on Perm. strata and are overlain, by an inferred uncon., by Valanginian Cret. The Malone Jurassic is mostly cgls., brown sss., and lss., the sss. in part conglomeratic with well rounded ls. and chert pebbles. Some lss. contain chert pebbles. Lithology and position indicate near-shore facies. The Cret. part of Malone fm. is here named *Torcer fm.* [This restricted definition has not been considered by U. S. Geol. Survey for its publications.]

Maloney metamorphic series.

Ordovician: Central Washington (Skykomish Basin).

W. S. Smith, 1916 (Jour. Geol., vol. 24, pp. 559–570). *Maloney metamorphic series.*—Qtzites, schists, and crystalline lss., with associated greenstones. Thickness 4,000 ft. Weaver correlates this series with Cache Creek series of Dawson. On lithologic grounds formerly believed=[G. O.] Smith's Peshastin series of Snoqualmie area, but fossils identify it as Ord., instead of Carbf., as the Peshastin is called by [G. O.] Smith and the Gunn Peak by Weaver. Younger than Easton schist. [On p. 560 he uses *Maloney (Gunn Peak) metamorphic series*. Type loc. not given, and compiler has been unable to locate it.]

Maloney sand.

A subsurface sand, of Penn (?) age, in Stephens Co., southern Okla.; lying at 2,600 ft. depth in Empire pool, the Kagey sand lying at 2,300 ft.

Mal Pais gravel.

Age (?): Cuba.

C. W. Hayes, 1901 (Rept. geol. reconn. Cuba, p. 114).

Malpais basalt.

Tertiary (Pliocene?): Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 72, etc.). *Malpais basalt.*—Flow or flows, with a few small intrusions. Dark olivinitic basalt, of a holocrystalline variety that is properly designated dolerite. Caps Malpais Mesa, SW. part of Goldfield dist. Thickness 100 to 200 ft.

Maltrata division.

Cretaceous: Mexico.

J. D. Villarello and E. Böse, 1902 (Mexico Inst. Geol. Bull. 16, p. 16).

Mamacoke gneiss.

Pre-Cambrian: Southeastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 150–152, and map). *Mamacoke gneiss.*—Larger area decidedly gneissic, containing much biotite and more rarely hornblende, but elsewhere the rocks are very granitic in appearance. These different types of rock are probably of different age and possibly of different origin. Much field work is needed. Exposures on Mamacoke Island are typical of large part of area. The eastern part consists of many alternating bands, usually less than 2 ft. thick, of black biotite and white feldspar and quartz; the western is a normal reddish-gray granitic gneiss. Probably igneous and pre-Camb.

H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7, p. 38). *Mamacoke gneiss* is of igneous origin.

Mamainse diabase.

Pre-Cambrian: Ontario.

E. S. Moore, 1926 (Ont. Dept. Mines 35th Ann. Rept., vol. 35, pt. 2, p. 60).

†Mammoth limestone.

Lower Ordovician and Upper, Middle, and Lower Cambrian: Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 620, footnote). In Tintic folio the Eureka ls. of this rept. will be named *Mammoth fm.*, to avoid duplication of names. [For description see †*Eureka ls.* The accompanying map shows the fm. well exposed at and around Mammoth, Juab Co. In Tintic folio, No. 65, 1900, the †Eureka ls. was renamed †Mammoth ls. In detailed rept. on Tintic dist. (U. S. G. S. P. P. 107, 1919) it was subdivided by G. F. Loughlin and W. Lindgren into 9 fms. (of Lower Ord. and Upper, Middle, and Lower Camb. age), and †Mammoth ls. was abandoned.]

Mammoth andesite.

Tertiary: Central Nevada (Cedar Mountains).

A. Knopf, 1921 (U. S. G. S. Bull. 725H). *Mammoth andesite* is well exposed on Mammoth claim, Cedar Mtns. Probably not younger than middle Mio.

Mammoth Cave series.

Mississippian: Western central Kentucky.

A. M. Miller, 1919 (Table of geological formations of Ky., p. 3). *Mammoth Cave series.*—Best developed in western Ky. Includes Newman [ls.] in part in eastern Ky. Includes St. Louis ls., Ste. Genevieve ls., Bethel ss., and Gasper [oolite].

A. M. Miller, 1919 (Dept. Geol. and Forestry of Ky., ser. 5, Bull. 2, p. 103). *Mammoth Cave ls. series.*—This name is proposed for the almost uninterrupted deposit of relatively pure ls. which has as a highly conspicuous feature the presence in it of caverns of considerable extent. Greatest development in State is in region surrounding the Western coal fields, where it may reach max. thickness of 600 ft. Is generally less than 100 ft. Includes Ste. Genevieve and St. Louis stages. Underlies Bethel ss. and overlies [discon., p. 250] Warsaw stage. Is closely=Maxville, Greenbrier, and Newman lss.

Apparently named for Mammoth Cave, Edmonson Co.

Mammoth Mountain rhyolite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). A single thick flow, of rather uniform character, at base of Piedra group of Potosi volcanic series in NE. part of Creede area and in mtns to E. and NE. Has been followed to E. as far as Bellows Creek, but not recognized to W., S., or N. of Creede area. Wedges out in upper drainage basin of Nelson Creek. Thickness 0 to 1,000 ft. Named for Mammoth Mtn. Overlain by rhyolite tuff.

Manana tuff.

Latest Pleistocene or Recent: Hawaii (Manana Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Manana tuff.*—Pelagonitized gray to brown lithic tuff, erupted from 2 vents. Composes Manana Island, 1½ mi. NW. of E. point of Oahu. Included in upper part of Honolulu volcanic series [q. v.].

Manasquan marl.

Eocene (lower): New Jersey.

W. B. Clark, 1893 (N. J. Geol. Surv. Ann. Rept. 1892, pp. 205–208). *Manasquan marl.*—Greensand throughout. Highly quartzose in lower 40 ft. The upper more glauconitic memb., 25 ft. thick, is known as the "ash marl." Underlies [uncon.] Shark River marl, and conformably overlies Middle Marl bed [Rancocas group]. Named for excellent section of strata on Manasquan River.

C. W. Cooke and L. W. Stephenson, 1928 (Jour. Geol., vol. 36, No. 2, p. 145), transferred this fm. from Upper Cret. to Eo., based upon contained fauna.

Manassas sandstone. (In Newark group.)

Upper Triassic: Northeastern Virginia.

J. K. Roberts, 1923 (Pan-Am. Geol., vol. 39, pp. 185–200). *Manassas ss.*—Sss. forming intermediate fm. of Triassic sediments of northern Va. Older than Bull Run shales and younger than Border cgls. The red sandstones are limited chiefly to W. side of Triassic basin typically developed around Manassas.

J. K. Roberts, 1928 (Va. Geol. Surv. Bull. 29, pp. 24–25). *Manassas ss.* is for most part intercalated with Bull Run shales, and extends in very broken belts from a few mi. S. of Potomac River over all areas to Carolina border. Where not disturbed by faulting and not covered by Recent material or soil the Border cgls. underlie Manassas ss. and the Bull Run shales overlie it.

Manastash formation.

Eocene: Central Washington (Mount Stuart and Snoqualmie quadrangles).

G. O. Smith, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, pp. 485–486). *Manastash fm.*—Carbonaceous beds of different character from preceding Roslyn fm. (Eo.).

G. O. Smith, 1903 (U. S. G. S. P. P. 19; and U. S. G. S. Ellensburg folio, No. 86). So far as known *Manastash fm.* is limited to SW. part of Mount Stuart quad. and adjacent part of Snoqualmie quad. Consists of ss., sh., and cgl. beds with some seams of carbonaceous material. Uncon. underlies Yakima basalt (Mio.). Although somewhat younger than Roslyn fm., which occurs a few mi. to N., the Manastash rests upon Easton schist (Carbf.?). This relation is believed to indicate nondeposition of the earlier Eo. sediments in this area.

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Manastash fm.* is 1,000 ft. thick. Occurs on headwaters of Manastash Creek.

E. J. Saunders, 1914 (Wash. Geol. Surv. Bull. 9), gave thickness of Manastash fm. as 1,900 ft.

†Manatee River marl.

Miocene (lower or later Miocene): Western part of peninsular Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 125–126). *Manatee River marl.*—Basal white marl and yellowish ss. at Rocky Bluff, on right bank of Manatee River, a few mi. above Braidentown, Manatee Co. The marl is "densely charged" with organic remains. [Mentions fossils and briefly discusses probable relations to other fms.] These imperfect data indicate most southern extension of Chesapeake group which has yet been determined on W. edge of Floridian peninsula.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept.). "Manatee River marl" is a part of Oak Grove sand memb. of Alum Bluff fm., and name is abandoned.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). "Manatee River marl" is here included in Hawthorn fm.

†Manayunk mica schists and gneisses.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania.

C. E. Hall, 1881 (2d Pa. Geol. Surv. Rept. C_6, map and pp. 27–28). *Manayunk mica schists and gneisses* [on map]; *Manayunk group* [in text].—Crosses the Schuylkill at Manayunk. Extends along Schuylkill River from S. of Mill Creek to mouth of Wissahickon Creek.

Replaced in part by Wissahickon fm.

Manchester shale.

Eocene: Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 52, 188). *Manchester shales.*—Very dark blue or, when wet, dense-black clay shales, 5 ft. thick. Exposed at Manchester Landing, on Ouachita River, where they underlie 3 ft. of blue and drab finely laminated micaceous sands. Included in Camden series. Same as shales at mouth of L'Eau Frais. [On pp. 56, 211, and elsewhere in this rept. these shales are called *L'Eau Frais shales.*]

Probably belong to Wilcox fm.

Named for exposures at Manchester Landing, near mouth of L'Eau Frais, Clark Co.

Manchester group. (In Newark group.)

Upper Triassic: Central southern Pennsylvania (Dauphin and York Counties).

G. H. Ashley, 1931 (Topog. and Geol. Surv. Pa. Bull. G1, p. 77). *Manchester group.*—Coarse-grained, highly micaceous greenish-gray, relatively soft ss. with interbedded red feldspathic ss. and sh., 7,000 to 8,000 ft. thick, composing basal fm. of Upper Triassic in Dauphin and York Counties. Underlies Conewago group. [Credited to [M. H.] Bissell. When the Triassic of New Cumberland and Middletown quads. (in which occurs Manchester Twp) was differentiated for 1931 geol. map of Pa. these rocks were mapped as New Oxford fm., of which they are a western extension, and the overlying Conewago of Bissell was included in Gettysburg sh.]

Manchioneal formation.

Pliocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 86).

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 419).

Mancos shale.

Upper Cretaceous (of Montana and Colorado age): Western Colorado, northwestern New Mexico, eastern Utah, southern and central Wyoming.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). *Mancos sh.*—Dark-gray or lead-colored shales, nearly always somewhat sandy. Contains thin calc. layers which in places become almost lss. and are usually rich in fossils. Sand locally increases to form ss., but no ls. or ss. layer is persistent and prominent enough to be traced far. Thickness 2,000 ft. Overlies Dakota fm. and in Telluride quad. is overlain by Eocene San Miguel fm. Named for characteristic occurrence in Mancos Valley and about town of Mancos, btw. La Plata Mtns and the Mesa Verde.

W. Cross and A. C. Spencer, 1899 (U. S. G. S. La Plata folio, No. 60). *Mancos sh.*—So named in Telluride folio. Throughout its thickness of 1,200± ft. in La Plata quad. it is an almost homogeneous body of soft, dark-gray or nearly black, carbonaceous clay sh., varied only by few thin fossiliferous bands or concretions of impure ls., which are too few and too discontinuous to serve as practical guides in subdivision of the great sh. series. Is limited below by Dakota ss. and above by lowest ss. of Mesaverde fm., which consists of alternating sss. and shales. The whole fm. is well exposed along N. face of the Mesa Verde near Mancos, below the scarp of ss. Fossils, identified by T. W. Stanton, are of Benton and Pierre age, but no distinctive fauna of Niobrara age has yet been found in it.

N. M. Fenneman and H. S. Gale, 1906 (U. S. G. S. Bull. 297). The 2,000 to 2,500 ft. of dark sh., containing ls. and ss. layers, which lies above Dakota ss. in Yampa coal field, NW. Colo., is here called *Mancos sh.* because it closely resembles typical

Mancos sh. of SW. Colo. and occupies a similar position above the Dakota. It is also overlain by beds which are apparently analogous to typical Mesaverde fm., which overlies the Mancos in SW. Colo. Fossils 200 ft. above Dakota ss. are pronounced by T. W. Stanton to be of Benton age, and fossils 600 ft. higher are pronounced by him to be of Niobrara age. Approx. upper half of the Mancos is of Montana age.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, p. 10). The marine *Mancos sh.* of SW. Colo. and NW. N. Mex. has yielded faunas of, in ascending order, Greenhorn, Carlile, Niobrara, and Pierre age. It grades into underlying Dakota ss., and into overlying Mesaverde group, the bdy with which is arbitrarily fixed. Writer believes lower part of Mesaverde group on the San Juan represents time interval of part of Mancos sh. of Animas River section. Thickness at type loc. is 1,200 ft. It varies in thickness in SW. Colo., up to a max. of 2,000 ft. near Telluride.

Mancos sandstone.

Upper Cretaceous: Northwestern Colorado (Routt County).

R. D. Crawford, 1920 (Colo. Geol. Surv. Bull. 23, pp. 11–15, map). *Mancos ss.*—Seen in only 3 exposures. Near S. border of Williams Park the exposed part of this memb. consists of alternating sss., shales, and lss., dominantly ss. with some fossiliferous ls. and numerous sh. partings; the ls. has strong bituminous odor. Thickness 20 to 40 ft. Lies 350 to 400 ft. above base of Mancos sh., of which it is a memb.

K. M. Willson, 1920 (Colo. Geol. Surv. Bull. 23, pp. 30–39). *Mancos ss.* consists of porous calc. ss. with numerous thin sh. partings. Is 25 to 35 ft. thick in Tow Creek anticline, and lies 460± ft. above base of Mancos sh.

Mancosian series.

A term applied by C. R. Keyes to the rocks underlying his Foxian series and overlying his Pierrean series.

Mandan amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 177, 205, 206, 248, 409, 490, 491, etc., figs. 23, 24, 25, 29, 34). *Mandan ophite*, 250 ft. thick. Usually comes not over 300 ft. below the Greenstone. [This rock has for many years been called *Mandan amygdaloid.*]

Belongs in Central Mine group. Older than Manitou amygdaloid and younger than Houghton cgl. The mineralized part is the Mandan lode.

Named for occurrence in Mandan mine, Keweenaw Co.

Mandan flow.

Includes Mandan amygdaloid and the underlying trap.

Mandanan series.

Tertiary (?): Western North Dakota and South Dakota.

C. [R.] Keyes, 1925 (Pan-Am. Geol. vol. 43, p. 135). The Cannonball shale is evidently not the sole member of the sedimental province in which it is found. So, while retaining the title for the member best known at present the provincial unit may well be designated the *Mandanan series*. Of Tertic age.

Probably named for development of Cannonball marine memb. of Lance fm. at and around village of Mandan, Morton Co., N. Dak.

Manele basalt.

Age (?): Lanai, Hawaiian Islands.

C. K. Wentworth, 1925 (Bernice P. Bishop Mus. Bull. 24, p. 39).

Mangas quartzite.

Upper Cambrian: Southwestern New Mexico (Silver City region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 9). *Mangas qtzite.*—Basal siliceous memb. 100 ft. thick, of Mid Cambric section exposed near Silver City. [Derivation of name not stated. According to E. Kirk and others the Middle Camb. is absent in N. Mex. This probably refers to Bliss ss., Upper Camb.]

Mangum dolomite member (of Blaine gypsum).

Permian: Southwestern Oklahoma, Texas Panhandle, and central northern Texas.

C. N. Gould, 1905 (U. S. G. S. W. S. P. 148, p. 71). *Mangum dol. memb.*—White, drab or yellowish dolomitic ls., 1 to 5 ft. thick, in places true dol., in places mag. ls.; in places aren. and soft, in other localities cavernous and honeycombed; often firm and solid. Top memb. of Greer fm.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pl. 9). *Mangum dol.* lies 64 ft. below Acme dol., and in midst of Blaine fm. of western Tex.

Named for Mangum, Greer Co., Okla.

Manhasset formation.

Pleistocene: Southeastern New York (Long and Fishers Islands), and southern New England islands.

J. B. Woodworth, 1901 (N. Y. State Mus. Bull. 48, pl. 1 and text). *Manhasset gravels and sands* (mapped) underlie Manhasset Neck, Great Neck, and Oyster Bay quad. Are of pre-Wisconsin Pleist. age. Include a local glacial deposit called *Manhasset boulder bed* [either Hempstead gravel memb. or Herod gravel memb. of Manhasset fm.], which is mapped along E. side of Manhasset Neck.

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 766–776). *Manhasset (glacial)* seems to represent waterlaid material when the ice was at no very great distance to N. Is younger than Sankaty interglacial beds (correlated with Yarmouth) and was followed by Vineyard interval of uplift and erosion. Is correlated with Iowan stage. Greater part of it is considered=Tisbury of Woodworth. A portion of the folded Manhasset of Woodworth may be referable to the Jameco.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Manhasset fm.* (also *Manhasset stage*, for the time).—Glacial deposits, 150 to 250 ft. thick, correlated with Illinoian stage of Mississippi Valley. Divided into (descending): (1) Hempstead gravel memb., resting uncon. on (2) Montauk till memb., which rests uncon. on Herod gravel memb.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Manhasset fm.* is present on Block, Nantucket, Marthas Vineyard, No Mans Land, and Cape Cod.

F. G. Wells, 1935 (Geol. Soc. Am. Proc. 1934, p. 121), regarded Manhasset fm. as of Wisconsin age.

Manhasset stage.

The time covered by deposition of *Manhasset fm.*

†Manhasset boulder bed.

See under *Manhasset fm.*

†Manhattan group.

Pre-Cambrian: Southeastern New York (Manhattan Island).

R. P. Stevens, 1867 (N. Y. Lyc. Nat. Hist. Annals, vol. 8, pp. 116–120). We have (on New York [Manhattan] Island) four (or six including those under water) beds of ls., with their associated shales and ls.-shales, the former metamorphosed into marble, and the latter into gneiss and calciferous gneiss granite or hornblende. The conclusion which we have arrived at is that the rocks of New York Island are metamorphosed Taconic, and worthy of the name *Manhattan group*.

F. J. H. Merrill, 1890 (Am. Jour. Sci., 3d, vol. 39, pp. 390–392). The name *Manhattan group* was proposed by R. P. Stevens to include the rocks of New York Island, and it seems proper that it should, for the present, be retained, including in it [descending], with the Manhattan schists, the Inwood ls. and the Fordham gneiss, the Yonkers gneiss, which though not found on Manhattan Island, is evidently a part of the same littoral deposit to which the Fordham gneiss belongs. Probably of Paleozoic age.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 210). Above Fordham gneiss is a series of sed. fms. consisting of Lowerre qtzite, Inwood ls., and Manhattan schist. This series has at various times been regarded as Precamb., Camb., or Cambro-Ord., but most recent investigations indicate Precamb. age, and the rocks are regarded as belonging to Grenville time.

†Manhattan gneiss.

D. S. Martin, 1888 (Geol. map of N. Y. City and vicinity). *Atlantic or Manhattan gneiss* (*age disputed*).—Underlies crystalline ls. and overlies *Highland gneiss* (*Laurentian*).

Probably refers to Fordham gneiss.

Manhattan schist.

Pre-Cambrian: Southeastern New York and western Connecticut.

F. J. H. Merrill, 1890 (Am. Jour. Sci., 3d, vol. 39, p. 390). *Manhattan schists*.—Highly schistose rocks, largely mica, with small proportion of quartz and usually little or no feldspar; garnet, staurolite, fibrolite, and cyanite are chief accessories; some small beds of gneiss are present; intercalated at many localities are hornblendic and augitic strata, usually only a few ft. thick, which resemble diorites and diabases and which may have originally been eruptive rocks, but whatever their origin they are now metamorphic rocks and may be called amphibolites and pyroxenites. Thickness probably more than 1,000 ft. Of limited extent in Westchester Co. Well exposed on Manhattan Island, of which they constitute the principal rock fm. Overlie Inwood ls. Form top fm. of Manhattan group.

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). *Manhattan schist* is considered to be of Hudson River age. Assigned to Ord.

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83), used *Hudson schist, of Sil. age*, to replace Manhattan schist (see under †*Hudson schist*); but Manhattan schist is now considered to be pre-Camb.

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378). *Manhattan schist* (coarsely crystalline mica schist) assigned to pre-Camb. In Highlands area of SE. N. Y. it uncon. underlies true Poughquag qtzite, which contains Camb. fossils, and conformably overlies Inwood or Sprout Brook ls.

C. P. Berkey, 1909 (Sci., n. s., vol. 30, p. 416). The most constant characters of *Manhattan schist*, in order of importance, are presence of a white pearly mica, coarse foliation, and a crumpled structure.

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, pp. 47–57). *Manhattan schist* consists of nearly black or streaked micaceous, coarsely crystalline, strongly foliated rock, several thousand ft. thick, generally supposed to be=Hudson River slates. Assigned to Ordovicic (?).

C. P. Berkey and J. R. Healy, 1912 (Columbia Univ. Contr., vol. 20, pp. 1907–1912). *Manhattan* (*Hudson*) *schist*.—Primarily a recrystallized sediment which has lost its sed. character from profound metamorphism. Includes gneisses, schists, phyllites, and slates. Several thousand ft. thick. Conformably overlies Inwood ls. Whether Ord., Camb., or pre-Camb. undet. No fossils.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 21). Berkey holds that in all probability these fms. [Lowerre, Inwood, and Manhattan] are pre-Cambric and offers good evidence that they are not metamorphosed Paleozoic sediments.

J. F. Kemp, 1912 (11th Int. Geol. Cong., Stockholm, Compt. rend., pp. 702–711). *Manhattan mica schist* assigned to pre-Camb. and equivalence with Huronian of Lake Superior suggested.

C. R. Fettke, 1914 (N. Y. Acad. Sci., vol. 23, pp. 194–248). The use of *Manhattan schist* has been confined entirely to those schists which make the uppermost or youngest of bedrock fms. in SE. N. Y., Westchester and Putnam Counties. Consists of several thousand ft. of coarsely crystalline mica schist. In Conn. the continuation of these schists has been described by Conn. Geol. Survey as Berkshire. Age still in doubt, and much more detailed study of geology of SE. N. Y. and western Conn. and Mass. will have to be made before definite conclusion can be reached.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225–226). *Manhattan schist* is of doubtful age, but is tentatively correlated with later Grenville sediments (pre-Camb.).

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull 799). *Manhattan schist* assigned to pre-Camb. and correlated with Wissahickon fm. of Glenarm series (Algonkian).

†Manhattan beds.

Permian: Northern Kansas.

Robt. Hay, 1893 (Kans. State Bd. Agric. 8th Bien. Rept., p. 101). *Manhattan beds*.—Series of beds, not worked out in detail, but containing ls. and buffy, limy shales, also the gyp. beds of Marshall Co. and Pottawatomie. Overlain by Fort Riley beds and underlain by upper coal measures. Assigned to Permo-Carbf.

Named for Manhattan, Riley Co.

†Manhattan limestone. (In Council Grove group.)

Permian: Northern Kansas.

C. S. Prosser, 1894 (Geol. Soc. Am. Bull., vol. 6, pp. 37, 40–41). *Manhattan ls.*—Light yellowish-gray massive ls., 5 ft. thick, containing much chert and in upper part great numbers of *Fusulina cylindrica*. Basal memb. of Cottonwood fm. at Manhattan and vicinity. Overlain by Cottonwood shales and underlain by 31 to 36 ft. of shales and marls with thin ls. layers. Is=Cottonwood ls. and Alma ls.

Same as Cottonwood ls.

Named for Manhattan, Riley Co.

Manhattan ridge. (Also Manhattan moraine.)

Pleistocene (late Wisconsin): Northeastern Illinois (Joliet quadrangle). See D. J. Fisher, 1925 (Ill. Geol. Surv. Bull. 51, p. 89, footnote), and M. M. Leighton, 1932 (16th Int. Geol. Cong. Guidebook 26, pp. 16, 51, pl. 2).

Manifold sand.

Name that has been applied by drillers to Big Injun sand.

Manigotagan granite.

Pre-Cambrian: Manitoba.

E. S. Moore, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 265).

Manistee limestone.

Mississippian: Western Michigan.

C. C. Douglass, 1839? (Mich. Leg. H. Doc. 27, btw. pp. 97 and 111). *Manistee ls.* occurs near Manistee River in T. 15 N. Overlies light blue argill. sh. [The 1916 geol. map of Mich. Geol. Surv. maps the rocks of T. 15 N. and surrounding region as Coldwater sh.]

Manistee moraine.

Pleistocene (Wisconsin stage): Northwestern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Belongs to Port Huron morainic system. Named for Manistee.

Manistique series.

Silurian (Niagaran): Michigan (eastern part of Upper Peninsula).

R. A. Smith, 1916 (Mich. Geol. Surv. Pub. 21, p. 152). *Manistique series.*—Succession of high mag. lss. and dolomites, of white, light and dark gray, buff, blue, and brown colors, and ranging in texture from earthy or finely crystalline to coarsely crystalline. Thickness 250+ ft. Underlies Engadine dol. and overlies Fiborn ls.; all included in Niagara. Named for exposures at Manistique, Schoolcraft Co.

Manitoba formation.

Devonian: Manitoba.

A. MacLean and R. C. Wallace, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 167).

Manitoban.

Devonian (Upper?): Manitoba.

J. B. Tyrrell, 1892 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 144E–199E).

†Manitoban substage.

Pleistocene: Great Lakes region.

M. M. Leighton, 1931 (Jour. Geol., vol. 77, pp. 51–53). *Manitoban substage of Wisconsin stage* is the *Iowan*. In view of fact that the Iowan drift is first deposit of last glacial stage, it must either be known as early Wisconsin or else the old terms "early Wisconsin," "middle Wisconsin," and "late Wisconsin" must be dropped. It is nevertheless proposed that the subdivisions of Wisconsin stage be made according to dominance of the ice fields. This has the advantage of recognizing historical chronology, of placing natural boundaries, and of focusing attention on the fact of shifting dominancy of ice centers. It also permits the listing of the moraines under these divisions and the giving of subordinate places to these minor oscillations. The following nomenclature is therefore proposed: *Wisconsin stage*, divided into Hudsonian (late Wisconsin), Quebecan (early and middle Wisconsin), and Manitoban (Iowan). [The Manitoban is shown as older than Peorian loess.] The name *Manitoban* is taken from province of Manitoba, Canada, in which general area the Iowan ice probably had its center of radiation.

M. M. Leighton, 1933 (Sci., vol. 77, p. 168), withdrew "Manitoban substage" and returned to the old name *Iowan*, which, however, he included in Wisconsin stage.

The U. S. Geol. Survey treats Iowan as distinct from and older than Wisconsin stage.

Manitou limestone.

Lower Ordovician (Beekmantown): Eastern Colorado.

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *Manitou ls.*—Best seen in upper part of Garden Park, where it consists of fine-grained pink or reddish dol. less than 100 ft. thick and contains same fossils that characterize the fm. at Manitou Springs and in Manitou Park, for which it is named. To E. is wanting at many places. In Garden Park is conformably overlain by Harding ss. Rests on Algonkian granite and gneiss, but probably a small thickness of qtzite and cherty ls. below Manitou ls. are of Camb. age.

Manitou ls. (of Beekmantown age) is now recognized over a large area on both the E. and W. sides of Front Range. It is in places overlain by Harding ss. and Fremont ls., both of Ord. age, and in other places by Parting qtzite memb. of Chaffee fm. (Dev.). It rests on Sawatch qtzite, the transition shaly beds at the top of which are now known as *Peerless sh. memb.*

Manitou amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Is older than Medora amygdaloid and younger than Mandan amygdaloid. The mineralized part is the Manitou lode. Named for occurrence in Manitou mine, Keweenaw Co.

Manitou flow.

Includes Manitou amygdaloid and the underlying trap.

Manitou series.

A time term applied by N. H. Winchell to upper part of Keweenawan series of northern Minn., or to rocks extending from base of a cgl. interpreted by him as corresponding to Puckwunge cgl. up to top of Keweenawan. (See Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, pp. xiv–xx, 295–298, 1899.) Named for exposures on Manitou River, Lake Co. "Intended to cover that part of the eruptive Keweenawan which followed the great gabbro revolution."

Manitou stone.

Trade name for a stone quarried in Fountain fm. (Penn.) near Boulder, Colo.

Manitoulin dolomite member (of Cataract formation).

Silurian (early): Ontario.

M. Y. Williams, 1913 (Ottawa Nat., vol. 27, p. 37). *Manitoulin memb.*—The lower or dol. memb. of Cataract fm. in Georgian Bay region. Thickness 11 or 12 ft. near Collingwood, Ont., and 50 or more ft. on parts of Manitoulin Island. Underlies the upper or Kagawong [Cabot Head sh.] memb. of Cataract fm. and rests on soft green sh. at top of Richmond fm. Named because of its importance on

Manitoulin Island. At Cabot Head 6 ft. or more of soft red sh. intervene btw. the green Richmond sh. and the base of Manitoulin dol.

See also C. Schuchert's 1914 description, under *Cataract fm.* He recognized the Manitoulin in Stony Creek, Hamilton, Dundas, Glenwilliam, Cataract, Collingwood, Owen Sound, Cabots Head, and Manitoulin Island sections, all in Ont.

Later repts by M. Y. Williams and other geologists state that *Manitoulin dol. memb.* of Cataract fm. overlies Whirlpool ss. on Niagara River and at Dundas, Ont.

Manitoulin limestone.

Silurian (pre-Niagaran): Michigan (east end of Northern Peninsula) and Ontario (Manitoulin Island).

J. J. Bigsby, 1824 (Notes on Geog. and Geol. of Lake Huron, pp. 199-204). *Manitouline ls.* is separated on W. and N. from that of St. Joseph by waters, low woods, and morasses, nothing being visible near promontory of True Detour for many mi. around, on shores of main and neighboring islands, but ls. shingle, white, slaty, and devoid of petrifactions. On E. the *Manitouline ls.* is connected by a chain of high and rocky islets with Cabot's Head. I have seen numerous specimens from both extremities of this ridge, but it is with Drummond, Little Manitou, and W. end of Grand Manitou that I am personally conversant. This ls. is distinguished from that of St. Joseph and the N. by its greater compactness and hardness and difference in organic remains and the silicified state in which they are found, all fossils of Drummond being quartzose or chalcedonic, those of Little and Grand Manitou and Cabot's Head and vicinity being less purely ss. The ls. usually rises to 250 ft. above lake level, often in confused stair-like ledges.

A. C. Lane, 1905 (Mich. Geol. Surv. Ann. Rept. 1903, p. 288), used in table of geologic fms. of Mich., *Niagara* (*Manitoulin*). Later repts state that it is pre-Niagara and=part of Albion ss.

See *Manitoulin dol. memb. of Cataract fm.*

Manitouline limestone.

See *Manitoulin ls.*

Manitounuck group.

Cambrian: Canada.

R. Bell, 1879 (Canada Geol. Surv. Rept. 1877-78, pp. 11C-19C).

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 197), assigned these rocks to Camb.

Manix lake beds.

Pleistocene: Southern California (San Bernardino County).

J. P. Buwalda, 1914 (Calif. Univ. Pub., Dept. Geol. Bull. vol. 7, p. 444). *Manix lake beds.*—Lake beds of aren. clays and fine argill. sands, both of light grayish green color; quartz, feldspar, and mica are the abundant coarser constituents. Most notable characteristic is evenness, persistence, and parallelism of individual strata. Thickness about 75 ft., but the beds thin out gradually toward W. Believed to be slightly younger than the Pleist. fangls. Are deposits of an extinct lake named *Manix Lake.* Well exposed along Mohave River 2 mi. SE. of Manix, about 120 mi. NE. of Los Angeles.

Mankato substage.

Pleistocene: Mississippi Valley.

M. M. Leighton, 1931 (Jour. Geol., vol. 39, pp. 51-53), proposed *Hudsonian substage* for late Wisconsin, *Quebecan substage* for middle and early Wisconsin, and *Manitoban substage* for Iowan, and included Peorian loess and Iowan drift in his Wisconsin stage, thus treating the Wisconsin as the 4th glacial stage, instead of the 5th.

M. M. Leighton, 1933 (Sci., vol. 77, p. 168) withdrew his names *Hudsonian, Quebecan,* and *Manitoban,* and divided his Wisconsin "age" into *Mankato* (late Wisconsin), *Cary* (middle Wisconsin), *Tazewell* (early Wisconsin), and *Iowan*. The name *Mankato* was taken from Mankato, Minn., "where the late Wisconsin deposits are excellently displayed;" the name *Cary* was from a town in McHenry Co., NE. Ill., "where the middle Wisconsin deposits are well displayed;" and the name *Tazewell* from Tazewell Co., Ill., "where the early Wisconsin deposits are well shown in their relations to underlying Peorian loess."

F. Leverett, 1933 (Sci., vol. 77, p. 560). In Feb. 10, 1933, issue of Sci., there appears a brief article by Dr. M. M. Leighton on "The naming of the subdivisions of the Wisconsin glacial age," in which he proposes the substitution of certain meaningless terms—Tazewell, Cary, and Mankato—for the significant terms, Early Wisconsin, Middle Wisconsin and Late Wisconsin, which have been in general use for considerable time and are readily understood by anyone reading geological literature, denoting as they do successive parts of the Wisconsin glacial stage. The incentive for suggesting the new names seems to have its basis in a newly acquired view of Dr. Leighton that the deposition of the Iowan drift came only a short time before that of the Early Wisconsin drift, and so it may properly be included in the Wisconsin stage.

Whether Iowan should be so included, if the entire field is taken into account, is far from being clearly established. This has been made forcibly apparent in a recent report by Dr. W. C. Alden on eastern Mont. and adjacent areas (U. S. G. S. P. P. 174, 1932). There are deposits in Mont. and the Dakotas which Dr. Alden is inclined to refer to the Iowan, but he considers them too old to be included in the Wisconsin stage. These are discussed by him under the heading "Illinoian or Iowan." But he thinks they do not appear to be as old as the Illinoian of Illinois.

Inasmuch as the entire series of drifts classed as Illinoian, Iowan, and Wisconsin fall in the last quarter of the Pleist. the distinctions in age aspects are less striking than btw. these drifts and those of middle and early Pleist. age, known as Kansan and Nebraskan. This being the case, it seems advisable to let the terms that are in general use stand, especially where they have significance, and are self-explanatory, and not replace them by a set of meaningless terms.

G. F. Kay and M. M. Leighton have agreed to adopt Tazewell, Cary, and Mankato. See under *Wisconsin stage*.

Mankomen formation.

Permian: Southeastern Alaska (central Copper River region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 40, map). *Mankomen fm.*—Interbedded sss., shales, and lss. with intrusive sheets. Thickness 6,700 ft. Fossils referred by Schuchert to Perm. Lies N. of Mankomen Valley and Mankomen Lake.

Manlius limestone. (Of Cayuga group.)

Silurian (late): New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 376). *Manlius water lime group*.—Embraces all beds of water lime S. of Erie Canal which are burnt for lime. Very constant in character. I have traced it from Cayuga Lake to hills in rear of Hudson. Its layers are dark blue and drab. It occupies interval btw. base of *Pentamerus* ls. [Coeymans ls.] (underlying *Delthyris* shaly ls.) and top of Onondaga salt group, which consists of salines and gyp. [As thus defined the unit apparently included Manlius, Rondout, and Cobleskill lss. and also Bertie ls. memb. of Salina fm. In 1839 (3d Ann. Rept. Geol. Surv. 3d dist., N. Y., p. 272) Vanuxem described the *Waterlime group of Manlius* as overlying "saliferous group of *Onondaga*" and underlying Oriskany ss.]

W. W. Mather, 1841 (N. Y. Geol. Surv. 5th Rept., p. 86), applied *Manlius water lss.* to beds btw. *Pentamerus* ls. and Onondaga salt group [the latter described as consisting of gray and porous ls. (pyritous ls.), gyp., red and variegated shales, etc., essentially same as Salina fm. of present terminology].

E. Emmons, 1842 (Geol. N. Y., pt. 2, p. 429), applied *Manlius waterlime* to beds btw. *Pentamerus* ls. above and Onondaga salt and plaster rock below. The same beds (overlain by *Pentamerus* ls. and underlain by Onondaga salt group) were called *Water-lime group* by Vanuxem in 1842, and *Manlius waterlimes and thin shales* by E. Emmons in 1846 (Agric. N. Y.).

For many succeeding years the term "Waterlime group" continued to be applied to the strata btw. "Lower Helderberg group" and "Onondaga salt group." In some repts. however, the unit was included in "Lower

Helderberg group" and in other repts it was included in "Onondaga salt group." The name *Manlius* was dropped for many years.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Manlius ls.* (the Tentaculite ls. of Gebhard, Mather, and later writers) underlies Coeymans ls. (basal fm. of Helderbergian group) and overlies Rondout waterlime. The name here used was introduced by Vanuxem and is entitled to first consideration. Is top fm. of Cayugan group, which includes Salina fm. at base. [In 1900 (Geol. Soc. Am. Bull., vol. 11, p. 251) Schuchert gave thickness of *Manlius or Tentaculite ls.* as 50 to probably 300 ft. or more.]

E. O. Ulrich and Schuchert, 1901 (N. Y. State Mus. Bull. 52, p. 658), classified Decker Ferry [Decker ls.] as occupying position btw. the Manlius and Rondout. The relations of the Decker to the Manlius and Rondout are, however, still in question.

In March 1903 (Am. Geol., vol. 31, pp. 160–175), Schuchert "redefined" Manlius, calling the beds *Manlius fm.*, which he described as 50 to 126 ft. thick, as underlying Coeymans ls. of Helderbergian group, as overlying Bertie fm. (forming top of Salina and formerly called "Lower Waterlime"), and as including Manlius (*Tentaculite*) ls., Rondout ls. (restricted to "Upper Waterlime"), and Cobleskill ls. (new name applied to 7 to 30 or more ft. of strata formerly called "Coralline ls." and included in the Rondout). Schuchert stated: This will be more in harmony with Vanuxem's conclusion, since he included the horizon having the Cobleskill fauna in his Manlius fm. From his definition of this fm. usage long ago excluded the lower Waterlime, and this part is here referred to as the Bertie ls. J. M. Clarke (in his Hdb. published in July 1903), also C. A. Hartnagel (N. Y. State Mus. Bull. 69, 1903), adopted the following classification: Manlius ls., Rondout waterlime, Cobleskill ls., and Salina fm. In 1905 (N. Y. State Mus. Bull. 82) J. M. Clarke and D. D. Luther used *Manlius group* to include *Manlius ls.* (74 ft. thick), Rondout dol. or waterlime (40 ft. thick), and Cobleskill dol. The broad use of Manlius apparently did not find favor with geologists, who, excepting Berkey, 1911, have continued to recognize the three subdivisions Manlius, Rondout, and Cobleskill. Berkey (N. Y. State Mus. Bull. 146) suggested it might be better to group the beds btw. top of the Manlius and base of the Cobleskill into a single unit and call it *Manlius series.*

In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28) E. O. Ulrich placed in Helderberg group of N. Y. a fm. beneath Coeymans ls. which he called *Keyser ls.*, taking the name from a locality in W. Va. The beds beneath the Keyser he designated as "Tentaculite ls.," "Cement rock," and "Cobleskill ls." In 1913 (Md. Geol. Surv. Lower Dev. vol., pp. 115–116) Ulrich stated that the Keyser represents "Manlius of the literature," and rests on the Rondout, beneath which comes the Decker Ferry [Decker]. These three fms. he included in Dev. But he stated that the *typical Manlius* underlies the Decker and overlies the Cobleskill, is of Sil. age, and is absent at Rondout, where the Keyser rests on Rondout and Rondout rests on Decker. In same volume C. K. Swartz, C. Schuchert, and C. S. Prosser classified the Manlius of eastern N. Y. and N. J. as Lower Dev., and Schuchert so classified it in the 1924 ed. of his Textbook of geol.

The relations and age of typical Manlius, typical Rondout, Decker ls., and Cobleskill ls. are matters about which geologists are not yet agreed.

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 25–35). If *Manlius* is to be employed with anything like its original value, the *group* represented comprises 6 strat. units at the very least. These 6 formational members are all present at Manlius, Onondaga Co., and are here given geographic names, as follows (descending):

(1) Bishop Brook ls. (*Helderbergian fauna*), (2) Pools Brook ls., (3) Jamesville ls., (4) Clark Reservation ls., (5) Elmwood beds, and (6) Olney ls. The beds uncon. underlie Oriskany ss. and rest on a sun-cracked waterlime which forms quarry floor at type loc., and is thought to be below or at least near lower limit of *Spirifer vanuxemi* in central Onondaga Co. Without being distinguished, Nos. 3 and 4 have been classed as Helderbergian by some authors, but they are undoubtedly included in Vanuxem's Manlius. One can hardly escape conclusion that upper part of Rondout of Hopkins (1914) and lower part of Hartnagel's 1903 Manlius are identical.

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285, p. 27) included all of Manlius in Sil.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 318, 346-347). When Clarke transferred Helderberg lss. to Dev., the Manlius was, because of rather Sil. aspect of its meager fauna, left in Sil., and since then has been subject of much discussion as to age. Some, following Clarke, class entire Manlius as Sil., others would place it in Dev., and a third group place Dev.-Sil. bdy within the Manlius. In eastern Helderberg region a distinct irregular uncon. occurs btw. the Manlius and overlying Coeymans. The *Upper Manlius beds* of western N. Y. are considered as Keyser, and Dev., by Ulrich. [In this 1931 rept the Manlius is described under Sil. heading, and on pp. 191, 317, and 318 it is included in Sil., but in tables on pp. 190 and 192 *Upper Manlius or Keyser* (*in parens*) is included in Dev. It is shown as overlying the Rondout.]

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 68). *Olney ls.* and *Elmwood waterlime* have been very generally assigned to Sil., and there appears to be no good reason for questioning this practice. A system reference for *Clark Reservation and Jamesville lss.* rests perhaps upon less secure ground. Inasmuch, however, as positive Dev. relations have not been proved for these higher units it is deemed best to include them in Sil.

W. Goldring, 1935 (N. Y. State Mus. Bull. 303) assigned *Manlius ls.* to Sil.

†Manlius group.

†Manlius series.

†Manlius waterlime group.

See under *Manlius ls.*

Mann Creek formation.

Tertiary: British Columbia.

J. F. Walker, 1931 (Canada Geol. Surv. Summ. Rept. 1930, pt. A, p. 136).

Mannetto gravel, also **formation.**

Pleistocene: Southeastern New York (Long and Fishers Islands) and southeastern Massachusetts (Marthas Vineyard).

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367-390). *Mannetto gravel*, name proposed in unpublished rept. of A. C. Veatch on geol. of underground waters of Long Island [U. S. G. S. P. P. 44]. Named for Mannetto or High Hill S. of Huntington, L. I. Consists of 500 ft. of gravel composed of quartzose and weathered granitic pebbles. Uncon. underlies Jameco gravel and uncon. overlies Cret. clay.

A. C. Veatch, 1906 (U. S. G. S. P. P. 44). *Mannetto gravel.*—Mostly quartz gravel, but contains some very decayed pebbles and boulders of probable glacial origin. Classified as a glacial deposit uncon. underlying Jameco gravel.

M. L. Fuller, 1906 (Sci., n. s., vol. 24, pp. 467-469). *Mannetto gravel* believed to be pre-Kansan and to represent outwash of same glacier that farther inland deposited till.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Mannetto gravel* (glacial), the earliest Pleist. deposit of Long Island. Consists of 40 to 330 ft. of stratified and in places cross-bedded gravels, mainly of well-rounded pebbles of quartz, from ½ inch to inch in diam., mixed with coarse yellowish quartz sand, but everywhere carrying a few deeply weathered granitic pebbles and scattered large boulders of crystalline rock deeply weathered or disintegrated. Includes a few thin intercalated beds of yellowish clay. Rests uncon. on Cret. deposits. Time of deposition called *Mannetto stage*. Is correlated with pre-Kansan of Mississippi Valley. Named for exposures on Mannetto Hills (West Hills).

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Mannetto fm.* of Marthas Vineyard consists of a bed of glacial gravel underlain by stony blue clay ice-laid till without boulders. It underlies Jameco fm. and overlies Weyquosque fm. The time of deposition is called *Mannetto stage*, and is correlated with later part of Nebraskan stage of Mississippi Valley and with Jerseyan drift of N. J.

Mannetto stage.

The time covered by deposition of *Mannetto gravel.*

Mannie clay. (In Richmond group.)

Upper Ordovician: Western Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 39, 44). *Mannie sh. or shaly clay.*—Brownish and bluish fossiliferous shaly clays, 16 to 35 ft. thick, forming top of Richmond group in Tenn. River Valley. Overlies Leipers Creek ls.

Is upper part of Fernvale fm.

Named for Mannie or Allens Creek, Lewis Co.

Manning beds.

Eocene: Eastern Texas (Angelina County).

E. T. Dumble, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 462, 463). *Manning beds.*—Light-greenish sands and carbonaceous sandy clays. Top memb. of Jackson beds. Underlie Corrigan sands. Separated from underlying Caddell beds by lignitic or carbonaceous chocolate-colored clays and sands with light-brown sss. and coarse-grained gray sss. Named for exposures at station on St. Louis & Santa Fe Ry.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 685). [See 1933 entry under *McElroy memb. of Fayette ss.*]

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, p. 1307). Stratigraphically above Wellborn sss. occur a series of beds designated *Manning beds*. Dumble [Univ. Tex. Bull. 1869, p. 134, 1920] described a Manning section which included more beds than are referred to as *Manning beds* in this paper, which include all beds stratigraphically above Wellborn sands and below Dilworth sands. They extend from Sabine River to Atascosa River, and consist of lignitic chocolate-brown shales with thin partings of sand; brown carbonaceous sands; tuffaceous sss. and beds of volcanic ash and cross-bedded glass; chocolate-brown diatomaceous shales, and brown bentonitic shales. Essentially nonfossiliferous and essentially nonmarine.

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17, and pp. 32–43, on area btw. Walker and Gonzales Counties). *Manning fm.* is here retained for the beds btw. top of Wellborn fm. (of which Carlos ss. is top memb.) and base of Whitsett fm. It does not seem to be appropriate to use McElroy fm. for these strata, because Miss Ellisor includes Wooley's Bluff clays, Wellborn sands, and Manning beds in the McElroy. Also, in paleontologic repts on wells McElroy has come to be almost synonymous with *Textularia hockleyensis* zone, but, as Miss Ellisor points out, this foraminifer ranges up into uppermost Jackson strata. The Manning is here divided into (descending): (1) Chocolate-colored lignitic clay with interbedded tan sand and ss. and gray tuffaceous ss. and thin beds of lignite, but chiefly nonmarine, 0 to 25 ft.; (2) *Yuma ss.*, 3 to 25 ft.; (3) same as No. 1; (4) *Dilworth ss.*, 2 to 22 ft.; and (5) chocolate-colored lignitic clay with interbedded tan sand and ss. and gray tuffaceous ss., thin beds of lignite; mostly nonmarine [thickness not given]. Thickness of Manning fm. 250 to 350 ft.

Manning Canyon shale.

Pennsylvanian and upper Mississippian: Central northern Utah (Oquirrh Mountain region) and western Utah (Gold Hill district).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Manning Canyon sh.*—Dominantly sh., with some thin beds of ls. and in lower half two fairly persistent qtzite beds. The part above upper qtzite is Penn., that below it is upper Miss. Thickness 1,140± ft. Grades into underlying "Great Blue" ls. and into overlying Oquirrh fm. Where lss. greatly predominate over sh. the beds are assigned to Oquirrh fm. Outcrops in a narrow band from Manning Canyon on SE. to valley of S. Fork of Ophir Creek, in Fairfield quad. [This name first appeared in print in 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, pp. 423, 430), in a paper on the Paleozoics of Gold Hill quad., Utah, by T. B. Nolan, who identified Gilluly's Manning Canyon fm. in Gold Hill quad.]

See also T. B. Nolan, 1934 (U. S. G. S. P. P. 177).

Mannington sandstone. (In Washington formation.)

Permian: West Virginia and eastern Ohio.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel, and Tyler Counties, p. 226). *Mannington ss.*—Massive cliff-forming ss., 25 to 50 ft. thick, underlying Little Washington coal and overlying Waynesburg B coal. Named for Mannington, Marion Co., W. Va.

C. R. Stauffer and C. R. Schroyer, 1920 (Ohio Geol. Surv., 4th ser., Bull. 22), give 5 sections in Ohio showing 8 to 99 ft. of *Mannington ss.* lying 17 ft. below Washington coal and 21 ft. below Lower Marietta ss.

†Mansfield group.

Eocene: Northwestern Louisiana and western Mississippi.

E. W. Hilgard, 1869 (Am. Jour. Sci., 2d, vol. 48, pp. 340–341; see also Prel. rept. geol. reconn. La., pp. 8–9, 1869). It will be extremely difficult to define the portions corresponding to each of the various marine epochs [of the Eocene]; meanwhile I propose to designate as *Mansfield group* that portion which, from its geographical position and general uniformity of materials, seems to be= lower portion of the Vicksburg bluff. It is very characteristically developed near Mansfield, La., and there presents a feature foreign to the other lignitic groups I have investigated, viz, a ledge, ¾ to 2 ft. thick, of an impure laminated ls. with numerous but mostly fragmentary impressions of lignitized stems and leaves. A narrow (¼ to ½ inch wide) band of this rock seems to extend from Mansfield as far as Shreveport, appearing mostly a few ft. below the hilltops. Bluish-gray clayey sands and mouse-colored laminated clays are predominant materials with which lignite beds are frequently associated. Appears to lie stratigraphically higher than Jackson marine and to underlie the marls and lss. at Vicksburg, Miss.

F. V. Hopkins, 1870 (La. Geol. Surv. 1st Ann. Rept., pp. 78, 83). *Mansfield group* of Hilgard is a large mass of lignitic strata which dips under Jackson group. It is probably parallel to Northern Lignitic of Miss.

F. V. Hopkins, 1871 (La. Geol. Surv. 2d Ann. Rept., pp. 3–35). *Jackson group* underlies Vicksburg group and overlies Claiborne group. It consists of marine strata, often containing massive clays, with characteristic fossils; lignitic beds that tell of swamps; nonfossiliferous laminated sands and clays that must have been deposited in brackish water subject to great variations in freshness. Dr. Hilgard named the lignitic beds and laminated sands and clays the "Mansfield group," and in this I followed him last year, but the fossils I have had the good fortune to discover show that the group is parallel in age with the Jackson marine strata. I have submitted my collections to Dr. Hilgard, who has kindly determined them for me, and agreed to retain Mansfield group only as a subdivision of the Jackson.

As used in La. included Claiborne and Wilcox strata as well as Jackson fm. In Miss. the name was applied to Forest Hill sand, now regarded as basal fm. of Vicksburg group.

Named for exposures near Mansfield, DeSoto Co., La.

Mansfield red beds. (In Chemung formation.)

Upper Devonian: Central northern Pennsylvania (Tioga and McKean Counties) and northeastern Pennsylvania (Susquehanna and Wayne Counties).

J. P. Lesley, 1875 (2d Pa. Geol. Surv. Rept. I, pp. 45, 100, 108), mentions (p. 45) red beds which "cannot represent Bedford sh. of Ohio," but which "will perhaps hereafter be identified with the *Mansfield red beds* (of the Survey of 1841) crossing the Tioga River." On p. 100 he mentions "red beds in the top VIII (Chemung) called by me, in my report [published ??] of 1840, the *Red Mansfield Beds* of Tioga County." On p. 101 he says the *Mansfield beds* are best developed in Tioga Co. The compiler is unable, without spending more time than the matter warrants, to find where Lesley in 1840 or 1841 published the name *Mansfield red beds*.

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. R, pp. 43, 73). *Mansfield Red Beds.*—Red and gray sl., sh., and ss., 300 ft. thick, lying 350 ft. below top of Chemung in McKean Co., Pa. The red shales are no doubt the representatives of those which are found in the Chemung in vicinity of Mansfield, Tioga Co., and described by Lesley in 1841 [1878], Rept. G, p. 94. Overlain by 350 ft. of gray sl. and ss. and underlain by 650 ft. of gray sl. and ss. all belonging to Upper Chemung.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G5). *Mansfield reds*, 90 ft. thick in Susquehanna and Wayne Counties. Lie 40 ft. below top of Chemung fm. Consist of olive, greenish, and brick-red shales, with 5 ft. of shaly green ss. near middle.

Mansfield sandstone. (In Pottsville group.)

Pennsylvanian: Southwestern Indiana.

T. C. Hopkins, 1896 (Ind. Dept. Geol. and Nat. Res. 20th Ann. Rept., 1895, pp. 186–213). *Mansfield ss. and cgl.*—Coarse-grained massive variegated ss., with some cgl., lying at base of Coal Measures. Thickness few ft. to more than 100 ft. In previous Ind. repts called *Conglomerate*, also *Millstone grit*. Overlain, uncon. in places, by coal-bearing shales and sss.; uncon. underlain by Miss.

For many years this name was applied to all Pottsville rocks of Ind., Ill., and western Ky., but that use of the name has now been discontinued, and in Ind. it is now applied to basal few to 300± ft. of Pottsville group, or to the beds beneath Brazil fm.

Named for Mansfield, Parke Co.

†Mansfield formation.

Pre-Cambrian (middle and lower Huronian): Northwestern Michigan (Felch Mountain district).

H. L. Smyth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 114–115). *Mansfield fm.*—Chiefly fine- to medium-grained soft mica schists which are exposed at only a few places in Felch Mtn range. But a series of phyllites, less metamorphic but otherwise similar and occupying same [?] strat. position immediately above Randville dol., outcrop to NW., at Mansfield mine and N. of it near Michigamme River in T. 43 N., R. 31 W. For these reasons it is convenient to name the fm. from the Mansfield locality. [Thickness not stated.] Overlain by Groveland fm. [Vulcan fm.].

The rocks to which Smyth applied "Mansfield fm." in Felch Mtn dist. were later (U. S. G. S. Mon. 52, p. 303, 1911) named *Felch schist*, being said to be younger than the rocks at Mansfield mine, to which Clements applied the name "Mansfield sl." In 1935, however (U. S. G. S. P. P. 184), C. K. Leith, R. J. Lund, and A. Leith assigned Felch schist to middle and lower Huronian.

†Mansfield formation (also slate).

Pre-Cambrian (*middle* Huronian): Northwestern Michigan (Crystal Falls district).

J. M. Clements, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 36–48, 62, pl. opp. p. 84). *Mansfield fm.* (heading).—Chiefly sl. Includes graywackes, clay slates, phyllites, siderite slates, cherts, ferruginous cherts, and iron ores interbedded. Colors olive green and purplish black to bright red. Max. thickness in Crystal Falls dist. 1,500 to 1,900± ft. Appears to correspond stratigraphically and lithologically to Siamo sl., of Marquette dist. Named "*Mansfield sl.*" because of exposures at Mansfield village and Mansfield mine. Overlies Randville dol. On the whole the Hemlock volcanic fm. is younger than Mansfield sl., but some of lower Hemlock beds are contemp. with some of upper Mansfield beds.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 291–296, 303, 324). One of principal local sed. units within Hemlock fm. was described and mapped in U. S. G. S. Mon. 36, 1899, on Crystal Falls dist. as "*Mansfield sl.*" Is here called *iron-bearing sl. memb.* Is interbedded [p. 291 says *at top*; pp. 295 and 607 say *near top*] of Hemlock fm.

Mansfield beds.

Pennsylvanian: Southeastern Massachusetts.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 188–191). [In table on p. 134 *Mansfield beds* are included in Rhode Island Coal Measures and are placed above Cranston beds and below Tennile River beds. In description of *Mansfield* *area*, Bristol Co., Mass., on pp. 188–191, the name "Mansfield beds" is not employed, but the beds overlying the Wamsutta "series" there are described as quartz pebble and qtzite cgls. and gray sss.]

Mansonville slates.

Upper Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11).

†Manti beds.

Eocene (middle): Central Utah (Wasatch Plateau region).

E. D. Cope, 1880 (Am. Nat., vol. 14, pp. 303–304). A series of calc. and siliceo-calc. beds which contain the remains of different species of vertebrates from those which have been derived from either the Green River or Amyzon beds. There is nothing to determine to which part of the Eocene this fm. should be referred, but it is tolerably certain that it is to be distinguished from the Amyzon beds. Petrographically it is most like the Green River, as it consists in large part of shales. Until its proper position can be ascertained I propose that the fm. be called *Manti beds*. [Apparently named for Manti, San Pete Co.]

Later work proved these beds to be Green River fm., by which name they are now known.

Manuels formation.

Middle Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Manuels fm.*—Fossiliferous black, brown, and olive shales, thin sss., and Kalkballen, with phosphorite at base. Assigned to Middle Camb. Overlain by Elliott Cove fm. (Upper Camb.) and discon. underlain by Hanford fm. (Lower Camb.). [Derivation of name not stated.]

Manzanan series.

Pennsylvanian: New Mexico.

See under *Mosca ls.*

Manzanilla formation.

Tertiary (Miocene?): Trinidad.

R. J. L. Guppy, 1866 (London Geol. Soc. Quart. Jour., vol. 22, pp. 572–573). *Manzanilla beds*. Assigned to lower Mio.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 344). *Manzanilla beds* of Trinidad Island assigned to middle Eo.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol., No. 7, p. 69). *Manzanilla fm.*, Trinidad, assigned to Mio.

Manzanilla beds.

Oligocene: Costa Rica.

A. H. Redfield, 1923 (Econ. Geol., vol. 18, p. 362) and 1924 (Revista económica San Salvador, año 11, No. 4, p. 175). Assigned to Olig.

Manzanita dacites.

See under *West Prospect basalt*.

Manzano group.

Permian: New Mexico (widespread).

C. L. Herrick, 1900 (Am. Geol., vol. 25, p. 337; Jour. Geol., vol. 8, pp. 112–126; N. Mex. Univ. Bull., vol. 2, pt. 2, fasc. 3, p. 4). *Manzano series*.—Large series of coarse red qtzites and sss. interbedded with dark earthy lss. and shales. Rests on large series of massive gray siliceous lime (which separates it from underlying Coyote ss.) and is overlain by 500 ft. of reddish ls., ss., and gyp. containing Perm. fossils near base. [Derivation of name not stated.]

C. H. Gordon, 1907 (Jour. Geol., vol. 15, pp. 810–816). *Manzano group* divided into (descending): (1) Gray ls., 0 to 500 ft.; (2) alternating yellow, pink, and white sss. and shales, with lenses of gyp. and subordinate ls., 500 to 1,000 ft.; (3) dark-red sss. interstratified with red sandy shales and some thin beds of bluish drab earthy ls., 400 to 800 ft. Overlies, with uncon., Madera ls., top fm. of Magdalena group.

W. T. Lee, 1909 (U. S. G. S. Bull. 389). *Manzano group* is here divided into 3 fms., named (descending) *San Andreas ls.*, 150+ ft.; *Yeso fm.*, 610+ ft.; and *Abo ss.*, 300+ ft. The Abo rests uncon. on Madera ls., the upper fm. of Magdalena group, and the Manzano is separated from overlying fms. by an uncon. It is clear, from Herrick's original definition of *Manzano group* and from his other writings, that he included in his Manzano group only (1) the lower or red ss. here named *Abo ss.*, with which he associated the overlying gyp.; (2) the middle or chocolate-colored sediments; and (3) the upper or vermilion beds. The present writer has combined Nos. 2 and 3 and herein named them *Yeso fm.* The massive upper ls., which overlies the gypsiferous sh. and ss. and which is here named *San Andreas ls.*, is not described in any of the literature of Rio Grande region, although Herrick includes it in his sections. It contains an abundant fauna, which clearly allies it with the red beds in the Penn. [now called Permian], and it is therefore included in Manzano group, although it was not originally so included by Herrick. So far as known the San Andreas ls. is uppermost memb. of Manzano group, but it cannot be asserted at present that there are no younger Penn. beds in Rio Grande region, or that no Triassic occurs there. The red sediments near Carthage, which apparently are above San Andreas ls., are the only ones known that may represent Perm. or Triassic time. They differ considerably in general appearance from known Manzano, and nothing was found to indicate whether they belong in Manzano group or represent a younger fm. [The Manzano group has for several years been classified as Perm.]

Mao clay.

Miocene: Dominican Republic.

T. W. Vaughan et al., 1921 (Dominican Rep. Geol. Surv. Mem. 1, p. 74).

Mao Adentro limestone.

Miocene: Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Maple Green andesite.

Devonian: New Brunswick.

W. V. Howard, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 484).

Maple Hill limestone. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 80). *Maple Hill ls.*—Bluish-gray, somewhat aren. irregular ls., 2 to 4 ft. thick. Forms a small fall in Maple Creek about 2 mi. SW. of Maple Hill, Kans. Is well shown under Pony Creek bridge S. of Falls City and at other places in Nebr., thinning to NE. Overlies Pierson Point sh. and underlies Table Creek sh., all included in McKissick Grove sh. memb. of Wabaunsee fm.

The sh. overlying Maple Hill ls. was, in Aug. to Sept. 3, 1932 chart of R. C. Moore, named *French sh.*, and *Table Creek sh.* was restricted to upper part of the original Table Creek. In Oct. 1932 chart, however, Moore and Condra transposed these names, and described the sh. resting on Maple Hill ls. as *Table Creek sh.* [restricted].

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10). *Maple Hill ls.* underlies Table Creek sh. and overlies Pierson Point sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), discarded McKissick Grove sh. and treated its subdivisions as fms. in Wabaunsee group.

Maple Mill shale. (In Kinderhook group.)

Mississippian: Southeastern Iowa and probably western Illinois (Pike County).

H. F. Bain, 1895 (Am. Geol., vol. 15, p. 322). *Maple Mill sh.*—Nonfossiliferous dark green to blue argill. sh., 30 to 200 ft. thick. Underlies English River grits, and is younger than Louisiana ls., which is absent. Basal fm. of Kinderhook in SE. Iowa. [In Iowa Geol. Surv., vol. 5, 1896, Bain gave thickness of Maple Mill sh. in Washington Co., Iowa, as 160 to 290 ft.]

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines, vol. 21, 2d ser., pp. 21–23, chart opp. p. 282). *Maple Mill sh. memb. of Hannibal fm.*—Blue or green, argill. locally calc., drab, sparsely fossiliferous sh. Thickness at Prospect Hill, Burlington, Iowa, 33 ft. (19 ft. exposed and 14± ft. more concealed). Basal memb. of Hannibal fm. at Burlington, where it grades into overlying English River ss. memb. of the Hannibal. At Kinderhook, Pike Co., Ill., 43 ft. of similar sh. is tentatively correlated with Maple Mill memb. Uncon. overlies Sweetland Creek sh.

L. R. Laudon, 1931 (Iowa Geol. Surv., vol. 35, pp. 341–387+). *Maple Mill fm.*, basal fm. of Kinderhook series, rests uncon. on Sheffield fm. and Cedar Valley ls. and is conformably overlain by English River fm.

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 40, 245). Fms. equiv. to Hannibal fm. are English River ss. and part or all of underlying *Maple Mill sh.* of SE. Iowa. [In table on p. 245, Moore showed Maple Mill sh. as underlying English River ss. and overlying Sweetland Creek sh.]

Type loc. appears to be at Burlington, Iowa.

Mapleton sandstone.

Devonian: Northeastern Maine (Aroostook County).

H. S. Williams, 1899 (Am. Jour. Sci., 4th, vol. 8, p. 360, footnote). *Mapleton ss.*—A massive and in places coarse red ss., in which plants (*Psilophyton*, etc.) have been found. Is of Dev. age but somewhat younger than Chapman ss.

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 136–137). *Mapleton ss.*—Reddish-brown sss. and coarse cgls., in beds 10± ft. thick, covering nearly all of E. half of Mapleton Twp. Thickness 180 ft. Overlain by fine-grained gray sss. having appearance of Chapman ss. Believed to uncon. overlie Aroostook ls., but contact not seen.

On 1933 geol. map of Maine, by A. Keith, included in Middle and Lower Dev. block.

†Mapleton granite.

Devonian: Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 105–106, 146–148). *Mapleton granite* (*locally known as Munson's granite*).—In parts of field it is almost black; in other places it is of light color. The dark and light areas are not confined to any particular locality, and transition from one to the other may occur within a few inches or be imperceptible for rods. Field relations indicate it is intrusive. Named for occurrence on a low rounded hill in NE. corner of Mapleton Twp, Aroostook River, Aroostook Co. The granite forms part of the hill.

On 1933 geol. map of Maine, by A. Keith, the igneous rocks of Mapleton region are mapped as (1) rhyolite, andesite and trachyte of Dev. age; (2) rhyolite breccia, tuff, and sl. of Dev. age; and (3) diabase and amygdaloid of mainly Sil. age but including some Dev.

F. W. Toppan, 1932 (Geol. of Maine, p. 78), assigned this granite to Dev.

Maplewood shale.

Silurian: Western New York (Rochester region).

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Maplewood sh.*—Basal div. of N. Y. Clinton. Max. exposure in Genesee Gorge at Maplewood Park, Rochester, where 21 ft. of fine-grained unctuous bright-green nonfossiliferous sh. of uniform texture rests on Thorold ss. This is Hall's "lower green sh." and Hartnagel's "Sodus" exclusive of uppermost 3 ft. This sh. probably terminates eastward without reaching Sodus, the true Sodus sh. being a higher memb. Strat. relations of the Maplewood are with the beds below rather than above. Older than Bear Creek sh. and Martville ss.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 191, 347, etc.), placed *Maplewood sh.* below Reynales ls. and above Thorold ss. at Rochester and elsewhere. This is position assigned to *Maplewood sh.* by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), who listed it (p. 317) as present in western, west-central, and central N. Y. In central N. Y. she showed it as lying on Oneida cgl., instead of on Thorold ss.

J. T. Sanford, 1935 (Jour. Geol., vol. 43, No. 2, Feb.–Mar., p. 174). *Maplewood sh.* occurs only in vicinity of Rochester.

G. H. Chadwick, 1935 (A. A. P. G. Bull., vol. 19, No. 5, p. 702), stated the ss. beneath Maplewood sh. at Rochester is not Thorold ss., but a younger ss., of Clinton age, which he has named *Kodak white ss.*

Maquay formation.

Oligocene or Miocene: Cuba.

N. H. Darton, 1926 (Wash. Acad. Sci. Jour., vol. 16, p. 331).

Maquereau series.

Ordovician (?): Quebec (Gaspé Peninsula).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, pp. 270-271). *Maquereau series.*—Oldest rocks at Port Daniel, on S. shore of Gaspé Peninsula. Unfossiliferous arkoses. Probably earliest Ord. Underlies Mictaw series (black shales and tuffaceous graywackes of late Trenton to early Eden age).

C. H. Kindle, 1935 (Geol. Soc. Am. Proc. 1934, p. 354). *Maquereau fm.* assigned to pre-Camb.

C. H. Kindle, 1936 (Eastern Geol., No. 1, April 1936, p. 1). *Maquereau fm.* is assigned to pre-Camb. because boulders of its rocks make up basal cgl. of Mictaw fm. (Middle Ord.).

Maquoketa shale. (In Richmond group.)

Upper Ordovician: Iowa, western Illinois, southern Minnesota and Wisconsin, and eastern Missouri.

C. A. White, 1870 (Iowa Geol. Surv. vol. 1, pp. 180-182). *Maquoketa shales.*—Bluish and brownish shales, 80 ft. thick, forming top fm. of Lower Ord. in Iowa. Equiv. to [so-called] Hudson River shales of Hall. Overlain by Niagara ls. and underlain by Galena ls.

Adopted by U. S. Geol. Survey as middle fm. of Richmond group in Lower Miss. Valley, where it is overlain by Girardeau ls. and underlain by Fernvale ls. In Upper Miss. Valley region the Fernvale and Girardeau lss. are absent, and the Maquoketa was for many years considered sole representative of Richmond group, and was there defined as resting on Galena dol. and as overlain by Niagara dol. In eastern Iowa and SW. Wis., however, 10 to 40 ft. of interbedded ls. and sh. at base of Maquoketa were in 1907 named *Dubuque fm.* by Sardeson and excluded from what he called *Maquoketa sh. proper*, but included in his Maquoketa stage. These basal beds are of basal Richmond age, and according to E. O. Ulrich (Wis. Acad. Sci. Trans., vol. 21, pp. 71-93, 1924) they are much older Richmond than Fernvale ls., and therefore are older than true Maquoketa sh. They are present in western Wis. btw. Maquoketa and Galena. The U. S. Geol. Survey has adopted Dubuque fm. as distinct from and as underlying Maquoketa sh. In Iowa and western Ill. a few ft. of pre-Niagara Sil. rocks have been reported as overlying Maquoketa sh., and in western Wis. E. O. Ulrich has reported the discovery of 60 ft. of dol. of late Medina age in rocks heretofore called Niagara dol. He has named these rocks *Burroughs dol.* In that area, therefore, the Maquoketa is uncon. overlain by Burroughs dol. and not by Niagara dol. In NE. Iowa and SW. Wis. the Maquoketa becomes a *group*, divided into fms., which have been named (descending): Brainard sh., 120 ft.; Fort Atkinson ls., 40 ft.; Clermont sh., 10 to 15 ft.; Elgin ls., 50 to 70 ft.

Named for exposures on Little Maquoketa River, Dubuque Co., Iowa.

†Maquoketa series.

A term applied by F. W. Sardeson (Am. Geol., vol. 19, 1897, pp. 330-336) to Ord. beds overlying his Galena series in Upper Miss. Valley States and divided into (descending): Wykoff fm.=Richmond ls.; Maquoketa fm.=Utica sh.; transition fm. (*Triplecia* bed).

Maquoketan series.

A term employed by C. [R.] Keyes instead of *Maquoketa group* or *Maquoketa sh.* of other geologists.

Marac formation.

Eocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in Geol. No. 7, p. 40).

†Marais des Cygnes coal series.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., pp. 22–24). *Marais des Cygnes coal series.*—Series of lss., sss., shales, and coals, 303 ft. thick, including beds Nos. 178 to 202 inclusive of geol. section of eastern Kans. Underlies Well Rock series and overlies Pawnee ls. series.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). Marais des Cygnes coal series abandoned. Included Pleasanton fm. and possibly higher strata.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 63–67, 72). †Marais des Cygnes coal series of Swallow included Bourbon, Memorial, Lenapah, Nowata, Altamont, and Bandera fms.

Named for exposures on Marais des Cygnes River, Kans.

†Marais des Cygnes shales.

Pennsylvanian: Kansas and Missouri.

C. R. Keyes, 1900 (Iowa Acad. Sci. Proc., vol. 7, p. 84). *Marais des Cygnes shales.*—Restriction of G. C. Swallow's name to shales lying btw. Pawnee ls. below and Bethany ls. above, instead of accepting the name *Pleasanton*, introduced in 1895 to cover the strata btw. the lss. mentioned.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). Marais des Cygnes shales of Keyes is same as Pleasanton fm., the upper ls. referred to being Hertha ls., and not Bethany Falls ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 63–67, 73). †Marais des Cygnes shales of Keyes included Bourbon, Memorial, Lenapah, Nowata, Altamont, and Bronson fms.

Named for Marais des Cygnes River, Kans.

Marathon conglomerate.

Pre-Cambrian (upper Huronian): Central northern Wisconsin (Marathon County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 362). *Marathon cgl.* (also, in heading, *Marathon City cgl.*).—Mainly a cgl., occurring in and near Marathon, Marathon Co. Probably not more than 100 ft. thick. Appears to be basal cgl. portion of a much thicker sed. fm. which has been eroded away. Rests uncon. on granite. Is of either upper or middle Huronian age.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this fm. to *Animikie group* (*upper Huronian*).

†Marathon series.

Ordovician (Middle and Lower) and Upper Cambrian: Western Texas (Marathon region).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, pp. 37–38). *Marathon series.*—Named by Baker. Consists of (descending): (1) Yellowish-brown shales interbedded with thin gray ls., of Middle Ord. age, 375 ft.; (2) 500 ft. of interbedded green, gray, and black shales and thin brown sss., exact age unknown; (3) 130 ft. of dark-gray thin-bedded ls. of Lower Ord. age; (4) 300 ft. of fine-grained, coarse-grained, and conglomeratic sss. interbedded with green or light bluish-gray shales; (5) 300 ft. of interbedded dark-colored sss. and shales, containing Lower Ord. fossils 100 ft. below top. The entire succession has not yet been found at one locality, and it may contain other unknown members. In places one or more of upper members were removed by erosion prior to deposition of Maravillas chert. Overlies Upper Camb. Brewster fm. and is uncon. overlain by Maravillas chert.

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1066–1067). "Marathon series" was named for Marathon region, without reference to definite type loc., and included 5 subdivisions, which are here named (descending): Woods Hollow sh. (of Middle Ord., Trenton age), 200 to 500 ft.; Fort Peña fm. (of Black River or Chazy age), 200 ft.; Alsate sh. (of Beekmantown age), 100 ft.; *Marathon ls.* (of Beekmantown age), 850 to 1,000 ft.; and Dagger Flat ss. (of Upper Camb. age).

300+ ft. The term "Marathon series" is therefore too inclusive and indefinite for further use, and it is here proposed to restrict the term to the lss. and associated rocks which actually crop out within town of Marathon, and which are here designated *Marathon ls.*

Marathon limestone.

Lower Ordovician (Beekmantown): Southwestern Texas (Brewster County).

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1066–1069, 1079). *Marathon ls.*—Lss. and associated rocks of Lower Ord. (Beekmantown) age, which crop out in streets and vacant lots of town of Marathon. The basal beds, which rest on Dagger Flat ss. (Upper Camb.) crop out 1 mi. SW. of railway station on N. side of old road to Alpine; and the highest beds, which dip beneath Alsate sh., occupy a NE. belt of outcrop which crosses Boquillas road 1¼ mi. S. of station. Thickness of fm. 350 to 1,000 ft. Most conspicuous parts of fm. are beds of flaggy dense gray or black ls., weathering ashen gray or bluish, and breaking with conchoidal fracture; partings of sh. separate most layers and there are a few thick members of greenish clay sh.; the sh. partings and the clay sh. probably comprise ⅙ to ½ of fm.; btw. the lss. are a few layers of ss. and many beds, 1 to 4 ft. thick, of intraformational cgl.; near middle is Monument Spring dol. memb., 75 ft. thick. The Marathon ls. correlates with El Paso ls.

Marathon sandstone member.

Upper Devonian: Southern central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). *Marathon ss. memb.*, 35 ft. thick; underlies Triphammer sh. memb. and overlies Williams Brook coquinite memb.; all included in Ithaca facies subgroup of Ithaca-Enfield group of fms. in Ithaca region. The Marathon and Triphammer probably constitute Oneonta of the East. [Derivation of name and character of ss. not stated.]

Marathon City conglomerate.

See under *Marathon cgl.*, pre-Camb.

Maravilla dolomite.

Name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 65, No. 1, Feb. 1936, pp. 42, 49, 50) to cover Udden's Vidrio dol., Gilliland dol., and upper Tessey dol. of Glass Mtns, Tex. Named for "intermittent stream that flows by Marathon town to Rio Grande but heads in the Glass Range, where it is the drainage channel of the deep Gilliland Canyon."

Maravillas chert.

Ordovician (Upper): Western Texas (Marathon region).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex., Bur. Econ. Geol. and Tech. Bull. 44, pp. 38–39). *Maravillas chert.*—Named by Baker. Lower part is of Middle Ord. age, and consists of 400 ft. (max.) of hard gray ls. with nodules and lenticular masses of dark-colored chert. The upper 300 ft. consists of thin alternating beds of dark-colored chert and gray lss., often conglomeratic, and is of Lower Sil. age. [Upper Ord. in 1919 ed. of book cited.] Uncon. overlies Marathon series and uncon. underlies Caballos novaculite in Marathon region.

C. L. Baker and W. F. Bowman, 1917 (Univ. Tex. Bull. 1753, table opp. p. 78), assigned Maravillas chert to Trenton and Fernvale epochs.

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, p. 1073), assigned entire fm. to Upper Ord. (Trenton is Middle Ord.).

See also under *Solitario fm.*

Named for Maravillas Gap, Brewster Co.

Marble Bay formation.

Jurassic or Triassic: British Columbia.

O. E. LeRoy, 1908 (Canada Dept. Mines, Geol. Survey Branch Pub. 996, p. 16). [Assigned to "Devono-Carbf." More recent Canada repts assign the fm. to Jurassic or Triassic.]

Marble Canon limestone.

Carboniferous: British Columbia.

G. M. Dawson, 1896 (Canada Geol. Surv., n. s., vol. 7, pp. 26B, 39B to 40B). [Assigned to Carbf. and all later repts classify it thus.]

Marble Cliff limestone. (In Columbus limestone.)

Middle Devonian: Central Ohio.

C. S. Prosser and W. C. Morse, 1915 (Outlines of field trips in geology in central Ohio, pp. 14, 17). *Marble Cliff ls.* proposed for upper memb. [thickness & character not given] of Columbus ls. on account of excellent exposures in banks of Scioto River and extensive quarries at Marble Cliff [Franklin Co.]. Underlain by Bellepoint ls. memb. of Columbus ls. and overlain by Delaware ls.

†Marbled limestone.

A name applied in early repts on Ariz. to Muav ls. (Middle Camb.) of present nomenclature.

Marble Falls limestone. (Of Bend group.)

Pennsylvanian (Pottsville): Central Texas.

R. T. Hill, 1889 (Am. Geol., vol. 3, p. 289). *Encrinital or Marble Falls ls.*—Basal fm. of Carbf. in Burnet and Travis Counties, Tex. Thickness 500 ft. Overlies Sil. and underlies 300 ft. of Carbf. bituminous shales and sss. at Marble Falls and Smithwick.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 87–96). *Marble Falls ls.*—Shaly fossiliferous ls., 300 ft. thick. Is basement ls. over which the river falls at Marble Falls.

S. Paige, 1912 (U. S. G. S. Llano-Burnet folio, No. 183). *Marble Falls ls.*—Alternating lss. of dark-gray, light-gray, dove, and dark-blue to black color. Many beds contain abundant cherty nodules, largely dark or black. The bottom is in most places marked by a thin ls. cgl. and in one place by a very coarse angular cgl. or breccia, but there are localities where little or no discordance in sedimentation could be observed. At Marble Falls it includes at top 20 ft. of thin-bedded black sh. underlying the soft Smithwick sh. Thickness 250 to 450 ft. Underlies Smithwick sh. and uncon. overlies Ellenburger ls. (Ord. and Camb.). Assigned to Penn. Is younger than the Miss. sh. included in Bend series of Tex. Survey [and later named Barnett sh.].

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 26; Univ. Tex. Bull. 2132). *Marble Falls ls.* overlies Barnett sh. (Miss.). The latter is absent at type loc. of Marble Falls [Burnet Co.].

Marblehead limestone. (In Columbus limestone.)

Middle Devonian: Northwestern Ohio.

E. Orton, 1888 (Ohio Geol. Surv. vol. 6, pp. 75, 746–750, 758). *Marblehead ls.* described by Hawes (10th Census, vol. 10, p. 80) as bituminous dol., but other portions of Corniferous ls. are much more bituminous.

C. K. Swartz, 1907 (Johns Hopkins Univ. Circ. No. 7, p. 62). *Marblehead memb.*—Gray ls., 38 to 41 ft. thick, forming middle memb. of Columbus fm. Overlain by Venice memb. and underlain by Bellepoint memb.

Named for Marblehead Peninsula, near Sandusky.

Marble Hill marble. (In Richmond group.)

Upper Ordovician: Southeastern Indiana.

D. D. Owen, 1859 (Rept. geol. reconn. Ind. made in 1837, pp. 28, 29, et seq). *Marble Hill rock.*—Shell marble, 20 ft. thick, quarried at Deans quarry, Marble Hill. Overlain by dark-colored Ord. marlite and underlain by 177 ft. of alternating blue Ord. ls. and marls.

W. W. Borden, 1874 (Ind. Geol. Surv. 5th Ann. Rept., p. 139), described *Marble Hill marble stratum*, 20+ ft. thick, as lying lower in "Cincinnati group" than his Madison rocks.

Named for Marble Hill, near Madison, Jefferson Co.

Marcellon quartz porphyry.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Columbia County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 519). *Marcellon quartz porphyry* [two varieties described], occurs in sec. 7, town of Marcellon, Columbia Co.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). "May be supposed to be pre-Huronian."

Marcellus shale. (In Hamilton group.)

Middle Devonian: New York, eastern and central Pennsylvania, New Jersey, western Maryland and Virginia, and West Virginia.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 295–296). *Marcellus shales.*—Shales uncon. overlying Seneca ls. [upper part of Onondaga ls.] and separated from overlying Ludlowville shales by (ascending) dark slaty fossiliferous sh., compact blue sh., and fissile olive or bluish sh. The lower part of Marcellus mass is black and slaty, with ls. nodules or concretions.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept.). The upper shales of Marcellus are less highly colored than underlying shales and break into small fragments, flat and showing tendency to peculiar concretionary structure. They are overlain by Skaneateles shales and underlain by Marcellus shales (deep black).

J. Hall, 1843 (Geol. N. Y., div. 4, 4th dist., pp. 177–183). *Marcellus sh.*—Overlies Corniferous [Onondaga] ls. and underlies Hamilton group. Admits of two divisions. The lower div. is very black, slaty, and bituminous and contains iron pyrites in great profusion; some portions are calc.; and it is always marked by one or more courses of concretions or septaria which are often very large. This div. terminates upward by a thin band of ls., above which the sh. is more fissile, and gradually passes from black to olive or dark slate color.

E. Emmons, 1846 (Agric. N. Y., vol. 1). The Hamilton and Marcellus shales are difficult to separate except by fossils.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63). The *Marcellus beds or stage* as generally applied in N. Y. geology are divided into (descending): Cardiff sh. (="Upper shales of Marcellus" of Vanuxem), 50 to 100 ft.; Stafford ls., 8 inches; and black slaty Marcellus sh., 50 ft. The Marcellus beds or stage underlie Skaneateles sh. and rest on Onondaga ls. Authors recommend restricting Marcellus to basal black sh. At Marcellus village, Onondaga Co., from which place the name is derived, only the lower layers of this black sh. are well exposed, and our observations both in that region and westward indicate desirability of restricting Marcellus to these lower shales. [In subsequent repts Luther dropped Marcellus in broad sense, but some geologists continued to use it. C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19) used the name in both senses.]

In subsequent repts the Cardiff sh. has been both included in and excluded from Marcellus sh. The greatly predominant usage, however, has been to restrict Marcellus to the scantily fossiliferous black shales btw. the Cardiff and the Onondaga ls. These black shales, with the included thin Cherry Valley ls., aggregate 62 to 145 ft. in thickness btw. Unadilla Valley and Seneca Lake region, to W.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 116–134, 214–236), included Cardiff in Marcellus and included Marcellus in his Hamilton group. (See 1930 and subsequent entries under *Cardiff sh. memb.* and under *Hamilton fm.*)

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), included Marcellus in Hamilton.

The following recent repts exclude Marcellus from the Hamilton: R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285); D. H. Newland and C. A. Hartnagel, 1932 (N. Y. State Mus. Bull. 295, p. 106); R. L. Moodie, 1933 (N. Y. State Mus. Hdb. 12, p. 36); W. Goldring, 1933 (N. Y. State Mus. Hdb. 14, p. 37, and 16th Int. Geol. Cong. Guidebook 4, p. 28); C. P. Berkey (?), 1933 (16th Int. Geol. Cong. Guidebook 9, pl. 9).

The following recent repts include Marcellus in the Hamilton: G. H. Chadwick and G. M. Kay, 1933 (16th Int. Geol. Cong. Guidebook 9A); D. H.

Newland, 1933 (16th Int. Geol. Cong. Guidebook 4, table opp. p. 6); B. Willard and A. B. Cleaves, 1933 (Geol. Soc. Am. Bull., vol. 44, pp. 757–782); B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 32–37); W. Goldring, 1935 (N. Y. State Mus. Bull. 303, p. 148); and B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1275–1290). Willard introduced the new name *Mahantango fm.* for the post-Marcellus rocks in Pa. that have for many years been called *Hamilton fm.*

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 34–35). The black sh. above Cherry Valley ls. has been named *Chittenango memb.* of Marcellus by Cooper. This sh. is the Marcellus *par excellence*, which typifies the formational series. But the term "Marcellus" should not be used in a larger sense for the series and in a more restricted sense for the black beds above the Cherry Valley. A separate name for this sh. is justified, although many geologists will probably regret the discontinuance of the older term for this rock. Base of the Chittenango is well defined by top of Cherry Valley ls., but top is impossible of precise delimitation at most localities, because of gradation into overlying Cardiff sh.

W. Goldring, 1936 (letter dated Jan. 17, 1936). Dr. Cooper's definition of the Hamilton as including the Marcellus is accepted by the New York State Survey and will be so used by the staff in future publications. We do not decide such matters for outside geologists temporarily working for the State, though we suggest our preferences and ask them to take recognition of them.

For many years the U. S. Geol. Survey treated *Marcellus sh.* and *Hamilton fm.* as distinct fms. The N. Y. State Survey has now, however, adopted Cooper's 1930 classification, which treats the Hamilton as a *group*, including the Marcellus sh. This is also present classification of U. S. Geol. Survey in N. Y. In south-central Pa., however, it still treats Hamilton and Marcellus as distinct fms.

March Point formation.

Upper Cambrian: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. No. 1, p. 83).

Marcy anorthosite.

Pre-Cambrian: Northern New York (Essex County).

H. P. Cushing, 1899 (N. Y. State Geol. 18th Ann. Rept.). In Essex Co. two types of pre-Camb. anorthosite "have been dubbed by Kemp *Whiteface type* and *Mount Marcy type*." [The compiler has been unable to find where Kemp used *Mount Marcy type*.]

W. J. Miller, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 400–462). *Marcy anorthosite.*—By far the most abundant facies of the anorthosite of the Adirondacks. I shall call it *Marcy anorthosite* because of its great exposures on Mount Marcy [Essex Co.]. The most typical portion is very coarse-grained, light to dark bluish gray, and consists very largely of basic plagioclase feldspar, mainly labradorite, much of it practically devoid of foliation. [See further explanation under *Whiteface anorthosite*.]

J. F. Kemp, 1921 (N. Y. State Mus. Bull. 229–230, p. 33). The *Marcy type* of anorthosite, as named by W. J. Miller, is characterized by blue to very dark, almost black plagioclase. Assigned to Algoman intrusives of pre-Camb.

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 82). [See under *Adirondack anorthosyte*.]

Marengo moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin and northeastern Illinois. See W. C. Alden, 1904 (U. S. G. S. P. P. 34), and M. M. Leighton and G. E. Ekblaw, 1932 (16th Int. Geol. Cong. Guidebook 26, p. 47).

† Mareniscan series.

A term proposed by C. R. Van Hise in 1892 (U. S. G. S. Bull. 86) for the "dark-colored fine-grained schistose part of Archean crystalline complex" of Lake Superior region, and abandoned by him in 1909 (U. S. G. S. Bull. 360, p. 26) in favor of *Keewatin series*, of which it is a synonym. Van

Hise stated (U. S. G. S. Bull. 86, p. 490) that the name was derived "from Marenisco Twp, Mich., S. of Gogebic range, where these rocks have a typical development."

Maria latite.

Age (?): Quebec.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 72).

Marianna limestone. (In Vicksburg group.)

Oligocene (lower): Western Florida and southern Alabama and Mississippi.

L. C. Johnson, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 128–132). *Mariana building stone* is an orbitoidal ls. of Vicksburg type [but he included it in Mio.].

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 51–59). *Marianna ls.*—Soft porous light-gray to white marine lss., containing some marl and more rarely clay beds; layers of chert common. Characterized by abundance of *Orbitoides mantelli* and other Foraminifera associated with many other fossils; *Pecten poulsoni* and *P. perplanus* common. [*P. perplanus* does not occur in Marianna ls. as now defined, but is characteristic of Ocala ls., according to C. W. Cooke.] Lithologically resembles Ocala ls. at Ocala, but differs from it in character of its fauna. Also closely resembles "Peninsular" ls. Thickness approx. 220 ft. It is believed to underlie Ocala ls. In western Fla. is uncon. overlain by beds belonging to Apalachicola group or by post-Plio. fms.

Later work by C. W. Cooke (U. S. G. S. P. P. 95, p. 109, 1915) resulted in showing that Marianna ls. overlies Ocala ls., and (Wash. Acad. Sci. Jour., vol. 8, pp. 187, 195, 1918) in introducing *Glendon ls.* for upper memb. of the Marianna. In 1923 (U. S. G. S. P. P. 133) Cooke elevated Glendon to rank of a fm. and restricted Marianna ls. to the "chimney rock." He later found that in part of western Ala. and Miss. the Marianna overlies Red Bluff clay, which is strat. equiv. of lower part of the Marianna to E. As now defined the Marianna ls. is the white ls. or "chimney rock" that overlies Ocala ls. at Marianna and carries *Lepidocyclina mantelli* and *Pecten poulsoni*. (C. W. Cooke and S. Mossom, 1929, Fla. Geol. Surv. 20th Ann. Rept.) It is basal fm. of Vicksburg group. (See Fla. Geol. Surv. 20th Ann. Rept., 1929.)

Named for exposures at Marianna, Jackson Co., Fla., E. edge of town, where the rock is quarried.

Mariato formation.

Pleistocene: Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 261).

†Maricopa shale.

Miocene (upper and middle): Southern California (Sunset-Midway district).

W. A. English, 1916 (U. S. G. S. Bull. 621, pp. 191–215, report on Cuyama Valley). The *Maricopa sh.*, which overlies the white ss. of Vaqueros fm. S. of Cuyama Valley and which forms upper part of Monterey group, has been mapped separately only as far E. as Salisbury Canyon [about 25 mi. W. of Maricopa type loc.]. It consists of about 1,700 ft. of brown sh., in which reef-like outcrops of white ss. are locally prominent. The sh. is made up mostly of clastic fragments, locally clayey, and not noticeably diatomaceous. It is uncon. overlain by Santa Margarita fm. The name *Maricopa sh.* is used in rept on Sunset-Midway region [afterward published as U. S. G. S. P. P. 116, 1920], for great thickness of diatomaceous sh. which in prel. rept was mapped as *Monterey sh.* [Above definition of Maricopa sh. (the first in print) applies the name to only lower part of typical Maricopa sh. as defined below by R. W. Pack, and the name *Maricopa* was later discarded for Cuyama Valley region.]

R. W. Pack, 1920 (U. S. G. S. P. P. 116). *Maricopa sh.*—Mainly thin-bedded siliceous, diatomaceous sh., containing numerous thin calc. layers and in lower part a relatively small amount of arkosic ss., but in upper part numerous lenses of arkosic ss. and boulder beds. Typically developed in gulch that drains N. through secs. 13 and 24, T. 11 N., R. 24 W., where exposed thickness is about 4,800 ft. Rests conformably on Vaqueros fm. and is uncon. overlain by beds here tentatively called *Etchegoin fm.*, but which probably include at base a representative of Jacalitos fm. The upper part of the diatomaceous shales included in the Maricopa is = Santa Margarita fm. as mapped in W. part of San Emigdio Mtns, which contains a typical Santa Margarita fauna and overlaps onto Vaqueros and Tejon fms. Named for exposures W. of Maricopa and Maricopa Flat, Kern Co.

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, pp. 125–149). [*Monterey sh.* as defined in this rept applied to a lithologic unit of Mio. age, and replaced *Maricopa sh.* and *Salinas sh.*, both of which are now discarded by U. S. Geol. Survey.]

Marietta sandstone. (In Dunkard group.)

Permian: Ohio, Pennsylvania, West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 35). *Marietta ss.*—In places two or three massive sss., each 25 to 40 ft. thick, separated by thin shales; in other places one ss. 100 ft. thick. Overlies Washington coal in SE. Ohio, western Pa., and W. Va.

Named for Marietta, Washington Co., Ohio.

†Marietta beds.

Lower Cretaceous (Comanche series): Northeastern Texas and southern Oklahoma.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 13, pp. 302, 303, 328–337). *Marietta beds.*—Friable brown laminated clays, marked a few ft. above their base by peculiar segregations, pseudoconcretions, in shape of large thin lenses of indurated siliceous ls., often 4 or 5 ft. in diam. and 1 to 2 ft. thick, which split into fissile laminae on weathering. Lowest memb. of Denison beds. Underlies North Denison sands and overlies Fort Worth ls. [As thus defined probably included Denton and part at least of Weno clay members of Denison fm. L. W. Stephenson (U. S. G. S. P. P. 120H, p. 140, 1918) gave thickness of "Marietta beds" as here defined as 160 ft.]

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 115). *Marietta* overlies Denton subgroup (which rests on Fort Worth ls.) and underlies Pawpaw fm. The Denton subgroup is basal div. of Denison beds. [As thus defined is = Weno clay memb. of Denison fm.]

Named for Marietta, Love Co., Okla.

Marietta. (In Carbondale formation.)

Pennsylvanian: Northwestern Illinois (McDonough County).

T. E. Savage, 1930 (Ill. Acad. Sci. Trans., vol. 22, p. 498). Carbondale series of Macomb region divided into (descending): Ipava sh. and ss., Summum or Vergennes ss., Marietta ls. and sh., Francis Creek sh., Colchester (No. 2) coal, and clay or sh. (thin).

Probably named for Marietta, Fulton Co., just E. of McDonough Co. line.

Marigold oolite. (In Chester group.)

Mississippian: Southwestern Illinois (Randolph County).

A. H. Sutton, 1934 (Jour. Geol., vol. 42, No. 6, pp. 626, 627, 628). Impossible to delimit Golconda from the higher Glen Dean with any degree of certainty except in one general locality. This is in *area S. of Marigold* [Randolph Co.], where the two are separated by a thin horizon of chert and cherty ss. from 1–3 ft. thick. Writer believes this zone represents NW. extension of Hardinsburg ss. Beds below sandy zone contain Golconda fossils and those above Glen Dean fossils. This cherty sandy horizon overlies *Marigold oolite*. [This name is not defined, but it is referred to on 2 pages and fossils from it are listed.]

Marilla moraine.

Pleistocene (Wisconsin stage): Western New York. Named for Marilla, Erie Co., N. Y. Is shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17.

Marin sandstone. (In Franciscan group.)

Jurassic (?): Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, table on p. 416). *Marin ss.*, 1,000 ft. thick, underlies San Miguel cherts and overlies Sausalito cherts. A subdivision of the Franciscan.

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, table on pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Marin ss.*—Massive dark-gray ss., obscurely stratified. Thickness 1,000 ft. Underlies Ingleside chert and overlies Sausalito chert. Included in Franciscan group. Named for occurrence on Marin Peninsula, Marin Co.

Marino formation.

Incorrect spelling of Moreno.

Marion granite.

Pre-Cambrian (Laurentian): Central southern Wisconsin (Waushara County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 522). *Marion granite.*—Pinkish feldspathic granite mottled with gray and green. Forms 3 low knobs in town of Marion. Closely resembles Montello granite, but is coarser grained, less closely textured, and has marked tendency to decompose. Assigned to Laurentian.

†Marion formation. (In Sumner group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 786–789). Vari-colored shales and marls with lss. and gyp., 400 ft. thick, overlying Chase fm. and underlying Dakota ss. (Cret.) in central Kans. Toward middle of fm. a cgl., named *Abilene cgl.* [The Tert. age of typical Abilene cgl. is now regarded as established.]

F. W. Cragin, 1896 (Colo. Coll. Studies vol. 6, pp. 1–48). Sumner div. of Big Blue series divided into Wellington shales (above) and Geuda salt measures (below). "Prosser's term Marion fm. is equiv. to Geuda salt measures plus lower part of Wellington." Rests on Chase lss.

C. S. Prosser, 1897 (Kans. Univ. Geol. Surv. vol. 2). *Marion fm.* restricted to lower part of Marion fm. as originally defined, and upper part is here called *Wellington fm.* I now agree with Cragin that upper 200 to 445 ft. of bluish gray, greenish, and reddish shales originally included in Marion fm. should be a distinct fm. The div. line is difficult, but absence of lss. and of fossils in the Wellington may serve as means of separation. The Marion as here defined consists of thin buff lss., shales, and marls, with beds of gyp. and salt, and is Geuda salt measures of Cragin. It overlies Chase fm., top memb. of which has been called "Marion concretionary ls.," but is here replaced by *Winfield concretionary ls.*

L. C. Wooster, 1905 (The Carboniferous rock system of eastern Kans.). *Wellington beds* consist of (descending): (1) Varicolored shales and marls; (2) shales and marls alternating with gyp. and thick beds of rock salt; (3) buff lss. and marls. Thickness 400 ft. Overlie Marion beds, top memb. of which is Abilene cgl. [Tert.], which consists of ls. and quartz pebbles. [This was a restriction of Marion fm., which as originally defined included the salt measures.]

J. W. Beede, 1909 (Kans. Acad. Sci. Trans., vol. 22, pp. 248–256). *Marion stage*, limited to following fms. (descending): (1) Abilene cgl. (?), correlation not positive; (2) Pearl shales, 70 ft.; (3) Herington ls.; (4) Enterprise sh., 44 ft.; (5) Luta ls., 0 to 30 ft. Overlies Winfield ls.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3). *Marion fm.*, 150± ft. thick, divided into (descending): Abilene cgl. memb., Pearl sh. memb., Herington ls. memb., Enterprise sh. memb., and Luta ls. memb.

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2, p. 63, footnote). It appears that so-called Abilene cgl., which has previously been referred to uppermost part of Marion fm., is in reality a Tert. deposit. It contains fragments of rock which apparently belong to Dakota ss., and at no point has it been observed in a strat. position beneath Wellington sh.

Subsequent repts treated Pearl sh. as top memb. of Marion fm. and included the salt beds in overlying Wellington fm.

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, in cooperation with U. S. Geol. Survey). Wellington fm. redefined so as to include all beds below "Red Beds" and above Herington ls., and "Marion fm." abandoned.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser.), continued to use *Marion fm.* to include Pearl sh. at top and Luta ls. at base, the underlying fm. being called *Winfield.*

R. C. Moore, 1936 (Jour. Geol., vol. 44, No. 1; and Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), did not use *Marion*, but divided the beds extending from top of Herington ls. to top of Luta ls. into 2 fms. named *Nolans ls.* above and *Odell sh.* below.

Typical Abilene cgl. is now generally acknowledged to be of Tert. age.
Named for exposures in Marion Co., Kans.

Marion concretionary limestone. (In Chase group.)
Permian: Central Kansas.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 772, 773, 780, 783, 797). *Marion concretionary ls.*—Massive ls., 10 ft. thick, containing large flint concretions, which weather brown and contain *Productus* and a few other fossils. Composed of two beds of ls. separated by thin sh. Top memb. of Chase fm.

Is upper bed of Winfield ls. of Prosser, 1902, and other geologists, and appears to be Cresswell ls. of Condra and Upp, 1931. (See under *Winfield ls.*)
Named for Marion, Marion Co.

Marion flint. (In Chase group.)
Permian: Central Kansas.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 773, 779–786, 797). *Marion flint.*—Light-gray ls., generally containing flint, 4 ft. thick; near top of Chase fm. Separated from overlying Marion concretionary ls. by 13 ft. of yellowish shales.

This bed was later included in Winfield fm. It appears to be Stovall ls. of Condra and Upp, which they treated as basal bed of Winfield ls. (See Kans. Perm. chart compiled by M. G. Wilmarth, 1936.)
Named for Marion, Marion Co.

Mariposa slate.
Upper Jurassic: Northern California (Mariposa, Calaveras, and neighboring counties).

G. F. Becker, 1885 (U. S. G. S. Bull. 19, pp. 18–23). *Mariposa beds.*—An immense thickness of highly metamorphosed auriferous slates occurring along foothills from Mariposa to Nev., and containing *Aucella, Belemnites*, and other fossils. Thin-bedded strata prevail, and silicification and serpentinization are predominant characteristics. The beds are upturned into a nearly vertical position, and are uncon. overlain by Chico beds. Regarded as identical with Knoxville beds.

Beds of ss. and cgl. are also included in Mariposa sl., and contemp. greenstone is associated and in part interbedded with the fm. In 1910 (Jour. Geol., vol. 18, charts opp. pp. 217 and 221) J. P. Smith restricted *Mariposa* to lower part of Mariposa sl. of previous repts, or to the slates of the Gold Belt carrying *Aucella erringtoni* and *Cardioceras alternans*, and applied the new name *Colfax fm.* to upper part of the Mariposa, or to the "tuffs and shales of the Gold Belt with *Perisphinctes colfaxi.*" The U. S. Geol. Survey uses the original broad definition of Mariposa, and classifies it as older than Knoxville and of Upper Jurassic age.
Named for occurrence on Mariposa estate, in Mariposa Co.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Mariposa group.

Mesozoic: Sierra Nevada, California.

N. L. Taliaferro, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 149). *Mariposa group.*—Between Stanislaus River and Mariposa Creek, a distance of 45 mi., the Bedrock Complex is divided into 2 groups, Tuolumne group and Mariposa group. The latter uncon. overlies the former, and consists of over 3,000 ft. of acid and intermediate volcanics, sss., and cherts and 2,000 to 2,500 ft. of slates. On Merced River and southward into Indian Gulch quad. it is divided into *Mariposa slates* above, 2,000± ft. thick, and Indian Gulch aggls., tuffs, sss., and cgls., 3,500 ft. thick below.

Mariquita diabase.

Age (?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 322).

Maris rhyolite.

Miocene (upper) or later: Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723, pp. 50–51). Intrusive dikes and irregular masses of brecciated rhyolite cutting Round Rock and Bald Mtn lake beds members of Esmeralda fm. Exposed at Maris mine.

Marjum limestone.

Middle Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll. vol. 53, No. 1804, pp. 9, 10). *Marjum fm.*—Gray to dark, more or less thin-bedded aren. ls., 1,092 ft. thick. Underlies Weeks fm. and overlies Wheeler fm. Type loc. is cliffs on S. side of Marjum Pass.

Markey ground moraine.

Pleistocene (Wisconsin stage): Northern central Michigan (Roscommon County).

W. A. Ver Wiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 164). Lies N. of Houghton Lake, in SW. part of T. 23 N., R. 3 W., Markey Twp.

Markham sand.

A subsurface sand, of Penn. age, in Ponca City field, Kay Co., Okla., correlated with upper part of Cherokee sh. Is older than Bixler sand and younger than Barnett sand.

Markley sandstone.

Oligocene and upper Eocene: Western California (San Francisco Bay region).

B. L. Clark, 1918 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, pp. 54–111). *Markley fm.*—Heterogeneous assemblage of beds, mostly of shallow-water origin but possibly in part continental. Thickness 3,300 ft. Lithology very different from that of San Ramon fm. but very probably it is contemp., at least in part, with the San Ramon. The upper 1,300 ft. consists of alternating layers of clay sh., sandy sh., and ss., and contains a meager fauna. The lower 2,000 ft. is predominantly ss. and contains no fossils. In former paper writer included latter beds in the Tejon, but he now believes them to be lower Olig. Discon. underlies Kirker fm. The Kirker and Markley fms. compose San Lorenzo series in this area. Named for exposures in vicinity of Markley Canyon, Mount Diablo region.

T. L. Bailey, 1930 (Calif. Univ., Dept. Geol. Sci. Bull., vol. 19, No. 15, p. 326) and 1931 (Geol. Soc. Am. Bull., vol. 42, No. 1, p. 304) assigned this fm. to Eo.

B. L. Clark, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 1, p. 304). Fossils found in *Markley fm.* by T. Bailey indicate it is probably Eo. and=Tejon fm.

On Dec. 4, 1932, B. L. Clark (unpublished rept) assigned *Markley ss.* to Olig. and Eo.

†Marks Head marl.

Miocene (lower): Southern South Carolina and eastern Georgia.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, 19). *Mark's Head phase.*—Soft blue marls with characteristic bed of shells embedded in a sandy blue mud matrix. Thickness 27 ft. Of Mio. age. Extends from Mark's Head, on scarp of Savannah River Swamp, NW. of Porter's Landing [Effingham Co., Ga.], by Raysor's Bridge, S. C., and thence below Mount Hope on Santee River, S. C. Underlies Edisto phase (also Mio.) and overlies Parachucla phase (Olig.).

O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, pp. 60, 363+, map, etc.). *Marks Head marl.*—Very sandy greenish or drab clay, fine gray or brownish phosphatic sand and sandy laminated clays with calc. nodules. Thickness in Ga. 45 ft. Is early Mio. Rests uncon. on Alum Bluff fm. (Olig.). Overlain uncon. by Duplin marl (late Mio.), which Sloan erroneously correlated with Edisto marl of Edisto River, S. C.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). The early Mio. beds in eastern Ga. and S. C. that have heretofore been called "Marks Head marl," "Edisto marl," "Parachucla sh.," "Parachucla marl," and "Combahee sh." are in this rept included in Hawthorn fm., a Florida name that is here extended into eastern Ga. and S. C. In eastern Ga. the Hawthorn is represented by †Marks Head marl and part of Alum Bluff fm. of Veatch and Stephenson, whose Marks Head marl included, although unwittingly, the †Parachucla marl and †Parachucla sh. of Sloan. The Hawthorn is in Ga., and in most places in S. C., overlain by Duplin marl (upper Mio.), but in a small area in NE. part of Colleton Co., S. C., it is locally separated from the Duplin by a deposit of upper Mio. age to which the name *Raysor marl* is here applied. The Hawthorn rests uncon. on Glendon fm. (Olig.) and older fms.; in Ga. and Fla. it rests on Tampa ls. (lower Mio.).

Marks-Mills red beds.

Eocene (upper): Cleveland Co., Arkansas.

G. D. Harris, 1894 (Am. Jour. Sci., 3d, vol. 47, p. 304). *Marks Mills Red Beds (substage).* [No definition except that the beds are included in Jackson "stage" of Ala. and Miss., are older than "Moody's Branch beds" and younger than Claiborne "stage." In Ark. Geol. Surv. Ann. Rept. for 1892 (1894), pp. 98–101, Harris describes fossils collected from the red beds of Marks Mills battlefield, Cleveland Co., Ark., but does not use term "Marks Mills beds." The Jackson fm. of Miss. is now divided into two members, Yazoo clay memb. above and Moodys marl memb. below. The relation of the beds in Cleveland Co. to the members of Jackson fm. in Miss. is undet.]

Mark West andesite.

Pliocene: Northern California (Sonoma County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 58–87). *Mark West andesite.*—Thickness varies up to 1,500 ft. Conformably underlies Sonoma tuff. Is certainly post-San Pablo and probably post-Orindan.

Apparently named for Mark West Springs, Sonoma Co.

Marland sand.

A subsurface sand in Okla., which is said by some geologists to be referable to base of Chattanooga sh. (Dev.?) and by other geologists to correlate with upper part of Tyner fm. (Ord.).

Marlboro clay. (In Nanjemoy formation.)

Eocene: Eastern Maryland and Virginia.

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 65). A bed of red clay at base of Potapaco memb. or substage of Nanjemoy fm. is well defined at Upper Marlboro, Md., and has been referred to as *Marlboro clay.*

W. B. Clark and B. L. Miller, 1906 (Va. Geol. Surv. Bull. 2, pt. 1, p. 17). The basal bed of Nanjemoy fm., known as *Marlboro clay*, extends from central Md. across the Potomac into Va., and is well developed btw. Potomac Creek and the Rappahannock. It consists of 25 ft. of compact clay, lower part pink, upper part white.

Marlboro formation.

Pre-Cambrian: Eastern Massachusetts and eastern Rhode Island.

B. K. Emerson and J. K. Perry, 1907 (U. S. G. S. Bull. 311, pp. 7, 8, 11, 13–36 and map). *Marlboro fm.*—As developed in region from Woonsocket to Pawtucket, R. I., it includes a great variety of green schists, amphibolites, steatites, and lss. Also includes Smithfield ls. memb., 0 to 150 ft. thick, which changes into tremolite schist, steatite, and serpentine. Overlies Grafton [Westboro] qtzite. Named for Marlboro, Mass. [where the fm. makes a long vertical wall along Main St.].

See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597), and L. LaForge, 1932 (U. S. G. S. Bull. 839). Seems to underlie Woburn fm.

†Marlborough rock.

See under †*Piscataway sands.*

Marlbrook marl. [Restricted.]

Upper Cretaceous (Gulf series): Southwestern Arkansas, northwestern Louisiana, and northeastern Texas (?).

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72, 84–86, 188). *Marlbrook-Columbus or Gryphaea vesicularis chalk marls.*—White chalky marl containing large percentage of yellow and pale-blue clays, and decomposing readily under influence of moisture. When freshly exposed and moist the marls have delicate blue tint, but when dry they are pure white. Thickness probably 200 ft. Underlie Big Deciper beds and overlie Brownstown or yellow *Exogyra ponderosa* marls. [According to C. H. Dane and L. W. Stephenson, R. T. Hill's Big Deciper beds are in upper part of Saratoga chalk. See C. H. Dane, Ark. Geol. Surv. Bull. 1, p. 103. 1929.]

A. C. Veatch, 1906 (U. S. G. S. P. P. 46, p. 26). *Marlbrook marl.*—Series of blue chalky, somewhat glauconitic marls in places impure chalk. Thickness 50 to 750 ft. About 200 to 300 ft. above base is very chalky layer which has been called *Saratoga chalk marl* or *Saratoga fm.* Overlies Annona chalk and underlies Nacatoch sand. Probably Marlbrook fm. as here used contains in upper part beds which Hill classed with Washington (Nacatoch) sand.

L. W. Stephenson and C. H. Dane in 1927 (A. A. P. G. Bull., vol. 11, No. 1) and 1929 (Ark. Geol. Surv. Bull. 1) restricted *Marlbrook marl* to beds in SW. Ark. that uncon. underlie Saratoga chalk and conformably overlie Annona chalk. This is present approved definition.

Typically exposed for a little over 1 mi. N. of Saratoga, on road to Mineral Springs, Howard Co. Also exposed along Marlbrook Creek, in T. 10 S., R. 24 W., Hempstead Co., Ark.

†Marlbrook-Columbus marl.

Upper Cretaceous: Southwestern Arkansas.

See *Marlbrook marl.*

Marlette moraine.

Pleistocene (Wisconsin stage): Eastern Michigan (Tuscola Co.). See Mich. Geol. Surv. Rept. 1908, pp. 148–196.

†Marlin chalk member (of Taylor marl).

Upper Cretaceous (Gulf series): Eastern Texas (Limestone, McLennan, and Falls Counties).

C. H. Dane and L. W. Stephenson, 1928 (A. A. P. G. Bull., vol. 12, pp. 51–55). *Marlin chalk memb of Taylor marl.*—In Limestone Co. chalk at approx. position of Pecan Gap chalk reappears in section and has been traced S. through E. corner of McLennan Co. and through Falls Co. to point a few mi. S. of Brazos River. It is a pure-white chalk, in part hard and tough, and in part soft and marly. The granular texture and admixture of sand which is found in places in Pecan Gap chalk has not been observed in Marlin chalk, but essential lithology is similar and fauna in part comparable. Is believed to be of approx. same age as Pecan Gap chalk, but paleontologic evidence is not conclusive. It lies 250 ft. below top of Taylor marl in Falls Co., and about 550 ft. above Durango sand memb. To W. and NW. of Prairie Hill it rests on sandy sh. and calc. sand undoubtedly=upper part of Wolfe City sand memb. Total thickness less than 50 ft. in vicinity of Mart and probably thins to NE. Is typically exposed 0.4 to 0.9 mi. S. of courthouse at Marlin, Falls Co., along edge of bottom lands of Brazos River, in a small scarp facing W.

This chalk is now regarded by Tex. Geol. Survey and U. S. Geol. Survey as same as Pecan Gap chalk memb. of Taylor marl, and Marlin chalk memb. has therefore been discarded.

Marlow formation.

Permian: Southwestern, central southern, and central Oklahoma.

R. W. Sawyer, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 312–320, map). *Marlow fm.*—Brick-red shales and even-bedded brick-red sss. with bands of fine white sand and sandy gypsums. Entire fm. is gypsiferous, many of shales containing veins of satin-spar and the sss. more or less gyp. At top is a thin layer of almost pure gyp. 1± ft. thick. Thickness 120± ft. [Later repts give thickness as 110 to 135 ft.] Underlies Whitehorse ss. as here defined, but is believed to be part of Whitehorse ss. as originally defined. Rests on Dog Creek sh. to W. and on Duncan ss. to E. Named for exposures at Marlow, Stephens Co.

F. C. Greene, 1924 (A. A. P. G. Bull., vol. 8, No. 3, p. 321). I question propriety of establishing the name "Marlow" until it can be shown more definitely that it is not Dog Creek sh.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 324–341). The Marlow fm. of Sawyer and other geologists includes Dog Creek sh. and Blaine gyp.

C. D. Stephenson, 1925 (A. A. P. G. Bull., vol. 9, No. 3, pp. 626–631). *Marlow sh.* is correlated with Dog Creek sh. and Blaine gyp., but in Grady, Caddo, and Canadian Counties it has not been deemed advisable to subdivide it. About 35 ft. below its top occurs Verden channel ss., the 35 ft. interval up to base of Whitehorse ss. as here used (=Upper Whitehorse of some authors) being occupied by sh. containing locally some gyp. beds.

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 405–432). Base of *Rush Springs memb.* is by definition a gyp. bed. Top of this gyp. is contact btw. Marlow and Rush Springs members of the Whitehorse. There may be some question as to whether this gyp. is in horizon of Upper Relay Creek dol. or of Lower Relay Creek dol. At any rate it seems consensus of opinion is that Marlow-Rush Springs contact should be drawn at top of Upper Relay Creek dol. Base of Marlow is top of Dog Creek sh., and where exposed this is a definite and easily recognized contact. Top of Rush Springs is base of Cloud Chief. In NW. Okla. it is not possible to separate the Marlow from Rush Springs memb. Together they constitute lower 100 ft. or more of Whitehorse as this fm. is exposed in Harper, northern Woodward, and western Woods Counties. The Marlow is entirely ss. with exception that in places a gyp. ledge 2 ft. thick occurs at base, and farther W. a gyp. bed 5 or 6 ft. thick occurs 20 to 35 ft. above base. This ss. is of characteristic Whitehorse color and appearance. The Marlow memb. of central-western Okla. is approx. 100 ft. thick.

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437). Evans' grouping of Marlow, Rush Springs, and Cloud Chief in a single unit is a logical step, but his separation and correlation of the members within that group is open to serious question. [Long discussion.]

F. C. Greene, 1932 (Tulsa Geol. Soc. Summ. and Abstracts, 1932, Tulsa Daily World), stated that *Rush Springs memb. of Whitehorse ss.* overlies Marlow memb. of the Whitehorse and underlies Weatherford dol.

See also D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1454–1475).

†Marmaton formation.

†Marmaton group.

Pennsylvanian: Eastern Kansas and western Missouri.

C. R. Keyes, 1897 (Iowa Acad. Sci. Proc., vol. 4, pp. 23–24). *Marmaton fm.*—Sh., 30 to 50 ft. thick, carrying thin beds of ls., forming middle memb. of Henrietta fm. in SW. Mo. and SE. Kans. Underlies Pawnee ls. and overlies Fort Scott ls. [As thus defined is same as Labette sh.]

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 92–94). As Marmaton River crosses this fm. at right angles, and has cut channel in it, the name *Marmaton* *fm.* will be given to it. It includes all beds above Cherokee sh. and below top of Pleasanton shales. [As thus defined it included Henrietta and Pleasanton fms. and extended up to base of a ls. (called Hertha ls.), underlying Ladore sh.]

Haworth continued to use *Marmaton fm.* (1904, 1908, 1913), but other writers used *Pleasanton and Henrietta fms.*, although Beede (1909) called these combined fms. *stage B* of Carbf. of Kans. and Okla. In 1912 the U. S. Geol. Survey discarded *Marmaton* from its classification, using instead (as did Hinds and Greene, 1915) the subdivisions *Pleasanton* and *Henrietta*. R. C. Moore and W. P. Haynes in 1917 revived *Marmaton fm.* (for the beds btw. top of Cherokee sh. and base of Hertha ls.), reduced Pleasanton to rank of memb., and discontinued Henrietta in Kans., treating the subdivisions of latter as members of *Marmaton fm.* The Kans. Geol. Surv. continued to use this classification until 1932; some Okla. geologists also used it; but U. S. Geol. Surv., Nebr. Geol. Surv., Mo. Geol. Surv., and some other geologists continued to use *Pleasanton* and *Henrietta*. In Bull. 5 (1932) of Nebr. Geol. Surv. is a chart (credited to G. E. Condra, R. C. Moore, and C. O. Dunbar) in which the rocks of Nebr. beneath the ls. (called Hertha ls.) underlying Ladore sh. are called *Marmaton group* and divided into *Pleasanton sh.* above and *Henrietta fm.* below.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, p. 89). Strata at top of *Marmaton group* that overlie the uncon. separating Des Moines and Missouri series are removed from Marmaton and included as part of lowermost Missouri beds. [The beds removed by Moore he listed as (ascending): Unnamed sh. and ss.; Uniontown ls. (so-called Hertha of some repts); Ladore sh. [not Ladore sh. of previous repts]; Schubert Creek ls. ("called 'Hertha' by Hinds and Greene"); Tennison Creek sh.; Critizer ls.; and Mound City sh. The ls. overlying the Mound City, which according to Moore had also been called *Hertha ls.* by Hinds and Greene, Moore named *Sniabar ls.* This definition of Marmaton group (in which both *Pleasanton* and *Henrietta* were discarded, their subdivisions being treated as fms. of Marmaton group) was adopted by Moore and G. E. Condra in their Oct. 1932 revised classification of Penn. rocks of Kans. and Nebr., also by Moore in his 1935 classification of Penn. rocks of Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 41–43). Some rocks formerly classed as upper Marmaton are transferred to Missouri series (see fig. 6). [Fig. 6 draws top of *Marmaton group redefined* at discon. at top of Nowata (?) sh. and omits all mention of overlying Lenapah ls. and Memorial sh. (new). Page 58 states:] Subdivisions of Marmaton group (upward order) are Fort Scott ls., Labette sh., Pawnee ls., Bandera sh., Altamont ls., Nowata sh., Lenapah ls., and Memorial sh.; the upper units have not been traced definitely northward from exposures in southern Kans.

Named for exposures on Marmaton River, Vernon Co., Mo., and Bourbon Co., Kans., whose channel, throughout almost its entire length, is within the fm.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Maromas granite gneiss.

Late Carboniferous or post-Carboniferous: Central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 143 and map). *Maromas granite gneiss.*—The rock exposed in Maromas quarries is a biotite gneiss of medium to fine grain, varying in color and in amount of biotite present. Massive in some places, but usually well foliated and jointed. Along NE. border of area it becomes a decided "augen gneiss." A granulitic facies is developed for a mile along W. border. Intrudes Bolton schist.

Maroon conglomerate (also **Maroon formation**).

Permian and Pennsylvanian (?): Western central Colorado.

G. H. Eldridge, 1894 (U. S. G. S. Anthracite-Crested Butte folio, No. 9). *Maroon cgl.*—Includes all beds above Weber ls. (100 to 550 ft. thick) and uncon. below

Gunnison ss. [Morrison fm.]. Max. observed thickness over 4,500 ft. Lower div. consists of alternating yellowish-gray grits, thin lss., and sh. beds reaching max. observed thickness of 2,000 ft. The upper div. is composed of alternating beds of cgl. and ss., with some shales and occasional ls. beds, and reaches max. observed thickness of 2,500± ft. at Mount Teocalli and Double Top; it is of a peculiar red or chocolate color, except in regions of local metamorphism, where greenish hues occur, arising from development of minerals containing lime and iron silicates. Named for typical developments on Maroon Creek, N. of quad. [In Aspen quad.] [As thus defined includes the so-called "Weber grits" of later repts.]

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48), restricted *Maroon fm.* to beds (1,500 ft. thick) above the so-called "Weber grits."

The present approved definition of Maroon fm. is for the beds above †Weber grits and below Entrada ss. and Morrison fm. However, because of variation in lithology and the difficulty of separating the Maroon strata (which also include grits, especially in their upper part) from the underlying beds, the name *Maroon fm.* has in several areas been used to include the equivalent of †Weber grits.

Marquettan series.

A term applied by C. [R.] Keyes to the Huronian rocks of Lake Superior region.

Marquette quartz porphyry.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Green Lake County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 520). *Marquette quartz porphyry.*—Occurs near village of Marquette, Green Lake Co.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). "May be supposed to be pre-Huronian."

Marquette member.

Lower Cretaceous (Comanche series): Central Kansas.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9, pp. 31–32). *Marquette memb.*—Zones 5 to 10 of Natural Corral section, consisting of (descending): (10) 2 ft. of cross-laminated medium-grained friable yellow ss.; (9) 17 ft. of friable fine-grained yellowish ss. with a somewhat compact 6-inch band near middle and a similar 2-in. band about 7 ft. below top; (8) 7 to 8 ft. of compact yellowish-white ss.; (7) 10 ft. of blue paper sh.; (6) 2 ft. of pale-yellow ss.; and (5) 14 ft. of blue gypsiferous sh. Overlies Windom memb. and underlies Mentor memb., all included in Belvidere fm.

Apparently named for exposures near Marquette, McPherson Co.

Marquette rhyolite.

Pre-Cambrian: Southeastern Wisconsin (Green Lake County).

C. C. Wang, 1932 (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428). *Marquette rhyolite* lies 1 mi. SW. of village of Marquette [Green Lake Co.] in a group of knobs rising abruptly 50 to 150 ft. above surrounding sandy and marshy plain. The mass of the rhyolite is dark reddish purple or dark purplish on fresh surface and dull reddish or grayish red on weathered surface. Mainly porphyritic, with pinkish feldspar phenocrysts scattered through the dense dark groundmass, but in some localities it becomes largely felsitic.

Marquette granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. granite in Wis. (area not stated).

†Marquette series.

A term applied in some early repts to the Huronian rocks of Marquette dist., Mich. In many early repts on this dist. the upper Huronian rocks were called "Upper Marquette series" and the middle and lower Huronian rocks were called "Lower Marquette series."

†Marquettian system.

Pre-Cambrian: Northeastern Minnesota (Marquette district).

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept., p. 365). *Marquettian system.*—Includes Ogishke group (cgls., 10,000 ft.), Tower group (earthy schists, 15,000 ft.), and Graywacke group (2,500 ft.). Thickness 27,500 ft. Overlies Vermilion group. Heretofore called Keewatin.

Marseilles morainic system.

Pleistocene (Wisconsin stage): Northwestern Indiana and northeastern Illinois. Shown on moraine map in U. S. G. S. P. P. 106. Named for Marseilles, Ill. In some earlier repts called "Marseilles-Iroquois moraine."

Marsh shale.

Pre-Cambrian (Belt series): Southern central Montana (Belt Mountains).

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Marsh shales.*—Reddish shales and thick-bedded sss., 300 ft. thick, forming top fm. of Belt series in Marysville-Neihart region. Overlies Helena ls. and uncon. underlies Camb.

Named for Marsh Creek, N. of Marysville.

Marsh sand.

A subsurface sand, of probable Dev. age, in western N. Y., lying near horizon of Richburg sand.

Marshall sandstone.

Mississippian (Osage or Kinderhook): Michigan (Southern Peninsula).

A. Winchell, 1861 (Mich. Geol. Surv. 1st Bien. Rept. Prog., pp. 80, 139). *Marshall group.*—Consists of (descending): (1) Reddish, yellowish, and greenish sss., 147 ft. (exposed at Marshall, Pt. aux Barques, etc.); (2) shaly micaceous ss., 10 ft.; (3) cgl., 2 ft. (exposed at Point aux Barques grindstone quarries). Thickness of group 159 ft. Contains Chemung Dev. fossils. Grades into overlying unfossiliferous Napoleon group and rests on Huron group. [Regarding propriety of excluding or including Napoleon, see under *Napoleon ss.*, 1861 entry.]

In 1871 (Mich. Geol. Surv. Rept. Prog., pp. 26–33) A Winchell defined *Marshall group* as overlain by Michigan salt group [Michigan fm.] and underlain by Huron group, thus including in it the beds previously called Napoleon ss.

A. C. Lane, 1893 (as reported by M. E. Wadsworth, Mich. Geol. Surv. Rept. 1891 and 1892, pp. 62–73), applied *Marshall ss.* to beds overlain by Grand Rapids group and underlain by Coldwater shales. This is present accepted definition.

†Marshall shale.

Mississippian: Northwestern Arkansas and northeastern Oklahoma.

J. C. Branner and F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. xiii, 26, 53–54). [According to p. xiii the fm. was named by Branner; the description is by Simonds.] *Marshall sh.*—Black, more or less bituminous sh., 0 to 80 ft. thick, overlying Batesville ss. [not Batesville ss., but the younger Wedington ss.] and underlying Archimedes [Pitkin] ls. [See under *Fayetteville sh.* for explanation of erroneous correlations in above definition.]

Preoccupied. The sh. at Marshall type loc. is same as Fayetteville sh. See under *Fayetteville sh.*

Named for a sh. mtn just E. of Marshall, Searcy Co., Ark.

Marshall granite.

Pre-Cambrian (post-Glenarm series): Western central and northern Virginia.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. geol. map of Va.). *Marshall granite.*—Pink to green granite and quartz monzonite. Intrusive into Lynchburg gneiss, Lovingston granite gneiss, and Catoctin greenstone. Assigned to pre-Camb. Mapped at and around Marshall, Fauquier Co.

Marshall moraine (also **morainic system**).

Pleistocene (Wisconsin stage): Southern Minnesota and Grant County, South Dakota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 99–103). In places develops into a system of unnamed moraines. Village of Marshall, Lyons Co., stands on it.

Marshall green-shale zone.

Name applied by drillers and oil geologists to a deposit of green sh., ls., dol. and sand, of Ord. age and 5 to 160 ft. thick, encountered in wells beneath "First Simpson sand" and above "Second Simpson" ("Wilcox") sand, in Lucien field, T. 20 N., R. 2 W., northern Okla. (See B. B. Zavoico, 1935, Tulsa Geol. Soc. Digest 1934, pp. 59–62, and loose plate. Derivation of name not stated.)

Marshall limestone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois (Clark County).

See 1934 entry under *LaSalle ls. memb.*, the only known use of the name. Derivation unknown.

Marshall Hill conglomerate.

Pre-Cambrian (upper Huronian): Central northern Wisconsin (Marathon County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 357). *Marshall Hill cgl.*—Mainly a graywacke grading into cgl. on one hand and into sh. on the other hand. Basal cgl. forms lowest part. Is either upper or middle Huronian. Forms large part of broad upland known as Marshall Hill, about 6 mi. N. of Wausau.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598). *Marshall Hill cgl.* belongs to Animikie group (upper Huronian).

Marshall Lake series.

Pre-Cambrian: Ontario.

P. E. Hopkins, 1917 (Ont. Bur. Mines Ann. Rept., vol. 26, p. 206).

† Marshalltown shale.

Mississippian: Central northern Iowa (Marshall County).

S. W. Beyer, 1897 (Iowa Geol. Surv. vol. 7, pp. 211, 226–227). *Marshalltown shales.*—Nonfossiliferous ash-blue to deep-blue shales interbedded with argill. lss. with chert nodules in upper calc. layers. Exposed near Marshalltown Flouring Mills. Thickness 15 ft. Referred provisionally to Kinderhook. Younger than Le Grand beds.

Only recorded use. Name established for a fm. in N. J.

Marshalltown formation. (In Matawan group.)

Upper Cretaceous: New Jersey.

G. N. Knapp, as reported by R. D. Salisbury, 1899 (N. J. Geol. Surv. Ann. Rept. State Geol. 1898, pp. 35, 36). *Marshalltown bed.*—Marly clay sand underlying Wenonah bed and overlying Columbus bed [Englishtown sand]. Included in Clay Marl series [Matawan group].

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 155). *Marshalltown bed.*—Ranges from sandy clay to clayey marl. Thickness 30 to 40 ft. Underlies Wenonah sand and overlies Columbus sand.

Named for occurrence near Marshalltown, Salem Co.

Marshburg slates.
Marshburg shale. } (In Pottsville formation.)

Pennsylvanian: Northwestern and central northern Pennsylvania (McKean, Elk, and Forest Counties).

C. A. Ashburner, 1885 (2d Pa. Geol. Surv. Rept. R_2, pp. 307, 325). *Marshburg slates*, 2 ft. thick in Forest Co.; contain a coal bed. Included in Pottsville cgl.

Lie btw. Kinzua Creek ss. above and Olean [?] cgl. below. [On pp. 67–119 and 225–241 of same vol. he gives sections in Elk Co. in which he shows 10 ft. of *Marshburg* sh. btw. Kinzua Creek ss. and Olean ss. and cgl. Marshburg is in McKean Co.]

S. H. Cathcart, 1934 (Pa. Topog. and Geol. Surv. Bull. 110, p. 14), states this coal and sh. are same as Sharon.

Marsh Creek group.

Pliocene (?): Southeastern Idaho (Bannock County).

A. C. Peale, 1879 (U. S. Geol. and Geog. Surv. Terr. 11th Ann. Rept., pp. 612, 641, 642). *Marsh Valley group* (p. 612), *Marsh Creek group* (p. 642).—These beds are exposed on Marsh Creek above Red Rock Gap, are very white, friable sss., which dip a degree or two from the mtns. Farther down the valley they are covered by the basalt flow. They are probably older than the deposits I have included under Cache Valley group. Thickness 85 ft.

Probably a part of Salt Lake fm.

Marshfield sandstone.

Lower Ordovician (Beekmantown): Southwestern Missouri.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull. 1, pt. 1, pp. 8, 42). *Marshfield ss.*—Ss., 100 ft. thick; equiv. of Bolivar ss., First ss., Pacific ss., and Crystal City ss. Underlies Finley ls. and overlies Jefferson City ls.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 260, p. 234, and Bull. 267, p. 12), correlated *Marshfield ss.* with either Jefferson City ls. or Roubidoux fm., considering it older than St. Peter ss.

E. M. Shepard, 1907 (U. S. G. S. W. S. P. 195). *Marshfield* and Bolivar sss. are commonly believed to represent St. Peter ss., but Ulrich regards them as lenses in Jefferson City ls.

J. Bridge, 1930 (personal communication), stated that this ss. is now definitely known to be a ss. in Cotter dol.

Marshfield moraine.

Pleistocene (Wisconsin stage): North-central Wisconsin.

S. Weidman, 1907 (Wis. Geol. and Nat. Hist. Surv. Bull. 16, p. 452). The town of Marshfield, Wood Co., is located on this moraine.

Mars Hill conglomerate.

Silurian: Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 119, 134–136). *Mars Hill cgl.*—With exception of Mars Hill diabase dikes, Mars Hill is composed of a cgl. which in places becomes quite fine grained. It is quite distinct from all other sss. and cgls. thus far found in NE. Maine. Absence of igneous fragments is noticeable, and great abundance of sl. fragments makes it almost a sl. cgl. The sheared and broken condition of whole mass and of its individual pebbles, and its intimate association with the crumpled and brecciated slates and lss. at its base, indicate an age at least as great as the Aroostook slated ls., and it is considered, on lithologic grounds alone, to belong to that series. Named for development on Mars Hill, on Int. Bdy, Aroostook Co.

Mars Hill diabase.

Age (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 115, 177–179). *Mars Hill diabase* occurs in two dikes situated close together on SW. flank of Mars Hill. The dikes differ widely in appearance and type of structure. The easternmost dike closely resembles Aroostook Falls diabase and is considered as normal for this region. The other dike is exceedingly basic in composition and is microscopically characterized by a glossy base. Named for occurrence on Mars Hill, Aroostook Co.

Marsh Valley group.

See *Marsh Creek group.*

Marsouin series.

Silurian: Canada.

J. W. Dawson, 1896 (Canada Roy. Soc. Proc. and Trans., n. s., vol. 2, sec. 4, p. 93).

†Martha Washington sandstone.

Pennsylvanian: Southwestern Indiana (Spencer County).

E. T. Cox, 1871 (Ind. Geol. Surv. 2nd Ann. Rept., p. 169). *"Martha Washington" ss.* forms the bluff at Rockport [Spencer Co.] and presents a vertical face of 30 to 50 ft. on side fronting the river. I found *Rockport ss.* to be the millstone grit.

Probably same as Mansfield ss. Has also been called †Lady Washington ss. and †Lady Washington Rock.

D. D. Owen (Geol. Surv. of Ind., 2d Rept., 1839, p. 7). Rockport is built on a conspicuous bluff, on Ohio River, 90 to 100 ft. high, which forms a mural escarpment of ss. to height of 70 or 80 ft. known familiarly as "The Lady Washington."

Martin limestone.

Upper and Middle Devonian: Southeastern and central Arizona.

F. L. Ransome, 1904 (U. S. G. S. P. P. 21). *Martin ls.*—Dark-gray, hard, compact, fossiliferous lss.; occasional beds of lighter hue and sometimes calc. shales of decided pinkish tint. The ls. beds are usually less than 4 ft. thick, being thicker than those of Abrigo ls. and thinner than those of Escabrosa ls. Thickness 340 ft. Rests, apparently conformably, on Abrigo ls. (Camb.) and is overlain, apparently conformably, by Escabrosa ls. (Miss.). Upper limit not always sharply defined. Named for Mount Martin, on Escabrosa Ridge, where fm. is typically developed and well exposed.

As thus originally defined, and as used in subsequent repts, *Martin ls.* included all of Dev. of SE. Ariz. In 1936 A. A. Stoyanow restricted Martin ls. to upper 260 ft. of Martin ls. of previous repts, and applied *Picacho de Calera fm.* to lower 73 ft. of the Dev. ls. in Picacho de Calera Hills and Rincon and Whetstone Mtns. In Santa Catalina Mtns he named the upper 150 ft. of the Dev. the *Lower Ouray fm.* (a name transplanted from SW. Colo.) and applied *Martin ls.* to underlying 145 ft. The U. S. Geol. Survey has not yet had occasion to consider these restrictions. (See also *Santa Rita ls.*)

Martin sandy zone.

A subsurface sand in upper part of Colorado sh. of Bowdoin dome, central northern Mont. Lies higher than *Bowdoin sand zone* (25 to 100 ft. thick), which overlies *Phillips sand* (20 to 83 ft. thick).

Martin Bridge formation.

Upper Triassic: Northeastern Oregon (Wallowa Mountains region).

R. W. Chaney, 1932 (16th Int. Geol. Cong. Guidebook 21, p. 4). *Martin Bridge fm.*—Calc. sh., ls., aggl., basalt, andesite, and tuff, of Upper Triassic age. [Named for locally well-known bridge on Eagle Creek, according to C. P. Ross, personal communication.]

J. Gilluly, J. C. Reed, and C. F. Park, Jr., 1934 (U. S. G. S. Bull. 846, p. 12). The Triassic rocks of Wallowa Mtns have been named *Martin Bridge fm.* They consist of 1,000 to 3,000 ft. of ls., limy sh., and interbedded volcanic rocks of Upper Tr. age. A comparable thickness of chiefly andesitic volcanic rock exposed in valley of Cliff River is believed by C. P. Ross to be contemp. with Martin Bridge fm. [C. P. Ross states (personal communication) that latter rocks were probably included in Martin Bridge fm. of Chaney.]

†Martin Canyon beds.

Tertiary (lower Miocene and upper Oligocene): Northeastern Colorado.

W. D. Matthew, 1901 (Am. Mus. Nat. Hist. Mem., vol. 1, pt. 7, pp. 355–374, 444). *Cedar Creek and Martin Canyon beds.*—Upper part of White River fm. and younger than Horsetail Creek beds (*Titanotherium* beds). Fine light-colored, pinkish or buff clays, much softer than underlying Horsetail Creek beds. Include *Leptauchenia* and *Oreodon* clays. Correspond with Darton's Brule clays, though how accurately it is impossible to say in absence of lists of Brule fauna.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 65, 106, 112). Martin Canyon beds = lower (or lower Miocene) part of Arikaree and upper (or upper Olig.) part of Brule fm. [Osborn repeated this assignment in 1918 (Am. Mus. Nat. Hist. Mem., vol. 2, pt. 1, pp. 9, 12, 13).]

Named for Martin Canyon of Cedar Creek, Logan Co.

Martinez formation.

Eocene (lower): Western California.

W. M. Gabb, 1869 (Calif. Geol. Surv., Pal., vol. 2, p. xiii, as reported by J. D. Whitney from unpublished paper by Gabb, and footnote by Gabb on p. 129). The term *Martinez group* is proposed provisionally for upper part of "Div. A" of Calif. repts, to include a series of beds, of small geographical extent, found at Martinez and on N. flank of Monte Diablo. It may eventually prove to be worthy of ranking only as a subdivision of Chico group. Underlies Tejon group and overlies Chico group.

T. W. Stanton, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, p. 1028). The *Martinez group* of Calif. Survey is not a simple fm. that can be considered a mere subdivision of the Chico, but consists of two distinct parts, one of which is Cret. and inseparable from the Chico, while the other is Eo., and is here classed as Lower Tejon.

J. C. Merriam, 1897 (Jour. Geol., vol. 5, pp. 767-775). *Martinez group.*—The name *Martinez* is here applied to that part of Gabb's Martinez group which remains after the removal of the Chico Cret. element. Is the Lower Tejon of Stanton, and consists of sss., shales, and glauconitic sands. At Martinez it appears to be conformably overlain by the Tejon and conformably underlain by the Chico, although an uncon. probably exists at its base. Differs from adjoining fms. in slightly different aspect of its sss. and the presence in them of considerable quantities of glauconite. The sss. of the Martinez are grayish, those of the Chico yellowish or bluish, and those of the Tejon white to dull red. The fauna also differs from the Chico and Tejon faunas, and is a unit, although it grades to some extent into Tejon fauna.

The present generally accepted definition of Martinez fm. is for the beds uncon. underlying Meganos fm., uncon. overlying Chico fm., and varying in thickness up to 3,500 or more ft. The rocks consist of cgl., ss., and sh. characterized by fossils of lower Eo. age. See definition of Meganos fm.

Martinez marine member.

Eocene: Southern California (Ventura County, south of Simi Valley).

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 11). On SW. side of the faults the Martinez group has been separated into following lithologic units: Martinez marine memb., Las Virgenes ss., and Simi cgl. These members grade into one another both laterally and vertically, but with sufficient abruptness that their boundaries can be accurately mapped. The fossiliferous *Martinez marine memb.* of Martinez group consists of 800 to 2,400 ft. of beds that may be subdivided into a ss. above and a sh. below but their boundaries are too indefinite to be indicated on map. With exception of about 200 ft. of light-gray sh. at top, the marine memb. of the Martinez consists of medium- to fine-grained sss. with occasional beds of coarse-grained ss. in lower part.

Martinian series.

A term introduced by C. [R.] Keyes in 1915 to cover upper part of Dev. section in N. Mex., the lower part of the Dev. being called *Perchan series*. (See his conspectus of geol. fms. of N. Mex., 1915.) In 1922 he applied *Martinian series* to lower part of Upper Dev. in Ariz. and *Perchan series* to upper part. (See *Martin ls.* and *Percha sh.*)

Martin Lake limestone. (In Palo Pinto formation.)

Pennsylvanian: North-central Texas (Wise County).

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 22). *Martin Lake ls.* lies 20 ft. below Boone Creek ls. and higher than Hudson Bridge ls., all included in Palo Pinto fm. Consists of 4 ft. of reddish brown ls. that is a veritable bed of *Fusulina*. It is lowest of a series of 3 lss. outcropping around S. and W. sides of Martin Lake, 2 mi. S. of Bridgeport. Not found elsewhere in Wise Co.

Martinsburg shale.

Upper and Middle Ordovician: West Virginia, western Virginia and Maryland, southeastern Pennsylvania, and New Jersey.

H. R. Geiger and A. Keith, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 156-163, pl. 4). *Martinsburg sh.*—Sh. [character not described] in Blue Ridge region near Harpers Ferry, W. Va., of small but uniform thickness, overlying Shenandoah ls. and underlying Massanutten ss. Is=Hudson River. [The ss. in this area, as Mr. Keith later discovered, is not Massanutten ss., but a ss. underlying Shenandoah ls., while the Martinsburg is here overlain by Triassic.]

A. Keith, 1894 (U. S. G. S. Harpers Ferry folio, No. 10, p. 3). *Martinsburg sh.*—Black and gray calc. and argill. shales of fine grain. Contain 80 percent of argill. and siliceous matter, remainder being chiefly carbonate of lime. Thickness 700 to 1,000 ft. Overlies Shenandoah ls. and underlies Newark fm. Equiv. to Hudson River and Utica of Rogers. [This folio includes type loc. of fm.]

Is of Maysville, Eden, and Trenton age. The present definition of U. S. Geol. Survey includes in it 300 ft. of shaly lss. of Trenton age that were originally included in underlying Chambersburg ls.

Named for Martinsburg, W. Va.

Martinsburg limestone. (In Washington formation.)

Permian: Southwestern Pennsylvania (Washington County) and eastern Ohio.

E. V. d'Invilliers, 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, p. 2579). *Martinsburg ls.*—A fairly local deposit, underlying Waynesburg "A" coal. Burned for lime on Bacon Street Run, Morgan Twp [Washington Co.], and elsewhere. Also frequently found beneath coal XII (Zollarsville, Waynesburg "A") in Ohio.

Martinsville limestone.

Pennsylvanian: Central eastern Illinois (Clark County). See under *Quarry Creek ls.*

Martinsville sand.

A subsurface sand in St. Louis ls. (Miss.) of Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Martinville limestone.

Pennsylvanian: Illinois.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 39, No. 4, p. 320). *Martinville ls.*, 25 ft. thick, underlies Platte (?) sh., 200 ft. thick, and overlies Lawrence (?) sh., 100 ft. thick, in Ill. geol. section. [Probably is a misprint for *Martinsville ls.*]

Martville sandstone.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327-368). *Martville ss.*—Type loc. is Bentley's quarry, intermediate btw. Martville [Cayuga Co.] and Hannibal, where about 10 ft. of thin grayish green ss. and sh., with fossils, are seen at top of quarry resting with a sh. contact on the 4 or 5 ft. of light-gray or slightly mottled ss. considered Oneida (or Thorold) by Vanuxem, below which is the red Medina ss. Lies beneath horizon of Furnaceville ore. Considered younger than Maplewood sh. Belongs in lower part of Clinton fm.

J. T. Sanford, 1935 (Jour. Geol., vol. 43, No. 2, p. 180). Strat. position and lithologic character of Martville ss. of Chadwick indicate the beds are but a sandy, perhaps beach, phase of the Reynales. It is suggested, therefore, if "Martville" is to be retained, it be used to designate a memb. of the Reynales.

Marvel limestone.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930 (Econ. Geol., vol. 25, pp. 309–310 and map). *Marvel dolomitic ls.*—Essentially a light bluish-gray cherty rock, showing frequent irregular mottling due to brecciation. All traces of organic structure destroyed. Age unknown. Complexly folded. From general characteristics a lower Paleozoic age is assumed. Underlies Surprise fm., usually with gradation from a true ls. to a true schist for a distance of 5 to 30 ft. Exposed along Marvel Canyon, S. part of Panamint Range. ["Interbedded schist in Marvel dolomitic ls." is mapped separately.]

F. MacMurphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July-Oct. 1932, pp. 329–356). [Repeats 1930 definition. "Thickness unknown."]

Marvin Creek limestone.

Devonian or Mississippian: Central northern Pennsylvania (McKean County).

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. R, pp. 68–69). *Marvin Creek ls.*—Near bottom of the Pocono a well-defined bed of ls. has been found in every section in McKean Co. where the rocks of this part of section are exposed. Along Shepherd Run, in S. part of Bradford Twp., it consists of a hard bluish-gray fossiliferous ls. 2 ft. thick, and is overlain by 25 ft. of flaggy ss. and sh. and underlain by 50 to 60 ft. of greenish-yellow sandy sl. Greatest development seems to be in Marvin Creek Valley. On W. slope of Chappel Hill, in Sergeant Twp, it consists of hard siliceous and argill. ls. 5 ft. thick, containing fragments of fossils of Chemung type. Is probably same as Lower Meadville ls. of Crawford Co.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Smethport sh.*, basal memb. of Knapp fm. (Miss.) in NW. Pa., includes *Marvin Creek ls.*, *Syringothyris* zone. [In 1934 (Bulls. Am. Pal., vol. 21, No. 71) Caster discarded his Smethport sh. and introduced *Kushequa sh.* for basal memb. of his Cussewago stage, and included Marvin Creek ls. in his Kushequa sh.]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 105–106). The persistent ls. in midst of Kushequa sh. may best be known compositely as *Marvin Creek ls. zone*, because it is utterly impossible to differentiate which one of the many lss. Ashburner saw on Marvin Creek when he denominated it. At least 2 separate lenses of ls. in the Kushequa occur along Marvin Creek. In Warren Co. this zone lies discon. on Oswayo sh. In Marvin Creek Valley and around Kushequa village this zone is composed chiefly of large plates and bones of fishes. Marvin Creek ls. has been traced and extensive collections made over most of McKean, Elk, and Forest Counties, Pa.

†Marylandian.

A term introduced by A. Heilprin (Phila. Acad. Nat. Sci. Proc. 1882, pp. 183–184, 1883; also Phila. Acad. Nat. Sci. Jour., 2d ser., vol. 9, pt. 1, p. 120, 1884) for the "Lower Atlantic Miocene, older deposits of Md. and possibly the lower beds in Va. ('Yorktown' epoch in part, of Dana)." See under †*Carolinian*. Corresponds to an indefinite part of Chesapeake group of present nomenclature.

Mary Lee coal group.

Pennsylvanian: Central Alabama.

A group of coal beds in Pottsville fm. of Warrior coal field, lying 80 to 150 ft. above Black Creek coal group, and the coals occurring within a vertical section of 220± ft. Includes Newcastle (at top), Mary Lee, Blue Creek, Jaggar, and Ream coals and near its base the Lick Creek ss. memb.

†Mary River formation.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). *Mary River fm.*—Sss., of Foxian (?) age, composing uppermost Cretacic fm. in Alberta. [Apparently same as Saint Mary River fm., of Tert. (?) age.]

Marysville sands.

Pleistocene: British Columbia.

S. J. Schofield, 1915 (Canada Geol. Surv. Mem. 76, p. 85).

Marysville formation.

Eocene (middle): Northern California (Sutter County).

Howel Williams, 1929 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, pp. 112, 121–124). *Marysville fm.*—Loose buff sands, usually traversed by parallel strings of ferruginous calc. concretions and by thin lenticular masses of compact, green-gray ss. and, more rarely, ls. In many places this sandy facies is associated with a thick development of green-gray glauconitic shales that weather to a deep reddish brown soil. In some places, on W. side of the Buttes, there is a *Melania*-bearing grit at base. Lithology and thickness are very variable over small areas. The ferruginous concretions range in size from a hen's egg to 4 or 5 ft. long. Thickness 300 to 600 ft. Discon. overlies Chico beds, and underlies, with minor discon., White Ione sands. Fauna referred by B. L. Clark to Meganos (middle Eo.). The fm. is present at Marysville and on Marysville Buttes.

Maryville limestone.

Middle Cambrian: Northeastern Tennessee, southeastern Kentucky, southwestern Virginia, and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Maryville ls.*—Massive blue ls., with little change in appearance except frequent earthy, siliceous bands and occasional grayish blue and mottled beds. Thickness 150 to 550 ft. Underlies Nolichucky sh. and overlies Rogersville sh.

Foregoing is original definition of fm. at type loc. The name, however, first appeared in print in 1894, in U. S. G. S. Estillville folio (No. 12), by M. R. Campbell, who accepted Keith's name, correlating the rocks of Estillville quad. with those in Knoxville quad. He described the fm. as consisting of 550 to 650 ft. of comparatively pure heavy-bedded blue ls. carrying large masses of chert in SE. part of quad., "which make it difficult to separate from Knox dol." Underlies Nolichucky sh. and overlies Rogersville sh.

Named for Maryville, Blount Co., Tenn.

Maryville rock.

Carboniferous: Eastern Kansas.

G. C. Broadhead, 1886 (St. Louis Acad. Sci. Trans., vol. 4, p. 489), mentioned a mag. ls. quarried at Maryville, Kans., and casually alluded to it, in one place, as "the Maryville rock."

This name is listed in U. S. G. S. Bull. 191.

Mascall formation.

Miocene (middle): Central northern Oregon (John Day Basin).

J. C. Merriam, 1901 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 2, No. 9, p. 305). *Mascall fm.*—Ashes, tuffs, and possibly gravels. Generally been considered wholly a lake deposit, but doubtful whether it owes its origin solely to this mode of accumulation. Has been called Cottonwood beds, Loup Fork, *Ticholeptus* beds (in part), and *Amyzon* beds. Cottonwood is preoccupied in Kans.; doubtful if true Loup Fork occupies same horizon; *Ticholeptus* beds belong to another horizon; *Amyzon* beds are older and=Clarno fm. (Eocene). Thickness at Rattlesnake Creek, near Cottonwood not less than 800 to 1,000± ft. Uncon. underlies Rattlesnake fm. (Plio.) and [uncon.] overlies Columbia [River] lava. Type exposure near Mascall ranch, 4 mi. below Dayville.

F. C. Calkins, 1902 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 3, No. 5). In John Day Basin Mascall fm. is preserved only in monoclinal trough extending along S. end of Basin from Spanish Gulch to Canon City.

Some geologists assign the flora of this fm. to upper Mio., others assign it to middle Mio., and others to middle or upper Mio. The U. S. Geol. Surv. at present classifies the fm. as middle Mio.

Mascarene series.

Silurian and Devonian (?): New Brunswick, Canada.

L. W. Bailey and G. F. Matthew, 1873 (Canada Geol. Surv. Rept. 1870-71, pp. 148-163), 1876 (Canada Geol. Surv. Rept. 1874-75, p. 85), 1877 (Canada Geol. Surv. Rept. 1875-76, pp. 352-366). [Assigned to upper Sil. in all of these repts, but Ells (Canada Geol. Surv. Summ. Rept. for 1903, p. 154, 1904, and Canada Roy. Soc. Proc. and Trans., 2d, vol. 11, sec. 4, p. 28, 1906) assigned the rocks to Dev.]

†Mason series.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvii, 276-281). *Mason series.*—Sandy shales and schists with mica, forming basal div. of Texan system. Overlies Archean Fernandan system and underlies Llano series [restricted sense].

Is a part of Packsaddle schist.

Probably named for Mason Co.

Mason shale. (In Conemaugh formation.)

Pennsylvanian: Southern West Virginia.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 281). *Mason shales.*—Dark or black sh., 3 ft. thick, immediately underlying Lower Cambridge ls. Frequently contain marine fossils, especially in upper half, in Pa., Md., and northern W. Va. Named for Mason, on Elk River, Kanawha Co., W. Va.

Mason clay. (In Conemaugh formation.)

A name applied to the light-gray to drab, brown, or pink clay, 1 to 10 ft. thick, underlying Mason coal in Ohio.

Mason City limestone or dolomite.

Upper Devonian: Central northern Iowa.

W. H. Norton, 1897 (Iowa Geol. Surv. vol. 6, p. 148). *Mason City substage.* [Only definition is use of name in table for upper part of Cedar Valley ls., overlying Solon substage of Cedar Valley and underlying Lime Creek stage, in which was included the ls. later named Nora ls. by Thomas.]

S. Calvin, 1897 (Iowa Geol. Surv. vol. 7, pp. 145-160). *Mason City substage* of Cerro Gordo Co., is=upper part of Cedar Valley ls. as developed in Johnson and adjacent counties. It consists of (descending): 22 ft. of variable beds, 21 ft. of argill. and argillo-dolomitic beds; 30 ft. of stromatoporoid beds; 14 ft. of regularly bedded white or light-gray fossiliferous ls.; 20 ft. of dol., generally compact and regularly bedded; and 20 ft. of earthy dol., including near top thin calc. bed with peculiar stromatoporoids and *Pachyphyllum woodmani*. Underlies Hackberry substage of Lime Creek sh. or stage.

C. H. Belanski, 1927 (Am. Mid. Nat., vol. 10, No. 10), restricted *Mason City substage* to lower heavily dolomitized part of beds previously included in Mason City, part of the upper beds being named by him *Rock Creek substage* and the uppermost beds (First *Actinostroma* zone) being included in his Nora substage. He defined type exposure of the Mason City as located at Nora Springs, "because the zones there are more distinct and their faunas more readily determined than at Mason City." He divided his Mason City into (descending) *Lepidocentrus* zone, *Trigonotreta* zone, and *Aulopora* zone.

See also under *Shell Rock ls.*

Named for exposures at Mason City, Cerro Gordo Co.

Mass amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Is younger than North Butler amygdaloid and older than Merchants amygdaloid. Belongs to Central Mine group. The mineralized part is the Mass lode. Named for occurrence in Mass mine, Ontonagon Co.

Mass flow.

Includes Mass amygdaloid and the underlying trap.

Massacre volcanics.

Pliocene? (lower Pliocene?): Southern Idaho (Power County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Massacre volcanics.*—Well-consolidated red to brown basic cindery tuff, in places containing angular fragments of underlying fms. At many places contains at base a persistent fine-grained blue basalt flow 23± ft. thick. Thickness of fm. 150± ft. The feeder dikes form Massacre Rocks, a group of knobs of diabase, in sec. 6, T. 9 S., R. 30 E., Power Co. Older than Rockland Valley basalt and younger than Eagle Rock tuff.

†Massanutten sandstone.

Silurian and Upper Ordovician: Western Virginia and Maryland and northeastern Virginia.

H. R. Geiger and A. Keith, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 156–163, pl. 4). *Massanutten ss.*—Ss. [character and thickness not described] overlying Martinsburg sh. and underlying the Newark in Blue Ridge near Harpers Ferry, W. Va. Is=Medina. Named for Massanutten Mtn, which is characterized by the ss. [The typical Massanutten ss. overlies Martinsburg sh., but the ss. in the particular area covered by above map was later found by Keith to be an older ss. (the Antietam), faulted over, and to underlie Shenandoah ls., instead of overlying Martinsburg sh. (See Harpers Ferry folio, No. 10).]

N. H. Darton, 1892 (Am. Geol., vol. 10, pp. 13, 14). *Massanutten ss.*—Rocks of Massanutten fm. vary in local characters, mainly in color, thickness of bedding, and degree of silicification, but white and red qtzites prevail. In most sections basal beds are alternating dark sss. and shales, succeeded by white and gray qtzites, which in turn give place to thinner bedded red and brown sss. and shales. Fossils rare. Thickness 600 to 800 ft. Has been called Medina and Clinton. Overlies Martinsburg shales and underlies Lewistown ls. in Staunton quad. and in central Appalachian Virginia region. [As thus defined Massanutten ss. included the overlying Rockwood fm., which is 150 to 200 ft. thick in Staunton quad. and 800 to 1,000 ft. thick in Massanutten Mtn area.]

N. H. Darton, 1894 (U. S. G. S. Staunton folio, No. 14, p. 2). *Massanutten ss.*—Hard ss. and qtzite; most prominent memb. a hard massive qtzite, usually white or gray, which outcrops in high cliffs or steep slopes at crest of the mtns. This memb. is underlain by considerable thickness of red or brown thinner-bedded ss. and qtzite, which merges into sandy beds of underlying Martinsburg sh. Thickness 450 to 700 ft. Merges into overlying Rockwood fm.

Now divided into Tuscarora qtzite (Sil.) and Juniata fm. (Upper Ord.).

Named for Massanutten Mtn, NW. Va. (Rockingham, Shenandoah, and Page Counties).

Masset volcanics.

Tertiary: British Columbia.

J. D. MacKenzie, 1915 (Canada Geol. Surv. Summ. Rept. 1914, pp. 35, 36).

Massie clay.

Silurian (Niagaran): Southwestern Ohio (Clark County).

A. F. Foerste, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 168), applied *Massie clay* to beds underlying his Euphemia dol. and overlying his Laurel ls. in Springfield area. Derivation of name not stated; but in 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 129) he stated it is exposed on Massie Creek, short distance W. of Cedarville, Ohio. On p. 152 he stated *Massie clay sh.* is 5½ ft. thick S. of Yellow Springs, Ohio, and that on Massie Creek, W. of Cedarville, Ohio, it carries a typical Waldron fauna. On p. 153 he gave further details, under heading *Massie clay*, and stated that the Massie Creek locality (N. side of creek, at a well known spring) is only place in Ohio where a fauna (listed) closely resembling Waldron fauna has been found, but that a clay (closely resembling typical Waldron) underlying Euphemia dol. at Bryan Farm State Park, S. of Yellow Springs, 5 mi. NW. of Cedarville, is identified as *Massie or Waldron clay sh.*, although no diagnostic fossils were found there.

†Massillon sandstone. (In Pottsville formation.)

Pennsylvanian: Eastern Ohio.

J. S. Newberry, 1874 (Ohio Geol. Surv., vol. 2, p. 131). *Massillon ss.*, 20 to 80 ft. thick, in Lower Coal Measures. Separated from underlying coal No. 1 by 5 to 40 ft. of gray sh. Overlain by 20 to 50 ft. of sh.

Same as Connoquenessing ss. memb. of Pottsville fm.

Named for Massillon, Stark Co.

Mass Mountain.

Mississippian: Northern California (southern part of Klamath Mountains).

N. E. A. Hinds, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 158), in table divided Mississippian of S. part of Klamath Mtns into *Baird rhyolitic pyroclastics and sediments* (above) and *Mass Mountain basalt flows and pyroclastics* (below). Latter is probably a misprint for *Bass Mtn.*

Masuk sandstone member (of Mesaverde formation).

Upper Cretaceous: Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology of Henry Mtns, pp. 4+). *Masuk ss.*—Heavy-bedded yellow ss., 500 ft. thick, overlying Masuk sh. in Masuk Plateau, Henry Mtns.

Now treated by U. S. Geol. Survey as basal memb. of Mesaverde fm. in Henry Mtns region.

†Masuk shale. (In Mancos shale.)

Upper Cretaceous: Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology of Henry Mtns, pp. 4+). *Masuk sh.*—Gray argill. sh., slightly aren. toward top. Thickness 500 ft. Underlies Masuk ss. and overlies Blue Gate ss. in Masuk Plateau, Henry Mtns.

Now treated by U. S. Geol. Survey as top memb. of Mancos sh. in Henry Mtns region. Name conflicts with Masuk ss., the adopted name.

Masukian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 64–65, 280, 303). Shales, 1,600 ft. thick, uncon. underlying Pennell [Masuk] ss. in Utah and uncon. overlying 1,000 ft. of unnamed shales. Same as Gilbert's Masuk shales, and same as Lewis sh. of western Colo., "which should be replaced by Gilbert's earlier name."

Matachewan series.

Pre-Cambrian: Ontario.

D. G. H. Wright, 1922 (Ont. Dept. Mines 31st Ann. Rept., vol. 31, pt. 7, p. 15).

Matagami series.

Pre-Cambrian: Quebec.

J. A. Bancroft, 1913 (Quebec Dept. Colonization, Mines and Fisheries, Mines Branch, Rept. on Mining Operations 1912, pp. 150, 157).

Later writers spell this name *Mattagami.*

†Matanuska series.

Tertiary, Cretaceous, Jurassic: Alaska.

W. C. Mendenhall, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 307–309). *Matanuska series.*—Chiefly shales, red, green, buff, and black especially abundant; many coarser beds, most important of which is heavy bed of cgl., probably not less than 1,000 ft. thick, that makes base of Castle Mtn. Also, near top near Limestone Gap and along upper course of Bubb Creek, a ls. bed, 300 ft. thick, containing Lower Cret. fossils. Matanuska River flows nearly along strike of the series. Probably overlaps Sunrise series (upper Paleozoic?). Assigned tentatively to Lower Cret. or older.

G. C. Martin, 1926 (U. S. G. S. Bull. 776). Matanuska series of Mendenhall included all sed. rocks seen by him, in a rapid reconn., in Matanuska and Nelchina Valleys, and included rocks ranging from Lower Jurassic to late Tert. The larger part of area supposed to be occupied by this "series" contains these Upper Cret. strata, and nearly all exposures on banks of Matanuska River, from source to mouth, consist of these Upper Cret. rocks. Therefore the name *Matanuska fm.* is here adopted, with a different definition.

Matanuska formation.

Upper Cretaceous: Southern Alaska (Matanuska Valley).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 317-327, table opp. p. 474). The Upper Cret. rocks of Matanuska Valley here designated *Matanuska fm.* consist of marine sh. and ss., at least 4,000 ft. thick on Granite Creek, of which lower half is practically all sh. and upper half alternating beds of ss. and sh., the ss. predominating. Cgl. is present but not in thick or numerous beds. Base not seen. Probably rests uncon. on rocks ranging in age from Lower Jurassic to Lower Cret. Is uncon. overlain by Tert. arkose and cgl. Contains Upper Cret. fossils.

Matanzas series.

Pliocene: Cuba.

J. W. W. Spencer, 1894 (Geol. Soc. Am. Bull., vol. 6, p. 124).

Matapedia series.

Ordovician: Quebec.

G. W. Crickmay, 1932 (Am. Jour. Sci., 5th, vol. 24, p. 377).

Matawan group (also **formation**).

Upper Cretaceous: New Jersey, Delaware, and northeastern Maryland.

W. B. Clark, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, pp. 335-336, and Jour. Geol., vol. 2, pp. 161-177). *Matawan fm.*—Chiefly dark-colored clays with interbedded layers of sand, the latter very pronounced in upper part. At some points greensand beds appear, but greensand is less pronounced than in overlying fms. Thickness 275 ft. Is Clay Marls of previous repts. Conformably underlies Navesink fm. [broad use of Navesink] and overlies Raritan fm. [broad use of Raritan fm., which included Magothy fm. at top], from which its fauna differs greatly. Typically developed on shore of Raritan Bay in vicinity of Matawan Creek and along banks of the creek.

W. B. Clark, R. M. Bagg, and G. B. Shattuck in 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 315-358) redefined *Navesink*, by separating from it the sands at base, under name *Mount Laurel sands*. They also introduced *Monmouth*, to include the Redbank, Navesink, and Mount Laurel deposits. The Matawan group therefore underlies Mount Laurel sand, the basal fm. of Monmouth group. In Md. the subdivisions are not recognized and the Matawan is classified as a *fm.*

Matewan sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 199). *Matewan ss.*—Massive, medium-grained, micaceous, light gray, cliff forming. Thickness 20 to 60 ft. Lies 5 ft. below Matewan coal and overlies Eagle A coal. Named for town in Mingo Co.

Matfield shale. (In Chase group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 714). *Matfield shales.*—Variously colored shales, with some shaly, buff, occasionally cherty lss. and a light-gray ls., 2 ft. or more thick, about 30 ft. below top. Thickness of fm. 60 to 70 ft. Overlies Wreford ls. and underlies Florence flint. Included in Chase stage.

Named for development in Matfield Twp, Chase Co., Kans.

Matilija sandstone member.

Eocene: Southern California (Ventura County).

P. F. Kerr and H. G. Schenck, 1928 (Geol. Soc. Am. Bull., vol. 39, p. 1090). *Matilija ss. memb.*—Basal memb. of Tejon fm. Comprises beds, 2,500± ft. thick, in which ss. predominates over sh. The resistant massive arkose at base forms convenient guide for separating from underlying Chico fm., upon which it rests without apparent angular discordance. Is discon. overlain by Cozy Dell sh. memb. Well exposed at type loc. (in canyon at Matilija Springs), also on top of Topatopa Bluff, and on San Cayetano Mtn. Near the springs is a bed of lignitic facies distinguished by abundant mollusks embedded in a green and purplish sandy sh., and the same bed is found farther E. at same position in geologic column.

†Matinal series.

Nongeographic name introduced by H. D. Rogers (Am. Jour. Sci., 1st, vol. 47, pp. 153–158, 1844) to include all rocks beneath Medina group of N. Y. and base of †Calciferous ss. [Beekmantown]. Redefined by Rogers in 1858 (Geol. Pa., vol. 1, pp. 105, 124–126, 239, 246, 252, 260+, and vol. 2, p. 752) and restricted to beds btw. base of Trenton ls. and base of Oneida cgl. Divided into (descending): (1) *Matinal shales* (*Hudson River slates of N. Y.*), 1,200± ft. thick in Centre Co., Pa.; (2) *Matinal black sl.* (*Utica sl. of N. Y.*), 300 to 400 ft. thick; and *Matinal argill. ls.* (*Trenton ls. of N. Y.*), 300–350 ft. in Northampton, Mifflin, and Centre Counties, Pa.

Named to indicate "morning period of the great Appalachian Palaeozoic day," according to Rogers 1844 citation above.

†Matinal limestone.
†Matinal shales.
†Matinal slate.

See under *†Matinal series.*

Mattagami series.

Pre-Cambrian: Quebec.

See *Matagami series.*

Mattagami series.

Lower Cretaceous or Upper Jurassic: Ontario.

F. H. McLearn, 1927 (Canada Geol. Surv. Summ. Rept. 1926, pt. C, p. 20).

Mattapan volcanic complex.

Devonian or Carboniferous: Eastern Massachusetts and northeastern Rhode Island.

L. LaForge, 1917 (U. S. G. S. Bull. 597, pp. 200–201 and map). *Mattapan volcanic complex.*—The Carbf. volcanic rocks of Boston dist. and the associated stocks and dikes of granite porphyry, felsite, and other rocks. Comprises an extensive series of flows, volcanic breccias, and accompanying pyroclastic sed. beds, associated with and to some extent cut by intrusive felsites and granophyric rocks. The later flows of Mattapan volcanic complex are at several places interstratified with Brookline and Dorchester members of overlying Roxbury cgl. Named for exposures in Mattapan, Dorchester dist. of Boston. [In U. S. G. S. Bull. 839, 1932, LaForge changed age to Dev. or Carbf., he then being inclined to regard it as early Dev., and separated the so-called "later flows of Mattapan volcanic complex" as a distinct fm. called *Brighton melaphyre.*]

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 100–134). *Mattapan volcanics (restricted).*—The rocks assigned to Mattapan complex in U. S. G. S. Bull. 597 belong to at least 3 distinct strat. horizons. Youngest of all are the basic lavas interbedded with Roxbury cgl., which are considered to be of Perm. age. Writer prefers to restrict *Mattapan* to the group of volcanics which underlie Roxbury cgl.—in some places with slight angular uncon.—but which rest on eroded surface of Dedham granodiorite and contain pebbles of it. They are here tentatively considered to be of Penn. age. Oldest of all the extrusive volcanic rocks are certain felsites, tuffs, and breccias which are intruded by Dedham granodiorite and are thus of pre-Camb. age. The Mattapan volcanics do not contain fossils, and are difficult to date, for New England was seat of volcanic activity throughout most of Paleozoic. Thickness varies from 0 to 2,000 ft. On accompanying map and structure sections the Mattapan volcanics have not been separated from Basement Complex.

L. LaForge, 1932 (U. S. G. S. Bull. 839). The Dev. or Carbf. igneous rocks of Boston area can be divided into 2 general groups—an older group, composed chiefly of volcanic rocks, forming the Lynn and Mattapan volcanic complexes, and a younger group of intrusive rocks comprising Quincy granite and associated rocks. Some or all may be Dev. or part of them may be Carbf. The subdivision of the volcanic rocks is difficult problem. The division into 2 fms. (Lynn and Mattapan volcanic complexes) herein adopted is based partly on lithologic character and partly on structural relations, but there is considerable probability the two are contemp., and their separation may therefore be invalid. Hence the fm. names must be regarded as adopted only tentatively, chiefly as most convenient way of expressing facts whose relations are not yet fully understood. The Mattapan volcanic complex comprises the late Paleozoic volcanic rocks in and adjoining S. part of Boston Basin. The Brighton melaphyre may represent final eruptions of Mattapan time and hence be a part of Mattapan complex, but it is here treated as younger than Mattapan. Most of Mattapan rocks are of same types as those of Lynn complex. Thick beds of volcanic ash and of coarse tuff, mud flows, and water-laid sediments composed of reworked tuff with some extraneous pebbles are perhaps more abundant in the Mattapan. The sed. rocks are tuffs, tuff breccias, and mud flows composed largely of andesitic material; in places they are associated with aggls. Near top are some interbedded lenses of cgl., ss., and sl. The cgl. and ss. lenses have been confused with lower part of Roxbury cgl., with which, in fact, the Mattapan may be in part contemp. The Mattapan contains some dikes and larger intrusive masses.

Matteawan granite.

Pre-Cambrian: Southeastern New York (Poughkeepsie quadrangle).

W. W. Mather, 1843 (Geol. N. Y., vol. 1, pl. 18). [This geol. cross section shows *Matteawan granite* exposed btw. Fishkill Landing and New Beacon Mtn.]

C. E. Gordon, 1910 (N. Y. State Mus. Bull. 140, pp. 16–20). Greenish granitic rocks of Poughkeepsie quad., identical with gneisses of Fishkill Mtns. "This strip, which will be referred to as the Glenham belt, was described by Mather as the 'Matteawan granite.' "

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148, pp. 11, 18, 25–27, 33, 34, 78, 79, 85, 104). The *Glenham belt* is an inlier of pre-Camb. gneisses. Extends as a narrow strip from point just N. of carpet mill at Glenham, Dutchess Co., northeastward to Vly Mtn. South of Glenham belt, in town of Matteawan, are two small inliers of the gneisses connecting the Glenham belt with the Highlands. [On p. 18, immediately following the heading *Glenham gneiss*, is following statement:] "The prevailing and characteristic rock of the Glenham belt is a granitic gneiss. It appears to be an altered derivative of other gneisses. Is usually red, from disseminated iron stains, and over much of the belt is deeply chloritized." Is "Matteawan granite" of Mather.

†Matthews Landing group.
†Matthews Landing series. } (In Midway group.)

Eocene (lower): Southwestern Alabama.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 57–60).

For definition, see *Naheola fm.*, which replaces it.

Named for exposures at Matthews Landing, on Alabama River, in Wilcox Co.

Matthews Landing marl. (In Midway group.)

Eocene (lower): Southwestern Alabama.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 57–60).

For definition, see under *Naheola fm.*, of which this bed is basal memb.

Named for exposures at Matthews Landing, on Alabama River, in Wilcox Co.

Matura formation.

Pliocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol., No. 7, p. 84).

Mauch Chunk shale.

Mississippian (Chester): Pennsylvania, western Maryland, and northern West Virginia.

J. P. Lesley, 1876 (2d Pa. Geol. Surv. Rept. L, App. E, pp. 221, 222, chart opp. p. 224). *Mauch Chunk Umbral Red sh.*, No. XI, 100 ft. thick in Boyd's Hill gas well at Pittsburgh, Pa. Underlies Pottsville Seral cgl. and overlies Umbral or Mountain ls. (24 ft. thick), which rests on Pocono (No. X, Upper (gray) Catskill, Vespertine of Rogers). [Type loc. not stated.]

C. A. Ashburner, 1877 (Am. Phil. Soc. Proc., vol. 16, pp. 521, 536). *Mauch Chunk (Umbral) Red sh.*—New name proposed by present State Geologist [J. P. Lesley]. Underlies Pottsville (Seral) cgl. and overlies Pocono (Vespertine) Gray ss. Is No. XI of repts. Thickness 1,100 ft. Upper memb. consists of 910 ft. of red and gray sss. and shales. Middle memb. is Mountain ls., 49 ft. thick, which in Greenbrier Mtn, Pocahontas Co., W. Va., attains thickness of 822 ft. and is known as *Lewisburg ls.* [Greenbrier ls. of later repts]. The lower memb., of reddish and greenish sss. and shales, is 141 ft. thick.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxiii–xxx). *Mauch Chunk Red sh.*—New name proposed by State Geologist [J. P. Lesley] of Pa. for Rogers's Umbral, No. XI. "Thickest, most solid, and best exposed at Mauch Chunk [Carbon Co., eastern], Pa." Thickness 3,000 ft. Underlies Pottsville cgl. and overlies Mountain ls. [Greenbrier ls.]. Included in Kenawha River system.

J. Barrell, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 450+), stated that max. thickness of 3,000 ft. is at Pottsville, Pa. J. P. Lesley (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 1, pp. 1815, 1895) gave a detailed section of the Mauch Chunk at Mauch Chunk, Carbon Co., Pa., that footed 2,168 ft.

Maude argillites.

Jurassic: British Columbia.

J. D. MacKenzie, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 40).

Mauldin beds.

Permian: Central southern Oklahoma (Garvin County).

A. R. Denison, 1923 (A. A. P. G. Bull., vol. 7, No. 6, pp. 627–644). *Mauldin beds.*—Subsurface Perm. deposits, 200 ft. thick, lying at depth of 1,200 to 1,400 ft., consisting of a series of gas sands alternating with red and blue shales, called Mauldin producing horizon, after original large gas well. The sands appear to be lenticular. Underlies Garvin beds (also a subsurface Perm. fm.) and rests on strata ranging in age from Perm. to possible Camb. Lies above Newberry sands (Perm.).

Maumee.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Maunawili volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii; Div. Hydrog. Bull. 1). *Maunawili volcanics.*—Basalt and cinders. Exposed on Maunawili ranch, 2 mi. W. of Waimanalo. Included in middle part of Honolulu volcanic series [q. v.].

Maury glauconitic member (of Ridgetop shale).

Mississippian (lower): Western and central Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 141, 143). *Maury green shale (Ball or Kidney phosphate).*—Green or greenish sh., few in. to 5 ft. thick, with embedded roundish concretions of calcium phosphate from size of marbles to that of a man's head, and in kidneylike, cakelike, and gourdlike forms of various sizes. Underlies Tullahoma fm. and overlies [uncon.] Chattanooga black sh. (Dev.).

Because of fossils, thinness, and structural relations is now treated as basal memb. of Ridgetop sh. (See N. F. Drake, 1914, Tenn. Geol. Surv. Res. of Tenn., vol. 4, No. 3, p. 105.) But according to J. H. Swartz, 1924 (Am.

Jour. Sci., 5th, vol. 7, pp. 28, 30), the Maury sh. of western Tenn. carries a much younger fauna than Maury sh. of central Tenn. According to G. H. Girty (personal communication) the Maury sh. of Waynesville quad. contains fossils of basal Miss. (probably basal Kinderhook) age, and he has no fossils from typical Maury sh.

Named for Maury Co., central Tenn.

Mauumae volcanics.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 42, 45). *Mauumae volcanics.*—Materials ranging from medium-textured black ash through coarser aggl. and rhyoclastic lava to flow lava. Erupted from Mauumae.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Mauumae volcanics.*—Pyro-explosion deposits and basalt composing Mauumae cinder cone. Included in middle part of Honolulu volcanic series [q. v.]. Assigned to late Pleist.

Maverick limestone.

Miners' local name for an ore-bearing ls., 0 to 5 ft. thick, in lower part of Oquirrh fm. (Penn.), Stockton dist., central northern Utah. Lies 230 ft. below South Ada ls. of miners and 40 ft. above their Honerine ls. Is a stray ls. found in workings of Honerine mine, "Maverick" being a Western word meaning unbranded. (See U. S. G. S. P. P. 173, 1932.)

Maxfield limestone.

Upper Cambrian: Central northern Utah (central Wasatch Mountains).

F. F. Hintze, Jr., 1913 (N. Y. Acad. Sci. Annals, vol. 23, p. 107). *Maxfield fm.*—Alternating lss. and shales, 481 ft. thick, uncon. overlying Alta sh. (Lower Camb.) and uncon. underlying Benson ls. [Detailed section of beds given.] Contains largest ore deposits in region, including the rich galena bedded vein of Maxfield Mine at Argenta [mail Salt Lake City]; for which the fm. is named. No fossils, but tentatively assigned to Ord.

L. D. Burling, 1914 (Canada Geol. Surv. Mus. Bull. No. 2, pp. 100-102). Hintze's Maxfield ls. at type loc. contains Middle Camb. fossils.

Fossils from base of Maxfield ls. are assigned by C. D. Walcott, E. Kirk, and C. E. Resser to Upper Camb. and fossils from upper part have been assigned by E. O. Ulrich to Upper Camb. The fm. overlying Maxfield ls. is now tentatively called *Jefferson (?) ls.* and the fm. underlying it is the Ophir sh.

Maxinkuckee moraine.

Pleistocene (Wisconsin stage): Northern Indiana. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Maxinkuckee Lake, Marshall Co.

Maxner limestone.

Mississippian: Nova Scotia.

W. A. Bell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 166).

Maxon sandstone. (In Trinity group.)

Comanche series (Lower Cretaceous): Western Texas (Glass Mountains).

P. B. King, 1930 (Univ. Tex. Bull. 3038, pp. 91-93, map). *Maxon ss.*—Outcrops in prominent ledge midway up scarps along E. side of Marathon Basin. Extends S. from vicinity of Gap Tank at least as far as SE. corner of Marathon Basin. Southernmost observed outcrop is 1 mi. N. of Jones ranch house. First described by Baker and Bowman, but age not discussed. Later mentioned by T. W. Stanton (Am. Jour. Sci., 5th, vol. 16, p. 404, 1928), who noted that it has much same age and relationships as Paluxy sand of north-central Tex. These sands are but part of a transgressive series of basal sands of indefinite strat. position. For this reason, within area of this rept (Glass Mtns), the basal sands in the N.

are termed Basement sands; those to S. occur at definite level btw. rocks of Fredericksburg and Trinity ages and are deserving of a formational name. Paluxy cannot appropriately be applied here because the two sands are now widely separated and probably were never a continuous deposit. A new name (Maxon) is thus necessary. Type loc. is Maxon Station, near point where the Southern Pacific leaves Marathon Basin. It outcrops in rather prominent ledges about 100 ft. above valley level E. of station and caps several buttes of Glen Rose fm. to W. of it. It is a brown, well indurated, coarse to medium-grained ss. with prominent cross bedding. In places there are one or more thin shaly layers. It is 90 ft. thick 1½ mi. S. of Gap Tank, sec. 61. According to Stanton it is 145 ft. thick in scarps immediately N. of Tesnus Station. Near the tank it loses its massive character and is interbedded with cgl. and sandy marl. Passes out by overlap about 1 mi. N. of this place. In Mesas 5 to 8 mi. E. of Gap Tank it can be traced N., overlapping beyond point of disappearance of Glen Rose fm., to form Basement sands of that area. No fossils found. Stanton writes: "Whether it should be classified as Trinity or Fredericksburg is largely a matter of personal preference. Following the precedent established in classifying Paluxy sand of north central Tex., which is in approx. same strat. position, it would be placed in Trinity, but it may well be in part at least of Fredericksburg age."

Maxon sand.

The *Maxton* sand (Miss., subsurface) of Appalachian region has been incorrectly spelled *Maxon* in many repts.

Max Patch granite.

Pre-Cambrian: Western North Carolina (Madison County) and eastern Tennessee.

A. Keith, 1904 (U. S. G. S. Asheville folio, No. 116). *Max Patch granite.*—Almost wholly coarse granite, in places porphyritic and in places of uniform grain. The minerals are orthoclase, and plagioclase feldspar, quartz, biotite, and a little muscovite. The porphyritic varieties are light gray or dull white. Another variety of great extent is a coarse red granite, which appears to be a modification of the usual massive rock. Intrudes Cranberry granite and the older gneisses. Surrounds Max Patch Mtn, Madison Co., N. C.

Maxton sand.

A name that has been applied to subsurface sands of different ages. In northern Ky. and Ohio to a sand in Pottsville fm. (Penn.). In western Pa. to a sand that probably corresponds to basal memb. of Pottsville fm., also to an older sand (of Miss. age) that lies at horizon of Mauch Chunk fm., above the †Pencil Cave. In W. Va. it has also been applied to two sands, both of Mauch Chunk age, the upper one said to probably correspond to the bed called by W. Va. Survey *Princeton cgl. or ss. memb. of the Mauch Chunk*, and the lower one said to probably correspond to the bed called *Droop ss. memb.* by that Survey. According to I. C. White (1919) the sand was first discovered near Sistersville, Tyler Co., W. Va., and named for its discovery on land of a farmer named *Maxton* (not Maxon). According to Hennen (Fayette Co., W. Va. Rept., p. 338) the higher of the sands in W. Va. is the true Maxton; according to D. B. Reger the lower sand in W. Va. is the true Maxton sand. (See W. Va. Geol. Surv., vol. 1A, pp. 176–180; also W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, p. 418.) According to W. Stout et al, 1935 (Geol. of nat. gas, A. A. P. G., pp. 902-903), Maxton sand of Sistersville pool is correlated with some certainty with Sharon cgl., basal memb. of Pottsville fm.

Maxville limestone.

Mississippian: Ohio and northeastern Kentucky.

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 80, 84). There is, above Logan ss. group, a ls. horizon, although the ls. is not everywhere persistent, It often gives place to ss. of the usual coal measure grit. But as these lss. group themselves upon one geological horizon, and always rest upon Logan ss. group, I have no doubt that they have the same age and were formed at same time. I have called it *Maxville ls.*, from village of that name in Perry Co., Ohio, where it has been extensively burned into quicklime.

The commonly accepted definition of Maxville ls. is that it underlies Pottsville fm. (Penn.) and overlies Logan fm. It ranges in thickness up to 110 ft.

Maxville block ore. (In Pottsville formation.)

An ore bed which in early repts was included in Maxville ls. In 1922 (Ohio Geol. Surv., 4th ser., Bull. 25) Helen Morningstar called the bed *Harrison ore*, gave its thickness as 6 in. in Scioto Co. and 4 ft. in Jackson Co., and included it in base of Pottsville fm. "Is patchy, but has been traced from Scioto Co. to Muskingum Co." "Formerly included in Maxville ls., but Morse in 1910 proved it is Penn."

Maxwell limestone. (In McLeansboro formation.)

Pennsylvanian: Central western Illinois (Peoria County).

E. F. Lines, 1912 (Ill. Geol. Surv. Bull. 17, pp. 89, 90). *Maxwell ls.*—Ls., 13½ ft. thick, forming top part of McLeansboro fm. where it outcrops. Upper 12 ft. fine-grained argill. and siliceous ls. in ½-in. layers at top and 4-in. layers at bottom; basal 4 to 5 ft. coarse-grained grayish ls. containing calcite crystals and fossils. Underlain by clay sh. containing thin coal; overlain by soil. [Probably named for occurrence at or near Maxwell, Peoria Co.]

Maxwell terrane.

A name applied by C. [R.] Keyes to 800 ft. of sh. in his Ratonan series (early Eocene and probably same as Raton fm. of SE. Colo.). Derivation of name not stated. Uncon. undelies Denver fm. and overlies Houten ss. "The Maxwell, Houten, and underlying Maya cgl. taken together probably correspond to Eldridge's Arapahoe fm. farther N." (See Iowa Acad. Sci. Proc., vol. 22, 1915, p. 257.)

Maya conglomerate.

Name applied by C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 22, p. 257, 1915, and Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 9) to basal memb. of Tert. section in NE. N. Mex. Thickness 100 ft. Derivation of name not given. Underlies Houten ss. [See under *Maxwell*.]

Mayaguez shales.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61).

Maybelle limestone.

Permian: Central northern Texas (Baylor County).

A. S. Romer, 1928 (Univ. Tex. Bull. 2801, p. 74). In Baylor and Archer Counties, Tex., the Wichita group (Clyde fm.?) is topped by a scarp-forming ls. known locally as *Maybelle ls.* This and lower members of the ls. belt are continuous with Lueders ls.

M. M. Garrett, A. M. Lloyd, and G. E. Laskey, 1930 (Tex. Bur. Econ. Geol. geol. map of Baylor Co.). *Maybelle ls.*, a memb. of Lueders fm., lies 45 ft. below Lake Kemp ls., the top memb. of Lueders fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 174). *Maybelle ls.* is a memb. of Lueders fm., E. of Lake Kemp, Baylor Co.

Derivation of name unknown.

May Creek formation.

Devonian (?): Southwestern Oregon (Riddle quadrangle).

J. S. Diller and G. F. Kay, 1924 (U. S. G. S. Riddle folio, No. 218). *May Creek fm.*—Mica schist and mica slates, 1,000+ ft. thick. Thrust fault contact with Galice fm. (Jurassic). No fossils in Riddle quad., but to SW., in similar rocks, fossils in ls. lentils have been identified as Dev., hence May Creek fm. is classified as Dev. (?). Exposed for 3 mi. along May Creek and to beyond mouth of May Creek.

In other parts of SW. Oreg. this fm. is chiefly schist, and is there called *May Creek schist*.

†Mayes formation.

Mississippian: Northeastern and central eastern Oklahoma.

C. W. Shannon and L. E. Trout, 1915 (Okla. Geol. Surv. Bull. 19, pt. 1, pp. 127–130). *Mayes fm.*—Dark-gray to black ls. separated by thin bands of black sh. Thickness thin to 100 ft. Of Chester age. Conformably underlies Fayetteville sh. Uncon. overlies Boone fm. Usually a thin sh. memb. separates Boone and Mayes.

L. C. Snider, 1915 (Okla. Geol. Surv. Bull. 24, pp. 27–35, 47). *Mayes fm.*—Dark-gray to black ls., locally argill., weathering drab or light gray, the ls. beds separated by thin bands of black sh. In some places 4 or 5 ft. of sh. at base and 3 or 4 ft. of sh. at top. Thickness 8 to 100 ft. Uncon. overlies Boone fm. Conformably underlies thick bed of black sh. forming basal memb. of Fayetteville fm. Is basal fm. of Chester group. In Tahlequah quad. includes lss. mapped by Taff as upper part of Boone, but described as lower ls. bed of the Fayetteville. In Muskogee quad. includes equiv. beds mapped by Taff with Fayetteville and described as lower ls. bed of that fm.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, pp. 59–60). *Mayes fm.—Named by L. C. Snider, 1915.* Consists of dark-gray to black ls., locally argill., separated by thin beds of black sh. Thickness 3 to 100 ft., averaging 40 ft. Occurs around margin of Boone ls., on which it usually rests discon. Is of Chester or older Mississippian age. *Is composed of beds that are assigned by some geologists to Moorefield sh., Batesville ss., and lower part of Fayetteville sh.* Fossils listed.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 30). *Mayes fm.* is of middle Chester age.

G. S. Buchanan, 1927 (A. A. P. G. Bull., vol. 11, No. 12), R. Roth, 1928 (Econ. Geol., vol. 23, pp. 48–51), E. G. Woodruff and C. L. Cooper, 1928 (Okla. Geol. Surv. Bull. 40U). *Mayes fm.* assigned to Meramec epoch.

E. Bloesch, 1928 (Okla. Geol. Surv. Bull. 40EE, pp. 24–30). *Mayes fm.* is of lower Chester and upper Meramecian age.

H. A. Ireland, 1930 (Okla. Geol. Surv. Bull. 40NN). *Mayes ls.* is of Chester age.

I. H. Cram, 1930 (Okla. Geol. Surv. Bull. 40QQ). *Mayes fm.* is here *restricted* to beds containing "Spring Creek" fauna, of Meramecian age. In Cherokee and Adair Counties [central eastern Okla.] these beds are 0 to 70 ft. thick. The Mayes fm. as heretofore used in Okla. included these beds and lower part of overlying Fayetteville sh. as here defined. In Batesville region, northern Ark., the upper Boone contains this fauna, but these beds are believed not to be present in typical Boone of Boone Co., Ark., where upper beds are of Warsaw age and uncon. overlain by Hindsville ls. memb. of Batesville ss., of Chester age. Rests on Boone without evidence of uncon.

The U. S. Geol. Survey discarded this name from its classification in 1925. Named for Mayes Co.

Mayflower amygdaloids.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belong to Central Mine group. The Old Mayflower amygdaloid is younger than Isle Royale amygdaloid and older than Old Colony ss. Its mineralized part is the Old Mayflower lode. The New Mayflower amygdaloid is older than Isle Royale amygdaloid and younger than New Arcadian amygdaloid, and its mineralized part is the New Mayflower lode. Named for occurrence in Mayflower mine, Houghton Co.

Mayflower flows.

The Old Mayflower flow includes Old Mayflower amygdaloid and the underlying trap. The New Mayflower flow includes New Mayflower amygdaloid and underlying trap.

Mayflower schist.

Ordovician (?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Mayflower schist.*—Chloritic "knotted" or spotted schist and schistose sl., prevailingly dark, with commonly a greenish tinge; more aluminous than schists of underlying Gold Hill fm.; for most part without admixture of other rocks, but in some sections outcrops of a dark-gray ls. similar to overlying Zanzibar ls. were seen, and seem to be interbedded with the schist, but may represent infolded parts of Zanzibar ls. Exposed thickness 800 ft.; maximum probably not much greater. In fault contact with Gold Hill fm. Exposed in Mayflower Gulch.

Maynardville limestone.

Upper Cambrian: Eastern Tennessee.

C. R. L. Oder, 1934 (Jour. Geol., vol. 42, No. 5, pp. 474–476, 494, 497). *Maynardville ls.*—Thin-bedded to massive, light-bluish gray to dark-gray, fine to coarse-grained, more or less laminated ls., with dark-gray dol. forming upper third of fm. Basal third carries ls. cgl. in which small black clay balls suggest oolitic textures. Sometimes thin bluish-green calc. sh. occurs in lower part and dark-gray chert occurs sparingly in upper beds. On W. side of valley top is usually marked by 2 ft. of dark-gray shaly dol. with undulating upper contact. On E. side of valley upper limit is formed by 5 to 10 ft. of ss. Thin aren. zones occur. Thickness 60 to 250 ft. In places formerly mapped with underlying Nolichucky sh., but on older geol. maps of Claiborne and Union Counties it was included in Knox dol. Its known fossils consist of problematical cystid plates and an unidentified sp. of *Cryptozoon*. Croixan trilobites occur in the Nolichucky up to base of Maynardville, but they have not been discovered within the latter. In lithology it compares with lower Knox beds. Hence it seems well to consider it, at least tentatively, as basal memb. of Knox dol. and as marking beginning of deposition of Ozarkian series of Camb. system in east Tenn. Uncon. underlies Conococheague-Copper Ridge fm. Named for Maynardville, Union Co.; well exposed along State Highway 33, about 5½ mi. NE. of town.

Mayne Creek formation.

Mississippian: Central northern Iowa.

F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, pp. 52, 92, 105, 108). *Mayne Creek fm.*—Chiefly soft brownish dolomitic ls., aren. at several horizons; occasionally chert nodules yield well-preserved fossils. Thickness about 68 ft. Underlies Eagle City beds and overlies Chapin beds. Is a fm. in Kinderhook group. Named for exposures in N. bluff of Mayne Creek, NE¼ sec. 21, Reeve Twp., Franklin Co.

L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, pp. 388–396), stated that he had made slight change in basal bdy of *Maynes Creek memb. of Hampton fm.*, as he called the beds. See under *Chapin beds.*

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 242, 245). I regard *Maynes Creek ls.* as = part of Fern Glen [of Osage group].

May Pen beds.

Pleistocene or Pliocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 84).

Maysville group.

Upper Ordovician: Northern Kentucky, southwestern Ohio, and southern Indiana.

A. F. Foerste, 1905 (Sci., n. s., vol. 22, p. 150). *Maysville div.*—Hitherto identified as Lorraine, but fauna is so different from typical Lorraine as to warrant another name. Includes (descending) Arnheim, Mount Auburn, Corryville, Bellevue, Fairmount, and Mount Hope beds, all of which are exposed along railroad S. of Maysville, Ky.

The Arnheim was many years ago transferred to Richmond group. The Mount Hope sh. and Fairmount ls. are now treated as members of Fairview fm. and the Bellevue ls., Corryville sh., and Mount Auburn (concretionary strata) as members of McMillan fm.

Mayville limestone.

Silurian: Southeastern Wisconsin.

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, pp. 336–345). *Mayville beds*.—Usually a rough, coarse, gray, mag. ls., with considerable difference in the layers. Max. thickness 100 ft.; average 60 ft. Is lowest memb. of Niagara series. Underlies Waukesha beds and overlies Cincinnati [Maquoketa] sh. In Sheboygan region it underlies Byron beds (considered=basal beds of Waukesha ls.). Fossils [listed]. Named for max. development and finest exposure S. of Mayville, Dodge Co.

T. E. Savage, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 305–324), correlated *Mayville ls.* with his Kankakee and Edgewood lss. of Ill.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93), stated that *Mayville dol.*, as he called it, is of middle Clinton age.

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 278). Mayville is pre-Niagaran and correlates with Edgewood of Ill.

Mayville ore bed.

See under *Neda fm.*

Mayville moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Mayville, Tuscola Co.

Maywood formation.

Silurian (?): Central western Montana (Philipsburg region).

F. C. Calkins and W. H. Emmons, 1913 (U. S. G. S. P. P. 78). *Maywood fm.*—Flaggy reddish, gray, and whitish mag. lss. and gray, whitish, and olive-green calc. sh., with beds of light-colored calc. ss. about 40 ft. above base. Thickness 200–300 ft. Of marine origin. No fossils. May be Lower Dev., Sil., Ord., or Upper Camb. Overlies Red Lion fm., possibly uncon. Underlies Jefferson ls. conformably. Named for Maywood Ridge, W. of Princeton, on whose NE. face, 2 mi. above mouth of South Boulder Creek, the best exposure occurs.

Maywood clay.

Pleistocene: British Columbia.

C. H. Clapp, 1913 (Canada Geol. Surv. Mem. 36, p. 109).

Mazarn shale.

Lower Ordovician (Beekmantown): Southwestern Arkansas and southeastern Oklahoma (McCurtain County).

H. D. Miser, 1917 (U. S. G. S. Bull. 660, p. 68). *Mazarn sh.*—Sh. with small amounts of ls. and ss. The sh. is ribboned, consisting of alternating black and green layers that split at an angle with the bedding. Thickness 1,000 ft. in Caddo Gap and De Queen quads., Ark.-Okla. The name is applied to the part of "Ouachita sh." lying below Blakely ss. Named for Mazarn Creek [eastern Montgomery Co., Ark.]. Overlies Crystal Mtn ss. and underlies Blakely ss.

Mazatzal quartzite.

Pre-Cambrian: Central Arizona.

E. D. Wilson, 1922 (Pan-Am. Geol., vol. 38, pp. 299–312). The massif of Mazatzal Range is composed almost entirely of schists, slates, and qtzites of pre-Camb. age, the sedimentaries being usually disposed at high angles. The great succession of indurated sss. to which the title *Mazatzal qtzite* is here applied, constitutes main part of the mtns from central Mazatzal Peak northward. There are, however, four separate and distinct areas of the qtzite, which is a hard, vitreous rock, light-brown to gray in color, fine-grained, and often cross-bedded, but possessing at various levels also many phases of cgl. the subangular to rounded pebbles of which vary from very coarse sand to small boulders one-half foot or more in diam. Occasionally there are lenticular layers (up to 150 ft. in thickness) of maroon-colored, gray-spotted, hard aren. shales which frequently display ripple marks and sun cracks.

N. H. Darton, 1925 (Univ. Ariz. Bull. 119, pp. 234–235), reported uncon. btw. Mazatzal qtzite and overlying Apache group (pre-Camb.) on Haigler Creek, near Payson.

Named for development in Mazatzal Range.

Mazomanie sandstone.

Upper Cambrian: Central southern Wisconsin (Dane County).

E. O. Ulrich, 1920 (Wash. Acad. Sci. Jour., vol. 10, pp. 73–78). *Mazomanie ss.*—A more or less decidedly calc. fm.; a magnesian ss.; contains considerable disseminated glauconite. Approx. thickness 10 to 100 ft. Rests on Franconia ss. and underlies St. Lawrence fm.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 548). *Mazomanie fm.*—Fine to medium-grained gray to dark-red ss. irregularly cemented by dol.; locally beds of red, green, and gray calc. sh.; base consists of gray dol. with purple spots very similar to St. Lawrence or Black Earth memb. of Trempealeau fm.; entire fm. contains more or less dol. Max. thickness 165 ft.; average 100 ft. Thins out to W. and overlaps Franconia for distance of 10 to 20 mi. Is known from far NE. Wis. to near Spring Green, Wis. In northern Ill. it was formerly correlated with the Madison and Mendota of Wis., but it bears no resemblance to those fms. Underlies Trempealeau fm. [St. Lawrence fm.] and overlies Franconia fm.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 21–79). *Mazomanie ss.* is same as Franconia ss., and not younger, as Ulrich claims.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 13). Formerly it was rather generally believed Mazomanie fm. of Ulrich was=the Franconia. Ulrich then advanced the view that there are 2 distinct fms., the Mazomanie representing an invasion from the E. and the Franconia from the W., and the former overlapping the latter. Little evidence was advanced to support this view. Recent studies have shown that Mazomanie faunas extend W. beyond the Miss. and that Franconia faunas underlie those of the Mazomanie wherever lower part of the succession is fossiliferous. Also, Pentland's study of the Franconia and Mazomanie shows a homogeneity of mineral content which could hardly have been possible had the materials been derived from different regions. As *Franconia* has priority it is here used, and it is recommended that *Mazomanie* be abandoned or given rank as a memb.

A. C. Trowbridge et al., Sept. 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 116–117). The strata designated "Mazomanie" by Ulrich in 1920 are now known to be a part of Franconia fm., from which they differ in being somewhat coarser-grained and more dolomitic. Ulrich at first supposed Franconia is confined to W. side of Wisconsin arch and the Mazomanie to the east. Later studies showed this is error, and most geologists have abandoned *Mazomanie* as a synonym, although it has been given wide currency among well drillers in E. Wis. and in Ill. [Type section by F. T. Thwaites, on p. 116, calls the beds *Franconia*.]

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, Nov. 30, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, p. 1702). Upper beds of Hudson memb. of Franconia fm. in various parts of Wis., notably central area, contain fauna Ulrich assigned to his proposed Mazomanie fm., but which writers designate *Prosaukia* subfaunal zone. Lower part of Hudson memb. contains *Ptychaspis* subfauna. Ulrich named his Mazomanie fm. from Mazomanie village, on Wisconsin River, near which the strata are exposed in conspicuous cliff. [Summarize parts of Ulrich's definition.] Nothing of kind described by Ulrich exists. His Mazomanie continues westward to Miss. River and beyond, and his Franconia continues E. over the arch with undiminished thickness. Writers do not consider the Mazomanie to merit rank of a fm. but to be little more than a minor subdivision of Franconia fm.

E. O. Ulrich, 1936 (Geol. Soc. Am. Proc. 1935, p. 113). *Mazomanie ss.* is quite distinct from "Franconia," both faunally and lithologically, and is younger.

Mazourka formation.

Lower Ordovician: Central eastern California (Inyo Range).

F. B. Phleger, Jr., 1933 (Southern Calif. Acad. Sci. Bull., vol. 32, pt. 1, pp. 1–6). *Mazourka fm.*—A succession of argill. shales and lss. 675 ft. thick. Lower 125 ft. consists of calc. sh. interbedded at irregular intervals with thin-bedded lenses of dark-gray argill. ls. Rest of fm. consists of argill. ls. interbedded at infrequent intervals with a few thin sh. layers. Typically exposed in Mazourka Canyon btw. Barrel Spring Canyon and Lead Canyon trail. Conformably underlies Barrel Spring fm. and conformably overlies ls. that Kirk considers to be of Beekmantown age. Fossils (identified by Kirk) listed. The fm. is faunally a unit and undoubtedly of Chazy age.

Meade gravel.

Pleistocene: Southwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 52). *Meade gravels.*—Highly fossiliferous gravels and sands, mostly unconsolidated, 10 to 40 ft. thick, laid down in deep and broad valleys. Overlain by Pearlette ash, into which they frequently grade. Supposed to be late Plio. and to belong to Tule div. of Cummins (*Equus* beds of Cope). Named for Meade Center, Meade Co.

Meadow limestone.

Pennsylvanian: Southeastern Nebraska, eastern Kansas, and northwestern Missouri.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 13, 22, 37). *Meadow ls.*—First distinct ls. memb. of Braddyville fm. above Forbes ls. Has wide distribution in Nebr. and apparently in Kans. and Mo. Is usually in one bed, but in places is in 2 beds. Light bluish gray, massive, hard, semicrystalline; upper part weathers light-colored and basal part buff. Lies 6 to 10 ft. above Forbes ls. and 5 to 6 ft. below Union ls. Thickness 2 ft. 7 in. to 4 ft. Outcrops W. of Meadow, Nebr., and at other places.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 43, 51), named the sh. overlying Meadow ls. the *Iowa Point sh.* and the sh. underlying it the *Jones Point sh.*, and assigned all 3 to Calhoun sh. memb. He also renamed *Union ls.* (preoccupied) the *Coal Creek ls.*

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 12, 26, 28, 31, 47). It has been found that *Meadow ls.* as originally defined should be extended to include a sh. and a ls. next above; that (by tracing) the true Meadow ls. is basal bed of Stanton ls. memb., instead of in Calhoun sh. memb.; that the sh. underlying the Meadow is not the Jones Point sh. but Vilas sh. memb; that the true Jones Point sh. is basal bed of Calhoun sh. memb. and Iowa Point sh. is top bed of Calhoun sh. memb. The ls. separating Jones Point sh. and Iowa Point sh. not being the ls. that outcrops W. of Meadow it is here named *Sheldon ls.* and the sh. overlying Meadow ls. is here named *Eudora sh.* The Meadow ls. as here redefined is 10½ ft. thick, and consists of (descending): ls., 4 ft.; sh. 3 ft.; ls. 3½ ft.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), reported 2 units btw. Meadow ls. and underlying Vilas sh., and applied *Linwood sh. memb.* to the upper one (1 to 2½ ft. thick) and *Naish ls. memb.* (also Naish *ss.*) to the lower one (1 to 1.8 ft. thick). He included both of these newly named units in Stanton ls. Whether his Linwood and Naish had previously been included in Meadow ls. or in Vilas sh. was not explained. This classification was adopted by Moore and Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pt. 1, pp. 76–79), introduced *Captain Creek ls.* for basal memb. of Stanton ls., underlying Eudora sh. memb. and overlying Vilas sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 132, 191), discarded *Meadow ls.*, applying *Captain Creek ls.* to typical Meadow ls., which is said to be basal memb. of Stanton ls., and *Sheldon ls.* to the bed in Calhoun sh. that was originally but erroneously named *Meadow ls.* He did not explain fate of Linwood sh. and Naish ls.

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser., pp. 48–49). *Meadow* was originally assigned by Condra and Bengston to what has later been correlated as lower ls. memb. of Plattsburg ls. fm. at Meadow Station, N. of Louisville, Nebr.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Meadow marble member (of Sevier shale).

Lower Ordovician (Chazy): Central Tennessee.

C. H. Gordon, 1924 (Tenn. Dept. Ed., Div. Geol. Bull. 28, pp. 39–40, 63–65, and map). The marble here called *Meadow marble* has not been mapped hitherto. Its outcrop makes its appearance about 2 mi. SW. of Meadow Station and ends near Miser, 2¾ mi. NE. of Friendsville. It consists of light gray and pink marble, identical in appearance with corresponding variety of Holston marble fm. It has its best development from Meadow Station to point SE. of Kiser, a distance of about 2½ mi. Thickness roughly estimated at 200 to 300 ft. Difference of opinion exists as to strat. position of this marble, some, including writer, holding it to constitute a lentil near middle of Tellico fm., while others consider it to be at base of overlying Ottosee (Sevier). The latter view makes it correspond in position with the variegated marble at Vestal, whereas marble identical with the latter outcrops ¾ mi. E. of the Meadow with several hundred ft. of typical Tellico intervening btw. the two marble fms.

Adopted by U. S. Geol. Survey as a local basal memb. of Sevier sh. in E. part of Loudon Co. and W. part of Blount Co.

Named for exposures near Meadow Station, Loudon Co.

Meadow Creek trachyte.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). Fine-grained volcanic flow, with fairly large but ill-defined phenocrysts of sanidine, nearly identical with Flag Spring trachyte, which it overlaps slightly in position. Occurs on N. side of Meadow Creek.

Meadow Creek limestone.

A name erroneously credited to Condra and Bengston (1915) in Kans. Geol. Surv. Bull. 22, 1936, pp. 132, 191. Condra and Bengston named the ls. *Meadow ls.*, and did not use *Meadow Creek ls.*

Meadows sand.

A subsurface sand, of probable early Penn. (Cherokee) age, in Kay Co., central northern Okla., lying lower than Bartlesville sand. L. C. Snider (1913) says it is same as Tucker sand.

Meadowvale member.

Upper Ordovician (Richmond): Ontario.

W. S. Dyer, 1925 (Ont. Dept. Mines 32d Ann. Rept., vol. 32, pt. 7, p. 124).

†Meadville Upper limestone. (In Cuyahoga formation.)

Mississippian: Northwestern Pennsylvania.

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3). *Meadville Upper ls.*—A remarkable shell bed in upper part of Crawford shales. At Meadville it lies about 25 ft. beneath Shenango ss.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4). *Meadville Upper ls.* might at many places be called a fishbone cgl.

This is a ls. bed in midst of Meadville sh. memb. of Cuyahoga fm. of present nomenclature. The U. S. Geol. Survey does not apply same name to a unit and to a part of that unit. Caster proposed (1934) it be renamed *French Creek ls.*

†Meadville group. (In Pocono group.)

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q4, pp. 83–90). *Meadville group.*—Consists of (descending): (1) *Meadville Upper sh.*, 25 ft. (bluish-gray or ashen-gray sh., argill. at top, sandy lower down, sometimes flaggy, never massive); (2) *Meadville Upper ls.*, 1 ft.; (3) *Meadville Lower sh.*, 40 ft. (generally ash gray sh. with sandy flags, which increase in number toward bottom; (4) *Sharpsville Upper ss.*, 50 ft. (layers of fine bluish-gray or grayish-brown flagstone 1 to 2 ft. thick, alternating with thin layers of grayish sh.); (5) *Meadville Lower ls.*, 1 to 2 ft. (impure, hard, flinty, persistent); (6) *Sharpsville Lower ss.*, 10 to 30 ft. (series of flags 6 in. to 2 ft. thick, exactly like Upper Sharpsville ss.; and (7) Orangeville sh., 100 ft. Underlies Shenango group [Burgoon ss.] and overlies Corry ss.

Replaced by Cuyahoga fm. Nos. 1, 2, and 3 of above description correspond to *Meadville sh. memb.* of present nomenclature, and Nos. 4, 5, and 6 correspond to Sharpsville ss. memb. In NE. Ohio the Cuyahoga is treated as a *group* and the Meadville, Sharpsville, and Orangeville as *fms.*

Named for Meadville, Crawford Co., Pa.

Meadville shale member (of Cuyahoga formation).

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

See under †*Meadville group*.

†Meadville Lower shale. (In Cuyahoga formation.)

A name applied in early Pa. repts to lower part of Meadville sh. memb. of Cuyahoga fm. of present nomenclature. See original description under †*Meadville group*, 1881. See also *Harvest Home sh. memb.* and *Bykam ls. memb.*

†Meadville Lower limestone. (In Cuyahoga formation.)

A name applied in early Pa. repts to a thin ls. in middle of Sharpsville ss. memb. of Cuyahoga fm. See original description under †*Meadville group*, 1881. Also see *West Mead ls. memb.*

†Meadville Upper shale. (In Cuyahoga formation.)

A name applied in early Pa. repts to upper part of Meadville sh. memb. of Cuyahoga fm. of present nomenclature. See original description under †*Meadville group*, 1881. See also *Custards sh. memb.*

Meadville monothem.

Meadville stage.

Names applied by K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 129), to the rocks designated "Meadville group" by I. C. White (1881), which were later proved to be same as Cuyahoga fm. of Ohio, by which name they have been called in many repts, and divided into (descending) Meadville sh. memb., Sharpsville ss. memb., and Orangeville sh. memb. Caster discarded Meadville sh. memb., dividing it into several newly named units, and reverted to an old and conflicting usage of "Meadville."

Meaford member.

Upper Ordovician: Manitoulin Island and southern shore of Georgian Bay.

A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, pp. 7, 51, 53). *Meaford memb.*, of Waynesville age, is lower memb. of Richmond fm. Underlies Kagawong memb. of Richmond fm. Intended to include all those strata which contain a fauna suggesting their Waynesville age. Thickness probably reaches 90 ft. at Streetsville. [Also calls it Meaford *fm.*] Named for exposures near Meaford, Ontario, although better exposed on Manitoulin Island.

Meagher limestone.

Middle Cambrian: Central Montana (Little Belt Mountains and Fort Benton quadrangles).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). Wolsey sh. is succeeded by the thin-bedded *Meagher lss.*, 110 ft. thick, which are overlain by several hundred ft. of Park shales and ls. cgls. All are included in Barker fm.

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Meagher ls.* is a thin-bedded ls., often formed mainly of flat ls. pebbles, and carries Middle Camb. fossils. It rests on Wolsey sh. and underlies Park sh., all included in Barker fm. [Derivation of name not stated, but Barker fm. is mapped over large areas in Meagher and other counties of this quad.]

W. H. Weed, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 285). *Meagher ls.* caps summits of Belt Park buttes. It consists of thinly and irregularly bedded pure lss., gray, mottled with patches of buff aren., clayey matter. The exposed edges of the beds show wavy, almost crinkled bedding planes. Over 60 ft. exposed on Keegan Butte. Lower strata carry no distinguishable fossils and weather into very small irregular gravelly debris. Upper beds spotted with green glauconite grains and contain numerous fossil fragments.

Meakin sand.

Upper Cretaceous: Southwestern Arkansas (Smackover oil field, Ouachita and Union Counties).

H. G. Schneider, 1924 (Am. Inst. Min. and Met. Engrs. Trans., vol. 70, pp. 1078–1099). *Meakin oil and gas sand.*—Fine-grained sand, 18 ft. thick, forming basal part of Marlbrook fm. Named for Meakin farm, on which first producing well was drilled.

H. G. Schneider, 1925 (A. A. P. G. Bull., vol. 9, No. 7, pp. 1116–1117), gave 55 ft. as thickness of *Meakin sand* in Smackover field, and stated that it is also known as *Louann sand* and, in E. part of field, as *Primm gas zone.*

Meander shales.

Devonian: Northwest Territory.

A. E. Cameron, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. B, pp. 13, 29).

Mecca oil rock.

A subsurface sand in Ohio that lies at horizon of Berea ss. or Bedford sh.

Mechunck limestone.

Cambrian: Central Virginia.

W. A. Lambeth, 1901 (thesis presented to Univ. Va., p. 14). *Mechunck ls.*—Lss. interbedded or wrapped up in the mica slates. They vary in thickness and physical condition, the bed in Monticello area, Albemarle Co., showing no crystallization, while one near Lynchburg has been worked for marble. Are generally schistose or slaty, with seams filled with calcite. Assigned to Camb.

Meda rhyolite.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 65, etc.). *Meda rhyolite.*—A flow of light-gray to pink rhyolite, which rests on Milltown andesite and on the overlying dacite and dacite vitrophyre. Overlain by andesite breccia. Probably varies much in thickness. Exposed in vicinity of Meda Pass and close to road S. of Myers Mtn.

Medford diabase.

Upper Triassic: Northeastern Massachusetts.

A. W. G. Wilson, 1901 (Boston Soc. Nat. Hist. Proc., vol. 30, No. 2, pp. 353–374 and map). [See also U. S. G. S. Bull. 839, 1932, by L. LaForge.]

Named for occurrence in Medford, Mass.

Medford "granite."

Quarrymen's term for Medford diabase.

Medford black granite.

Commercial name of Medford diabase.

Medford gravel.

Commercial term for the coarsely granular residual material from the weathering of Medford diabase. Is used for road material.

Media shale.

Miocene: Central California (San Joaquin Valley).

G. M. Cunningham and W. F. Barbat, 1932 (A. A. P. G. Bull., vol. 16, No. 4, pp. 419–421). *Media sh.*—Sh., with some ss. and characteristic sh. pelecypod fauna; in lower part of Temblor fm. Thickness 450 to 490 ft. Overlies Carneros ss. memb. of Temblor, 168 ft. thick, and at Devils Den is separated from overlying beds by an angular uncon. [Derivation of name not stated.]

G. C. Gester, 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169). *Temblor sh.* in McKittrick-Midway-San Emigdio region divided into (descending) Gould sh., Button bed ss., Media sh., Carneros ss., Santos sh., and *Phacoides* reef.

†Medicine beds.

Cretaceous (Upper and Lower): Central southern Kansas.

C. N. Gould, 1898 (Am. Jour. Sci., 4th, vol. 5, pp. 169–174). *Medicine beds.*—Deep-sea to fresh-water transition beds from Kiowa shales (top fm. of Comanche series) below to Dakota leaf-bearing ss. above. Includes (descending) Reeder ss., Kirby clays, Greenleaf ss., and Spring Creek clays.

C. N. Gould, 1901 (Kans. Acad. Sci. Trans., vol. 17, p. 133), suggested discarding term and "classing all the strata in either Comanche or Dakota, although exact line of demarcation can scarcely be drawn."

This name was discarded by U. S. Geol. Survey in 1921. The †Reeder ss. is Upper Cret. Dakota ss., the †Kirby clay, †Greenleaf ss., and †Spring Creek clay are regarded as local facies of Cheyenne ss. without strat. value. The name has since been discarded by Kans. Geol. Survey. (See their Bull. 9, 1924, by W. H. Twenhofel, although Twenhofel revived *Belvidere* to include part of these beds, as explained in 1924 entry under *Belvidere sh.*)

Named for upper Medicine River, W. of Belvidere, Kiowa Co.

Medicine Bow formation.

Upper Cretaceous: Southern Wyoming (Hanna Basin, Carbon County).

C. F. Bowen, 1918 (U. S. G. S. P. P. 108, pp. 228, 229, etc). *Medicine Bow fm.*—Alternating beds of light-colored to gray carbonaceous sh., gray to brown ss. showing cross-bedding, ripple marks, and other features of irregular deposition, and thin irregular beds of coal. Fresh- and brackish-water invertebrates, land plants, and vertebrate bones. Thickness 6,200± ft. Underlies fresh-water Ferris fm. (Tert.?), without proof of uncon., and conformably overlies Lewis sh. (marine). Best exposed along both sides of North Platte River at mouth of the Medicine Bow. Assigned to Upper Cret. Is="Lower Laramie" of Veatch.

Medicine Lodge gypsum. (In Cimarron group, in Kansas.)

Medicine Lodge gypsum member (of Blaine gypsum in Oklahoma).

Permian: Southern Kansas and western Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 27–39). *Medicine Lodge gyp.*—Persistent bed of massive gyp., 12 to 30 ft. thick, usually of grayish white color, forming basal memb. of Cave Creek fm. Separated from overlying Shimer gyp. memb. of Cave Creek fm. by 7 to 10 ft. of Jenkins clay. Underlain by Flower-pot shales.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., p. 48). *Medicine Lodge gyp. memb. of Blaine div.* is 18 to 24 ft. thick. Is separated from overlying Shimer gyp. memb. by red sh. that corresponds to Jenkins clay of Cragin, which is overlain by Altona dol. memb. Overlies Magpie dol. memb. of Blaine.

Gould later abandoned Altona dol. and Magpie dol., and defined Medicine Lodge as overlain and underlain by red shales (see 1906 and 1927 entries under *Altona dol. memb.*), but he did not explain to what his Altona dol. and Magpie dol. were equivalent.

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, p. 405). Nearly all geologists who have traced the Blaine think Medicine Lodge memb. of Blaine of Kans. is=Ferguson memb. of Okla. section. It is suggested that, at least for NW. Okla., Medicine Lodge memb. should be made name of lowest massive gyp. ledge of Blaine and that very probably the term *Ferguson* should be dropped. E. C. Parker, Robt. McNeely, I. H. Stein, and writer are agreed that base of Medicine Lodge gyp. of Kans. can be correlated with base of Ferguson gyp. of Okla. But as writer has not personally traced base of Blaine S. of Fairview, Okla., he makes no positive statement in regard to the Ferguson. [In table on p. 408 Shimer gyp. memb. is placed below Lovedale gyp. memb. and above Medicine Lodge gyp. memb., all included in Blaine fm. On p. 410 Evans states: Shimer gyp. is in every way similar to the Medicine Lodge, from which it is separated by 20± ft. of red sh. The Shimer is 13± ft. thick and has a dol. bed at base very similar to dol. bed at base of the Medicine

Lodge. The Shimer is well exposed in all of NE¼ T. 26 N., R. 21 W., showing its relationship to both the Medicine Lodge and Lovedale members.]

Named for Medicine Lodge River and town of Medicine Lodge, Barber Co., Kans.

†Medicine Lodge beds. (In Cimarron group.)

Permian: Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of Kans.). *Medicine Lodge beds*.—Include (descending): Medicine Lodge (Cave Creek) gyp. (29 ft. thick); Flowerpot shales (170 ft. thick); Cedar Hills sss. (150 ft. thick); and Salt Plain shales (150 ft. thick). Overlies Harper beds and underlies Dog Creek shales.

Medicine Peak metaquartzite.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 632). *Medicine Peak metaqtzite*.—Lower memb. a very massive, violet-gray metaqtzite about 1,700 ft. thick; certain beds dark steel gray; is generally cross-bedded. Upper memb. is unusually pure and uniform metaqtzite nearly 4,000 ft. thick, generally not quite so coarse as lower memb. and cross bedding not conspicuous. Conformably underlies Lookout schist and conformably overlies Heart metagraywacke. Forms S. end of Medicine Bow Peak Ridge. Assigned to early Algonkian.

†Medidial series.

Nongeographic name applied by H. D. Rogers (Am. Jour. Sci., 1st, vol. 47, pp. 153–158, 1844) to the rocks of Appalachian region btw. base of Marcellus sh. and base of Schoharie grit or top of Oriskany ss. Rogers abandoned this name in his 1858 classification (Geol. Pa., vol. 1, pp. 59, 104–109; vol. 2, pt. 2, pp. 751–775).

Named to indicate "afternoon period of the great Appalachian Palaeozoic day," according to Rogers, 1844 citation above.

Medina group.

Silurian (early) and Upper Ordovician: New York and Michigan.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 374, on 3d dist.). *Medina ss*.—In former repts called *red ss. of Oswego*. Predominant color red, more rarely whitish and greenish. Confined to Oswego Co., to high grounds of Oneida at Florence village and other parts of town of Florence, and to extreme N. parts of Onondaga and Cayuga Counties. Occupies strat. position btw. Oneida cgl. above and Salmon River ss. below.

J. Hall, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 453–455, on 4th dist., western N. Y.), gave following rock succession for N. Y. (descending) Rochester sh., 2d Green sh., Pentamerus ls., Green sh. and iron ore, and Medina ss.; and stated: *The Medina ss., red marl and sh.*, is lowest rock in 4th dist., being found bordering shore of Lake Ontario, from Niagara river to E. limits of Wayne Co. The Salmon River group, however, forms bed of the lake, and in some places is probably at no great distance from shore, as boulders and pebbles containing the peculiar fossils of that group are found on the lake beach in Niagara Co. and other places. The Medina consists of upper gray portions, and below of red and variegated beds [marl and sh.] [In 1862 Hall gave thickness as 1,000± ft.]

L. Vanuxem, 1842 (Geol. N. Y., pt. 3), stated that Medina ss. is overlain by Oneida cgl. and rests on Grey ss. of falls of Salmon River and Oswego [Oswego ss.], which in turn rests on Hudson River group.

J. Hall, 1843 (N. Y. Nat. Hist., Geol. 4th dist., quarto, pp. 31, 34–57). *Medina ss*.—Usually a red or slightly variegated ss., solid and coherent in E. extremity of dist., becoming friable and marly in W. extension, and admitting an intercalated mass of gray quartzose ss. containing marine shells, while in red portions are rarely found other than marine vegetables and fucoids. The locality which gives the name exhibits the rock best developed, and with its characteristic fossils. The rock is the lowest of 4th dist. In Oswego Co. it rests on the Gray ss. that overlies Hudson River group. It is overlain by Clinton group and sh. of the Niagara. At Albion there is a low fall on Sandy Creek over the same ss. At Medina, on Oak-orchard

Creek, this rock forms the beautiful little cascade pictured on preceding page. The deep gorge and high cliffs on either side of the Niagara at Lewiston are more than half excavated in this rock; and the partial obstruction of the water at the whirlpool is caused by a part of same mass. Its alternations of harder and softer masses produce cliffs or cascades along its whole extent. Where best developed the rock consists of (descending): (1) The gray or greenish-gray argill. ss. forming terminal part, which in 3d dist. is considered a distinct rock forming the Oneida or Shawangunk cgl.; in 4th dist. it always appears more or less as a part of Medina ss., possessing the same lithological features. Thickness at Medina 4 ft. (2) A repetition of No. 4, gradually passing into a more sandy form in W. part of dist., but in E. part of dist. the whole div. is more siliceous, and No. 3 does not appear. (3) Gray quartzose ss., 25 ft. thick on Niagara River, entirely distinct from mass below. (4) Red marl and marly or shaly ss., sometimes banded and spotted with green, the bands being both horizontal and vertical.

In succeeding years some N. Y. geologists placed Oneida cgl. beneath Medina ss. (see details under *Oneida cgl.*), and the upper gray portion of the Medina came to be known as "Medina gray ss.," "Upper Medina," and "White Medina;" while the lower red portion was called "Medina red ss.," "Medina red sss. and shales," "Red Medina," and "Lower Medina." The use of the name *Medina* was also extended to Canada, Pa., N. J., Md., Va., W. Va., Ky., Ga., Ohio, and Ind., for rocks believed to correspond to all or some part of typical Medina of N. Y.

In 1891 (Smithsonian Inst. 45th Ann. Rept. Bd. Regents, pp. 252–253) G. K. Gilbert stated that at Niagara Falls, beneath Clinton group and extending downward for several hundred ft., is a great bed of soft sandy sh., interrupted, so far as we know, by a single hard layer, a ss. ledge 10 to 20 ft. thick.

In 1893 (Geol. Soc. Am. Bull., vol. 4, pp. 116–117) C. S. Prosser gave strat. position of the Medina btw. Clinton above and "Oswego ss. or Oneida cgl." below, and gave its thicknesses, in different parts of the State, as 400 (central N. Y.) to 1,075 (western N. Y.).

In 1899 (N. Y. State Geol. 16th Ann. Rept., pp. 199–226) D. D. Luther used *Medina group* to include *Medina ss.* (740 ft. at Syracuse) and "underlying" Oneida cgl. (25–100 ft.); and F. J. H. Merrill (N. Y. State Mus. Bull., vol. 4, No. 91) also used Medina in these two senses. The same year (Sci., n. s., vol. 10, pp. 874–878) J. M. Clarke and C. Schuchert stated that *Medina ss.* underlies Clinton and overlies Oneida cgl., and that "it is= Oswego ss. of Vanuxem" [Vanuxem used *Grey ss. of Oswego*]. They also introduced *Oswegan period or group* to include Medina ss. and Oneida cgl. In 1899 (Geol. Soc. Am. Bull., vol. 10, p. 135) G. K. Gilbert stated that in type dist., about Medina, N. Y., *Medina fm.* is 800 ft. thick, and consists chiefly of red sh. with beds of soft argill. sss., usually white or gray, in upper 100 ft.

In 1901 (N. Y. State Mus. Bull. 45) A. W. Grabau applied *Medina series* to the beds btw. Clinton above and Oswego ss. below, and gave their thickness as 1,200 ft. at Niagara Falls and vicinity. In Buffalo Soc. Nat. Hist. Bull. 6, No. 1, pp. 20–21, 1901, he called the same rocks *Medina ss.* and gave 1,266± ft. as thickness in Niagara region; and he used *Oswegan group* to include Medina ss. and underlying Oswego ss. or Oneida cgl.

In 1902 (N. Y. State Mus. Bull. 52, table opp. p. 658) E. O. Ulrich and C. Schuchert gave position of *Medina* as btw. Clinton above and Oneida below, as did several other geologists in succeeding years. In 1905 (Sci., n. s., vol. 22, pp. 528–535) A. W. Grabau stated that lower 1,100 ft. of the Medina represents Richmond time, and he assigned these beds to Ord. In 1906 (N. Y. State Mus. Bull. 92, pp. 120–124) Grabau applied

Medina sss. to upper 125 ft. of Medina rocks and *Medina shales and sss.* to underlying 1,140 ft., and again expressed opinion that latter beds are of Richmond [Ord.] age. In 1907 (N. Y. State Mus. Bull. 114) C. A. Hartnagel stated "there is evidence which may show that all the Oswego and probably part of the [overlying] Medina could with propriety be included with the Lower Siluric" [Ord.].

In 1908 (Sci., n. s., vol. 27, pp. 622–623) A. W. Grabau restricted *Medina ss.* to "Upper Medina or Medina proper" of previous usage, and introduced *Queenston shales* for the 1,100 ft. of *red Medina shales* of previous usage, which he stated are of Richmond age and which he assigned to Ord. (The Queenston is unfossiliferous in western N. Y., but is now generally conceded to be=beds not far distant in Ontario that carry a Richmond fauna.) He also included Medina ss. as thus restricted and Oneida cgl. in the Clinton. The same year (Sci., n. s., vol. 28, p. 347) G. H. Chadwick proposed *Lewiston sh.* for the same sh. that Grabau named *Queenston*, and he also assigned it to Ord., and restricted Medina to post-Queenston beds, which he included in the Niagaran. (Because of priority of publication *Queenston* is name now used by geologists.) In 1909 (Jour. Geol., vol. 17, p. 238) A. W. Grabau applied *Whirlpool ss.* to the 25 ft. of white quartzose ss. forming basal memb. of "true or Upper Medina" and resting on the beds of Richmond age.

In 1911 (Geol. Soc. Am. Bull., vol. 22) E. O. Ulrich applied *Medina ss.* to the post-Queenston part of the original Medina (which he included in Sil. and correlated with Oneida cgl.), and assigned the older and uncon. *Lewiston (Queenston) sh.* and the underlying Oswego ss. to Ord.

In 1912 (N. Y. State Mus. Hdb. 19) C. A. Hartnagel included *Queenston (Lewiston) sh.* in *Medina beds*, and assigned all to Sil.

In 1913 the term *Albion* was suggested by J. M. Clarke as a name for the post-Queenston part of the Medina, to which Grabau and Chadwick were restricting the name *Medina ss.* (See *Albion ss.*) The same year E. O. Ulrich (Geol. Soc. Am. Bull., vol. 24, pp. 107–108) recommended that *Medina* "be retained in its original significance," and that it be called *Medina series*, a "term equivalent in rank to Niagaran;" also that "Lower Medina" be called *Juniata* (a well-established Pa. name), instead of *Queenston sh.*, more recently proposed; and he transferred the Richmond (and the Queenston) to Sil. In 1913 (12th Int. Geol. Cong., Canada) Ulrich used *Medinan* as a series term to cover *Albion ss.* and Richmond (Queenston sh.), both of which he assigned to Sil. In Niagara folio of U. S. Geol. Survey, No. 190, 1913 (Paleozoic geology by E. M. Kindle), *Medina group* was used to include *Albion ss.* (Sil.) and *Queenston sh.* (*Sil. or Ord.*), the latter fm. not having yielded fossils, and its age being questioned by some geologists. The same year (Canada Geol. Surv. Guidebook 4, pp. 127–140) W. A. Parks proposed that Medina be still further restricted, by removal of Whirlpool ss. and some 80± ft. of overlying red and gray shales included in Albion ss. as defined, but to which Schuchert in 1913 applied name *Cataract fm.* Parks stated that Cataract fm. of Schuchert represents an invasion from N. and W. at commencement of Sil. time. In Geol. Soc. Am. Bull., vol. 24, pp. 461–463, 1913, A. W. Grabau included in top of the Medina of Niagara Gorge 6 ft. of beds which he designated as *Sodus sh.*, a memb. that had previously been assigned to the Clinton.

In 1914 (Sci., n. s., vol. 39, June 19, pp. 915–918) E. M. Kindle disclaimed responsibility for use of names *Albion ss.* and *Medina group* in Niagara folio, and expressed opinion that Grabau's application of *Medina* to beds above base of Whirlpool ss. "is the usage which the writer believes should and will prevail," and that Albion ss. should be dropped. Kindle proposed that these beds be called *Medina fm.* He included Thorold ss. in his *Medina fm.* This usage was followed by M. Y. Williams (1914 and later repts), who also referred Queenston sh. to Ord., and stated that Whirlpool ss. overlapped it; and by C. Schuchert, 1914 (Geol. Soc. Am. Bull., vol. 25, Sept., pp. 277–320), although some of Schuchert's sections restricted *Medina ss.* to beds above his Cataract fm. [now said to correspond to lower part of Albion ss.]. Schuchert stated that Grabau's restriction of Medina to beds above the [unfossiliferous] Queenston sh. was "altogether correct," for "at Medina along Oak Orchard Creek one practically sees only these red and white sss. characterized by the well-known fauna."

In 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368) G. H. Chadwick still further restricted *Medina* at top, by removing Thorold ss. member (5 ft. thick), and applying *Medina* to the beds btw. base of Thorold ss. and base of Whirlpool ss.

In 1923 (Md. Geol. Surv. Sil. vol., pp. 244, 267, 347, etc.) E. O. Ulrich and R. S. Bassler transferred top memb. (Thorold ss.) of Albion ss. and of Medina group to Clinton fm., and used *Medinan* to include this restricted Albion ss. and the uncon. underlying Queenston sh., both of which they assigned to Sil. They proposed that Albion be retained for the "sandy facies that prevails in N. Y. and rather generally in Appalachian Valley," and used *Alexandria group* to cover Albion ss. and contemp. deposits. In same vol. C. K. Swartz used *Medinan series* to cover only Tuscarora fm. (=Albion ss.), and assigned the underlying Juniata ss. (=Queenston sh.) to Ord. In Denison Univ. Bull., Jour. Sci. Lab., vol. 20, pp. 50–51, 1923, A. F. Foerste included in *Medinan* only the rocks to base of Whirlpool ss., or those equiv. to Albion ss.

The 1924 ed. of Schuchert's Textbook of geology used *Alexandrian* as time term for post-Richmond part of the original Medina. Two repts of W. Va. Geol. Surv. (Rept. on Mineral and Grant Counties, 1924, and Rept. on Mercer, Monroe, and Summers Counties, 1926, both by D. B. Reger) used *Medina White ss.* (instead of Tuscarora ss.), *Red Medina series* (instead of Juniata fm.), and *Grey Medina ss.* (basal 250 to 300 ft. of Sil. system and said to be=Oswego ss. of N. Y.), because *Medina* has long priority. I. C. White, then State Geologist of W. Va., used same classification in 1926 (Geol. Soc. Am. Bull., vol. 37, p. 509). A 1924 rept of Ohio Geol. Surv. (4th ser., Bull. 28, by W. Stout and R. E. Lamborn, chart opp. p. 358 and elsewhere) included in *Medina beds* all rocks btw. base of Sodus sh. and base of Queenston sh. The Pa. Geol. Surv. included in *Medina period-series* the Tuscarora ss. (=Albion ss.), the Juniata fm. (=Queenston sh.), and the Oswego ss., according to Pa. Geol. Surv., 4th ser., Bull. M₇, by B. L. Miller, pp. 57–60, 1925, and G. H. Ashley, State Geologist, Geol. Soc. Am. Bull., vol. 37, p. 510, 1926. The 1916 geol. map of Va. applied *Medina* to Tuscarora ss. (=Albion ss.) and placed Juniata fm. in Ord. E. O. Ulrich, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 279–348) used *Medinan* to include all beds btw. base of Clinton and base of Richmond. The 1928 geol. map of Va. used *Tuscarora ss.* and *Juniata fm.*, and included both in Sil.

C. A. Hartnagel and W. L. Russell, 1929 (A. A. P. G. Structure of No. Am. oil fields, Symposium, vol. 2, pp. 274–278), used *Medina series* to include both the white and the red beds, or all beds below the Clinton and above the so-called "Hudson River." W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), used *Medinan* to include Albion ss. and Queenston sh., but included Thorold ss. and Oneida cgl. in the Clinton. J. T. Sanford, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 194), stated that Thorold ss. is a transition phase composed of Medina sediments reworked by Clinton seas, included it in the Clinton, and applied *Medina ss.* to underlying rocks. G. H. Ashley and J. D. Sisler, 1933 (Pa. Topog. and Geol. Surv., 4th ser., Bull. M19), stated *Medina series* of central Pa. includes Tuscarora (=Albion), Juniata (=Queenston), and Oswego (=Oneida). C. R. Fettke, 1935 (Pa. State Coll. Bull., Min. Industries Exp. Sta. Bull. 19), stated: *Medina group* has been restricted to beds below Thorold ss. and above Queenston sh.

The U. S. Geological Survey has not yet formally discarded the original and long-established definition of *Medina group*, to include the gray Albion ss. (Sil.) and the red Queenston sh. (Ord.). But it avoids the use of the name in its publications, a group name to include fms. belonging to 2 systems being contrary to its practice; and the several modern restricted definitions of the name, to various portions of the upper (and very minor) part of the assemblage to which *Medina* was originally and for many years applied, tending to confuse, rather than clarify, the nomenclature.

Medina sandstone.

See under *Medina group*, 1840 and later.

Medina shales.

See under *Medina group*, G. K. Gilbert, 1891, and A. W. Grabau, 1906.

Medina "series."

Same as *Medina group*. See under *Medina group*, A. W. Grabau, 1901, and E. O. Ulrich, 1913. Other writers also have used this form of the name.

Medinan.

A time term that has been used in several senses: (1) to include Albion ss. and Queenston sh. and contemp. deposits (see under *Medina group*, E. O. Ulrich, 1913); (2) Albion ss. only (see under *Medina group*, E. R. Cumings, 1922, A. F. Foerste, 1923, and C. K. Swartz, 1923); (3) Albion ss. restricted to beds beneath Thorold ss. memb. at top and Queenston sh. (see under *Medina group*, E. O. Ulrich and R. S. Bassler, 1923, and E. O. Ulrich, 1926).

Medora amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name in use locally many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Is older than Allouez cgl. and younger than Manitou amygdaloid. The mineralized part is the Medora lode. Named for occurrence in Medora mine, Keweenaw Co.

Medora flow.

Includes Medora amygdaloid and underlying trap.

Medora coal group.

A term applied to a group of strata forming upper part of Tongue River memb. of Fort Union fm. in SW. N. Dak., and including coals B to E, both inclusive. (See A. G. Leonard, 1908, N. Dak. Geol. Surv. 5th Bien. Rept.)

Medora Knob facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons. Div. Geol. Pub. 98, pp. 76, 237, etc., 1931) to a lithologic development of his Edwardsville fm. in a part of southern Ind.

Meek Bend limestone. (In Millsap Lake formation.)

Pennsylvanian: North-central Texas (Parker County).

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept., by G. Scott and J. M. Armstrong, on geol. of Parker Co. (See 1933 entry under *Millsap Lake fm.*) Type loc. not stated.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15, 16). *Meek Bend ls.*, 20 ft. thick, is included in Lazy Bend memb. of Millsap Lake fm. by Scott and Armstrong (unpublished ms.). Is typically exposed in Parker Co.

†Meekoceras beds.

A term that has had considerable usage in SE. Idaho and northern Utah, for the basal 50 ft. of Thaynes group (Lower Triassic), which is characterized by genus *Meekoceras*. The *Meekoceras* zone (as the U. S. Geol. Survey designates the beds) has also been recognized (by J. P. Smith and others) in Nev. and Calif. So far as known it is confined to those areas in the United States, but it occurs in other parts of the world.

Meers quartzite.

Pre-Cambrian: Southwestern Oklahoma (Wichita Mountains).

M. G. Hoffman, 1930 (Okla. Geol. Surv. Bull. 52, pp. 26, 31, 45). *Meers qtzite.*—Oldest rock in Wichita Mtns. Outcrops at N. base of Mount Sheridan along Medicine Bluff Creek, and ¼ mi. SW. of old Meers townsite, where it covers an area ¼ mi. wide. This outcrop was first described by Taylor in 1915. A small exposure (200 ft. long by 50 ft. wide) of qtzite not previously described was found at top of hill in SW¼SE¼ sec. 34, T. 4 N., R. 14 W. Another small mass cuts across the road immediately S. of Meers townsite. These 3 exposures of metamorphosed sedimentary rock are here named Meers qtzite. They all occur in north-central part of the Wichitas.

Meeteetse formation.

Upper Cretaceous: Northern Wyoming (Bighorn Basin).

D. F. Hewett, 1914 (U. S. G. S. Bull. 541, pp. 91, 102). *Meeteetse fm.*—Argill. ss. and sandy sh. with many beds of brown carbonaceous sh. and lenticular coal near top. Thickness 1,110 ft. in Shoshone River region. Poorly exposed along the river, and therefore more thoroughly studied in region S. of it, where it contains a Montana flora. Overlies Gebo [Mesaverde] fm. and underlies Ilo [Lance] fm. Named for town of Meeteetse, on Greybull River.

Later work proved that this fm. includes equivalents of Bearpaw sh. and upper part of Judith River fm.

Megalonyx beds.

A paleontologic name applied by E. D. Cope to strata containing fossil remains of *Megalonyx*. According to H. F. Osborn (U. S. G. S. Bull. 361, 1909, pp. 82, 83, 87, 88) this genus occurs in strata ranging in age from middle Plio. to middle Pleist.

Meganos formation.

Eocene (lower): Western California.

B. L. Clark, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 94, 281–296). The name *Meganos group* is given to the new group situated btw. typical Martinez and typical Tejon. It is believed that deposits of this group have wide distribution throughout Coast Ranges of Calif. In certain localities they have been referred to Martinez group and at other places to the Tejon. Uncon. underlies typical Tejon and contains a faunal representative differing considerably from that of typical Tejon and also differing from typical Martinez fauna of the lower Eo. Uncon. overlies typical Martinez group. Includes *Turritella andersoni* beds.

B. L. Clark and R. B. Stewart, 1925 (Geol. Soc. Am. Bull., vol. 36, p. 227), and B. L. Clark, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull. vol. 16, No. 5), *restricted* Meganos to lower part of Meganos as above defined, and applied *Domengine* to the beds btw. typical Tejon and Meganos restricted. (See under *Domengine fm.*) The U. S. Geol. Survey has accepted this restricted definition of Meganos.

Named for exposures on Meganos ranch or land grant, SE. of Martinez, Contra Costa Co. In 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, p. 71) B. L. Clark and A. O. Woodford stated that type section of Meganos restricted is a strip beginning about 1½ mi. E. and a little N. of Clayton and ending in vicinity of Byron Hot Springs.

Meguma series.

Pre-Cambrian: Nova Scotia.

J. E. Woodman, 1904 (Am. Geol., vol. 33, p. 368, and vol. 34, p. 13).
C. W. Knight, 1911 (Min. Soc. Nova Scotia Jour., vol. 16, p. 94). *Meguma series* assigned to Algonkian.

Mehama volcanics.

Oligocene: Central northern Oregon (Cascade Mountains region).

T. P. Thayer, 1933 (Pan-Am. Geol., vol. 59, No. 4, p. 317). *Mehama volcanics*, subaerial, uncon. underlie Stayton lavas (Mio.) in Cascades. Probably grade westward into Illahe fm., which contains lower-middle Olig. fossils. [Derivation of name not stated.]

Mehrten formation.

Miocene and Pliocene (?): Northern California (Mokelumne River Basin).

A. M. Piper, H. S. Gale, and H. E. Thomas (U. S. G. S. W. S. P. 780, in press). *Mehrten fm.*—Fluviatile ss., siltstone, and cgl., commonly well assorted and well stratified; incloses layers of coarse aggl. of mud-flow origin; dominantly of andesitic detritus associated with andesitic eruptions in High Sierra Nevada. Thickness 75 to 400 ft. Underlies Laguna fm. (Plio.?) and uncon. overlies Valley Springs fm. (Mio.). Exposed near Mehrten dam site, 3½ mi. upstream from Clements bridge. Is believed to be of Mio. and Plio. (?) age.

†Meigs Creek white limestone. (In Monongahela formation.)

A name applied by W. T. Griswold (U. S. G. S. Bull. 198, pp. 17–19, 1902) to ls. later named *Dinsmore ls. bed*. Probably named for association with Meigs Creek coal.

Meiocene.

An early spelling of Miocene.

Meisner sand. See *Miscner sand*.

Melbourne bone bed.

Pleistocene: Florida (east coast, central part; west coast; and interior).

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). *Melbourne bone bed.*—Disconnected patches of sand and other materials (clay, carbonaceous matter, cavity fillings) which at Melbourne and elsewhere contain a large and characteristic vertebrate fauna and heretofore have been called "No. 2 bed" and "bone bed." Max. known thickness 10 ft. Wherever examined the bed lies uncon. on coquina or shell marl of Anastasia fm., but in interior of State it rests on older fms. Where the bone bed does not lie at surface of ground it is overlain by wind-blown sand, or, more commonly, by muck, peat, or alluvium. At Melbourne, Brevard Co., it consists chiefly of sand that appears to be wind blown. Farther inland, where wind action was less effective, the Melbourne bone bed is to be looked for in old lake beds, in flood plains, in accumulations of residual sands and clay, and in sinks and caverns. Has been found at intervals along the 100-mile stretch btw. Vero and New Smyrna, and probably occurs along east coast both N. and S. of those towns. On west coast it has been explored on Pinellas Peninsula near Seminole and near Sarasota. The Melbourne fauna has been found also in caverns or sinks near Lecanto, Citrus Co., and at Ocala.

Mellen or High Bridge granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. granite in Wis. (area not stated).

†Mellenia series.

Miocene (upper): Southern California.

O. H. Hershey, April 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pl. 1, map). [On legend of map of part of southern Calif. *Mellenia series* appears btw. San Pablo series below and upper Plio. above.]

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 349–372). *Mellenia series.*—Fresh-water sediments, 1,700 ft. thick, composed of cgls., shales, and sss., uncon. underlying Lang div. and believed to be younger than San Pablo fm.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753, p. 52). As "Mellenia," so far as could be ascertained, is not a place name, and its origin is doubtful, this series of strata is here renamed, to correspond to rule of nomenclature of U. S. Geol. Survey, *Mint Canyon fm.*, the beds being particularly well developed in Mint Canyon region.

Melmont.

Eocene: Western Washington (Puget Sound region).

W. F. Jones, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 122), divided the Eocene coal-bearing rocks of Pierce Co. into (descending): (1) Burnett, 8,000 ft.; (2) Wilkeson, 950 ft.; (3) Carbonado, 2,300 ft.; (4) *Melmont*, 1,400 ft.; and (5) *Fairfax*, 2,000 ft. Melmont and Fairfax are apparently named for towns in N. part of Pierce Co., but they are not defined.

Melozi formation.

Upper Cretaceous: Southwestern Alaska (Nulato-Norton Bay district, Lower Yukon River region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 395–412, chart opp. p. 474). Upper Cret. of lower Yukon region divided into 4 conformable fms. (descending) Kaltag fm., Nulato fm., *Melozi fm.*, and Ungalik cgl. The 3 first are contemp. with Shaktolik group. The Melozi consists of 1,000+ (possibly several thousand) ft. of fresh-water sh. and ss., containing fossil plants and fresh-water invertebrates. Named for exposures on N. bank of Yukon River from 8 to 20 mi. below Melozi telegraph station.

See under *Shaktolik group*. Also see U. S. G. S. P. P. 159, 1930.

Melrose.

A name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to 25 ft. of Carbf. qtzite in Mont. Derivation of name not stated.

Melrose granite facies (of Columbia granite).

Pre-Cambrian: Central Virginia (Campbell County).

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, pp. 22–23, map). *Melrose granite facies of Columbia granite.*—Is much coarser-grained and darker-colored than Columbia granite. In area E. of McKeever Ferry the Melrose granite (pre-Camb.) has been converted into augen gneiss. Intrudes Wissahickon fm. [Mapped at and around Melrose, Campbell Co.]

Memorial shale.

Pennsylvanian: Eastern Kansas.

R. H. Dott, 1936 (see Kans. Geol. Surv. Bull. 22, by R. C. Moore, pp. 58, 67). Moore stated: *Memorial sh.* (mss. by R. S. Dott) is name applied to beds of undet. thickness btw. top of "Eleventh St." ls. [Lenapah] and uncon. at top of Marmaton group, top of Des Moines series. [The brackets around *Lenapah* are Moore's. This new name replaces Dudley sh. as restricted by Moore in 1932. Derivation of name not stated.]

Memphis loess.

Pleistocene: Southwestern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 162). *Memphis loam.*—Bluff loam. The fm. upon which most of city of Memphis stands

Fine siliceous earth or loam, more or less calc. and of light ashen, yellowish, or buff color. Quite compact.

†Memphis sandstone. (In Peacock formation.)

Permian: Central northern Texas (Hall County to Motley County).

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, p. 953, pl. 10). A fossiliferous limy pink to red ss. is present in Hall Co. approx. 250 ft. above base of Whitehorse ss. Although similar in appearance to Verden "channel" ss. of Okla., the authors have called this bed *Memphis ss.*, from buttes formed by it near Memphis, the county seat of Hall Co. Is 3 to 10 ft. thick and similar in general characteristics to Verden ss. except that it crops out in belt 10 or 12 mi. wide, and is much higher in geologic section, the Okla. memb. being in upper part of Dog Creek sh. Most southerly outcrop of this bed is in northern Motley Co., near town of Northfield.

Replaced by Dozier ss. memb. of Peacock fm., q. v.

R. Roth, 1932 (Jour. Geol., vol. 40, No. 8, p. 703), believes Memphis ss. is a continuation of Dozier Hills, which are channel deposits, and that it marks base of his Custer fm., which he assigned to Lower Triassic.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 167). The name *Memphis ss.* has been abandoned by U. S. Geol. Survey and Dozier ss. substituted for it.

Memphremagog slate.

Ordovician: Northeastern and southeastern Vermont.

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., p. 115, footnote). U. S. G. S. has adopted *Memphremagog sl.* instead of *Montpelier sl.*, preoccupied. [For definition see 1906 entry under †*Montpelier sl.*]

C. H. Richardson, 1908 (6th Rept. Vt. State Geol., p. 276). *Memphremagog slates.*—Black, carbonaceous, highly fissile sl. Youngest memb. of Lower Trenton series in Vt. Consists of: (1) shallow sea deposits; (2) Coventry ls., deposited in deepening sea; (3) muds and silts laid down near the shore; (4) ls. deposited in subsiding sea; (5) finely triturated clays in shallow, quiet sea. Named for Lake Memphremagog.

G. H. Perkins, 1912 (8th Rept. Vt. State Geol., pp. 21–56). Reference of *Memphremagog sl. to* Trenton is to be regarded as probable, not certain.

C. H. Richardson, 1912 (8th Rept. Vt. State Geol.). *Memphremagog sl.* extends from Lowell Mtn to Lake Memphremagog. Is definitely Lower Trenton.

C. H. Richardson and H. G. Turner, 1914 (9th Rept. Vt. State Geol., pp. 283–293). *Memphremagog sl.* has now been carried southward in somewhat broken belt to S. bdy of Greensboro. In its northern extension into Canada it bears abundant Lower Trenton graptolites.

C. H. Richardson, 1916 (10th Rept. Vt. State Geol., pp. 120–146). Western memb. of *Memphremagog slates* of previous repts was broken in Craftsbury, reappears in Hardwick, also in Woodbury, and continues into Northfield. The black or bluish-black slates and associated shales were named by this author *Memphremagog slates*, because of fact that in their northern extension in Vt. they dip under Lake Memphremagog and appear on E. side of lake, where they contain graptolites. This name is retained for the slates and shales in their southern extension as far S. as writer's work has extended, approx. 100 mi. The Memphremagog sl. and Waits River ls. range from Lower Trenton to Deepkill [Beekmantown].

C. H. Richardson, 1919 (11th Rept. Vt. State Geol.). *Memphremagog sl.*—In N. part of State is represented by 3 belts, roughly parallel, and separated from each other by belts of Waits River ls. Each sl. belt passes under Lake Memphremagog and reappears on E. side of lake in Canada. The E. belt in its more northerly extension is a black carbonaceous, often pyritiferous sl., which to S. becomes phyllite schist. Central belt is black clay sl. with perfect cleavage, occasionally pyritiferous. Western belt is black carbonaceous, highly fissile sl. These slates may represent 3 different noncalc. beds of Ord. sediments or one bed that has been repeated by a fan fold. All 3 belts contain graptolites, those found in Roxbury and Northfield proving the southern extension of the slates are of Deepkill (Beekmantown) age, according to Ruedemann.

C. H. Richardson, 1924 (14th Rept. Vt. State Geol.). *Memphremagog group.*—Slates and phyllites; in Bethel phyllites predominate. The slates extend unbroken from Lake Memphremagog S. for 100 mi. The phyllites have been more or less broken in their continuity by lss. The slaty characters were so pronounced in Newport and

Coventry that the terranes were named *Memphremagog slates*. In southerly extension the 2 easternmost members soon lose their slaty characteristics and become phyllites. In Bethel westernmost belt is nearly all phyllite. It has been obvious for long time these phyllites should receive a more definite name, and therefore *Randolph phyllite* has been selected for them. [See *Randolph phyllite*.]

C. H. Richardson, 1927 (15th Rept. Vt. State Geol., p. 150). *Memphremagog group* of slates and phyllites divided into *Randolph phyllite* and *Memphremagog sl.*

E. L. Perry, 1929 (16th Rept. Vt. State Geol.). *Memphremagog group of slates and phyllites* occurs in and near base of Waits River ls. in northern section.

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., pp. 192–211). *Memphremagog group* of slates and phyllites in SE. Vt. includes sl., *Brattleboro phyllite*, and Waits River ls., which usually is interbedded with the phyllite.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 13, p. 360), showed that in central Green Mtns, Vt., the Ord. consists of Randolph phyllite (correlated with Black River ls. of N. Y.), Waits River ls. (Chazy fossils), and Memphremagog sl. (Beekmantown fossils).

C. H. Richardson and J. E. Maynard, 1933 (18th Rept. Vt. State Geol., pp. 316–347). *Memphremagog group* (Ord.) consists of slates, phyllites, and qtzites. In N. half of State the sl. appears as a continuous belt from Northfield to Int. Bdy. On E. side of the Ord. the belt is more or less broken, but beds of sl. appear in nearly every twp southward from Waterford to Mass. line. Includes Brattleboro phyllite.

Menard limestone. (Of Chester group.)

Mississippian: Southern Illinois and western Kentucky.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 128). *Menard fm.*—Upper part, thin-and moderately thick-bedded close-textured fine-grained lss., with shaly partings and with some sh. beds 5 or more ft. thick; basal 35 ft. or more fine blue clay sh. Thickness 80 ft. Uncon. underlies Palestine ss. and overlies Okaw fm.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4 and No. 5, also Ill. Geol. Surv. Bull. 41, pp. 202–205, and Sci., n. s., vol. 51, p. 494) reported three fms. (Waltersburg ss., Vienna ls., and Tar Springs ss.) in southern Ill. btw. *Menard ls.* [restricted] and horizon of underlying Okaw fm., which are absent in Randolph Co. (See *Okaw fm.*) On p. 202 he stated: When these units (Waltersburg ss., Vienna ls., and Tar Springs ss.) were first observed they were considered as subordinate members of Menard fm., but as field studies have been carried to W. they have proved to be—in importance and magnitude with other Chester units and have come to be recognized as full fms. [In the three 1920 repts cited above Weller restricted *Menard* to beds above Waltersburg ss. This is present commonly approved definition.]

Named for Menard, Randolph Co., Ill., where it is well exposed immediately SE. of hospital for criminal insane.

Mendenhall sand.

A subsurface sand in Rico fm. (Perm.) of southern San Juan Co., SE. Utah.

Mendez formation.

Upper Cretaceous and Eocene(?): Mexico.

I. C. White, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 255).

Has been assigned to Upper Cret., to Eo., and to both.

Mendha limestone.

Upper Cambrian: Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. and Met. Engrs. Trans., No. 1647, p. 7) and 1932 (U. S. G. S. P. P. 171). *Mendha ls.*—Descending: (1) Blue-gray thick and thin ls., somewhat cherty, with layers of flat ls. cgl., 450 ft.; (2) dark-gray to black dolomitic ls., cherty, 350 ft.; (3) gray heavy-bedded crystalline ls., 300 ft.; (4) gray ls., thin- to thick-bedded, much oolitic and conglomeratic material, 800 ft. Conformably overlies Highland Peak ls. In fault contact with overlying Yellow Hill ls. (Lower Ord.). Named for Mendha mine, on W. side of Arizona Peak, which is entirely composed of these rocks. Larger areas are in Highland quad. Absent in Ely Range. Present in Bristol Range quad. Fossils basal Upper Camb. according to C. E. Resser.

Mendon schist.

Pre-Cambrian; Southwestern Vermont (Rutland County) and northwestern Vermont (Addison County).

C. L. Whittle, 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 347–355). [See 1st entry under *Mount Holly gneiss.*]

C. L. Whittle, 1894 (Jour. Geol., vol. 2, pp. 396–429). *Mendon series.*—A series, 200 to 2,000 ft. thick, of more or less metamorphosed clastic rocks of sed. origin. Referred to Algonkian. Overlies Mount Holly gneiss and underlies (uncon.?) Lower Camb. qtzite. So far as known best section occurs in town of Mendon, 1 mi. S. of Mendon village.

W. G. Foye, 1919 (11th Rept. Vt. State Geol., pp. 82–98). *Mendon series.*—Cgls., arkoses, qtzites, calcite marbles, dolomites, calc. schists, biotite schists, chlorite schists, actinolite schists, tourmalinized schists, and gneisses. Ripton cgl. is basal layer of Mendon series. Overlies Mount Holly gneiss. Is later Algonkian.

E. L. Perry, 1929 (16th Rept. Vt. State Geol., pp. 1–61), states there is erosion interval btw. *Mendon series* and Mount Holly series.

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., p. 284). In town of Mendon Cheshire qtzite is in contact with the dol. series. As we go up the hill from this quartz we go down through Mendon series, according to Whittle. Next outcrop to E. is shaly ls. 800 ft. thick. Next outcrop is impure qtzite, 500 ft. thick, which has been injected by volcanic material. Going up higher we find 50 ft. of the fine-grained dol. marble known as *Mendon dol.* It contains quartz grains. Highest outcrop reported is 350 ft. of green mica-quartz-actinolite schist, undoubtedly sedimentary and possibly injected by volcanic material. It could have been derived from Canajoharie sh. The *Mendon dol.* in Whittle's type loc. overlies, apparently conformably, the Camb. qtzite, which may be seen in bed of brook beside the dol. outcrop. The Mendon series as seen in Brandon is not strictly = the series in town of Mendon, and there is some doubt that the two sections are comparable as a series. Upon the basis of these meager facts the suggestion is offered that *Mendon series* may at present be assigned to Camb. and that there is no pre-Camb. along Green Mtn front. [In correlation table accompanying this rept. *"Mendon" dol.(?)* is assigned to Beekmantown D, and *Mendon series* to Lower Camb., Upper Camb., and Beekmantown.]

L. M. Prindle and E. B. Knopf, 1932 (Am. Jour. Sci., 5th, vol. 24, p. 265). Over Mount Holly gneiss lies a succession of mica schist and qtzite, including some ls. or dol. with a prominent structure that strikes nearly due N. This assemblage was called *Mendon "series"* by Whittle. Being chiefly schists, it is here called *Mendon schist.* It is of younger pre-Camb. age, and uncon. underlies qtzite containing Lower Camb. fossils.

E. J. Foyles, 1933 (18th Rept. Vt. State Geol., pp. 366–367). The establishment of *"Mendon series"* has hampered clear understanding of geol. history of W. side of Green Mtns. Has never been proved to be pre-Camb., and yet its records have often been used by authors as an infallible classic. Many series of somewhat similar nature but in no way exactly comparable have been correlated with it. For several years I have been unable to reconcile Mendon series with the fms. of the region. In summer of 1931 side trips from beaten path were made, and nothing unusual was encountered until the well-known dol. outcrop of type section was reached at 1,240 ft. above sea level. The dol. is large block 15 ft. long by 10 ft. wide, surrounded by glacial till and without recognizable bedding planes. It is concluded that *"Mendon dol."* is really Rutland dol., which arrived in its present position through faulting or glaciation. Although Whittle (Jour. Geol., vol. 2, 1894, pp. 396–429) thought "Mendon series" in Blue Ridge Mtn was completely overturned, there is no field evidence to prove it. "Mendon series" may prove to be Paleozoic.

Mendon dolomite.

Pre-Cambrian: Southwestern Vermont (Rutland County) and northwestern Vermont (Addison County).

See E. J. Foyles, 1929 and 1933 entries under *Mendon schist.* If this dol. belongs to Mendon schist, it is of pre-Camb. age, according to Prindle and Knopf (1932). But Foyles (1933) thinks it is Rutland dol. (Lower Camb.) faulted. (See under *Mendon schist.*)

Mendota dolomite member (of St. Lawrence formation).

Upper Cambrian: Southern Wisconsin.

R. D. Irving, 1875 (Am. Jour. Sci., 3d, vol. 9, pp. 441–442). *Mendota ls.* of south-central Wis., 30 ft. thick, underlies Madison ss. and rests on Lower or Potsdam ss.

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, p. 260). *Mendota ls.*—Alternating mag. ls., sandy calc. shales, and shaly and calc. sss.; the lss. soft, granular, porous, friable, rather thin-bedded, buff-colored, and frequently contain greensand; shales variegated with yellow, red, and purple; two kinds of ss. Thickness of fm. 60 ft. Should be included in Potsdam ss. series and not with Lower Mag. series. Base of Lower Mag. should be placed at top of Madison ss. Paleontology corroborates this view. Named by Prof. Irving from its occurrence on Lake Mendota, near Madison. Grades into underlying calc. ss. (155 ft. thick), which, with underlying sh. and sss., is also included in Potsdam ss. Also grades into overlying Madison ss.

R. D. Irving, 1877 (Geol. Wis., vol. 2, pp. 525, 577, 583–584, 590–592, 602, 603). Underlying Madison ss. and overlying Potsdam ss. proper is a well-marked and very persistent yellow ls. layer to which I have given specific name of *Mendota ls.*, from a large exposure at MacBride's Point [now known as Maple Bluff] on N. shore of Lake Mendota. Only intended as local name in central Wis.

In many subsequent repts this dol. was correlated with St. Lawrence fm. by several authors, including E. O. Ulrich; but later work led Ulrich to belief that it is younger than St. Lawrence fm. and younger than Jordan ss.

E. O. Ulrich, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 477–478). *Mendota dol.* is 25 ft. thick on Lake Mendota and at other points in area btw. the two cuts. It overlies Jordan ss. and underlies Madison ss. At Madison the Mendota is absent and the Madison rests on Jordan ss. All of 8 known outcrops of true Mendota are practically identical in lithologic character and contained fossils, and they arrange themselves in a narrow NW-SE belt (probably an erosion valley) some 50 mi. long and 4 or 5 mi. wide, that passes btw. the localities of the 2 cuts in which the true Mendota type of rock is absent. Hotchkiss, Weidman, and I agree that the beds immediately underlying these Mendota outcrops vary decidedly in age from place to place, hence contact is uncon., and that differential movement, emergence, and locally varying amounts of surface erosion occurred before deposition of the Mendota began.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93), defined *Mendota dol.* as underlying Madison ss. and overlying Devils Lake ss., and he assigned all three to his "Lower Ozarkian," and assigned the Jordan ss. and underlying St. Lawrence fm. to Upper Camb.

F. T. Thwaites, 1927 (Ill. Geol. Surv. Rept. Invest. No. 13, table 1, footnote). Writer is of opinion the Mendota is=lower part of Trempealeau fm., the original St. Lawrence.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 51, 55). There can be no doubt the Mendota of Irving directly overlies the greensand beds here called *Franconia*, directly underlies Madison ss., and includes not only the dol. but the overlying beds now called *Lodi*. Ulrich's chief basis for considering the Mendota younger than the St. Lawrence is paleontological. Ulrich, however, points out that Black Earth dol. contains 13 sp. of fossils, 10 of which are identical with sp. that occur commonly in the Mendota, but he interprets this as a preoccurrence of Mendota fauna in the St. Lawrence. We are of opinion that St. Lawrence, Black Earth, and Mendota dolomites represent same strat. unit and are of same age.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 21–23). Trempealeau fm. [redefined] is here divided into (descending) Jordan ss. memb., Mendota dol. memb., Lodi sh. memb., and basal greensand and greensand cgl. memb. All evidence indicates that the Black Earth, Mendota, and St. Lawrence [restricted] are different expressions of same dol. Writers prefer to wait for better evidence than has yet been presented before they can give serious consideration to Ulrich's interpretation of Mendota dol. [The Lodi sh. *overlies* Mendota, instead of underlies it, according to C. E. Resser and J. Bridge (personal communication, 1935).]

F. T. Thwaites, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 118). At close of 1914 field season writer and S. Weidman (then of Wis. Geol. Surv.) made an intensive study of Black Earth Valley. They discovered fossils in both Lodi siltstone and underlying dol. The rock is exactly like original Mendota in lithology, and most critical study by Ulrich failed to discern more than minute differences in fossils. Ulrich named the dol. "Black Earth" in 1916. Later students of this controversy, with aid of more fossils, insoluble residues, and heavy minerals, have confirmed conclusion of Weidman and writer. In 1933 Ulrich (in letter to G. O. Raasch) stated he had abandoned his former contention. [On pp. 129–130 Thwaites said: Type section of Mendota was what is now known as Maple Bluff (Macbrides Point in Irving's day). Irving correctly correlated Mendota with St. Lawrence [restricted] and Lodi members of what is now called Trempealeau fm. Ulrich, on basis of fossils collected by Alden, assumed that Mendota is much younger and lies in narrow erosional trough extending NW. to Baraboo region.]

The U. S. Geol. Survey now considers Mendota dol. and Black Earth dol. as synonyms. *Mendota* has long priority, and therefore *Black Earth dol.* has been discarded.

Menefee formation. (In Mesaverde group.)

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

A. J. Collier, 1919 (U. S. G. S. Bull. 691K). *Menefee fm.*—Middle fm. of Mesaverde group in SW. Colo. Approx. 400 ft. thick. Consists of ss., sh., and coal beds. Is "Middle Coal Group" of W. H. Holmes' subdivisions of Mesaverde group. Named for Menefee Mtn [Montezuma Co., Colo.], in which coal in it is being actively mined. Underlies Cliff House ss. and overlies Point Lookout ss.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, p. 5). *Menefee fm.* consists of rocks of fresh- and brackish-water origin with only a few marine beds.

†Menevian.

A term used in some early repts as synonymous with Acadian (Middle Cambrian). It is of British origin (Hicks and Salter, 1865).

Menifee sand.

A subsurface sand, of Dev. age, in eastern Ky.

†Meniscus limestone.

Nongeographic name applied by J. M. Safford to ls. of late Sil. (Cayugan) age in Tenn., which was later named †Sneedville ls. by Safford and Hancock ls. by A. Keith. Named for abundance of fossil sponge shaped like the glass lens called meniscus.

†Menominee series.

A term applied in some early repts to the Huronian rocks of Menominee dist., Mich. In many early repts on this dist. the upper Huronian rocks were called "Upper Menominee series" and the middle and lower Huronian rocks were called "Lower Menominee series."

Mentasta schist.

Paleozoic (pre-Devonian): Southeastern Alaska (Upper Copper River region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 26, in column of table credited to "Schrader, geologic reconn. of headwater region of Copper and Tanana Rivers, Alaska, Prof. Paper, in preparation"), showed *Mentasta schist* opp. *Pre-Sil. sediments.* A. H. Brooks, 1911 (U. S. G. S. P. P. 45, table opp. p. 206) also referred to *Mentasta schist* of Schrader's rept in preparation, and placed it tentatively opp. *Early Paleozoic (Sil., Ord., Camb.).* These are only recorded uses of *Mentasta schist.* Schrader's rept referred to was not published, and his subsequent duties called him to the States.

Menteth limestone member (of Moscow shale).

Middle Devonian: West-central New York.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63, p. 22). *Menteth ls.*—Compact layer, usually very pure, but in places quite argill. and nodular. Thickness 1 ft. Is a well-defined bench mark in Moscow shales [of the Hamilton]. Lies 75 ft. above Tichenor ls. Very fossiliferous. Forms first falls in ravines at Tichenor Point and Menteth Point, on Canandaigua Lake, Ontario Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 68). *Menteth ls. lentil.*—Is a lentil in Moscow sh., 75 ft. above its base. Noted for fine replacement of its fossils by silica.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 229–230). *Menteth ls.* is basal bed of Moscow fm. as here redefined. It is a crinoidal ls. 1 ft. thick, and is here included, with 8½ ft. of overlying beds of alternating lss. and shales, in *Portland Point memb.* of Moscow fm. It lies 55 ft. higher than true Tichenor ls. at Canandaigua Lake, but traced westward it approximates stratigraphically the Tichenor horizon. [See further explanation under *Portland Point memb.* and *Moscow sh. memb.*]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 369, 394). *Menteth ls.* is basal bed of Moscow sh., and lies 50 to 75 ft. above Tichenor ls. in Ontario Co. In Erie Co. it rests on Tichenor ls. through overlap, but thins out and disappears before reaching the lake, according to Cooper, 1930.

The U. S. Geol. Survey treats *Menteth ls. memb.* as basal div. of Moscow sh.

Mentor formation.

Lower Cretaceous (Comanche series): Central Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, p. 162). *Mentor fm.*—Fossiliferous, variegated, earthy mixtured, marine shales, with thin beds of brown ss. Thickness 50 to 60 ft. Formerly thought to belong to Dakota group, but now known to belong to upper part of Comanche series. Whether they overlie all of Kiowa sh., or only lower part of it, or whether they merge southward into upper part of Kiowa remains undet.

C. N. Gould, 1901 (Kans. Acad. Sci. Trans., vol. 17, pp. 132–167). "Mentor beds" of central Kans. same as Kiowa sh.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3, p. 123). Age and general character of so-called Mentor beds not satisfactorily determined.

I. Perrine, 1918 (A. A. P. G. Bull., vol. 2, p. 79). Type exposure of *Mentor beds* is on E. side of Smoky Hill River about 3 mi. E. of Mentor. They outcrop in Saline, McPherson, Ellsworth, Lincoln, Ottawa, and Clay Counties. Conformably overlie Kiowa shales and underlie Dakota ss.

W. H. Twenhofel, 1918 (Kans. Acad. Sci. Trans., vol. 28, pp. 213–222). Comanchean of central Kans. divided into (descending): (1) Some beds that have been called Dakota; (2) *Mentor beds* [restricted]; (3) unfossiliferous beds, 65±ft. thick, that are quite probably nonmarine; and (4) Kiowa sh. In Mentor beds it is proposed to include only the fossiliferous sss. and such associated beds as can be proven to be marine. These beds total 10±ft. in thickness. Are variable locally. At type loc. they consist of dark-brown friable fine-grained ss.; at Natural Corral the rock is heavy-bedded brown ss., coarser-grained than at Mentor, and in places carries many ferruginous concretions that are characteristic of Dakota.

W. H. Twenhofel, 1920 (Am. Jour. Sci., 4th, vol. 49, p. 291), correlated *Mentor marine ss.* with middle part of Kiowa sh.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9, pp. 31–32). It is here proposed to include in Belvidere fm. all strata from top of Mentor horizon down to Permian, and those above the Mentor in "Dakota." The Mentor beds drop out to N. The Belvidere [in McPherson Co.] divided into (descending): Mentor memb.; Marquette memb., 53 ft.; Windom memb., 3 ft.; Natural Corral memb., 30±ft. These memb. names are used only for convenience to designate occurrence of fossils and strat. position; the divisions are shown in few natural exposures. [This classification was followed by W. H. Twenhofel and A. C. Tester in 1926 (A. A. P. G. Bull., vol. 10, No. 6, pp. 553–561).]

Considered to be of Washita age, and to correspond to Kiowa sh. of southern Kans.

Meramec group.

Mississippian: Mississippi Valley region.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110). *Meramec group* proposed to include (descending) St. Louis ls., Spergen Hill ls., and Warsaw fm. Replaces broad usage of "St. Louis ls." and "St. Louis group." Overlain by Ste. Genevieve ls., basal fm. of Chester group.

S. Weller, 1907 (Ill. Geol. Surv. Bull. 6), excluded Ste. Genevieve ls. from Chester group, and subsequently continued to exclude it, but did not definitely place it in Meramec group until 1920 (Ill. Geol. Surv. Bull. 41) and 1921 (Ky. Geol. Surv., ser. 6, vol. 4), when he drew top of *Meramec group* at base of his Shetlerville fm., or in midst of Ohara ls. memb. of Ste. Genevieve ls. of Ulrich, stating that original Ste. Genevieve ls. of Shumard did not include Shetlerville fm. of Weller, and that it does not belong to Chester group, as contended by Ulrich, but to Meramec group.

For many years the U. S. Geol. Survey did not (because of divergent views of geologists who had made a special study of the problem) definitely assign Ste. Genevieve ls. to either Meramec group or Chester group. (See under *Ste. Genevieve ls.*) In May 1937, however, it was decided by the Federal Survey to include this fm. in Meramec group (which is the definition for some time followed by Ill. Geol. Survey), and to recognize the "Upper Ohara" of repts as a part of Renault fm., instead of the upper div. of Ste. Genevieve ls. The Ill. Geol. Survey at present includes the Warsaw in Osage group; the U. S. Geol. Survey has for many years included it in Meramec group.

Named for Meramec Highlands and Meramec River, W. of St. Louis, Mo.

Meramecian.

A time term used by some geologists to cover the epoch during which the Meramec group was deposited.

Merced formation.

Pliocene: Western California (San Francisco Bay region).

A. C. Lawson, 1893 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 1, pp. 142–151). For convenience the Plio. rocks here referred to will be designated *Merced series*, from Lake Merced, which lies in a structural or synclinal depression of the Plio. terrane, to S. of the city. The base of the series is observable at Mussel Rock. Basal bed is a stratum of partially carbonized forest material. Is a local or delta accumulation. Very fossiliferous. The delta gravels on the San Benito [on p. 153 casually called *San Benito gravels*] are direct equiv. of Merced series.

The Merced fm. (marine) in San Francisco region rests uncon. on Franciscan rocks or on an ancient alluvium of post-Franciscan and pre-Merced age. Is considered=nonmarine Orinda fm., which lies conformably on Pinole tuff. In Santa Cruz region the Merced rests on Purisima fm. It is considered older than Berkeley group. (See U. S. G. S. San Francisco folio, No. 193.)

This fm. is now being assigned to middle Plio. by Calif. geologists. (See E. Dorf, Carnegie Inst. Wash. Pub. 412, p. 7, 1933.)

Mercer limestone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477). *Mercer ls.*, 2 ft. thick, included near base of Tionesta group [=Mercer sh. memb. of present nomenclature].

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Mercer ls.* (*Lower Wurtemburg ls.*).—Tolerably compact dark-bluish ls. filled with fossils. Thickness 8 to 12 in. Persistent from Old Homewood furnace up the Beaver and Connoquenessing to Wurtemburg [Lawrence Co.], where it is *Lower Wurtemburg ls.* in Prof. Lesley's Slippery Rock section, in Rept. J.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). Rogers' name *Mercer ls.* here changed to *Lower Mercer ls.*, which is same as "Lower Wurtemburg" ls. of Lesley. The *Upper Mercer ls.* (here introduced to replace Mahoning ls. of Rogers) is same as Upper Wurtemburg ls. of Lesley. Named for Mercer, Pa. [See quotation under *Upper Mercer ls.*]

B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M_7, pp. 280, 281, 332). [See under *Wurtemburg ls.*]

Mercer shale member (of Pottsville formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2, pp. xxi–xxxvi, 319–333). *Mercer group.*—Middle part of Pottsville cgl. Underlies Tionesta (Homewood) ss. and overlies Connoquenessing ss. [Corresponds to *Mercer sh. memb. of Pottsville fm.*, the name in general use for many years.]

H. M. Chance, 1880 (2d Pa. Geol. Surv. Rept. G4). *Mercer coal group* underlies Homewood ss. and overlies Connoquenessing sss.

Mercer "formation."

Same as Mercer sh. memb.

Mercer "group."

See under *Mercer sh. memb.*

Mercer coal group.

See under *Mercer sh. memb.*

Merchants amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Is younger than Mass amygdaloid and older than Knowlton amygdaloid. The mineralized part is the Merchants lode. Named for occurrence in old Merchants mine, Ontonagon Co.

Merchants flow.

Includes Merchants amygdaloid and underlying trap.

Merchantville clay. (In Matawan group.)

Upper Cretaceous: New Jersey.

G. N. Knapp, as reported by R. D. Salisbury, 1899 (N. J. Geol. Surv. Ann. Rept. State Geol. 1898, p. 35). *Merchantville bed.*—Marly clay underlying Woodbury bed and overlying Raritan fm. [original broad usage of Raritan, which included Magothy fm. at top]. Basal bed of Clay Marl series [Matawan group].

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 159). *Merchantville clay.*—Black marly clay, glauconitic and micaceous; weathers rusty brown. Thickness 35 to 60 ft. Underlies Woodbury clay and overlies Raritan clay series [upper part of which is now called Magothy fm.].

Basal fm. of Matawan group.

Named for fact Merchantville, Camden Co., rests on this fm.

Meredith granite.

Late Devonian (?): Eastern New Hampshire (Lake Winnipesaukee region).

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, map, p. 83). *Meredith granite.*—Porphyritic granite. One of most striking rocks in N. H. Inasmuch as other porphyritic granites are present in State, it is proposed that this particular type be designated *Meredith granite*, from typical exposures in Meredith Twp [Belknap Co.]. Was called *porphyritic gneiss* by Hitchcock. Is closely related to Chatham granite in chronology and mineralogy. Intrudes Montalban schist [of Billings].

M. Billings, 1935 (letter dated Aug. 27). *Meredith granite* is lithologically precisely like the porphyritic phases of Kinsman quartz monzonite, and there is no doubt they should be correlated. This means the Meredith is definitely younger than Lower Dev. My guess is that it is late Dev.

Meriden ash bed.

Meriden type.

Upper Triassic: Central Connecticut.

B. K. Emerson, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 66–67, 72–77). *Meriden "ash bed."*—The bed at base of trap sheet W. of Lamentation Mtn, on Berlin turnpike, 1 mi. N. of Meriden, Conn. Differs from Greenfield bed only in much greater quantity of glass and in being only half as thick. Rests in places on unbaked ss.

B. K. Emerson, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 91–130). *Meriden type.*—Blending of mud and lava at base of Holyoke trap.

†Meridian series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 107, 137–138, 273+, and vol. 2, p. 755). Divided into *Meridian ss.* (*Oriskany ss. of N. Y.*), 150 ft. thick on Juniata River, underlain by Meridian sl., 170 ft. thick on Upper Juniata near Frankstown. The latter rests on *Pre-Meridian ls.* (*Lower Helderberg ls. of N. Y.*).

†Meridian sandstone.

†Meridian slate.

See under †*Meridian series.*

†Meridian formation.

†Meridian buhrstone.

Eocene (middle): Southeastern Mississippi and southern Alabama.

W J McGee, 1891 (U. S. G. S. 12th Ann. Rept., pt. 1, pp. 413–415, 491+). The most distinctive rock mass of Mississippi embayment. It is as characteristic and distinctive as ls., ss., sh., or marble; but by reason of its confinement to a comparatively restricted region it has never received the coordinate appellation it deserves. Is typically displayed in vicinity of Meridian; from these exposures it seems appropriate to designate the deposit *Meridian fm.*; or, if the general though unsatisfactory lithologic term be retained, *Meridian buhrstone*. Here it comprises hard siliceous ledges, with intercalated beds of imperfectly indurated siliceous clay or marl, the mass displaying moderately regular bedding; yet despite a high degree of uniformity in composition and structure there is wide diversity in texture, owing to variable degree of lithification. There is commonly a rude nodulation or segregation of materials in plates and lenses, variously disposed in attitude; the nodules, plates, and lenses are generally hard, brittle, refractory under the hammer, clinking sharply and breaking with conchoidal or splintery fracture, while intervening mass is less perfectly lithified, and sometimes quite friable. Sometimes nodules are an inch or less in diam., the plates and lenses but hand specimens; again the harder aggregations measure feet or yards, the nodules running into lenses which expand into ridges. Is middle Eocene. Underlies calcareous Claiborne.

Replaced by Tallahatta fm., a later but better-established name. Preoccupied by Rogers' †Meridian series of Pa. See additional explanation under †*Choctaw buhrstone*.

Named for development in vicinity of Meridian, Lauderdale Co., Miss.

Meridian sand member.

Eocene (middle): Southeastern Mississippi.

E. N. Lowe, 1933 (Miss. Geol. Surv. Bull. 25). [On p. 1 Lowe states that Claiborne group of Miss. includes *Meridian sand memb.* and Tallahatta, Winona, Lisbon, and Yegua (or "Cockfield") fms. On pp. 105–106 he gives sections around Meridian, Miss., where he shows basal memb. of Tallahatta fm. to consist of 75 ft. of sand, but he does not on those pp. use *Meridian sand memb.*]

Merigomish formation.

Carboniferous: Canada.

H. M. Ami, 1900 (Canadian Rec. Sci., vol. 8, pp. 162–163).

POLITECHNIKA ... ZAKŁAD GEOLOGII

Merkel dolomite member (of Clear Fork formation).

Permian: Central northern Texas.

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull., vol. 1, pl., pp. 95, 96, 97). *Merkel dol.*—Dol. with clay parting 3 to 4 ft. thick. Is characteristically ripple marked and weathers in thin plates like cross-bedded sss. Thickness of fm. 5 to 8 ft. Top memb. of Clear Fork beds. Named for exposures just W. of Merkel [Taylor Co.]. Traced across country to Abilene-Sweetwater section and to Double Mtn section.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, p. 49). *Merkel dol.* is highest dol. of Choza fm. of Clear Fork, lying 270 ft. below top of Choza.

J. W. Beede and W. P. Bentley, 1921 (Univ. Tex. Bull. 1850). *Merkel dol.* is 20 ft. thick in Coke Co.

J. W. Beede and D. D. Christner, 1926. [See 1926 entry under *Choza fm.*]

W. Kramer, 1934 (Jour. Geol., vol. 42, p. 193). *Merkel dol.*, top memb. of Clear Fork fm. of north-central Tex., may be traced as a continuous ledge-maker from NW. Taylor Co. northward for 50 mi. into NE. Stonewall Co. To N. of this continuous outcrop the horizon of the Merkel contains thin, apparently discontinuous dol. beds having many ripple-marked surfaces, and can be identified by its position a few ft. below San Angelo ss.

Some geologists spell this name *Merkle*, but P. O. Guide spells the town for which the dol. was named *Merkel*.

Merom sandstone.

Pennsylvanian: Southwestern Indiana and probably eastern Illinois.

J. Collett, 1871 (Ind. Geol. Surv. 2d Rept., p. 199). *Merom ss.*—Lower 10 to 25 ft. massive ss., with ferruginous seams and veins (called Anvil Rock ss.); upper 20 to 25 ft., soft ss. Overlain by loess and drift; underlain by thin bed of calc. cgl. succeeded below by Productal ls. Included in Coal Measures.

Probably=Inglefield ss., and possibly=in whole or in part Anvil Rock ss. of western Ky.

Named for Merom, Sullivan Co., Ind.

†Merom group.

Pennsylvanian: Southwestern Indiana.

G. H. Ashley, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, pp. 273–277). *Merom group.*—Upper or barren measures, 400 ft. thick, overlying Wabash group.

Preoccupied. Includes Merom ss., Wabash fm., and Inglefield ss.

Named for Merom, Sullivan Co.

Merriam limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 97). Members of Plattsburg ls. that are readily identified in many Kans. sections are, in upward order: *Merriam ls.*; "middle," *Hickory Creek sh.*; and *Spring Hill ls.* ("upper"). [Derivation of names not stated. On p. 46 *Merriam ls.* is described as consisting of 2 to 5 ft. of gray to buff massive ls.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 71–73). Basal memb. of Plattsburg ls., and perhaps most characteristic part of Plattsburg, is here termed *Merriam ls. memb.* In many places consists of 2 divisions, the lower a blocky, even layer, less commonly cross-bedded ls., drab to light gray, generally weathering white, often highly fossiliferous, up to 5 ft. thick, locally absent. The upper div., generally 1 ft. thick, is fine-grained dense gray massive blocky ls., in one layer, seldom fossiliferous, but contains in upper part numerous irregularly disposed hollow tubes. Underlies Hickory Creek sh. memb. Named for exposures at town of Merriam, Johnson Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

KANSAS

Merrimac rhyolite.

Pre-Cambrian (pre-middle Huronian): South-central Wisconsin (Baraboo district).

J. T. Stark, 1932 (Jour. Geol., vol. 40, No. 2, pp. 120, 121, 130). *Merrimac rhyolite.*—Flow rhyolite in Merrimac Twp, on S. flank of syncline near Merrimac, sec. 32, T. 11 N., R. 7 E. Assigned to pre-middle Huronian.

Merrimack quartzite.

Carboniferous (probably Pennsylvanian): Northeastern Massachusetts (Merrimack River region).

C. H. Hitchcock, 1870 (2d Ann. Rept. Geol. and Min. N. H., geol. map and p. 34). *Merrimack group.*—This name was informally applied by my father [where?] to the mica schists, slates, and qtzites contained in valley of Merrimack River in Mass. They skirt Exeter syenites in N. H., lying in troughs on the flanks of an anticlinal. Probably belong to the earliest Sil. series. [This "group" was in this rept mapped over a large area in SE. N. H., on both sides of Merrimack River and near town of Merrimack.]

C. H. Hitchcock, 1871 (Official Topog. Atlas Mass.). *Merrimac schists* belong to Eozoic.

C. H. Hitchcock, 1873 (Proc. Boston Soc. Nat. Hist., vol. 15, pp. 304–309). *Merrimack group.*—A convenient term to represent the qtzites and fine-grained mica schist following Merrimac River below Lowell, Mass.

C. H. Hitchcock, 1873 (Geol. Surv. N. H. Rept. 1872, p. 14). The *Merrimack group* seems to be distinct from the mica schist, though the two have heretofore been confounded.

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545). *Merrimack group.*—Micaceous qtzite not yet separated from Rockingham schist group. The occurrence in it of large beds of soapstone suggests Huronian age. It abounds in beds of coarse indigenous granite, which predominate in certain parts of Strafford Co., N. H.

C. H. Hitchcock, 1877 (Geol. N. H. pt. 2, pp. 588–591, 621, and btw. pp. 658 and 675). *Merrimack group.*—Ferruginous and mica schists and micaceous qtzite, varying to argill. schist; includes a little clay sl. Occupies principal area btw. Exeter and Newburyport ranges of sienite, as well as that btw. the 2 great gneiss areas of Pelham and Andover, Mass. This is typical area of this group, from which the name was derived. Thickness 4,300 ft. Older than Rockingham mica schist.

C. H. Hitchcock, 1879 (Macfarlane's Geol. Ry. Guide, pp. 56–59), assigned his *Merrimac qtzite and schist* of N. H. to Huronian, and gave thickness of 4,300 ft.

W. O. Crosby, 1880 (Boston Soc. Nat. Hist. Occ. Papers No. 3). "*Merrimac schists*" of Hitchcock's 1871 atlas of Mass. belong to Montalban system.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.). *Merrimac schists.*—Phyllites, mica schists, and qtzites, of Miss. age. Probably younger than subalkaline rocks, although separated from them by faults. Intruded by Andover granite.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 58, correlation table, map). The rocks of that part of Merrimack trough that lies btw. Lowell and Mass.-N. H. line are fairly homogeneous, and for present it seems best to map and describe them under one fm. name—*Merrimack qtzite*. The fm. was named by C. H. Hitchcock (Geol. N. H., vol. 2, p. 621, 1877) from Merrimack River, along which it causes the falls at both Lowell and Lawrence, Mass. It is typically shown in gorge of the river below Pawtucket Falls at Lowell, [etc.]. Consists chiefly of thin-bedded qtzite or quartz schist, as a rule somewhat actinolitic, generally gray or greenish gray, but at many places made chocolate-colored by red biotite, which is disseminated in it in small amount, and at other places stained rusty brown by oxidation of pyrite. At many places there are thin intercalated beds of sl. or slaty quartz schist, and at others thin lenses and roundish nodules of greenish calc. or epidotic rock, exactly as in Oakdale qtzite of Worcester trough, to which it is probably equivalent. [Mapped by Emerson up to N. H. line over a broad area in NE. Mass.; but F. J. Katz (U. S. G. S. P. P. 108–I, 1917) adopted local names for equiv. rocks a little farther N. in SE. N. H. and SW. Me. He stated that *Merrimack slates* of Hitchcock *in N. H.* included Eliot sl. and Kittery qtzite (both of Penn. (?) age), some unnamed pre-Carbf. (Algonkian?) slates, schists, and qtzites, and Berwick gneiss of Katz's classification. At present the name *Merrimack qtzite* is not used by U. S. Geol. Survey in N. H. D. White considered the fm. to be "probably Pennsylvanian."]

E. E. Fairbanks, 1927 (Boston Soc. Nat. Hist. vol. 38, No. 8, p. 405). *Merrimack qtzite* near Lowell, Mass., consists of well-bedded grayish to greenish qtzites containing interbedded phyllite members. Is probably Camb.

Merrimack group.

See under *Merrimack qtzite*.

Merriman limestone member (of Graford formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. Reeves, 1922 (U. S. G. S. Bull. 736E, p. 120). *Merriman ls. memb. of Brad fm.*—Fine-textured yellow ls., very hard, usually weathering into rectangular blocks. Thickness 4± ft. Lies 84± ft. below Ranger ls. memb. and 67 ft. above Adams Branch ls. (top memb. of underlying Graford fm.). Crops out near Merriman Church, S. of Ranger, Eastland Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 111), extended Graford fm. up to top of Merriman ls., and restricted Brad fm. to Placid sh. memb. and Ranger ls. member. He also applied the name *Merriman ls.* to the lss. formerly called *Clear Creek ls.* (preoccupied); but the Merriman ls. of Reeves corresponds to only the upper of the 2 lss. that were included in Clear Creek ls. of Drake and of Plummer and Moore. (See Wallace Lee and C. O. Nickell, Univ. Tex. Bull. soon to be published.)

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501), divided Brad fm. of McCulloch Co., Colorado River region, into following members (descending): Ranger ls., Placid sh., Clear Creek ls., and Cedarton sh., and stated (p. 205): Clear Creek ls. is also known as Merriman ls.

The U. S. Geol. Survey still uses Merriman ls. as defined by Reeves, that is, for a bed in Brazos River region which lies in lower part of Winchell memb. of Lee, Nickell, et al., which is top memb. of Graford fm. as redefined by Sellards and later delimited by Wallace Lee and C. O. Nickell, in publication cited above.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 24), showed Merriman ls. of Brazos River Valley as older than Clear Creek ls. of Colorado River Valley, and included Merriman ls. and some older rocks in Brad fm. On pp. 47–48 they define Merriman as top memb. of Graford fm. in Palo Pinto Co.; as consisting of 20 to 75 ft. of gray, massive, jointed, resistant, fossiliferous ls. ("previously mapped by Plummer and Moore as Adams Branch ls."); and as resting on Wolf Mtn sh. memb. of the Graford. On p. 50 they state that Merriman ls. varies in thickness from 175 ft. or more at Possum Kingdom Bend on the Brazos to 20 ft. or less on Keechi Creek near N. bdy of Palo Pinto Co.

Merritt sand.

Pleistocene: Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Merritt sand.*—Marine sand, 30 ft. thick, uncon. overlying San Antonio fm. and uncon. underlying Temescal fm. Forms the sand underlying cities of Oakland and Alameda. Named for occurrence on Lake Merritt, in city of Oakland. Thickness 44 ft.

Mervine sand.

A subsurface sand, of Penn. age, in central northern Okla. In Mervine pool, Kay Co., it is 25 ft. thick, lies at depth of 1,000 ft., the Hoover sand lying at 1,250 ft. Is said to be same as Newkirk sand.

Mesa sandstones.

Cretaceous: Mexico (Baja California).

W. M. Gabb, 1867 (Calif. Acad. Sci. Proc., 2d ser., vol. 1, p. 175). [Assigned to Cret., but C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 206), assigned *Mesa ss.*, divided into 3 members, to late Plio.]

Mesa formation.

A term applied by W. P. Blake, 1899 (Rept. Governor Ariz. to Secy Interior of U. S., p. 143) to deposits of wash, gravel, and sand, derived from breaking down of granite and gneissic rocks and forming the mesa upon which Univ. of Ariz. at Tucson is located.

Mesa basalt.

Tertiary (late): Northwestern Nevada.

J. C. Merriam, 1910 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 6, No. 2, pp. 21–53). *Mesa basalt*.—Widely spread over region of Virgin Valley and Thousand Creek. Consists of several fairly distinct layers. Thickness 25 ft. Appears to be last fm. laid down before present valley was excavated. So far as known not distinctly uncon. with underlying Virgin Valley beds.

†Mesabi moraine.

Pleistocene (Wisconsin stage): Northern Minnesota.

W. Upham, 1894 (Minn. Geol. and Nat. Hist. Surv. 22d Ann. Rept., pl. 1, p. 50). Forms a hilly belt along Mesabi range.

This name is no longer used, because detailed mapping by F. Leverett has shown that the morainal belt in region described follows a different course from that indicated by Upham.

†Mesabi gabbro.

A name applied by N. H. Winchell (Am. Geol., vol. 16, p. 333, 1895) to Duluth gabbro in Mesabi dist., NE. Minn.

†Mesabi series.

Pre-Cambrian (Huronian): Northeastern Minnesota (Mesabi district).

C. R. Van Hise and C. K. Leith, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 351–361). *Upper Huronian (Mesabi series)*.—Includes, in Mesabi dist., Virginia sl., Biwabik fm., and Pokegama fm. (descending).

C. K. Leith, 1933 (16th Int. Geol. Cong. Guidebook 27, p. 9), assigned Biwabik and Pokegama fms. to middle Huronian.

Mesa Negra beds.

See *Negra clays*.

Mesaverde group (also **formation**).

Upper Cretaceous (of Montana age): Western Colorado, northwestern New Mexico, eastern Utah, southern, central and northern Wyoming.

W. H. Holmes, 1877 (U. S. Geol. and Geog. Surv. Terr. 9th Ann. Rept., for 1875, pp. 245, 248, pl. 35). *Mesa Verde group*.—Divided into (descending): (1) Upper escarpment ss. or group, consisting of 190 ft. of massive ss.; (2) middle coal group, consisting of 800 to 900 ft. of ss., sh., marl, and lignite; (3) lower escarpment ss. or group, consisting of 120 ft. of massive ss. Underlies Sand Shale group [later named Lewis sh.] and overlies Colorado dark shales and ls. [later named Mancos sh.], which are 1,200 to 1,500 ft. thick in valley of Rio San Juan, SW. Colo. and NW. N. Mex.

W. Cross and A. C. Spencer, 1899 (U. S. G. S. La Plata folio, No. 60). *Mesaverde fm.* is a succession of alternating sss. and shales, with occasional marls or thin lss. and a number of coal seams, some of which are of excellent quality. Max. thickness in La Plata quad. 1,000 ft. It overlies Mancos sh. and underlies Lewis sh. Its fossils have been identified by T. W. Stanton as of Pierre age.

N. M. Fenneman and H. S. Gale, 1906 (U. S. G. S. Bull. 297). The beds in Yampa coal field of NW. Colo. herein designated *Mesaverde fm.* are apparently analogous in character of constituent members, in position btw. two great clay-sh. groups, and in contained fossils, to typical Mesaverde fm. of SW. Colo. In Yampa field, however, they attain thickness of 2,500 to 3,500 ft., while in SW. Colo. their max. development is 1,000± ft. In Yampa field they consist of ss., sh., and coal beds, the sss. and coals occurring in groups. They grade, through rapid transition, into overlying sh. here identified as Lewis sh., and rest on dark sh. here identified as

Mancos sh. The fm. is of Pierre and Fox Hills age, the fauna of the shales resembling Pierre fauna, the fauna of the sss. being more like Fox Hills fauna.

Subsequently the Meșaverde fm. was identified and mapped across central Wyo.

A. J. Collier, 1919 (U. S. G. S. Bull. 691, p. 296), replaced Holmes' descriptive terms in SW. Colo. with following geographic names (descending) Cliff House ss., Menefee fm., and Point Lookout ss., derived from localities on or near Mesa Verde, SW. Colo. According to J. B. Reeside, Jr. (1924, below), the Cliff House and Point Lookout sss. are both of marine origin; the Menefee fm. is of fresh-water and brackish water origin, but contains a few marine beds.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). The 3 fms. into which Holmes and Collier divided *Mesaverde group* in SW. Colo. are not distinguished at many localities, but the name Mesaverde as a designation for a coal-bearing series in upper part of Upper Cret. has been very widely used—as far away from type region as northern Wyo. The Mesaverde of SW. Colo. grades into marine Mancos sh. below and into marine Lewis sh. above, and the boundaries are arbitrarily fixed. Writer believes Mesaverde group on the San Juan represents time interval of part of Mancos sh., the Mesaverde group, and much of Lewis sh. of Animas River section. To S. of San Juan River, where Lewis sh. becomes much thinner even than on San Juan River, the top of Cliff House ss. may represent practically same time of deposition as very top of Lewis sh. along N. side of San Juan Basin. It seems very probable Point Lookout ss. and Cliff House ss. are really aggregates of successively overlapping beds which as a whole, with reference to a given chronologic plane, change their positions in strat. column from place to place. The Point Lookout ss. in its northern exposures is younger than in its southern exposures; the Cliff House ss. in its northern exposures is older than in its southern exposures. Writer has not noted any locality where such an overlap and passage from one lithologic phase to another is observable, but exposures are in general inadequate. That such a phenomenon can be shown in other and more favorable regions is well known, and it is almost certain something of the sort occurs here. In some areas in SW. Colo. top of Mesaverde may include beds as young as Fruitland and Kirtland fms. of San Juan Basin. The relations of Mesaverde group of SW. Colo. to beds similarly named in northern Colo., Utah, and Wyo. are not at all clear. In some parts of Wyo. the base of Montana group is definitely known and general relations of Mesaverde group of those regions to typical Mesaverde can be deduced, but not enough is yet known to make detailed comparisons possible. At some places there are no marine beds above basal part of Mesaverde, and most of Mesaverde and the later beds are fresh-water deposits. It is quite likely that the Mesaverde at some of these localities is really nearer to Fruitland and Kirtland fms. in age than to typical Mesaverde. The typical Mesaverde is wholly of Pierre age.

The Mesaverde group of Axial, Monument Butte, and Meeker quads, of NW. Colo. has been divided into Williams Fork fm. above and Iles fm. below; in Yampa coal field into (descending) Holderness fm., Twentymile ss., Mount Harris fm., Trout Creek ss., Milner fm., and Haybro fm. The Mesaverde group of Baxter Basin, Sweetwater Co., SW. Wyo., has been divided into (descending) Almond fm., Ericson ss., Rock Springs fm., and Blair fm. In Wasatch Plateau, Utah, it has been divided into (descending) Price River fm., Blackhawk fm., and Star Point ss.

Mescal limestone. (Of Apache group.)

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1915 (Wash. Acad. Sci. Jour., vol. 5, pp. 380–385). *Mescal ls.*—Cherty thin beds of varied color, generally gray or white, but some yellow, buff, and rusty brown beds. Most of ls. is mag., and some of it is dol. Thickness 225 ft. Rests conformably on Dripping Spring qtzite. Is separated from overlying Troy qtzite by 75 to 100 ft. of vesicular basalt, which is apparently coextensive with it, and is not separated from it on the map.

Named for exposures in Mescal Range, Ray quad.

Mescalero Sands.

According to N. H. Darton "Mescalero Sands" is a geographic name applied to a large area in SE. N. Mex. that is covered with dune sands. The Mescalero Valley runs through the area.

W. G. Blanchard, Jr., and M. J. Davis, 1929 (A. A. P. G. Bull., vol. 13, pp. 987-988). Mescalero sands and caliche, 0 to 250 ft. thick, are of Quaternary age, and throughout Llano Estacado overlie Dockum group (Triassic).

Meshik formation.

Miocene or Oligocene: Southwestern Alaska (Alaska Peninsula).

R. S. Knappen, 1929 (U. S. G. S. Bull. 797, pp. 198-201, map). *Meshik fm.*—Interbedded purple and green andesitic aggl., varicolored volcanic ash, and bentonitic clay (black, brown, and yellow), and black soil, all poorly stratified, and of fluviatile and eolian origin; some andesite flows. In general is finer grained in lower part, becoming much coarser above, until it consists entirely of coarse volcanic material and includes numerous lava flows. Typically developed along sides of valley of Meshik River and Meshik Lake. Thickness probably 2,000 to 4,000 ft. Rests on Eo. wherever base is exposed. No evidence of erosion preceding the fm. In absence of fossil evidence the Meshik is referred to Mio. or Olig.

†Mesnard formation.

Pre-Cambrian (Huronian): Northwestern Michigan (Marquette district).

M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, pp. 63-66). *Mesnard fm.*—Qtzite, argillites, and dol. Uncon. underlies Holyoke fm. and is believed to uncon. overlie Republic fm., but may prove to be same as Republic fm. Named for exposures at Mount Mesnard. [As defined is a broader unit than Mesnard qtzite of established usage.]

Mesnard quartzite.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 517+). *Mesnard qtzite.*—Chiefly qtzite, but includes cgls., graywackes, and graywacke slates, with all gradations; cgl. at base. Thickness 150 to 670 ft. Grades into overlying Kona dol. Rests uncon. on Basement Complex. Composes larger part of mass of Mount Mesnard, S. of Marquette.

†Mesnard epidote.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, p. 680). At top [of Central Mine group] is "Mesnard epidote," and just beneath it the heaviest flow, over 1,000 ft. thick at times, known as the Greenstone.

Basal fm. of Ashbed group, according to present classification, the Greenstone now being treated as top fm. of Central Mine group. Is same as †St. Mary's epidote.

Named for fact it occurs in old Mesnard mine, Houghton Co.

Meson beds.

Oligocene: Mexico.

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, p. 147).

Mesozoic era.

A major time term, meaning middle life, based on the life (zoic) contents of the rocks. It includes the Cretaceous, Jurassic, and Triassic periods. For definition see U. S. G. S. Bull. 769, 1925, pp. 9-10.

Messines formation.

Devonian: British Columbia.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 75, p. 50).

†Metamynodon sandstone.

A paleontologic name that has been applied by paleontologists to basal sss. of Brule clay (Olig.) in S. Dak. The U. S. Geol. Survey does not apply paleontologic names to lithologic units, and would use "*Metamynodon*-bearing sss." or "*Metamynodon* zone."

Metapán formation:

Lower Cretaceous: Guatemala, Honduras, and Salvador.

C. Schuchert, 1935 (Hist. geol. of Antillean-Caribbean region, pp. 337, 355, 359).

Metchosin volcanics.

Eocene: British Columbia.

C. H. Clapp, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 89). [In his early repts Clapp assigned these rocks to Jurassic (?) and to Jurassic. Since 1913, however, Clapp and others have assigned them to Eo.]

Meteor granodiorite.

Jurassic (?): Northeastern Washington.

C. E. Weaver, 1913 (Wash. Geol. Surv. Bull. 16, pp. 20–30). *Meteor granodiorite.*—Very variable in appearance; in many cases a distinctly plutonic rock passing into a porphyritic condition. Jurassic (?). Named for Meteor, Ferry Co.

Methow physiographic stage.

Pliocene: Central Washington (Cascade Range).

B. Willis, 1903 (U. S. G. S. P. P. 19, p. 70). Pre-Glacial, Pliocene. Characteristic feature, the Methow plain. Type loc. of the stage, generally throughout the broad mtn dist. and specifically in Yakima Valley.

Mettawee slate.

Lower Cambrian: Eastern New York (Washington County) and southwestern Vermont (Rutland County).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 67–70). *Mettawee sl.*—Grayish green, purple, or mixed green and purple, alternating with beds of calc. qtzite up to 5 ft. and ls. breccia up to 40 ft. Is the Cambric roofing slate of [T. N.] Dale. Extends typically from Pawlet, Vt., and Granville, N. Y., to Fairhaven, Vt. Named for Mettawee River, which drains the region [rising in Pawlet quad., in SW. part of Rutland Co., Vt., and flowing NW. into N. Y.]. Underlies Eddy Hill grit and overlies Bomoseen grit—all Lower Camb.

Mexia member (of Wills Point formation).

Eocene: Northeastern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 535, 559, 562). *Mexia memb.*—Dark, thinly laminated or compact fossiliferous clays, 50 to 75 ft. thick, of a fairly deep-water marine facies, with a thin glauconitic sand layer (*Venericardia bulla* zone) at base. [On p. 535 thickness of Mexia memb. is given as 215 ft.] Is lower memb. of Wills Point fm. Rests on Kincaid fm. and underlies Wortham aragonite lentil. Type loc. is clay pit at the brickyard in W. edge of Mexia, Limestone Co.

The U. S. Geol. Survey includes in Kerens memb. the 8 to 10-inch bed called *Wortham aragonite lentil* by Plummer. The Mexia as thus defined is overlain by Kerens memb.

Mexican sandstone.

Lower Cretaceous: Southeastern Arizona.

C. [R.] Keyes, 1935 (Pan-Am. Geol., vol. 64, No. 2, pp. 129, 138, 139). *Mexican ss.*—Medial ss. of Cinturan section (Cintura fm. of Ransome) in SE. Ariz. Underlies Dixie sh. and overlies Forrest sh. Thickness fully 500 ft. Named for Mexican gulch, E. of Bisbee. Was formerly thought to be W. extension of Muleros ss. of El Paso section, but of this there is now considerable doubt.

Mexico sandstone member.

Middle Devonian (Marcellus): Central Pennsylvania (Juniata County).

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, Proc. Pal. Soc. Feb. 28, pp. 202–203). *Mexico ss. memb.*—Fine ss., light gray to whitish, platy; bedded surfaces weather brown. Underlies Mahanoy black-sh. memb. and overlies Turkey Ridge ss. memb., all belonging to Marcellus fm. Usually barren. Well exposed in hill E. of Mexico, Juniata Co., also at Blue Springs, SW. of Mexico. Max. thickness 275 ft., in McCoysville section. Thins out in W. part of Juniata Co. Is 100 ft. thick to E., through Dalmatia, then disappears.

Meyer oil zone.

Name applied to the lower oil horizons (consisting of 850 or 860 ft. of Tert. brown sh. and sandy brown sh.) in Santa Fe Springs field, Los Angeles Co., Calif. Contains three distinct oil horizons. Is capped by Bell oil zone.

Meyersdale red shale. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties) and northern West Virginia; also Somerset County, southern Pennsylvania.

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 574). *Meyersdale red sh.*—Underlies Thomas coal and overlies Buffalo ss.; all included in Conemaugh fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 59, 98, pl. 6), shows *Meyersdale red bed* as everywhere lying a short distance below Lower Bakerstown (Thomas) coal, and in some places resting on Buffalo ss. and in other places included in Buffalo ss. On p. 59 he states that it is deep red, soft, breaks in small fragments, and may form 2 benches, one above and one below Meyersdale ls. On p. 98: "The Meyersdale red beds occur at horizon of upper part of Buffalo ss., which they replace locally." Are finely exhibited in cut of Western Maryland Ry E. of Meyersdale, Pa.

Meyersdale limestone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 59, 95, 110). *Meyersdale ls.*—Thin impure marine ls., associated with Meyersdale red sh. in Lower Youghiogheny Basin. It may lie above, below, or within Meyersdale red sh. Thickness 1 ft. [In strat. chart, pl. 6, he calls the ls. in midst of Meyersdale red sh. in Lower Youghiogheny Basin the *Pine Creek ls. and fauna,* and does not show any Meyersdale ls.]

Miami oolite.

Pleistocene: Southern Florida.

S. Sanford, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 209, 211–214). *Miami oolite.*—Soft white oolitic ls., containing streaks or thin irregular layers of calcite separating less crystalline streaks. Breaks with irregular fracture. At Miami it is plainly stratified and cross bedded. Thickness probably 12 to 50 ft. Is of marine origin. Is perhaps younger than Palm Beach ls. and is younger than lower part of Key Largo ls. All exposures of oolitic ls. on mainland of SE. Fla. are included under designation *Miami oolite.*

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). *Miami oolite* as here defined includes all oolitic ls. of southern Fla., including that on the keys. It includes the "Key West" oolite and part of "Lostmans River ls.," the rest of the latter being a part of Caloosahatchee marl. The only difference btw. Miami oolite and "Key West" oolite is that the Miami contains a little more sand than the "Key West."

†Michigamme jasper.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Menominee district).

H. L. Smyth, 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 219–223). *Michigamme jasper.*—Greatly altered ferruginous rock apparently carrying fragmental quartz grains. Top memb. of Lower Menominee of Menominee dist. Overlies principal iron fm. [Negaunee fm.? or Traders memb.?], which consists of red, black, and green slates.

H. L. Smyth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 137). The Groveland fm. was originally named by me *Michigamme jasper*. The name Michigamme was subsequently used for one of the Upper Marquette fms. in prel. rept. on Marquette dist. (15th Ann. Rept. U. S. G. S.), distributed in 1896. I now abandon the old name, although it is entitled to stand by rules of priority, in order to avoid confusion which would necessarily arise from its retention. It outcrops in vicinity of Michigamme Mtn, in sec. 33, T. 44 N., R. 31 W., and sec. 3, T. 43 N., R. 31 W.

Michigamme slate.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Upper Peninsula) and northeastern Wisconsin (Florence district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., p. 598). *Michigamme fm.*—Sl. and mica schist, 1,000 to 2,000 ft. thick. Top fm. of Upper Marquette series in Marquette dist. Overlies Ishpeming fm. [Ishpeming fm. was later divided into Bijiki schist above and Goodrich qtzite below and was discarded.]

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52), treated the Vulcan rocks of Crystal Falls dist. as a memb. of Michigamme sl., and Bijiki schist of Swanzy dist. as a memb. of the Michigamme.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), showed Michigamme sl. as overlying Clarksburg volcanics in Marquette dist. and overlying Quinnesec greenstone in Menominee dist.; called the included iron-fm. the *Bijiki iron-fm. memb.* in Marquette dist. and *Iron River iron-fm. memb.* in Iron River, Florence, and Crystal Falls dists.; transferred Vulcan iron-fm. to middle Huronian; and placed Goodrich qtzite as older than Greenwood iron-fm., which underlies Clarksburg volcanics, according to present interpretation.

Named for exposures on islands of Lake Michigamme, Marquette dist.

Michigan formation.

Mississippian: Michigan (Southern Peninsula).

W. H. Taylor, chairman, 1839 (Mich. Geol. Surv. Rept. State Geol. in re improvement of State salt springs, Mich. Leg. H. R. Doc. 2, p. 3). *Michigan salt group*, "so called by Prof. Winchell, see rept of last geological survey by Prof. A. Winchell." [Where?]

A. Winchell, 1861 (Mich. Geol. Surv. 1st Bien. Rept. Prog., pp. 91, 139). *Michigan salt group.*—Consists of (descending): (1) Carbonaceous and argill. sh., gypseous and pyritous marls; (2) shales, marl, mag. and siliceous lss., and thick beds of gyp.; (3) saliferous shales and alternating lss. Thickness 184 ft. Underlies the Carbf. ls. [Bayport ls.] and overlies Napoleon group, which may properly constitute upper part of Marshall group.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2, pp. 1–31). Lower part of Grand Rapids group was called *Michigan salt group* by Winchell.

A. C. Lane, 1900 (Mich. Geol. Surv. vol. 7, pt. 2, btw. pp. 1 and 30). *Michigan series.*—Consists of (descending): (1) Light-gray sh. with gyp. and pyrite, salty bluish shales, argill. hydraulic lss.; (2) blue to black micaceous shales; (3) ls. at Oak Point. Thickness 232 ft. Underlies Bayport ls. and overlies Napoleon ss. or Upper Marshall.

Michigan conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name in local use many years. According to B. S. Butler the cgl. may be same as Kearsarge cgl. of Central Mine group, or may be same as Bohemia cgl. (No. 8), top fm. of Bohemian Range group. Named for occurrence in old Michigan mine, in Ontonagon Co.

†Michigan period.

Term proposed by M. E. Wadsworth (Mich. Geol. Surv. Rept. 1891 and 1892, pp. 63–66, 1893) to cover Negaunee [middle Huronian] and †Holyoke [upper Huronian] fms. of the Huronian of Mich.

Michigan "salt group."

Same as *Michigan fm.*, which does not contain salt.

Michigan "series."

See *Michigan fm.*

Michipicoten schists.

Age (?): Ontario.

J. M. Bell, 1905 (Ont. Bur. Mines Rept. 1905, vol. 14, pt. 1, p. 300).

Mictaw series.

Middle and Upper Ordovician: Quebec (Gaspé Peninsula).

W. A. Parks, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 788). *Mictaw*, Ordovician, Quebec.

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, pp. 270–271). The newly named *Mictaw series*, of black shales and tuffaceous graywackes, the age of which has been for first time determined to be late Trenton-early Eden, overlies Maquereau series (probably earliest Ord.) and uncon. underlies Chaleur series (middle Sil.).

†Middendorf formation.

Upper Cretaceous: Coastal Plain of South Carolina and of Georgia east of Flint River.

E. Sloan, 1904 (S. C. Geol. Surv., ser. 4, Bull. 1, pp. 68, 72, 75–81). *Middendorf*—white sands (25 ft.), bed of dense white and drab kaolin with waxy luster (fossiliferous),—harsh sands; varicolored cross-bedded fine-grained sands; thin seams of colored clay interlaminated with sands; gravel. Uncon. overlies Hamburg beds. Thickness at Aiken, S. C., 93 ft. [Detailed section given.]

E. Sloan, 1907 (Summary of mineral resources of S. C., pp. 12, 13, 14). *Middendorf clays, etc.*, underlie Black Creek sh. and overlie Upper Hamburg clays. Consist of white sands (25 ft.), bed of dense white and drab kaolin with waxy luster (fossiliferous); harsh sands, varicolored cross-bedded fine-grained sands; thin seams of colored clay interlaminated with sands; gravel. The Lower Hamburg and Upper Hamburg and the Middendorf phases comprise sands, clays, and arkose which are exposed in upper three-fourths of Aiken Co., S. C., in greater part of Lexington Co., in lower part of Richland Co., in body of Kershaw Co., in lower part of Lancaster Co., and in northerly part of Chesterfield Co., S. C.

Later, for several years the †Middendorf deposits (100 to 200 ft. thick) were included in Black Creek fm., as its basal memb., under the name *Middendorf arkose memb.* (See additional explanation under *Black Creek fm.*) Still later they were treated as a distinct fm. uncon. below Black Creek fm. and uncon. above the crystalline rocks, the Hamburg clays of western S. C. having been found to be same as Middendorf deposits of eastern S. C. Still later the Middendorf and Hamburg deposits were proved to be same as Tuscaloosa fm., and both *Middendorf* and *Hamburg* were abandoned. (See C. W. Cooke, U. S. G. S. Bull. 867, 1936. Cooke considers it possible that further work in S. C. and N. C. may result in differentiating some older deposits from those now called *Tuscaloosa fm.* in those States.)

Named for exposures near Middendorf, Chesterfield Co., S. C.

†Middle Barren Measures.

A term applied in some early repts to Conemaugh fm. exclusive of Mahoning ss. memb.

Middleboro clay.

Middleboro moraine.

Pleistocene: Southeastern Massachusetts (Plymouth County).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, p. 985). *Middleboro moraine*.—A tolerably well-defined moraine on E. side of town of Middleboro [Plymouth Co.]. The brick clays worked in 1895 about 1½ mi. NE. of Middleboro are clearly the outwash from the ice sheet at time the moraine was deposited. [*Middleboro clays* is used in heading.]

Middleborough member.

Carboniferous: Nova Scotia.

W. A. Bell, 1926 (Canada Geol. Surv. Summ. Rept. 1924, pt. C, p. 159).

Middle Bridge formation.

Carboniferous (Pennsylvanian?): Nova Scotia (Cape Breton Island).

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 323).

Middleburg limestone. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., pp. 20, 25). *Middleburg ls.*—New name for middle part of Easly Creek sh. of Condra, 1927. Thickness btw. 4 and 9 ft., increasing southward to vicinity of Hooser and Dexter, Kans. Type loc. on Easly Creek, 1½ mi. S. of Middleburg School, in E.¼ of sec. 36, T. 1 N., R. 13 E., in SW. part of Richardson Co., Nebr., where it consists of (descending): (1) Gray ls., massive, granular, dense, weathers buff-gray, 1'4"; (2) ls., variegated light to dark gray, massive, tough, with many small dark-colored high-spired gastropods, 1'6"; (3) olive sh., 6" to 1 ft.; (4) ls., dark gray, blocky, dense, 2" to 3". Underlies Easly Creek sh. restricted and overlies Hooser sh.

G. E. Condra, 1935. (See under *Bader ls.*)

Middlebury moraine.

Pleistocene (Wisconsin stage): Northeastern Indiana. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Middlebury, Elkhart Co.

Middle Cambrian series.

Same as *Acadian series.* (See U. S. G. S. Bull. 769.)

Middle Creek limestone.

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 90, 97). [See under *Swope fm.*] Named by Newell.

J. M. Jewett, 1932 (pp. 99, 101, 103 of book cited above). *Middle Creek ls.* will be proposed by Newell to designate a persistent bed of bluish-gray ls. which he has traced from Kansas City to southern Linn Co. line and has been traced by writer from Linn Co. line to where it pinches out near Erie, Neosho Co. Thickness varies up to 5 ft. Underlies Hushpuckney sh. and overlies Elm Branch sh., all members of Swope fm. [Derivation of name not stated.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 26–27). *Middle Creek ls.*—Lowest memb. of Swope ls. Very uniform throughout Kans. and Mo. Named for exposures on E. side of Middle Creek at highway 3 mi. E. of LaCygne, Linn Co., Kans. In Miami Co. generally consists of 2 even layers of dark bluish gray, dense, and brittle ls., only locally separated by sh. Thickness 1' 4" to 2' 3". Underlies Hushpuckney sh. memb. and overlies Ladore sh. [restricted].

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 82–83). [See 1936 entry under *Ladore sh.*]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Middle Devonian series.

The commonly accepted definition includes Hamilton group, Onondaga ls., and Schoharie grit, and their time equivalents. Based on fossil content.

Middlefield granite.

Late Carboniferous or post-Carboniferous: Western Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pl. 34). [*Middlefield granitite* in folio; *Middlefield granite* on pl. 34.] Porphyritic muscovite biotite epidote granite. [A small N.-S. mass in Middlefield Twp, W. part of Hampshire Co. See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 258–259, map, and correlation chart).]

†Middle Freeport limestone.

See under *Freeport ls. memb.*, F. Platt, 1877. Same as *Lower Freeport ls.*

Middle Kittanning clay. (In Allegheny formation.)

A clay bed, 3 to 15 ft. thick, underlying Middle Kittanning coal, in western Pa.

†Middle Mahoning sandstone. (In Conemaugh formation.)

A name applied by W. G. Platt (2d Pa. Geol. Surv. Rept. H4, 1878) to 15 ft. of ss. in Indiana Co., Pa., overlying Philson coal and separated from an overlying 20- to 50-foot ss. (identified by him as "Upper Mahoning ss.") by 10 ft. of thin ss. and sh. The "Upper Mahoning ss." of this rept appears to be Buffalo ss. and the "Middle Mahoning ss." appears to be "Upper Mahoning" of other repts.

†Middle Mercer shales. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Middle (Mercer) shales* underlie Upper Connoquenessing ss. [?] and overlie Quakertown coal. Included in Connoquenessing ss.

Middle Ordovician series.

The commonly accepted definition includes Trenton and Black River groups and their time equivalents. *Mohawkian series* is used provincially for these rocks.

Middle Park formation.

Upper Cretaceous and Eocene (?): Middle Park, Colorado.

W. B. Clark, 1891 (U. S. G. S. Bull. 83, p. 137). *Middle Park beds* in many particulars similar to Denver fm. Upper part consists of sandy shales, sss., and grits chiefly of granitic origin; contains lignitic material and many fossil leaves. Lower part consists of 800 to 900 ft. of andesitic breccias and cgls. with interstratified sands bearing fossil plants; contains seams of lignitic material and many fossil leaves. Rests uncon. on Cret.

W. Cross, 1893 (Colo. Sci. Soc. Proc., vol. 4, pp. 192–214), gave thickness of Middle Park fm. as 5,500 ft. and correlated it with Denver fm. "Was called Laramie or 'Lignitic' fm. by Marvine," but it is of post-Laramie age.

F. H. Knowlton, 1930 (U. S. G. S. P. P. 155, pp. 5–6). Fossil plants from *Middle Park fm.* correlate it with Denver fm.

The age of Denver fm. was in 1935 changed from *Eocene* to *Cret. and Eo. (?)*.

Middle Park formation.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group*. Derivation of name not stated.]

F. MacMurphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July-Oct., 1932, pp. 329–356). *Middle Park fm.*—Fine-textured dark-gray quartz-biotite schist, spotted schist, green ottrelite schist, and dark-gray impure metamorphosed qtzitic rocks, 300± ft. thick, conformably overlying Sour Dough ls. and discon. (?) underlying Mountain Girl cgl.-qtzite—all fms. of Telescope group (lower Paleozoic?). [Probably named for Middle Park Canyon, shown on his map of S. part of Panamint Range.]

Middle River formation.

Carboniferous: Nova Scotia.

W. A. Bell, 1925 (Canadian Inst. Min. and Met. Bull. 158, p. 618).

Middlesex shale.

Upper Devonian: Western and west-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 23 and chart). *Middlesex black sh.*, basal part of Naples beds in Ontario Co. Overlain by Cashaqua sh. and rests on Genesee sh. Is "Lower black band" of repts. [See also N. Y. State Mus. Mem. 6, 1904.]

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1000–1029). *Middlesex black sh.*, 32 ft. thick in gorge of Genesee River; 6 to 10 ft. in Lake Erie section. Above this horizon there is no recurrence of Genesee fauna. The bottom of the passage beds [described as shales 3 ft. thick] immediately below the black band is therefore taken as base of Portage fm., and the stratum of black shales above has been designated by State paleontologist *Middlesex shales.* Overlain by Cashaqua sh. The passage shales rest on Genesee sh.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63). *Middlesex black sh.* consists of very black sh. somewhat slaty, with thin aren. gray flags in upper and lower portions. The affinity of the meager fauna with that of Cashaqua shales is evident. Basal fm. of Portage.

J. M. Clarke and D. D. Luther, 1908 (N. Y. State Mus. Bull. 118). In early repts *Middlesex black sh.* was considered upper part of Genesee black sl. In 1885 (U. S. G. S. Bull. 16) Clarke separated it from Genesee sl. and called it "Lower black band" of Portage group. Named for abundant exposures in town of Middlesex [and in Middlesex Valley, Yates Co.], from which locality it is continuous westward to Lake Erie, maintaining its general characteristics but diminishing in thickness to 6 ft.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), included Middlesex in Portage group.

G. H. Chadwick, 1920 (Geol. Soc. Am. Bull., vol. 31, No. 1, p. 118), 1923 (idem, vol. 34, p. 69), 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 96–100, 193), and 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 857–862) included Middlesex sh. in his Naples group (=Portage).

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10. p. 369), included Middlesex sh. and underlying West River sh. and Genundewa ls. in Portage group, restricting Genesee to the basal black sh. (Geneseo of Chadwick).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, pp. 201–202), included Middlesex in the Genesee.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), included *Middlesex sh.* in his Naples group.

The U. S. Geol. Survey treats *Middlesex sh.* as a fm. underlying Cashaqua sh. and overlying Genesee group (the top fm. of which in south-central N. Y. is Standish flagstone).

†Middleton formation.

Eocene (lower): Western Tennessee, Mississippi, and southern Alabama.

J. M. Safford, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 511–512; Am. Geol., vol. 9, pp. 63–64). The "clay ss." division No. 2 of section on p. 112 of Hilgard's "Agriculture and Geology of Miss." is same as the rock in Hardeman Co., Tenn., which for years I have spoken of as *Middleton bed,* and according to Dr. E. A. Smith the same fm. occurs in Ala. The particular and characteristic rock referred to is rarely more than 3 ft. thick, but it has associated with it a group of layers of much greater thickness. The group has importance in fact that it is lowest Eocene in Tenn., Miss., and Ala. With concurrence of Dr. Hilgard and Dr. Smith I propose for it the name *Middleton fm.* Immediately to E. of the fm. in Tenn. lie the Cret. (Ripley) beds, while to W. are the Flatwoods (Porter's Creek) clays. [As thus defined applies to Clayton fm. of present nomenclature, and apparently was included in Ripley fm. of Safford's previous repts.]

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 158, 159). *Middleton fm.*—Laminated sands and clays, 400 to 500 ft. thick. Basal Eocene. Is=Clayton, Porter's Creek, Midway, Flatwoods, Ripley in part. Underlies La Grange. Overlies 400 ft. of beds much like Coffee sand, which may prove to belong to Middleton but which are called Ripley (?). These Ripley (?) beds [true Ripley] overlie McNairy Shell bed [Selma chalk]. [As thus defined is essentially=Midway group.]

G. D. Harris, 1896 (Bulls. Am. Pal., vol. 1, pp. 18–22), established the Midway age of Porters Creek clay and Middleton fm., and latter name has been discontinued.

Named for exposures at and near Middleton, Hardeman Co., Tenn.

Middletown gneiss.

Carboniferous (?): Central southern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 143, and map). Between Bolton schist and Haddam gneiss is an irregular band of rock which should be separated petrographically from Haddam granite gneiss, which it almost surrounds. This is *Middletown gneiss.* It consists of a variety of rocks.

One general characteristic is presence of hornblende in small grains or, more usually, in long prisms or stellar aggregates of prisms. Many of the rocks possess granulitic structure. The dominant type is hornblende gneiss thoroughly injected with amphibolite and granitic seams and lenses. Where least injected with granite and amphibolite the rock is a fine-grained light-gray to greenish thin-bedded gneiss. It seems probable this heterogeneous group of rock types represents the contact zone btw. Haddam granite gneiss and surrounding fms. Crosses SE. part of Middletown Twp.

Middletown clay.

Name applied by R. F. Flint (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 965-987, 1933) to a late Pleist. clay that underlies parts of northern Middletown Twp, Conn.

Middle Washington limestone member (of Washington formation).

Permian: Southwestern Pennsylvania.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Middle Washington ls.*—Thickness 15 ft. Included in Washington County group [Washington fm.]. Lies 40 ft. below Jollytown coal and about 89 ft. above Lower Washington ls.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 35). *Middle Washington ls.*—Buffish ls., persistent; 3 to 20 ft. thick. Occurs in interval btw. Upper Washington ls. and Washington "A" coal.

Midland sand.

Pleistocene (Wisconsin): Western Washington (Puget Sound region).

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54). *Midland sands.*—Delta deposits of sands and sandy loams with occasional deposits of diatomaceous earth. Since these several deltas are scattered over a large area they must represent deposition at different stages in the glacial retreat, yet they all belong to same epoch and have resulted from similar conditions. Village of Midland is located on western area of these sands.

†Midway series. } (Narrow sense.)
†Midway limestone. }

Eocene (lower): Southern Alabama.

E. A. Smith, 1886 (Ala. Geol. Surv. Bull. 1, p. 14). *Midway or Pine Barren section.*—Thickness 25 ft. [Same description as in 1887 rept below.]

T. H. Aldrich, 1886 (Ala. Geol. Surv. Bull. 1, p. 60). *Midway group.*—A few ft. of material at base of Tert.; a bed containing a species of *Turritella* being immediately contiguous to the Cret. [Lists fossils from "1st Midway bed, consisting of a hard siliceous ls.," and "2d Turritella Rock."]

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 62-68, 70). *Midway series.*—Thickness 25 ft. White, argill. ls. holding a large nautilus, which is characteristic of the horizon, 10 ft.; calc. sands and a yellowish crystalline ls. with Turritellas, Carditas, and corals, the sands 6 ft. thick, the ls. 8 or 9 ft. thick. This section is best seen in eastern Wilcox Co., on Pine Barren Creek, but upper or Nautilus rock occurs at Midway, on Alabama River, and westward across Marengo Co. Overlies Cret. Ripley fm. and underlies Black Bluff series [Sucarnoochee clay].

These original uses apply *Midway* to basal fm. of Midway group of modern usage, or to the rocks now known as *Clayton fm.* This restricted application of name continued until 1892, when E. A. Smith (Sketch of geol. of Ala., Roberts and Son, Birmingham, Ala., pam. of 36 pp.) introduced *Clayton or Rutledge ls.* "for the impure ls. formerly known as Midway group," 200 ft. thick on Chattahoochee River, but thin to W., and underlying Sucarnoochee clay and overlying Ripley fm. The detailed paleontologic studies of G. D. Harris led, in 1894, to the broader use of *Midway* explained under *Midway group* (*broad sense*).

Named for exposures at Midway Landing and plantation, on W. side of Alabama River (about 5 mi. below Prairie Bluff), in Wilcox Co., Ala.

Midway formation } (Broad sense.)
Midway group.

Eocene (lower): Western Georgia to southern Texas, Arkansas, western Tennessee and Kentucky, southeastern Missouri, and southwestern Illinois.

G. D. Harris, 1894 and 1896 (Am. Jour. Sci., 3d, vol. 47, pp. 303–304, 1894; Bulls. Am. Pal. vol. 1, No. 4, pp. 10–38, 1896). *Midway stage.*—Basal Eocene. Includes Matthew's Landing marl (substage), Black Bluff clays (substage), and Midway clay and ls. (substage). Is a strat. and paleontologic unit.

The foregoing double use of *Midway* was employed in several subsequent publications by different authors, but since 1906 the name has been universally used in Harris's broad or group sense, the name *Clayton* being employed to designate the basal fm. of the group. In present usage the Midway is a group in Ala., Miss., SW. Tenn., and eastern Tex., divided into (descending) the following fms., all of marine origin:

Ala.	*Miss. and SW. Tenn.*	*Tex.*
Nāheola fm. [†Matthews Landing.]		Wills Point fm.
Sucarnoochee (Porters Creek) clay.	Porters Creek clay.	[restricted].
[†Black Bluff clays.]		Kincaid fm.
Clayton fm. [†Midway clay and ls.]	Clayton fm.	

It underlies Wilcox group and overlies the Cret. The Porters Creek clay of Midway group extends into western Ky., SE. Mo., and SW. Ills. In NE. La., NW. La., SE. Ark., SW. Ark., and parts of eastern Tex. the Midway deposits are called *Midway fm.*

Named for exposures at Midway Landing and plantation, on W. side of Alabama River (about 5 mi. below Prairie Bluff), in Wilcox Co., Ala.

†Midway andesite.

Tertiary: Central Nevada (Tonopah district).

J. E. Spurr, 1911 (Min. and Sci. Press, vol. 102, pp. 560–561; also "Rept on geol. of property of Montana-Tonopah Mining Co., Tonopah, Nev.," published privately), applied *Midway andesite* to the "Later andesite" of his 1905 rept on Tonopah dist., Nev. (U. S. G. S. P. P. 42). Thickness 0 to 500 ft. Named for Midway mine.

T. B. Nolan, August 1, 1930 (Univ. Nev. Bull., vol. 24, No. 4, pp. 16, 21). So far as writer's observations in mines of W. part of Tonopah dist. show, the rocks assigned to "Midway andesite" or "later andesite" by Spurr and J. A. Burgess cannot be separated from Mizpah trachyte by reason of any original differences in composition or texture, nor has he seen any examples of this rock capping any of the veins, or found in the literature references to any specific example of it (p. 16). All examples of "Midway andesite" cappings of veins that were seen by writer proved to be basal part of Fraction breccia.

C. V. Averill, Nov. 24, 1930 (Eng. and Min. Jour., vol. 130, No. 10, p. 532). [Refers to Nolan's rept.] I think the Midway andesite actually exists; but there has been endless confusion btw. it and Mizpah trachyte. The Midway andesite probably does not reach depths of more than a few hundred ft. in W. part of Tonopah dist. There was a flow of andesite (Midway andesite) of much later age than Mizpah trachyte, and it contains pebbles of the Mizpah. It is of purplish color, and is nearly fresh, solid, unbrecciated andesite.

T. B. Nolan, 1935 (Univ. Nev. Bull., vol. 29, No. 5, p. 20). All exposures of supposed "Midway andesite" that were accessible at time of this survey have yielded convincing evidence that the rock is identical with Mizpah trachyte. Averill, however, has recorded occurrence of an andesitic rock overlying Mizpah trachyte which he considers to represent uncon. overlap of "Midway andesite." This exposure was not seen by writer, but it may well be that at shallow depths in certain parts of Tonopah dist. there is an overlying flow, related to post-Esmeralda andesites or latites of Divide dist., although it is most improbable this rock is of any great extent or of econ. importance in productive part of Tonopah dist.

Midway volcanic group.

Miocene and Oligocene: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 10, 118°30′ to 119°). *Midway volcanic group.*—Lower part, Olig. andesites and basalt, flows and pyroclastic deposits; upper part, Mio. (?) trachyte and analcitic rhomb porphyry, flows and pyroclastic deposits.

C. W. Drysdale, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 136). *Midway volcanic group* assigned to Mio.

O. E. Le Roy, 1912 (Canada Geol. Surv. Mem. 21, p. 44).

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 398). *Midway volcanic group*, Mio. and Olig. Covers area about town of Midway, B. C., near Int. Bdy.

Midwayan.

Term used by some authors to cover the time of deposition of Midway group.

Mier sandstone member (of Yegua formation).

Eocene (middle): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1374, 1384). Basal 114 ft. of Yegua fm. of this region is characterized by a series of gray and red clay shales with a very heavy oyster bed (*Ostrea georgiana*) beneath a prominent bench-forming massive soft gray ss., 125 ft. thick, which is referred to in this rept as *Mier ss.* A typical exposure of this ss. can be seen in town of Ciudad Mier, Tamaulipas. Immediately above Mier ss. is a similar series of beds, 58 ft. thick, with almost identical sequence of gray and red clay shales, overlain by a heavy bed of oysters (28 ft.), and this in turn by another massive coarse-grained ridge-forming ss., 100 ft. thick, which is referred to in this rept as *Alamo ss.* A typical exposure of latter ss. can be seen along E. bank of Rio Alamo downstream from Ciudad Mier. Both of these sss. have been traced more than 50 mi. in Mexico and brought up to Rio Grande and traced into Tex. as far as Arroyo Tigre, in Zapata Co. The Alamo ss. lies 132 ft. below Alberca ss. and 86 ft. above Mier ss.

Miette formation.

Pre-Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll. vol. 57, No. 12, pp. 335, 340). *Miette sss.*, pre-Camb., B. C. and Alberta.

C. D. Walcott, 1915 (Problems Am. Geol., p. 179). *Miette fm.*, pre-Camb., Alberta.

C. D. Walcott, 1928 (Smithsonian Misc. Coll. vol. 75, p. 258). *Miette fm.*, Algonkian (Belt series), B. C.

Mifflintown limestone.

Silurian: Central Pennsylvania.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, pp. xxv–xxvi). *Mifflintown ls.*—Near bottom of upper red sh. memb. of Clinton fm. lie 6 ft. of hard calc. ss. layers, each 2, 3, or 4 inches thick, separated by very thin layers of calc. ss. mottled with red. This peculiar group is recognizable at distant localities and sometimes becomes a ls., as near Mifflintown [Juniata Co.], on W. bank of Juniata River, where some beds of very hard comparatively pure ls. 3 or 4 ft. thick crop out.

Miguel formation.

Upper Cretaceous: Southwestern New Mexico (Alamosa Creek Valley, Socorro County).

D. E. Winchester, 1920 (U. S. G. S. Bull. 716A). *Miguel fm.*—Yellow sss., massive and persistent, also soft sss., drab and yellow sandy shales, a few beds of clay, and several beds of coal in upper half. Abundant invertebrate fossils and a few plant remains. Contains 4 persistent massive yellow ss. members, 2 of which are here named, *Bell Mtn ss. memb.* being applied to the one at top and *Gallego ss. memb.* to the one near middle. The 2 lower sss. may represent Tres Hermanos ss. memb. of Lee. Thickness 2,080 ft. Underlies Chamiso fm. and overlies Dakota ss. Named for Miguel Creek, which crosses the beds in NW. part of area (Alamosa Creek Valley). Benton fauna abundant. Is not exactly=Mancos sh., hence local name.

Milams member (of Cook Mountain formation).

Eocene (middle): Eastern Texas (Angelina and Sabine Counties) and northwestern Louisiana.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Milams memb. of Claiborne fm.*—Name proposed for that memb. of the Claiborne occurring below Saline Bayou memb. and above Crockett memb. Type loc. is in NE¼ sec. 17, T. 13, R. 3 W., Winn Parish, La., which is ½ to ¾ mi. SW. of Milams, on Ark. Southern Ry. The section is (descending): (1) Red clay, weathering orange, 6 ft.; (2) gray plastic calc., fossiliferous, somewhat glauconitic clay with many corals, weathers dull orange red, with a few small lime nodules, 6 ft.; (3) gray calc., very glauconitic fossiliferous clay, weathering orange red, with numerous small calc. nodules, 10 ft.; (4) zone of calc. glauconitic concretions with fossil casts, 6 in.; (5) dark yellowish-gray, very glauconitic plastic fossiliferous clay, 3 ft.; (6) badly weathered orange-red, very glauconitic fossiliferous clay, 3 ft.; (6) badly weathered orange-red, very glauconitic fossiliferous sandy clay, many oysters, 10 ft., the upper 4 ft. very ferruginous and indurated.

Milan loam.

Pleistocene: Northwestern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 163). *Milan loam.*—Mellow clay, without laminar structure, of light-yellow or pale-reddish color, containing more or less fine sand. Thickness few in. to 15 ft., averaging 3± ft. Covers very generally the sands of the Lafayette and is basis of best subsoils and soils of upland parts of many counties in W. Tenn.

Named for Milan, Gibson Co.

Milburn shale. (In Canyon group.)

Pennsylvanian: Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvi). *Milburn-Strawn series.*—Alternating clays and shales and thin-bedded lss., with fire clay and coal, overlying Richland-Gordon sss. and underlying Brownwood-Ranger series.

R. S. Tarr, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 205–206). *Milburn shales.*—Shaly ss., argill. sh., clay, with some gyp. and coal, overlying Richland ss. and underlying Brownwood div. Thickness 100 to 150 (?) ft.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 98). *Milburn div.* as originally defined by Tarr consists of local impure deposits which are now included with Brownwood div. At close of preceding Richland subepoch, as shown by clays of Milburn beds, there was slight subsidence of sea floor, so that deeper sea deposits were laid down.

C. H. Gordon, 1911 (Jour. Geol., vol. 19, p. 117). *Brownwood div.* now includes Brownwood and Milburn of Tarr, and is=Canyon div.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, p. 13). Brownwood and Milburn of Tarr=Canyon group.

Named for Milburn, McCulloch Co.

Miles limestone member.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 5, 9). *Miles ls.*—Basal memb. of Falls City ls. fm. Is blue gray; locally weathers brownish and porous; 1+ ft. thick. Underlies Reserve sh. memb. and overlies Hawxby sh. fm. Type loc. in high hill W. of Miles ranch, 2± mi. SW. of Falls City [Richardson Co., Nebr.].

Milesburg formation.

Lower Devonian: Central Pennsylvania (Blair County).

C. Schuchert, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 552). *Milesburg fm. or Lower Oriskany.*—Thickness 130 ft. in Tyrone Gap, Bald Eagle Mtn. Consists of thin-bedded siliceous lss., of dark-blue to black color, underlain by black siliceous shales. Is=Shriver fm. of Md. Uncon. overlies Keyser fm. or Lower Helderbergian, and is overlain by Oriskany [Ridgeley] ss.

The U. S. Geol. Survey now uses *Oriskany group* in Blair Co., Pa., to include Ridgeley ss. above and Shriver ls. below.

†Milford chlorite schist.

Pre-Cambrian: Central and western Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, p. 100, and map). *Milford chlorite schist.*—Prevailing rock is greenish chlorite schist, varying in thickness and hardness. In places evenly foliated; elsewhere highly contorted. Quartz is important constituent and occurs in seams, lenses, and veins, and also distributed in minute particles throughout the schist. Small bands of impure serpentine occur at several localities. In places the rock is massive, with the schistose structure hardly at all developed, and consists largely of hornblende and feldspar. Occasionally this more massive variety is porphyritic from presence of crystals of labradorite. Believed to have been originally a diorite or similar basic igneous rock with intrusions in form of dikes. [Mapped over large area in Milford Twp.]

In 1909 (U. S. G. S. W. S. P. 232) Gregory assigned this schist to pre-Camb. Conflicts with *Milford granite*, a name of considerable commercial importance, which cannot be as easily replaced as the name for this schist.

Milford granite.

Devonian (?): Eastern Massachusetts and northeastern Rhode Island.

B. K. Emerson and J. H. Perry, 1907 (U. S. G. S. Bull. 311, pp. 26–33, 45–47, 66, and map). *Milford granite.*—Compact, massive rock, somewhat above medium grain, and of light color. Its two especially characteristic constituents constantly present are blue quartz and a microcline microperthite. Forms a great granite batholith that extends across Mass. and R. I. Is of post-Camb. and pre-Carbf. age Named for well-known quarries in Milford, Mass.

See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597), when **Milford granite** was assigned to Dev. (?).

Milford group.

Carboniferous and Triassic: British Columbia.

M. F. Bancroft, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 43), and J. F. Walker and M. F. Bancroft, 1929 (Canada Geol. Surv. Mem. 161, p. 12).

†Miliolitic limestone.

A name, of paleontologic derivation, applied in some early repts to Ocala ls. Based upon presence of miliolitic fossils.

Milk River sandstone.

Upper Cretaceous: Southern Alberta, Canada.

D. B. Dowling, 1917 (Canada Geol. Surv. Mem. 93, p. 47). *Milk River ss.*—Shales, sss., and coal beds, underlying Pakowki fm. (Claggett sh.) and overlying Colorado sh. in southern Alberta. Upper part consists of a series of green shales, carbonaceous shales, thin coal seams, and thin sss., overlain in places by a thick cross-bedded ss. capped by a black-chert pebble bed 1 to 6 in. thick. Lower part is composed of Virgelle ss. memb.

Is considered same as Eagle ss. of Mont.

Millbury ls.

Late Carboniferous or post-Carboniferous: Eastern Massachusetts (Worcester County).

B. K. Emerson and J. H. Perry, 1903 (Geol. of Worcester, with map). *Millbury ls.* is a narrow band or thin layer in Bolton gneiss. Occurs at Millbury, Worcester Co.

Mill Creek limestone.

Pennsylvanian: Northeastern Pennsylvania (Luzerne County).

C. A. Ashburner, 1886 (2d Pa. Geol. Surv. Ann. Rept. 1885, pp. 443+). *Mill Creek ls.*—Siliceous, ferruginous, and extremely hard ls., 12 to 15 inches thick. Very fossiliferous. Outcrops along N. side of Mill Creek, near Wilkes Barre, near breast of old Hallenback Dam, and about midway btw. River Street bridge and a bridge of Lehigh Valley R. R. which crosses the creek at its mouth. Lies 25 to 30 ft. higher than Canal ls. and 30 ft. below Joe Gibbs coal, the separating beds in both cases being ss.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 259). There can be little doubt that Mill Creek ls., near summit of Pa. anthracite coal series in Wilkesbarre basin, represents same geol. plane as Ames ls., since nearly every species described from it by A. Heilprin is found in Ames ls. [memb. of Conemaugh fm.] of vicinity of Morgantown, W. Va.

Mill Creek.

A plant-bearing series near base of Upper Cret. of Canada. (See J. W. Dawson, Roy. Soc. Canada Trans., vol. 3, 1886, sec. 4, p. 2.)

Mill Creek series.

Cretaceous: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 218).

Mill Creek moraine.

Pleistocene (Wisconsin stage): Northern Pennsylvania.

See U. S. G. S. Elkland-Tioga folio, No. 93, 1903. Begins at junction of Mill and Bailey Creeks, at E. edge of Tioga quad.

Mille Lacs moraine (also **morainic system**).

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154), and 1932 (U. S. G. S. P. P. 161, pp. 48–51). Named for Mille Lacs Lake, Aitkin Co.

Miller fire clay.

Pennsylvanian: Northern Missouri (Macon County).

H. A. Wheeler, 1893 (Mo. Geol. Surv. Sheet Rept. No. 2 (vol. 9), pp. 60–65). *Miller fire clay* underlies Lower Ardmore coal.

Named for Miller farm, 2½ mi. S. of Bevier, Macon Co.

Miller sand.

A subsurface sand in Empire pool, Stephens Co., southern Okla., lying at 1,500 ft. depth, the Nigh sand lying at 1,600 ft. and the Gas sand at 1,000 ft. According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 179, this sand is Perm.; according to Okla. Geol. Surv. Bull. 40E, 1926, it is Penn. The name has also been applied to a sand in Archer Co., Tex., that is considered to be same as Gose sand.

Miller limestone.

Mississippian: Nova Scotia.

W. A. Bell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 166).

Miller Peak formation.

Pre-Cambrian (Belt series): Central western Montana (Missouri to Helena region).

C. H. Clapp and C. F. Deiss, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 677–678, figs. 2, 3). *Miller Peak fm.*—On Miller Peak consists of (descending): (1) Purple massive to thin-bedded argillitic ss., some gray argillite, 235 ft.; (2) red and purple sandy argillite, with some thin beds of green and gray argillite intercalated with argillitic ss., 1,440 ft.; (3) pale green-gray argillitic ss., 85 ft.; (4) purple and green-gray sandy micaceous argillite weathering to rusty buff on joint faces, 590 ft.; (5) purple sandy thin-bedded mud-cracked siliceous argillite, with some beds of finely micaceous argillite and gray sandy argillite, 550 ft. Underlies (uncon.?) Hellgate fm. Type section is upper part of S. flank of Miller Peak, where it rests conformably on Wallace (Siyeh) ls. Is Lower Camp Creek series of Walcott.

Millers sandstone.

Devonian or Carboniferous: Northwestern Pennsylvania (Erie County).

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 457–464). [See definition under *Woodcock ss.*] Fossiliferous on Mill Creek below Dorset. Included in Bradfordian and also treated as memb. of Chagrin fm. [which U. S. Geol. Survey classifies as Upper Dev.].

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Millers ss. memb.* (*Venango 2d oil, "B"*) included in Cattaraugus fm., of Dev. age. [U. S. G. S. classifies Cattaraugus fm. as Dev. or Carbf.] Underlies Saegerstown sh. memb. and overlies North Warren sh. memb. [This is a restriction of Chadwick's Millers ss.]

Derivation of name not stated.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 89). *Millers ss.* of Chadwick is same as Pope Hollow cgl., Wrightsville cgl. of Warren Co., Pa., and Salamanca cgl. of Butts's Warren, Pa., folio, and of Glenn (N. Y. State Mus. Bull. 69, pp. 974–978, 1903). [Millers ss. of Chadwick included all beds btw. Saegerstown sh. and Amity sh., and would therefore be=Pope Hollow cgl., North Warren sh., and Bimber Run cgl. of Caster.]

Millersburg formation.

Pennsylvanian: Southwestern Indiana.

M. L. Fuller and G. H. Ashley, 1902 (U. S. G. S. Ditney folio, No. 84, p. 2). *Millersburg fm.*—Sss. and shales, 150 ft. thick, btw. base of Millersburg coal below and base of Somerville fm. above.

This name was dropped by Ind. Geol. Survey in 1922, the lowermost bed (Millersburg coal) being thrown into upper part of their redefined Petersburg fm., and the rest of the fm. into their overlying Shelburn fm. (new name). (See E. R. Cumings, Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, 1922.) Named for Millersburg, Elkhart Co.

Millersburg limestone member (of Cynthiana formation).

Middle Ordovician: Central Kentucky.

A. F. Foerste, 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, No. 4, p. 112). *Millersburg. ls. memb. or Orthorhynchula phase of Cynthiana fm.*—Richly fossiliferous argill., irregularly bedded lss., frequently weathering into irregular fragments called rubble, in basal part of Cynthiana fm. Base is formed by *Allonychia* horizon btw. Flanagan and Millersburg. Overlain by coarse-grained Nicholas ls. S. of Pleasant Valley and by coarse-grained ls. containing *Clitambonites* S. of Carlisle. The Greendale memb. as developed near Lexington is regarded as approx.=the much more richly fossiliferous Millersburg ls. farther E.

Named for Millersburg, Bourbon Co.

Miller's Cliff conglomerate.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 1489–1536). Sub-Olean cgl. is equiv. to *Miller's Cliff cgl.*, whose purely ss. character at Garland merely tells the common story of all pebble deposits. The *Miller's Cliff cgl.*, 20(?) ft. thick, consists of thin-bedded sss. It lies 200 ft. below Olean cgl. [Miller's Cliff is halfway btw. Lottsville and Wrightsville, Warren Co.]

†Millers River conglomerate.

Carboniferous: Northeastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 140, 156). *Millers River cgls.*—A broad exposure of cgl. beds underlying the red Wamsutta series in valley of Millers River, in Cumberland, R. I. In this gray series there are three or four thick beds of cgl. with small quartz and qtzite pebbles. Best exposed on farm of J. A. Miller, where thickness is unusually great, being 300 to 400 ft. Included in Pondville group.

Mapped as Pondville cgl. by B. K. Emerson, U. S. G. S. Bull 597, 1917.

Millersview limestone member (of Grape Creek formation).

Permian: Central Texas (Concho County).

W. Kramer, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1579, 1581). *Millersview ls memb.* is 2-foot gray bed lying 730 ft. above Coleman Junction ls. Crops out (in W ½ T. F. Benge survey No. 100) 4.5 mi. S.-SW. of Millersview on road having that bearing from the village. Has been traced across SE. part of Runnels Co. to point 4.5 mi. N. of SE. corner of that Co. As it is persistent ledge maker it is considered top memb. of Grape Creek fm.

Millerton formation.

Lower and middle Pleistocene: Western California (north of San Francisco Bay region).

R. E. Dickerson, 1922 (Calif. Acad. Sci. Proc., 4th ser., vol. 11, No. 19, with maps). *Millerton fm.*—Fossiliferous marine deposits, uncon. underlying Tomales fm. and overlying Merced group and its correlative the Sonoma group. Best strat. section seen (in headland 1½ mi. NW. of Millerton Station) consisted of (descending): (1) 23 ft. of carbonaceous tan-colored ss. and dark-gray sh.; (2) prominent cgl. 2 ft. thick; (3) 85 ft. of carbonaceous tan-colored ss. and dark-gray sh. with marine fossils in middle part; and (4) 50 to 65 ft. of cgl. at base.

Named for exposures in headland near Millerton Station, Marin Co.

Millerville green schist.

Post-Carboniferous (?): Eastern Alabama.

See under *Hillabee chlorite schist*, Smith 1896 entry. The 1926 geol. map of Ala. shows *Hillabee chlorite schist* at and around Millerville, Clay Co. Is intrusive.

Millett clay.

Southeastern California (Inyo County) and southwestern Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 61, 79). *Millett clays.*—Named for old Millett borax camp, in Furnace Canyon [E. of Death Valley, Inyo Co., Calif.], which was situated directly upon the principal borate-bearing beds, which appear to be Mio., and separated from higher clays of similar character by marked uncon. Thickness 1,000 ft. Uncon. below Negra clays and above Redhill sss. Top fm. of Furnacian series in Nev.

†Milliard limestone.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 79). "*Milliard lss.* is name suggested for Walcott's Cambric Dome ls. of House Range, Utah, which term is preoccupied by Hague." [There is no record of Hague having introduced the name *Dome*. Keyes applied *Milliard lss.* in Nev. section also. Walcott in 1912 replaced his *Dome ls.* with *Dome Canyon ls.*, the present approved name.]

Derivation of Milliard and type loc. not stated.

Millican formation.

Pre-Cambrian: Western Texas (Sierra Diablo region).

G. B. Richardson, 1914 (U. S. G. S. Van Horn folio, No. 194). *Millican fm.*—Fine-grained red ss., cherty ls., and cgl. Uncon. underlies Van Horn ss. and overlies (relations concealed) Carrizo fm.

Named for Millican's ranch, 10 mi. NW. of Van Horn.

Milligen formation.

Mississippian and Devonian (?): Southern central Idaho (Custer County).

L. G. Westgate and C. P. Ross, 1930 (U. S. G. S. Bull. 814, pp. 10, 24–29, map). The fine-grained argill. rocks that underlie Wood River fm. as here restricted are named *Milligen fm.*, from Milligen Creek, near center of largest exposure of fm. 6 mi. E. of Ketchum. Thickness several thousand ft.; at least 3,000. Included in Wood River fm. of Lindgren. Varies considerably in lithologic character, but most of it is black carbonaceous argillite; some beds are dominantly qtzitic and others calc. Some rocks are more or less distinctly laminated. In a few places beds of coal are intercalated in the argillite, and in places beds of qtzite, ls., and dolomitic ls. are intercalated. Also includes some beds of thick-bedded dark-blue impure dolomitic ls. as much as 4 or 5 ft. thick. Grades into overlying Wood River fm. restricted. Considered to be chiefly of Miss. age, but basal part may be Dev. Uncon. overlies Trail Creek fm., of Sil. age. Included in Wood River fm. of Lindgren.

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth) and 1934 (Geol. Soc. Am. Bull., vol. 45, No. 5, p. 967 and chart opp. p. 940). *Milligen fm. restricted* to lower 3,000± ft. of Milligen fm. as defined in 1930, above which lies 2,000+ ft. of Brazer (upper Miss.) ls. The Milligen in Custer, Bayhorse, and Sawtooth quads. consists of argillite, argill. qtzite, impure dolomitic beds, and locally beds of coarse grit to fine cgl. It overlies Grand View dol. (Upper Dev.).

Named for exposure on Milligen Creek, Hailey quad., 6 mi. E. of Ketchum.

Milliken sandstone member (of Fox Hills sandstone).

Upper Cretaceous: Northeastern Colorado (Larimer and Weld Counties).

J. Henderson, 1920 (Colo. Geol. Surv. Bull. 19). *Milliken ss. memb. of Fox Hills fm.*—Massive greenish-yellow concretionary ss., almost free from sh. except a few 1-in. bands in lower part. Contains many large brown concretions and bands, more or less ferruginous and calc. and usually highly fossiliferous. Cross bedded in places. Thickness 100 to 150 ft. Is upper massive ss. in Fox Hills of NE. Colo. Well exposed near Milliken Station, W. of La Salle [Weld Co.].

K. F. Mather, J. Gilluly, and R. G. Lusk, 1928 (U. S. G. S. Bull. 796B). *Milliken ss. memb.* is 39 to 63 ft. thick in NE. Colo., and lies at or near top of Fox Hills ss.

Millington moraine.

Pleistocene (Wisconsin stage): Eastern Michigan (Tuscola County). (See Mich. Geol. Surv. Rept. 1908, pp. 148–196.)

Million shale. (In Eden group.)

Upper Ordovician: Central Kentucky.

J. M. Nickles, 1905 (Ky. Geol. Surv. Bull. 5, p. 25). *Million shales.*—Name suggested by A. F. Foerste for all of Eden, including Utica sh. (Fulton layer of Foerste) at base, below Garrard ss. Underlain by Winchester group.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7), applied *Million bed* to 120 to 200 ft. of beds of Eden age, underlying Paint Lick bed and overlying Utica (Fulton layer), 0 to 3 ft. thick. This restricted definition of Million sh. was adopted by A. M. Miller in 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 651–657) and is the one recognized in later repts of Foerste and Miller.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull., vol. 17). That part of Eden below Paint Lick memb. was [in 1906 rept] grouped under term *Million* on account of its different faunal expression from that exhibited by the Eden at Cincinnati.

Named for Million, Madison Co.

Mill River conglomerate.

Upper Cambrian: Northwestern Vermont (Franklin County).

B. F. Howell, 1929 (16th Rept. Vt. State Geol., pp. 266–268). *Mill River cgl.*—New name, here proposed by writer, after consultation with Dr. Keith, for the conglomeratic ls. which overlies the Middle Camb. *Paradoxides* beds (St. Albans sh.) and underlies Highgate sh. (Upper Camb.). Its fauna has not been carefully studied but it is believed to be Upper Camb. Named for Mill River, just E. of which the fm. is exposed about 2 mi. SW. of St. Albans, ¼ mi. S. of road running W. from western foot of St. Albans Hill.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, p. 374), reported an abundant Upper Camb. fauna from some ls. layers in Mill River cgl., and stated that it rests uncon. on St. Albans sl.

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 359, 368, 370–371), reported reworked St. Albans (Middle Camb.) and Lower Camb. fossils in this cgl., which he called a basal cgl., assigned it to base of Upper Camb., correlated it with *typical* Milton dol., and introduced new name *Rugg Brook dol. cgl.* for the so-called Milton dol. of Keith, which underlies St. Albans sl. and uncon. overlies Parker sl. Thickness of his Rugg Brook cgl. 0 to 15 ft.

Mills moraine.

Pleistocene (Wisconsin stage): Northern central Colorado.

W. T. Lee, 1917 (Geologic story of Rocky Mtn Park, Colo., Nat. Park Service, Dept. Int., Wash., D. C., pl. 35).

Lee stated that he named the moraine for Amos Mills, who then owned Longs Peak Inn, at foot of Longs Peak, on side of which lies the moraine.

Mills bed.

Eocene (middle): Southern Texas (Rio Grande embayment).

F. M. Getzendaner, 1930 (A. A. P. G. Bull., vol. 14, No. 11, pp. 1436–1437). A unique bluish-white, very fine-grained noncalc. ss. (younger than Carrizo sand), in Bigford fm., containing imprints of grasslike leaves, was studied and partly mapped by writer, who carried it in his notebooks as "*Mills bed*," because he first studied it on the O. A. Mills ranch in Zavalla Co. It occurs in a long line of disconnected outcrops in Frio and Zavalla Counties and has been traced to eastern Frio Co., where it seems to lens out and the Carrizo sand and Mount Selman become contiguous fms.

†Millsap division. (In Strawn group.)

Pennsylvanian (Allegheny): Central and central northern Texas.

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 361, 372–374). *Millsap div.*—Mostly blue and black clays, with an occasional ss., hard ls., and bed of sandy sh. Thickness at least 1,000 ft. Found only in N. part of Carbf. area. Includes all Coal Measures strata below top of coal No. 1. Underlies Strawn div.

Later Tex. repts (1893, etc.) dropped *Millsap*, because of conflict with name of a well-established fm. of Miss. age in Colo., and included the beds thus designated in *Strawn fm.* This definition of Strawn was adopted by U. S. Geol. Survey in 1912. F. B. Plummer and R. C. Moore, however, in 1922 (Tex. Univ. Bull. 2132) divided the Strawn deposits into Mineral Wells fm. above and Millsap fm. below. (See under *Strawn fm.*) In 1933 (Univ. Tex. Bull. 3232, pp. 105, 109) E. H. Sellards divided *Strawn group* into (descending) Mineral Wells fm. restricted, Garner fm., and *Millsap Lake fm.*, the latter name being introduced to replace *Millsap fm.*

Named for Millsap, Parker Co.

†Millsap limestone.

Mississippian (lower): Eastern Colorado.

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *Millsap ls.*—Remnants of thin-bedded, variegated, dolomitic ls. with a few thin ss. layers. Chert nodules in upper layers carry characteristic Carbf. fossils. Thickness 0 to 30 ft. Uncon. underlies Fountain fm., and uncon. overlies Fremont ls. Named for Millsap Creek, Pikes Peak quad.

G. K. Gilbert, 1897 (U. S. G. S. Pueblo folio, No. 36). *Millsap ls.*—Coarse gray and red ss. (30 ft. thick) underlain by 200 ft. of gray and purple lss. with some sh., especially in lower part. Assigned to Carbf. Underlies Fountain fm. and conformably overlies Harding ss. Like the Harding, the lss. occupy 2 small areas W. of Beulah, separated by St. Charles Canyon. A Carbf. fossil was found near middle of the lss., but nothing was found to mark presence of Fremont ls., which in Pikes Peak dist. separates Millsap and Harding fms. Application of name Millsap to whole ls. series of Pueblo dist. is a somewhat arbitrary procedure and is subject to correction when more facts are available. Use of Millsap in Tex. has priority, and if retained in Tex. another name will have to be selected for this Colo. fm.

A. E. Brainerd, H. L. Baldwin, Jr., and I. A. Keyte in 1933 (A. A. P. G. Bull., vol. 17, No. 4, pp. 381–396) divided the beds beneath Fountain fm. and above Manitou ls. on E. slope of Front Range, Colo. (typical Millsap region) into Madison ls. (Miss.) 100 ft., and Williams Canyon ls. (of supposed Dev. age) 30 ft., and reported an uncon. btw. the two. (See under *Williams Canyon ls.*)

Millsap Lake formation. (In Strawn group.)

Pennsylvanian (Allegheny): North-central Texas.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106–108). To obviate dual usage of *Millsap* (for this Penn. fm. of Tex. and for a Miss. fm. in Colo.) G. Scott and J. M. Armstrong (ms. of rept on geol. of Parker Co., Tex.) used *Millsap Lake* for the Tex. fm., which usage is here adopted. The fm. is largely shales with some cgls. and thin sss.; lss. are present but are thin and usually lenticular in character. Max. thickness 3,000 ft. or more. Type loc., Millsap Lake, Parker Co. Divided by Scott and Armstrong (ms. of Parker Co. rept) into following members (descending): Grindstone Creek beds, Brannon ls., Steussy shales, Meek Bend ls., Hill Creek beds, Dennis Bridge ls., Kickapoo Falls ls., Lazy Bend beds, and Dickerson beds.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15–24). *Millsap Lake fm.* in Parker Co. has been divided by G. Scott and J. M. Armstrong (unpublished mss.) into 3 members (descending), Grindstone Creek memb., Lazy Bend memb., and Dickerson memb., and the Grindstone Creek and Lazy Bend members are divided into several beds [listed under those members]. Is basal fm. of Strawn group. Underlies Garner fm. and uncon. overlies Bend group, which is divided into Smithwick and Marble Falls fms.

Millsdale limestone.

Upper Ordovician (Richmond): Northeastern Illinois.

See under *Aux Sable ls.*

†Millstone grit.

A term applied in early repts to basal cgl. of Penn. series in Eastern and Central States. In Pa. it was applied to Pottsville fm. of present usage; in N. Y. it was applied by Eaton to Shawangunk cgl., according to W. W. Mather (N. Y. Geol. Surv. 4th Rept., 1840), also to Oneida cgl., according to L. Vanuxem (N. Y. Geol. Surv. 4th Rept., p. 374). The name was derived from fact that the conglomeratic beds were quarried for millstones. In western Ky. the name was applied to Caseyville ss. (of Pottsville group).

Millstone grit group.

Carboniferous: New Brunswick.

G. A. Young, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 314).

Millstream series.

Ordovician: New Brunswick.

G. A. Young, 1911 (Canada Geol. Surv. Mem. 18, p. 32).

Millsville member.

Carboniferous: Nova Scotia.

W. A. Bell, 1926 (Canada Geol. Surv. Summ. Rept. 1924, pt. C, p. 160).

Millsville conglomerates.

Pennsylvanian (lower): Nova Scotia.

J. S. Stewart, 1932 (Nova Scotia Dept. Public Works and Mines, Ann. Rept. on Mines 1931, pt. 2, p. 37).

Milltown andesite.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 47, etc.). *Milltown andesite.*—Mainly flows, but with some dikes and intrusive masses and with some tuff and breccia. Locally includes some effusive basaltic rocks that are not exposed at surface. Overlies Morena rhyolite, from which it is probably separated by an erosion interval. Where Morena and Sandstorm rhyolites are absent it rests on the latite. Thickness estimated at 700 ft. Named for small settlement of Milltown, about 1 mi. E. of Goldfield.

Millwood formation.

Millwood series.

Millwood shales.

Upper Cretaceous: Manitoba and British Columbia.

J. B. Tyrrell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 83E, 144E, 199E, 212E–215E). *Milwood series*, Cret., B. C. Included in Pierre.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 216). *Millwood fm.*, Cret., Canada.

D. B. Dowling, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 91). *Millwood*, Cret., Manitoba.

W. Malcolm, 1913 (Canada Geol. Surv. Mem. 29, p. 40). *Millwood shales*, Cret., Manitoba.

S. C. Ells, 1923 (Canada Mines Branch Summ. Rept. 1921, p. 36). *Millwood series*. Cret., Manitoba.

R. C. Wallace, 1925 (Geol. fms. of Manitoba, pub. by Nat. Hist. Soc. of Manitoba, p. 28). *Millwood series*, Cret., Manitoba.

M. Y. Williams, 1932 (Jour. Geol., vol. 40, No. 6, p. 561). *Millwood* of Manitoba underlies Odanah and correlates with Judith River, Claggett, and Eagle of Mont.

Milner formation. (In Mesaverde group.)

Upper Cretaceous: Northwestern Colorado (Yampa coal field).

M. R. Campbell, 1931 (Tentative correlation of named geologic units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Milner fm.*—Shales, thin-bedded ss., and coal beds underlying Trout Creek ss. and overlying Haybro fm. Included in Mesaverde group. Thickness 600 to 800 ft. The fm. crosses valley of Yampa River in T. 6 N., R. 86 W. and is named for Milner, a small village in this valley.

Milton formation.

Jurassic (?): Northern California (Downieville region).

H. W. Turner, 1894 (Am. Geol., vol. 13, pp. 232–234). *Milton series*.—Comparatively little-altered sediments containing large amount of fragmental diabasic material with some qtzite, fine-grained reddish clastic rocks, a variegated breccia, and a few ls. lenses. Considered older than Mariposa sl. and younger than Sailor Canyon fm.

Named for exposures in neighborhood of Milton, an old stage station on Middle Fork of Yuba River, in Downieville quad.

Milton dolomite.

Upper Cambrian: Northwestern Vermont (Chittenden County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 111–115). *Milton dol.*—Almost entirely massive dol., fine and coarse grained. Most beds 1 to 4 ft. thick, especially in lower part of fm., and bedding usually difficult to determine. Color dark bluish gray or steel gray through light gray to buff, most beds weathering dark. Beds of sandy dol. fairly common, but only a little dolomitic ss., mainly in upper third of fm. One peculiarity is its considerable content of black chert, which occurs in small irregular patches and pockets and very seldom in layers. Another peculiarity is its large content of dolomitic cgl., present at many horizons throughout fm. and almost invariably at top. The cgl. consists mainly of pebbles of dol. and dolomitic ss., the source of which is probably the beds of same character in lower parts of the fm. Upper 80 ft. at Highgate Falls consists of fossiliferous slabby dol. and ls. interbedded with 8 layers of cgl. that resembles tillite, but only one of which (15 ft. below top and 26 ft. thick) contains boulders of foreign origin. Fossils in upper 80 ft. determined by C. Schuchert to be Upper Camb. No fossils in middle and lower parts of fm.; Middle Camb. may be represented in lower part of Milton dol. or in upper part of underlying Colchester fm. Thickness of fm. 800± ft. Underlies Highgate sl. and rests uncon. on Colchester fm. (Lower Camb.). A few mi. SW. and NW. of St. Albans the fm. is cut out by erosion. Extends from Canada to Monkton. Best exposed in wide belt passing through town of Milton, about 3 mi. W. of Milton village.

A. Keith, 1924 (Vt. State Geol. Rept. 1923–4, p. 137, footnote). Later work has shown there was considerable interval btw. deposition of the dol. to which

Milton was applied in my 1923 paper and that of the thinly bedded [strata] there called *upper Milton*. I therefore propose to call the latter *Missisquoi fm.* [This name applied to fossiliferous upper 80 ft. of Milton dol. as originally defined in St. Albans region, and restricted *Milton dol.* to lower or unfossiliferous part.]

B. F. Howell, 1929 (16th Rept. Vt. State Geol., pp. 264–266). Keith stated that Upper Camb. fossils occurred in *Milton dol.*, but this record was based on an error, whereby certain Upper Camb. fossiliferous beds were wrongly correlated with true Milton. No fossils have been found in original Milton, and we do not know certainly whether it is Paradoxidian [Middle Camb.] or older, but as it seems to underlie the *Paradoxides* beds either uncon. or discon., it was probably laid down in late EoCamb. time. The underlying Colchester fm. has yielded many EoCamb. fossils. We now know that the Middle Camb. *Paradoxides* beds form a distinct fm. above the Milton. Keith was not certain to which of his fms. the *Paradoxides* beds at St. Albans (St. Albans sh. of writer) belonged, but later detailed search by Schuchert, Keith, and writer found that they overlie Milton dol. and underlie Highgate sl.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 13, July 19, pp. 372–373), excluded from his Milton dol. the upper 80 ft. of beds containing Upper Camb. fossils (which he in 1924 named *Missisquoi fm.*—preoccupied and now replaced by *Mill River cgl.*), and applied *Milton dol.* to the lithologically similar dol. cgl. underlying St. Albans sl. (Middle Camb.) and overlying Parker sl. (Lower Camb.) in St. Albans region.

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 359, 368, 369, etc.). In original account of Milton dol. Keith regarded it Upper Camb., though he had not found fossils in it [in its type area]. Ulrich was first to find these in typical area during summers of 1930 and 1931, and they confirmed Keith's reference. In his later field work Keith continued more detailed mapping N. to Canadian border, and, finding so many similar dolomites, confused some of them, and in his 1932 paper applied "Milton dol." to a much thinner dol. (about 30 ft.) in upper part of Lower Camb. (Parker) [overlying the Parker]. All of these Lower Camb. "Miltons" must be excluded and term be restricted to the original intention, namely, to the dolomites W. of Milton and of Upper Camb. age, and *to their equivalents*. In Milton region the true Milton dol. is 700± ft. thick, is conformably overlain by Highgate sl. and uncon. underlain by Parker sl. In Highgate Falls region the Upper Camb. beds separating Highgate sl. from the uncon. underlying Parker sl. are here given the following names (descending): *Highgate ls.-sl.*, 85 ft.; *Gorge cgl.*, 80 ft.; *Gorge ls.-dol.*, 140 ft. Writer has made 10 trips to region. [The Highgate ls.-sl. of Schuchert was included in Highgate sl. as originally defined by Keith, and the Gorge cgl., and Gorge ls.-dol. of Schuchert were clearly included in original definition of Milton dol., and are shown by Schuchert's diagram on p. 368 to be=typical Milton dol. The name *Gorge* is nongeographic.] At 3 widely spaced localities the Upper Camb. basal *Mill River ls. cgl.* overlies St. Albans sl. with erosion uncon. Its thickness is 5 to 15 ft.

The present definition of Milton dol. approved by U. S. Geol. Survey and A. Keith applies the name to the Upper Camb. strata underlying Highgate sl. and uncon. overlying Parker sl. (originally called *Colchester fm.*).

Milton quartzite.

Cambrian(?): Eastern Massachusetts (Boston region).

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 99, 101–103). *Milton qtzite* is proposed by writer for the coarse granular qtzite exposed just N. of the Quincy granite in town of Milton. It is a greenish, somewhat sheared grit which dips steeply to N. and is 400 to 500 ft. thick. All previous writers have assigned this rock to Roxbury cgl. (Perm.). Its separation from Roxbury cgl. originated with Dr. Kirk Bryan. It is entirely unlike latter fm., however, for it is well sorted and composed almost entirely of rounded quartz grains. Deposited under conditions very different from those which prevailed in Carbf. times in this region. Its close association with Quincy batholith implies a Camb. age, for great quantities of proved Camb. sediments are found as xenoliths in the Quincy granite and doubtless represent fragments of a collapsed roof. Assigned to *Camb.* (?).

E. J. Rhodes and W. H. Graves, Jr., 1931 (Am. Jour. Sci., 5th, vol. 22, p. 371). We visited Milton qtzite locality with Dr. [L.] La Forge and found *Milton fm.* an *arkose* rather than a qtzite. The pebbles of the Milton entirely resemble the matrix and sandy facies of Roxbury cgl. in a nearby outcrop. The Milton is not metamorphosed. Its original clays are still present and the rock has been but slightly altered by shearing. We are of opinion Milton fm. is a fine-grained portion of Roxbury cgl., to which fm. all writers preceding Billings assigned it.

Milton moraine.

Pleistocene (Wisconsin stage): Southern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Milton, Rock Co.

Milverton moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map in Smithsonian Inst. Ann. Rept. 1912, p. 297, 1913.

Milwaukee formation.

Middle Devonian: Southeastern Wisconsin (Milwaukee and vicinity).

W. C. Alden, 1906 (U. S. G. S. Milwaukee folio, No. 140). *Milwaukee fm.*—Only lower 15 to 25 ft. exposed, but following generalized section is based on exposures and well records (descending): Black sh., 15 ft.; soft bluish "soapy clay" or sh., 80 ft.; bluish mag. ls. ("cement rock"), 12 ft.; bluish ls. and softer bluish "soapy clay," 31 ft. Very fossiliferous. Hamilton fauna. Overlies Waubakee fm. Underlies Pleist. drift. Named for exposures near Milwaukee.

Milwood series.

Upper Cretaceous: Manitoba.

See *Millwood*, the correct spelling.

†Mimbres limestone.

Silurian and Ordovician: Southwestern New Mexico.

C. H. Gordon, 1907 (Sci., n. s., vol. 25, pp. 824–825; Jour. Geol., vol. 15, pp. 91–92). *Mimbres ls.*, 900 to 1,200 ft. thick, underlies Dev. Percha sh. and overlies Upper Camb. Shandon qtzite [Bliss ss.]. The greater part of these lss. contains Richmond fauna, but upper 100± ft. have yielded Sil. fauna.

Now separated into Fusselman ls. (Niagaran), Montoya ls. (Richmond), and El Paso ls. (Lower Ord.), and name abandoned.

Named for Mimbres Mtns, W. part of Sierra Co.

Mimbresian series.

A term introduced by C. [R.] Keyes to cover his Cristobal lss. (of Richmond, late Ord. age) of N. Mex. (See Iowa Acad. Sci. Proc., vol. 22, 1915, pp. 257–259.) In his Conspectus of geol. fms. of N. Mex., 1915, p. 9, he defined it as "term restricted to Late Ordovicic section in Mimbres, Caballos, and Franklin Ranges that carries the Richmond fauna." In 1922 (Pan-Am. Geol., vol. 38) he stated this is not Mimbres ls. of Government repts.

Minabariet formation.

Jurassic: British Columbia.

C. H. Crickmay, 1930 (Calif. Univ. Dept. Geol. Sci. Bull., vol. 19, No. 2, p. 33).

†Minden formation. (In Claiborne group.)

Eocene (middle): Northern Louisiana.

J. W. Whittemore, 1927 (La. State Dept. Cons. Bull. 14, pp. 6, 9, map); 1928 (idem. Bull. 16, p. 8); and 1929 (idem. Bull. 19, p. 6). *Minden or St. Maurice fm.* outcrops around Minden. Underlies Cockfield fm. and overlies Sparta sand.

I. Campbell and A. D. Miller, 1928 (A. A. P. G. Bull., vol. 12, No. 10, p. 990). *St. Maurice (Minden).*—Green and brown glauconitic sh., 130 ft. thick in Richland Parish, NE. La., where it underlies Quat. and overlies Sparta sand.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, No. 10, pp. 1339–1346). Those beds in La. which are stratigraphically same as Crockett memb. of Tex. have been locally referred to as *Minden beds*. Town of Minden [Webster Co., NW. La.] is not on so-called Minden beds, but is on Sparta sands. (Oral communication from

L. P. Teas, of Humble Oil & Refining Co.) As it is not advisable to use two names for same memb., the [new] name *Crockett*, which has been used in Tex., is suggested instead of *Minden*. The outcrops of the Crockett in Tex. are better exposures. For these reasons *Minden* is dropped and *Crockett* used instead.

H. K. Shearer, 1930 (A. A. P. G. Bull., vol. 14, No. 4, pp. 433–450). *Mount Lebanon fm.* is here proposed to replace *St. Maurice fm. restricted* of Spooner and Minden fm. The name *Mount Lebanon* has been used by Standard Oil Co. geologists and a few others since 1924, in referring to the upper marine fm. of the Claiborne. Name is taken from old town of Mount Lebanon, in Bienville Parish, which is surrounded by good fossiliferous exposures. Minden is not considered as satisfactory a name, because the typical exposures are several mi. from Minden, and the fm. there is not as characteristic as in Bienville Parish. The fm. generally consists of brown or green sh. and glauconitic sand containing a characteristic fauna. Thickness 350 ft. Underlies nonmarine Cockfield [Yegua] fm. and overlies Sparta fm. Includes Saline Bayou, Milams, and Crockett members of Tex. According to C. L. Moody and others who have done detailed work in Tex., the exposure at Cook Mountain, Houston Co., Tex., is definitely on the same fm. If this is true, *Cook Mountain* should be used as the fm. name, because it has priority over any of other names which have been proposed.

H. V. Howe, 1933 (A. A. P. G. Bull., vol. 17, No. 6, p. 625). The name "Minden" was suggested by writer during a course of lectures he was giving in Shreveport. It was not then known just how the Cook Mtn of Tex. fitted in La. section. As a result the name came into fairly common use by petroleum geologists and has crept into the literature several times without ever having been formally described. Portions of writer's office map of geol. of La., on which *Minden* appeared, were copied by Whittemore [the 3 books listed above] without writer's knowledge during his absence on summer vacation. Acknowledgment was given in later two publications, but writer never sanctioned placing this name in print. Another name for this fm. is *Mount Lebanon* of Shearer, who, when he proposed Mount Lebanon, suggested that Cook Mtn is the proper name if exposure at Cook Mtn definitely proved to be on same fm.

Minden fm. is now replaced by *Cook Mtn fm.*, the older name.

Mineola limestone.

Middle Devonian (Onondaga): North-central Missouri.

E. B. Branson, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 267–276). *Mineola ls.*—Extremely irregular in composition, ranging from very compact fine-grained ls. of high purity to ss. Commonest phase is a porous sandy ls. Occurs in patches. Thickness 0 to 40 ft. Uncon. underlies Callaway ls., and uncon. overlies fms. ranging from Kimmswick ls. to Jefferson City ls. Fauna closely related to Onondaga faunas of Ind. and Ohio. Contemp. with Cooper ls., but deposited in separate sea.

See later entries under *Cooper ls.*

Named for exposures, 4 or 5 mi. in extent, in vicinity of Mineola, Montgomery Co. Good outcrops in secs. 11 and 12, T. 48 N., R. 6 W.

Mineral Creek andesite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). Flows, breccia, and aggl.; predominantly andesitic; thin vesicular flows alternate with breccia and aggl.; some beds of reddish-purple feldspathic ss., of light-gray, dark-red, purple, and nearly black colors. Thickness 0 to 700 ft. Older than Fanney rhyolite and younger than Pacific quartz latite.

Named for exposures in S. walls of Mineral Creek Canyon above Cooney mine.

Mineral King beds.

Triassic (?): Southern California (Tulare County).

H. W. Turner, 1894 (Am. Geol., vol. 13, p. 231, and U. S. G. S. 14th Ann. Rept. pt. 2, p. 451.) *Mineral King beds.*—Clay sl., mica schist, qtzite, and crystalline ls, exposed at old mining camp of Mineral King, about 15 mi. SW. of Mount Whitney, at headwaters of Kaweah River, Tulare Co. Assigned to Triassic (?), on basis of poorly preserved fossils.

Mineral Wells formation. (In Strawn group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, p. 138). Strawn div. overlies Millsap div., and is divided [in table] into (descending) *Gordon, Mineral Wells sss.*, Brazos ss., etc. [Subdivisions not described.]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 32). *Mineral Wells fm.*—Sss. and shales, with coal No. 1 (Thurber coal) at base. Thickness 500 to 800 ft. Top fm. of Strawn group. Underlies Palo Pinto ls. (of Canyon group) and overlies Millsap [Millsap Lake] fm. Named for exposures in vicinity of Mineral Wells, Palo Pinto Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 108). *Mineral Wells fm.* is *restricted* by G. Scott and J. M. Armstrong (ms. on geol. of Parker Co.) to beds above Brazos ss. [Brazos River ss.] and they introduce *Garner fm.* for lower part of original Mineral Wells fm., or to include (descending) Brazos ss., Mingus sh., and Thurber coal members. [Sellards (1933) included in top of Mineral Wells fm. of Colorado River region the Capps ls. memb. This definition is present approved definition of U. S. Geol. Survey, and is the one followed by F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534).]

Mines dolomite.

Cambrian (Upper): Central Pennsylvania (Blair to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 527, 534, 537). *Mines dol.*—Cherty dol., oolitic, yielding much oolitic and platy scoriaceous chert. Thickness 250 ft. Underlies Larke dol. and overlies Gatesburg fm. Named for old mining town of Mines, several mi. SW. of Williamsburg, Blair Co. Best exposed in N. end of long ridge just SE. of Williamsburg.

Minesota conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; see map and p. 20). *Minesota cgl.*—A belt of cgl. and ss. 60 ft. wide. Its southern or lower half is ss.; the upper or northern half is cgl., which is usually highly metamorphosed and breaks with a trappean fracture, its divisional planes and lines of clearage [cleavage] dividing it imperfectly into irregular cubical or prismoidal blocks. Is distinguished by its firm and compact texture, its pebbles of feldspathic and syenitic rock, and the occasional presence of considerable epidote and carbonate of lime. This belt underlies the metalliferous deposits worked at Minesota mine. It is succeeded by the Minesota traps.

According to B. S. Butler (U. S. G. S. P. P. 144, 1929) is probably same as Kearsarge cgl. It belongs to Central Mine group.

Minesota trap.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and p. 20). These traps, 570 feet wide, as stated above, are termed the *Minesota traps*, and with the underlying [Minesota] cgl. generally, the *Minesota belts*. [Shown as underlying National ss. and overlying Minesota cgl.]

Named for occurrence at Minesota mine, Ontonagon Co.

Minford silt.

Pleistocene: Southern Ohio.

W. Stout and D. Schaaf, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, pp. 663-672). *Minford silts.*—Fine, highly laminated silts, composing upper and by far greater part of valley filling of old preglacial valleys of all larger streams in southern Ohio and well toward headwaters of smaller tributaries. In main the evidence favors glacial origin. Rests on the old alluvium, where locally present, and on the still older sands that lie on bed rock. Named for exposure in the cut of Chesapeake & Ohio Ry at Minford, Harrison Twp. Scioto Co.

Mingan formation.

Ordovician: Quebec (Mingan Islands).

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 688).

Mingo formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 33, 38, 207, and pl. XLA). *Mingo fm.*—Shales, sss., and coals, 950 ft. thick, underlying Catron fm. and overlying Hance fm. in Cumberland Gap coal field. Top defined by base of Poplar Creek coal in Log Mtns, and by base of Wallins Creek coal in Black Mtns. Base defined by base of Harlan coal to E., by base of Hance coal in central part of Cumberland Gap coal field, and by base of Bennett Fork coal at W. Correlated with upper part of Kanawha fm. and lower part of Sewell fm.

Named for Mingo Mtn, Claiborne Co., Tenn.

Mingus shale member (of Garner formation).

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, pp. 75, 76, and charts). *Mingus sh. memb. of Mineral Wells fm.*—Gray sandy sh., 250 to 300 ft. thick, overlying Thurber coal, which is basal bed of Mineral Wells fm. (of Strawn group). The sh. is nowhere well exposed in complete section, but is observed in coal mine shafts and well borings. Underlies Brazos River ss. Named for small mining town S. of Mineral Wells.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 108). G. Scott and J. M. Armstrong (ms. on geol. of Parker Co.) restrict Mineral Wells fm. to beds above Brazos ss. memb., and introduce *Garner fm.* to include lower part of Mineral Wells fm., or (descending) Brazos ss., Mingus sh., and Thurber coal members.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 23–30), divided *Garner fm.* into following members (descending): Brazos River ss. (25 to 75 ft. thick), Mingus sh. (145 to 210 ft. thick), and Thurber coal (2 ft. thick), and gave a detailed section of Mingus sh. in Palo Pinto and Parker Co. region.

Minho beds.

Cretaceous: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 24, p. 57).

Minidoka basalt.

Pleistocene: Southern Idaho (Minidoka County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Minidoka basalt.*—Vesicular, blue, pahoehoe basalt containing tiny crystals of olivine and thinly covered with loess. Thickness 30± ft. Overlies conformably the capping gravel memb. of the beds deposited in lake behind the Sand Spring lava dam. Older than Wendell Grade basalt and younger than Barley lake beds. Named for Minidoka Dam. Probably issued from one of cones near Minidoka.

Miniss series.

Pre-Cambrian: Ontario.

W. S. Dyer, 1933 (Canadian Min. Jour., vol. 54, No. 2, p. 72).

Minneapolis limestone.

Middle Ordovician: Southern Minnesota.

F. W. Sardeson, 1907 (Geol. Soc. Am. Bull., vol. 18, p. 185). *Minneapolis ls.*—Basal bed of Beloit fm., and heretofore known as Buff bed and Lower Buff bed. Underlain by St. Peter ss. and overlain by *Bellerophon* bed.

Is basal part of Platteville ls.

Named for Minneapolis.

Minnekahta limestone.

Permian? (may be Triassic): Western South Dakota, eastern Wyoming, northwestern Nebraska.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 514). *Minnekahta ls.*—Thin-bedded gray ls., 30 to 50 ft. thick, underlying Spearfish fm. and overlying Opeche fm. in Black Hills. In previous repts called *Purple ls.* Type loc. is region near the hot springs originally known as "Minnekahta" by Indians.

Minnelusa sandstone.

Pennsylvanian: Western South Dakota and northeastern Wyoming.

N. H. Winchell, 1875 (Black Hills of Dakota, by Wm. Ludlow, U. S. Eng. Dept. U. S. Army, pp. 38, 65, map). *Minne-lusa ss. or Upper ss.*—Nearly white, crystalline, subsaccharoidal ss., coarsely granular when weathered and hard; has somewhat aspect of a crinoidal ls. but without stem sections of crinoids. [In another place he describes it as white ss., locally stained with iron so as to have a brick-red color. Thickness 75 ft. in Black Hills, S. Dak. Underlies Upper ls. and overlies Lower ls. Named for Indian name of valley in which it was discovered.

T. A. Jaggar, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 178–181, and map). *Minnelusa lss. and sss.*—In northern Black Hills consist of (descending): (1) *Minnelusa saccharoidal ss.*, 200 ft.; (2) *Minnelusa "alternate" series*, 300 ft.; (3) *Minnelusa white ss.*, 100 ft. Separated from overlying Minnekahta ls. by 90 ft. of red ss. Rests on 200 to 700 ft. of gray ls. equiv. to Madison ls.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 510). *Minnelusa fm.*—Sss., mainly buff and red, in greater part calc.; some thin lss. Thickness 400 to 450 ft. Minnelusa was applied by N. H. Winchell in 1875 to a portion of the bright-colored sandy members of the Carbf. lying above the Gray or Pahasapa ls. In this rept the name will be employed to designate all sss. and lss. in Black Hills region lying btw. well-defined limits of Pahasapa ls. below and deep-red sss. and shales of Opeche fm. above. Minnelusa is Dakota Indian name for Rapid Creek.

Minnelusa is Sioux Indian name for rapid water. The fm. is exposed on Rapid River 4 or 5 mi. above Rapid City, S. Dak. The fm. possibly includes some Perm. at top and some Miss. at base.

Minnesota trap.

Minnesota conglomerate.

Pre-Cambrian (Keweenawan): Michigan.

See *Minesota trap* and *Minesota cgl.* These units were named for a mine (spelled Minesota) in Ontonagon Co.

Minnesotan series.

A term introduced by C. [R.] Keyes to include Glenwood sh. and St. Peter ss. of Iowa and Minn. (See Iowa Acad. Sci. Proc., vol. 19, pp. 147–151, 1912.) In 1931 (Pan-Am. Geol., vol. 56, pp. 348–349) he restricted the name to St. Peter ss., and assigned Glenwood sh. to Chazy epoch.

†Minnesota River Valley gneiss and granite.

A descriptive term applied by C. D. Walcott (Geol. Soc. Am. Bull., vol. 10, 1899, table on p. 222) to basement rocks in southern Minn., which he assigned to †Archean system.

Minnewanka formation.

Devonian: Alberta.

H. W. Shimer, 1926 (Canada Geol. Surv. Bull. 42, pp. 3, 6, 20).

Minnewaste limestone.

Lower Cretaceous: Western South Dakota (SE. part of Black Hills).

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 529). *Minnewaste ls.*—Nearly pure light-gray ls., 0 to 30 ft. thick, underlying Fuson fm. and overlying Lakota fm. Contains no fossils. Formerly included in Dakota ss. Minnewaste is Dakota Indian name for Cheyenne River. Extensively exposed in anticline 2 mi. E. of Hot Springs, S. Dak.

N. H. Darton and S. Paige, 1925 (U. S. G. S. Central Black Hills folio, No. 219, p. 12). In SE. part of Black Hills uplift the Lakota ss. is overlain by *Minnewaste ls.*, a thin sheet of ls., which terminates btw. Buffalo Gap and Fuson Canyon. This ls. is about 12 ft. thick in Buffalo Gap and 18 ft. thick on plateau S. of Calico Canyon.

Minnith zone. (In Powell limestone.)

Lower Ordovician (Beekmantown): Central eastern Missouri (Ste. Genevieve County).

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines, vol. 22, 2d ser., pp. 86–90). The base of the upper Powell is placed at bottom of zone of cellular ferruginous chert, which may be termed *Minnith zone*, in which there is a prolific fauna in most places where it is found, the distinguishing fossils being Trochonemoid gastropods. The Minnith zone consists of intercalated beds of argill. dol., decomposed dol., and soft, ferruginous chert. Where absent the contact btw. upper and lower Powell is marked by a thin ss. or cgl. or a slight uncon. At Minnith the Minnith zone rests directly on Cotter fm.

Named for exposures at and near Minnith, Ste. Genevieve Co.

Minong breccia.

Pre-Cambrian (Keweenawan): Northern Michigan (Isle Royale).

A. C. Lane, 1898 (Mich. Geol. Surv. vol. 6, pt. 1, pp. 87, 101, 105, and pl. I). Believed to be same as Kearsarge cgl.

Belongs in Central Mine group. Has also been called *Minong cgl.*

Named for occurrence in Minong mine, Isle Royale.

Minong porphyrite.

Pre-Cambrian (Keweenawan): Northern Michigan (Isle Royale).

A. C. Lane, 1898 (Mich. Geol. Surv. vol. 6, pt. 1, pp. 141, 142, 159, 161, 170, 177, 200, 201, 209, 212, and pls. 1 and 2). Shown as younger than Minong trap and older than Minong breccia.

Belongs to Central Mine group.

Named for occurrence in Minong mine, Isle Royale.

Minong trap.

Pre-Cambrian (Keweenawan): Northern Michigan (Isle Royale).

A. C. Lane, 1898 (Mich. Geol. Surv. vol. 6, pt. 1, pp. (see index), pls. 1 and 2). Shown as older than Minong porphyrite.

Belongs to Central Mine group. Is younger than Kearsarge West amygdaloid.

Named for occurrence in Minong mine, Isle Royale.

Minooka moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. Shown on moraine map (pl. 23) in U. S. G. S. P. P. 106. Named for Minooka, Grundy Co.

Minshall sand.

A subsurface sand in Conemaugh fm. (Penn.) of W. Va., that lies at or near horizon of Connellsville ss. memb. Named for F. W. Minshall, geologist, Marietta, Ohio.

Mint Canyon formation.

Miocene (upper): Southern California (Los Angeles County).

W. S. W. Kew, 1923 (A. A. P. G. Bull., vol. 7, pp. 411–420). *Mint Canyon fm.*—Land-laid deposits locally developed in vicinity of Mint Canyon, a branch of upper part of Santa Clara River N. of San Gabriel Mtns. Contains good vertebrate faunas at several horizons. Rests uncon. on beds that are probably = Sespe fm. In places overlain by strata containing an upper Mio. fauna and tentatively correlated with Modelo fm.; and in other places it lies uncon. beneath Pico fm. [In

U. S. G. S. S. Bull. 753, 1924, Kew gives thickness of Mint Canyon fm. as 4,000± ft. and states that the name is substituted for *Mellenia*, because latter is not geographic.]

Mint Spring marl member (of Marianna limestone).

Oligocene (lower): Southern Mississippi.

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, pp. 187, 195–196). *Mint Spring calc. marl memb.* (*of Marianna ls.*).—Sands and shell marls which in western Miss. replace "chimney rock" facies of Marianna ls. Between Vicksburg and Pearl River the Mint Spring marl occupies entire interval btw. Forest Hill sand [below] and Glendon ls. [above], but E. of Pearl River it is overlain by a thickening wedge of Marianna "chimney rock." Has not been recognized E. of Chickasawhay River.

A. R. Mornhinveg and J. B. Garrett, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 11, p. 1659). Writers propose to set upper limit of the Mint Spring at first ls. ledge, and the lower at last fossiliferous bed. Btw. these limits are included 20 to 25 ft. of marine strata, grading from sparingly fossiliferous lignitic sands and clays in lower part to sandy fossiliferous marls in upper part.

Miocene epoch (or **series**).

Next to last epoch of Tertiary period and the rocks formed during that epoch. For definition see U. S. G. S. Bull. 769, p. 53.

Mira series or formation.

Cambrian: Canada and Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 195).

Mira basalt.

Tertiary (upper Miocene): Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 69, etc.). *Mira basalt.*—A basalt flow, 100± ft. in greatest thickness, intercalated in Siebert [Esmeralda] fm. Underlies S. part of town of Goldfield. Caps Mira Mtn and some smaller hills in neighborhood. Prevailingly vesicular and characterized megascopically by large phenocrysts of vitreous feldspar disseminated sparingly through the rock.

Miraleste tuff bed. (In Monterey shale.)

Miocene (middle): Southern California (Palos Verdes Hills).

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, pp. 125–149). A distinctive tuff, readily recognized by abundance of pumice lapillae, which lies 125 to 175 ft. below top of middle div. of Altamira sh. memb., is here named *Miraleste tuff bed*, from Miraleste dist. Type region is on W. side of upper Agua Negra Canyon. Thickness of tuff varies from a few inches to 6 ft.

Mirando sand.

A subsurface sand in Fayette ss. (upper Eocene) in southern Tex. Lies lower than Cole sand and 500 ft. higher than Webster sand.

Mirando City sand.

A subsurface sand in the upper Eocene of Driscoll pool, Duval Co., Tex.

Misener sand.

A name that has been applied by drillers and oil geologists to a sand, or sands, encountered in oil and gas wells of many counties of eastern and northern Okla. and Cowley and adjoining counties of southern Kans. The name is said (N. W. Bass) to have been first applied to a sand in an oil pool near town of Beggs, Okmulgee Co., Okla. In that county (according to Okla. Geol. Surv. Bull. 40F, 1926) it lies in top of Viola ls.; it is not a sheet sand, but consists of small lenses; it occurs locally; and it has been correlated with Sylamore ss. The sand, as now commonly interpreted, is a transgressing unit that is treated by U. S. Geol. Survey as basal memb. of Chattanooga sh., and it overlies a widespread uncon. of pre-Chattanooga time. In some parts of Okla. it lies on Siliceous lime (Arbuckle ls.); in other places it lies on rocks as young as Hunton ls. (Dev. and Sil.). It is said (N. W. Bass, letter) to have been named for Fred D. Misener, an oil operator of Tulsa, and to have been found at depths of 3,009 to 3,054 ft. in No. 1 well (drilled btw. Dec. 19, 1919, and March 10, 1920) on McWilliams lease in sec. 23, T. 15 N., R. 10 E. (now included in Wilcox oil pool, Creek Co., Okla.), where it rests on Viola ls.

Misenheimer shale.

Middle Devonian: Southwestern Illinois.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 169–178). *Misenheimer sh.*, 0 to 25 ft. thick, overlaps Grand Tower ls. in a few places, and in these the basal part is dark sh. having greatly disturbed appearance and containing numerous shells of *Leiorhynchus limitare* and a few other fossils. Conformably underlies Lingle ls., Middle Dev. Well exposed in banks of Misenheimer Creek and tributaries in NE¼ sec. 34 and NW¼ sec. 35, Misenheimer Twp, Union Co., where it rests uncon. on Clear Creek chert or Dutch Creek ss. Corresponds to Marcellus and Hamilton of N. Y. Middle Dev.

Misinchinka schists.

Pre-Cambrian: British Columbia.

M. Y. Williams and J. B. Bocock, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 199).

Mispec group.

Mispeck group.

Devonian: New Brunswick.

G. F. Matthew, 1863 (Canadian Nat., vol. 8, p. 244).

Originally spelled *Mispeck;* later repts spell it *Mispec.*

Missi formation.

Pre-Cambrian: Saskatchewan and Manitoba.

E. L. Bruce, 1914 (Canadian Min. Jour., vol. 35, p. 504).

Mission argillite.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 72, map). *Mission argillite.*—Banded and massive argillites, calc. argillites, quartz mica schists, and narrow intercalated bands of qtzite and ls.; argillites and quartz-mica schists predominate. Bands of pure white ls., 2 to 100 ft. thick and traceable several mi., occur interbedded with the argillites. One of these lss., 3,000 ft. thick, has been named *Northport ls.* and mapped as a separate fm., but it is in reality interbedded with Mission argillites. Thickness of Mission argillite 12,000± ft. Rests on Clugston ls. Is top fm. of Stevens series. May possibly constitute several fms., but it would be difficult to map subdivisions, as they are not persistent for any great distances. [Town of Mission seems to be on this fm.]

Mission sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

M. I. Goldman and H. M. Robinson, 1920 (U. S. G. S. Bull. 686Y, pp. 362, 364). *Mission ss.*—Named for prominent occurrence along Mission Creek, especially in secs. 13, 14, 23, 24, and 25, T. 28 N., R. 11 E. Just NW. of center of sec. 23, T. 28 N., R. 11 E., it is conspicuous as the bed forming surface of prairie a few ft. above creek bottom N. of Gordon ranch. In T. 29 N., Rs. 11 and 12 E., it is part of a series of lenticular sss. overlying Possum ss. In T. 28 N., Rs. 11 and 12 E. it is a very constant, conspicuous bed of hard ss., 2 to 4 ft. thick, weathering in slabby blocks, prevailingly of pinkish color, in places carrying fossil shells in top part and forming surface bed over great part of the open country btw. Caney River and Mission Creek. Is generally overlain by sh. In SE. part of area it becomes more or less lost in a series of soft, massive, lenticular sss., and appears in sec. 31, T. 28 N., R. 12 E., as part of a continuous massive bed 20 ft. or more thick. Top lies 60 to 70 ft. below top of Cheshewalla ss. and 30± ft. below base of Hay Hollow ss.

Is=top bed of Revard ss. memb. of Nelagoney fm. (See 1922 entry under *Revard ss. memb.*)

Mission Canyon limestone. (Of Madison group.)

Mississippian (lower): Central northern Montana (Little Rocky Mountain region).

A. J. Collier and S. H. Cathcart, 1922 (U. S. G. S. Bull. 736F, p. 173). In this part of Mont. (Little Rocky Mtn region) the Madison ls. becomes a group divisible into two distinct fms., here named *Mission Canyon ls.* (the upper one) and *Lodgepole ls.* (the lower one). The Mission Canyon ls. is a massive white marine ls. 500 ft. thick, and not so fossiliferous as Lodgepole ls. It is named for exposure in Mission Canyon.

†Mission Creek series.

Tertiary, Cretaceous, Paleozoic: Southwestern Alaska (Yukon gold district).

J. E. Spurr, 1896 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 153–183). *Mission Creek series.*—Cgls., grits, sss., and shaly and coaly beds. Named for Mission Creek, in vicinity of which it is well exposed. Probably in part at least Lower Cret.

According to G. C. Martin this name included rocks of Tert., Lower Cret., and Paleozoic age. On Mission Creek it included Tert. and either Carbf. or Dev.

Mission Creek shale. (In Deer Creek limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northwestern Missouri, and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 49, 50). *Mission Creek sh.* overlies Haynies ls. and underlies Ervine Creek ls., all included in Deer Creek ls. It is ½ to 1½ ft. thick in Nebr. and SW. Iowa, 3 to 4 ft. thick in NW. Mo., and 2 to 3 ft. thick in NE. Kans. Named for exposures on Mission Creek, SE. of Iowa Point, Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 185–187). The sh. overlying "middle Deer Creek ls." (Rock Bluff ls.) and underlying Ervine Creek ls. in Kans. contains 2 persistent subdivisions, the lower half consisting of hard black fissile sh. and upper half of gray to yellowish soft clay sh. Because this sh. appears exactly=Larsh sh., Haynies ls., and Mission Creek sh. of Nebr. it is here called *Larsh-Mission Creek sh. memb.* Its thickness is 2½ to 7 ft. [See also 1936 entry under *Haynies ls.*]

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser.), abandoned this name, as explained in 1937 entry under *Burroak sh.*

Missisquoi schist.

Upper Cambrian (?): Northeastern and southeastern Vermont.

C. H. Richardson, 1919 (11th Rept. Vt. State Geol., pp. 120–140, in a description of Roxbury, S. part of Washington Co.). No definite name has been applied hitherto to the sericite schists, save describing them as *sericite schists and quartz sericite schists.* Author proposes *Missisquoi schists* for this terrane, which is prevailing schist in Missisquoi River valley in N. part of State [in Orleans Co.]. It is the schist in which most if not all serpentine and talc beds occur on *east* side of Green Mtns. Is certainly pre-Ord. and tentatively referred to Lower Camb.

C. H. Richardson and C. K. Cabeen, 1921 (Vt. State Geol. Rept. State Geol. 1919–1920, in description of Braintree Twp). The *sericite schist and quartz sericite schist* are known as *Missisquoi schists.* They are continuous from Missisquoi Valley southward for more than 100 mi.

C. H. Richardson and C. K. Cabeen, 1923 (Vt. State Geol. Rept. 1921–22, pp. 109–140, in description of Randolph Twp, SW. part of Orange Co., NE. Vt.). *Missisquoi group* as here used is made to include the sericite schists, qtzite, and the *chlorite* *schists* that are of sed. origin; some of chlorite schists may be igneous. All terranes of the group are Camb., or at least they are pre-Ord.

C. H. Richardson, 1924 (Vt. State Geol. Rept. 1923–24, pp. 77–103, in description of Bethel Twp, NW. part of Windsor Co.). *Missisquoi group.*—No fossils, but unquestionably pre-Ord. Includes hornblende schists that may be of sed. origin; *certain chlorite schists* that seem to be of same age as enclosing sericites and qtzites, i. e., Upper Camb.; sericitic qtzites, regarded as Upper Camb., which grade into sericite schists that are younger than Bethel schist and older than Ord.; and, in places, a cgl. that is regarded as a basal cgl., but if not basal then it is an intraformational cgl. and the Missisquoi group of terranes might then be regarded as Lower Camb. Rests uncon. on Bethel schist (Lower Camb.).

C. H. Richardson, 1927 (15th Rept. Vt. State Geol., pp. 127–158, describing Barnard, Pomfret, and Woodstock Twps, in Windsor Co., SE. Vt.). *Missisquoi group.*—Sericite schists and sericite qtzites, with minor beds of chlorite schists, hornblende schist, and gneiss that may not in all cases be of sed. origin. Is youngest Upper Camb. terrane in eastern Vt. Conformably overlies Bethel group.

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 208–246). *Gassetts schist* is a new, and the oldest, memb. of Missisquoi group, Upper Camb.

E. L. Perry, 1929 (16th Rept. Vt. State Geol., p. 31), stated that this Missisquoi fm. was named for Missisquoi or Missisco River, which rises in town of Lowell [Irasburg quad., Orleans Co.], and flows northward into Canada, then swings S. again into Vt. and empties into Lake Champlain in NW. Vt. The rocks on Missisquoi River in NW. Vt. are not same as Missisquoi schist of Richardson of NE. Vt.

†Missisquoi formation.

Upper Cambrian: Northwestern Vermont (Franklin County).

A. Keith, 1924 (Vt. State Geol. Rept. 1923–24, p. 137, footnote). *Missisquoi fm.* is here applied to thin-bedded upper part of Milton dol. as defined by me in 1923. [See 1924 entry under *Milton dol.*]

P. E. Raymond, 1924 (Vt. State Geol. Rept. 1923–24, pp. 137–138, 197–202). [Describes the Upper Camb. fossils from thinly bedded ls. and conglomeratic strata exposed in gorge of Missisquoi River at Highgate Falls (at Highgate village, St. Albans quad.), which were named *Missisquoi fm.* by Keith.] "Fauna resembles that of Hoyt ls."

B. E. Howell and A. Keith, 1929 (16th Rept. Vt. State Geol., pp. 266–268), introduced *Mill River cgl.* to replace this name, which is preoccupied by Missisquoi schist of Richardson, an Upper Camb. fm. on E. side of Green Mtns, Vt.

Mississagi quartzite.

Pre-Cambrian (Huronian): Western Ontario.

A. Winchell, 1888 (4th Int. Geol. Cong., London, Am. Comm. Repts., p. A14). *Mississaugui (vitreous) qtzite.*

W. H. Collins, 1914 (Canada Geol. Surv. Mus. Bull. 8, p. 26, etc.). [See under *Bruce series.*]

Mississinewa shale.

Silurian (Niagaran): Northeastern Indiana (Wabash County).

E. R. Cumings and R. R. Shrock, 1927 (Ind. Acad. Sci. Proc., vol. 36, pp. 71–84). *Mississinewa sh.*—Drab to bluish-gray calc. sh. underlying Red Bridge ls. and forming basal exposed part of Niagaran in northern Ind. To this fm., from base of the yellow ls. above, downward as far as typical development continues, is given the name *Mississinewa sh.*, from its exposures along the Mississinewa, at or near river level, at Wabash and Lagro. True base of fm. has never been seen by writers. At Wabash 75 ft. is exposed. Elrod and Benedict, on basis of well logs, reported 114 ft. at Lagro, and stated that fm. is probably as much as 250 ft. thick. Includes the "thick-bedded argill. ls." and "hydraulic ls." of Collett (1872) and equiv. fms.; also the "laminated sh.," "cement rock," and probably the "hydraulic ls." of Elrod and Benedict (1892).

E. R. Cumings and R. R. Shrock, 1928 (Ind. Cons. Comm., Div. Geol. Pub. 75, pp. 53, 56–71). *Mississinewa sh.* is lowest known fm. of Niagaran age in northern Ind. Fossils listed. Late Rochester and early Lockport time are represented in it. It includes all strata beneath Red Bridge ls. memb. of Liston Creek fm. and base of Niagaran. Thickness probably 250 ft. Should basal portion prove to be limy, then term *Mississinewa fm.* might be used. We can only conjecture what underlies it. It is conformable with Liston Creek fm., but in places is discon. overlain by younger fms.

151627°—38——10

Mississinewa morainic system.

Pleistocene (Wisconsin stage): Western Ohio, northeastern Indiana and southern Michigan. Shown in part on moraine map (pl. 32) in U. S. G. S. Mon. 53. In some earlier repts called *Mississinawa moraine*. Named for river in Ind. *Mississinewa* is spelling adopted by U. S. Geographic Board.

†Mississippi slate series.

A term applied by R. D. Irving (U. S. G. S. 7th Ann. Rept., pp. 440–441, 1888) to the Huronian rocks of Mississippi River region of central and eastern Minn.

†Mississippi clays.

Miocene: Mississippi River basin.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 157, 330). *Mississippi clays.*—Clays developed in basin [embayment] of Mississippi River. Miocene of Grand Gulf petezone.

Replaced by Hattiesburg clay and Pascagoula clay.

Mississippi lime.

Name loosely applied in different parts of the country to rocks encountered in wells, which may or may not be wholly of Mississippian age.

†Mississippi group.

Same as Mississippian series. See U. S. G. S. Bull. 769, p. 73.

Mississippian epoch (or **series**).

The oldest epoch of the Carboniferous period, and the deposits formed during that epoch. For definition see U. S. G. S. Bull. 769, pp. 73–78. Some geologists now treat the Miss. deposits as a system.

Missoula.

Name applied by C. [R.] Keyes (Pan.-Am. Geol., vol. 46, 1926) to 50 ft. of lss. of Carbf. age in Mont. Derivation of name not stated.

Missoula group.

Pre-Cambrian (Belt series): Central western Montana (Missoula to Helena region).

C. H. Clapp and C. F. Deiss, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 677, figs. 2, 3). *Missoula group.*—Divided into (descending): Sheep Mtn fm., 1,000 to 2,300 ft.; Garnet Range fm., 7,600 ft.; McNamara fm., 3,000 ft.; Hellgate fm., 2,200 ft.; Miller Peak fm., 2,900 ft. Rests conformably on Wallace (Siyeh) ls. Thickest exposures lie in mtns E. of city of Missoula.

Missouri group.

Pennsylvanian: Northwestern Missouri and Iowa.

C. R. Keyes, 1893 (Iowa Geol. Surv., vol. 1, pp. 114–116). *Missouri fm. or Upper Coal Measures.*—Shales, lss., sss., and clays overlying Des Moines beds, or Lower Coal Measures, and underlying Cret. rocks in Iowa. Thickness 1,200 ft.

In subsequent repts, by Keyes and others, called *Missourian series, Missouri stage, Missourian fm., Missourian stage, Missourian div., Missouri group,* and *Missouri series, with different upper and lower limits.*

Adopted by U. S. Geol. Survey many years ago, as a group name, to include rocks from base of Hertha ls. memb. of Kansas City fm. up to top of Penn. in Iowa and NW. Mo., overlying Des Moines group; well-defined faunal break btw. the two. (See H. Hinds and F. C. Greene, Mo. Bur. Geol. Mines, vol. 13, 1915.) Owing to great number of named subdivisions of Penn. rocks in Kans. and SE. Nebr., the U. S. Geol. Survey has been accustomed to treat the major subdivisions of Des Moines and Missouri age as *groups*, and therefore does not use *Missouri group* and *Des Moines* *group* in its rock classification of those States. These names (*Missouri group* and *Des Moines group*) were not used by Kans. Geol. Surv. in its classification until 1917 (Moore and Haynes).

R. C. Moore (1931 and 1932) proposed to restrict *Missouri series*, as he called it, by removing at top the Wabaunsee, Shawnee, and Douglas fms., which he called *groups* and assembled under the name *Virgil series*. (See under *Virgil series*.) He divided his Missouri series into (descending) Pedee group, Lansing group restricted, Kansas City group restricted, Bronson group, and Bourbon group. In 1936 (Kans. Geol. Surv. Bull. 22, pp. 41–43) Moore included in his *Missouri series* (*redefined*) all rocks above discon. at base of his Bourbon fm. and below discon. at base of his Tonganoxie ss., the overlying beds being assigned to his Virgil series. The U. S. Geol. Survey has not had occasion to consider, for its publications, these modifications.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for development in NW. Mo. and along Missouri River, Iowa.

Missouri series, stage, etc.

See under *Missouri group*.

†Missourian series, formation, division.

Variants of *Missouri group*, employed by some geologists.

Missouri Mountain slate (also **shale**).

Silurian (late): Southwestern Arkansas and southeastern Oklahoma.

A. H. Purdue, 1909 (Slates of Ark., Ark. Geol. Surv., p. 37). *Missouri Mtn sl.*—Mainly red clay sl., with green sl. in basal portion. Thickness 50 to 300 ft. Underlies Arkansas novaculite and overlies, probably uncon., Blaylock ss. May be Ord., Sil., or Carbf., but scarcely Dev. [As here defined replaces Slatington sh. of Purdue, and is applied to older rocks than those called "Missouri Mtn fm." in his earlier 1909 publication. This is established definition, while "Slatington sh." was never adequately defined and has been discarded.]

E. O. Ulrich tentatively refers this fm. to Cayugan epoch of Sil.

Named for exposures in Missouri Mtns, Polk and Montgomery Counties, Ark.

†Missouri Mountain formation.

Devonian and Pennsylvanian: Southwestern Arkansas.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557). *Missouri Mtn fm.*—Novaculite, ss., and sh. overlying Slatington sh. and composing top fm. of Ouachita Ord. area in Ark. Slatington sh. and Missouri Mtn fm. may possibly be of Sil. age. [As here defined the name was applied to beds which Purdue later in 1909 named *Arkansas novaculite* and *Fork Mountain sl.* The Arkansas novaculite is of Middle and Upper Dev. (?) age; the †Fork Mtn sl. is of Penn. age, and is now included in Stanley sh.]

Mistassini formation.

Cambrian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 197).

Mistassini limestone.

Pre-Cambrian: Quebec.

H. C. Cooke, 1919 (Jour. Geol., vol. 27, p. 74).

Mitchell limestone.

Mississippian: Southern Indiana.

C. E. Siebenthal, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., pp. 296, 298). *Mitchell ls.*—Impure lss., calc. shales, and fossiliferous lss., 150 to 250 ft. thick, overlying Bedford oolitic ls. [Spergen ls.] and underlying Chester or Kaskaskia group, although latter rocks are not present at Mitchell.

M. N. Elrod, 1899 (Ind. Acad. Sci. Proc. for 1898, pp. 258–267). Mitchell ls. of Siebenthal appears to extend from top of Bedford oolitic ls. to middle of Paoli ls. of this rept. *Mitchell ls.* is here restricted to 160 ft. of lithographic ls. and calc. sh. with chert inclusions, the lower portion argill. and hydraulic. It thus includes all of St. Louis ls. below Lost River chert (which underlies Paoli ls.), and it overlies Bedford oolitic ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29). *Mitchell ls.* of Ind. includes St. Louis, Ste. Genevieve, Cypress ss., and Tribune ls.

C. A. Malott, 1919 (Ind. Univ. Studies vol. 6, No. 40, pp. 7–20). *Mitchell ls.* extends to top of Beaver Bend ls., and includes St. Louis ls., Fredonia oolite, Gasper oolite, and Sample ss.

C. A. Malott, 1921 (Ind. Acad. Sci. Proc. for 1919, pp. 361–369). *Mitchell ls.*, 350 ft. thick, outcrops in so-called Mitchell Plain. Includes Gasper oolite, Fredonia oolite, and St. Louis ls.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, p. 127). Ashley has estimated thickness of *Mitchell ls.* of Ind. to be btw. 350 and 400 ft. As the Mitchell includes the Ste. Genevieve, which is about 160 ft. thick, it leaves 190 to 240 ft. for the St. Louis.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 507). It would seem best to follow Butts' example, discarding Mitchell and returning to long established names St. Louis and Ste. Genevieve, and the latter procedure is adopted in present revision. *Mitchell* may still be used as a convenient handle for the whole mass of cavernous lss. btw. the Salem [Spergen] and the clastic Chester.

W. N. Logan, 1926 (Ind. Dept. Cons. Div. Geol. Pub. 55, pp. 342–343). *Mitchell ls.* extends from top of Salem ls. to top of Beaver Bend ls.

Named for Mitchell, Lawrence Co.

Mitchell sand.

Subsurface sand that has been said to correspond to Connellsville ss. memb. of Conemaugh fm. in some parts of western Pa. and in Ohio. Is 10 to 50 ft. thick, and lies 90± ft. below Pittsburgh coal. It has also been correlated by some geologists with the older Morgantown ss. memb. of Conemaugh fm. First found on Mitchell farm, sec. 10, Marietta Twp, Washington Co., SE. Ohio.

Mitchell's Ferry beds.

Eocene (upper): Eastern Texas and western Louisiana.

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1317). *Mitchell's Ferry beds.—Massilina pratti* zone in wells. Very fossiliferous, gray, glauconitic, sandy clay, green when wet. Thickness 100 ft. Exposed at Mitchell's Ferry, on Sabine River, Tex., also in Mount Vernon Parish, La., on E. bank of Bayou Toro in SE¼NW¼ sec. 6, T. 3 S., R. 11 W. Belong to Whitsett fm. Are possibly eastern equiv. of lower part of Falls City shales.

Mitten black shale member (of Pierre shale).

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Mitten black sh. memb. of Pierre sh.*—Blue-black fissile sh. with few iron-stained calc. concretions. Marine fossils. Forms prominent scarp. Thickness 150 to 200 ft. Overlies Gammon ferruginous memb. of Pierre sh. and top lies 500 to 800 ft. below Monument Hill bentonitic memb. of Pierre. Named for exposures along Mitten Prong in T. 56 N., R. 68 W., Crook Co., Wyo.

Mizpah trachyte.

Tertiary: Central Nevada (Tonopah district).

J. E. Spurr, 1911 (Min. and Sci. Press, vol. 102, pp. 560–561; also Rept on geol. of property of Montana-Tonopah Mining Co., Tonopah, Nev., published privately), and 1915 (Econ. Geol., vol. 10, pp. 713–769). *Mizpah trachyte.*—Oldest rock of Tonopah dist. Called "earlier andesite" in U. S. G. S. P. P. 42, 1905. Its lower part is "Glassy trachyte," into which the Mizpah trachyte proper grades. Is intruded by West End rhyolite. Thickness 700+ ft. Named for Mizpah Hill, Tonopah dist.

T. B. Nolan, 1930 (Univ. Nev. Bull., vol. 24, No. 4, pp. 15–17). The "earlier andesite" of Spurr as originally defined included Sandgrass andesite of Spurr's 1915 rept (Econ. Geol., vol. 10, pp. 713–769). The name *Mizpah trachyte* is retained in present rept, although the rock is in reality a keratophyre or albite trachyte. A thickness of at least 2,000 ft. is indicated by hanging-wall exposures in Sand Grass and Tonopah Extension mines. Top is not known, except where it is uncon. overlain by Fraction breccia. It conformably overlies Tonopah fm. and must therefore be slightly younger. The "glassy trachyte" is here included in Tonopah fm.

Moab sandstone member, also **Moab tongue** (of Entrada sandstone).

Upper Jurassic: Central eastern Utah (Moab region).

J. B. Reeside, Jr., C. E. Dobbin, A. A. Baker, and E. T. McKnight, 1927 (A. A. P. G. Bull., vol. 11, No. 8, pp. 787, 799, 804, 805). *Moab tongue of Entrada ss.*—In unpublished rept by W. T. Lee was called *Moab ss.* Is top part of Entrada ss., and of lighter color than rest of Entrada. Thins out to W. into Summerville fm., with which it intertongues.

C. H. Dane, 1935 (U. S. G. S. Bull. 863). *Moab ss. memb. of Entrada ss.*—White cross-bedded fine-grained quartz ss., massive or in thick beds, with a few red sh. partings. Upper part of Entrada ss.

Named for exposures in Moab Valley, but not at or very near Moab.

Moat volcanics.

Late Devonian or late Carboniferous: Northern New Hampshire (North Conway quadrangle, White Mountains).

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, pp. 89+). In North Conway quad. two large areas of volcanics are exposed, the type loc. on Moat Mtn and a second large area on Mount Kearsarge (Mount Pequawket). These are composed of siliceous flow rocks and interbedded tuffs and breccias. I propose name *Moat volcanics* to include the Pequawket breccia and "quartz porphyry" of Hitchcock. (The "quartz porphyry" is=*South Moat flows* of this paper.) Thickness 8,300 to 11,800+ ft. Rest uncon. on Intervale clay slates. Are intruded by Albany and Conway granites. Type loc. on South Moat Mtn, North Conway quad., where excellent section is exposed from elev. 1,100 ft. upwards on South Moat trail to Red Ridge.

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., pp. 12–13, map). Remnants of *Moat volcanics* are present in Franconia quad., where the fm. is uncon. on Talford schist, from which it is separated by long erosion period. It is definitely younger than New Hampshire magma series; can not be older than late Dev., and may be late Carbf. Introductory fm. of White Mtn magma series. Thickness exposed in this quad. is 1,500± ft.; upper part has been cut away.

Moberly channel sandstone.

Pennsylvanian: Northern central Missouri.

C. F. Marbut, 1898 (Mo. Geol. Surv. vol. 12, pt. 2 (Sheet Rept. 12), pp. 323, 324, 331–332, 350). *Moberly ss.*—Sss., shales, and cgls., of unknown thickness, with basal cgl. of waterworn fragments of ls. and sh. Usually more heavily bedded and coarser than underlying Coal Measures sss., and often cross-bedded. Uncon. overlies Middle Coal Measures and underlies Pleist. drift, in Randolph, Howard, Chariton, and Monroe Counties.

Is a channel deposit, 0 to 100 ft. thick, occupying depressions in Pleasanton fm., and probably of Pleasanton age and contemp. with Warrensburg ss. Named for exposures at Moberly, Randolph Co.

†Mobile formation.

†Mobile Bay formation.

Pleistocene: Southwestern Alabama.

E. A. Smith, 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 285–296).

E. A. Smith, L. C. Johnson, and D. W. Langdon, Jr., 1894 (Ala. Geol. Surv. Rept. Coastal Plain, pp. 47, 50). *Mobile Bay fm.* (*Mon Louis Island*).—Stump-bearing clay which borders Mobile Bay and extends up larger rivers to inland margin of coastal plain. A phase of Port Hudson which we have called *Mobile or Mon Louis Island Terrace.* [On p. 47 is heading: *Estuarine or transition formations (Mobile).*] We have therefore in Mobile fm. a post-Tert. or Pleist. fm. younger than the Lafayette and older than the "Outside Keys" and older than the first bottoms of the rivers, and formed during the last great depression of the coast, preceding the last considerable elevation and of course preceding the subsidence that is now in progress. The shells which characterize the fm. could not have flourished here except at a time when Mobile estuary was freely open to the deep sea. This would make it contemp. with lower part of the Port Hudson and Biloxi, and it corresponds also with older part of second terrace deposits of the rivers. The Mon Louis or Mobile fm. forms natural connection btw. the marine Pleist. of outer coasts and the fresh-water Pleist. of rivers. Full extent of fm. not definitely known. Thickness undetermined.

Only known uses of names. According to C. W. Cooke (personal communication) the deposits are probably=Pamlico fm. of Atlantic Coast.

Moccasin limestone.

Middle Ordovician (Lowville): Northeastern Tennessee and western Virginia.

M. R. Campbell, 1894 (U. S. G. S. Estillville folio, No. 12, p. 2). *Moccasin ls.*—Red argill. ls., passing into blue flaggy Chickamauga ls. below and into blue and yellow Sevier sh. above, being intermediate btw. the deep-sea deposits of NW. part of quad. and aren. shore deposits of Bays syncline. Max. thickness 500 ft.

G. W. Stose, 1923 (Va. Geol. Surv. Bull. 24). *Moccasin ls. memb. of Lowville ls.*—Reddish argill. ls., 50 ft. thick, composing upper part of Lowville ls. in Wise and Scott Counties, Va. Underlain by fine-grained drab ls. of Lowville age.

According to late studies of C. Butts the Moccasin ls. is a facies of Lowville ls., and the two facies occur in different areas, *Moccasin ls.* being appropriate in SE. belts as far N. in SW. Va. as Roanoke, and *Lowville ls.* being appropriate along NW. side of the valley as far S. as latitude of Morristown, Tenn. These are the definitions at present followed by U. S. Geol. Survey.

Modelo formation.

Miocene (upper): Southern California (Ventura and Los Angeles Counties).

G. H. Eldridge, 1907 (U. S. G. S. Bull. 309). *Modelo fm.*—Consists of 1,700 to 6,000 ft. of strata, divided into a lower ss., massive and heavy-bedded, 200 to 2,000 ft. thick; overlain by 400 to 1,600 ft. of earthy sh., gray to brown, with ls. concretions that weather yellow; succeeded by upper ss. memb., about 900 ft. thick and similar to lower ss. memb. except that it is nonconcretionary and thinner-bedded. Top memb. consists of a body of brown, gray, or yellowish sh. of uncertain thickness (due to erosion uncon. above it) but variously estimated at btw. 200 and 1,500 ft. The upper sh. memb. is indistinguishable from the sh. btw. the two sss.; both vary from granular siliceous to earthy and fissile, and both carry calc. layers and here and there lenticular ls. concretions. Rests on Vaqueros ss. [younger than true Vaqueros, according to Kew] and is uncon. overlain by Fernando fm. The fm. is well developed in Hopper Canyon and at head of Modelo Canyon, Ventura Co.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753). The beds called *Vaqueros ss.* by Eldridge are younger than true Vaqueros ss., and *Modelo fm.* is here redefined to include Modelo fm. and the 2,000 to 3,000 ft. of so-called Vaqueros of Eldridge, all of which are upper Mio. As redefined the Modelo aggregates 9,000 ft. in thickness. It is primarily clay, diatomaceous sh. and fine-grained laminated ss. and cherty beds, and contains two or three large lenses of coarse brown and tan ss. varying in thickness up to about 4,000 ft. It rests uncon. on Topanga fm., and is uncon. overlain by Pico fm., the basal div. of Fernando group.

Later work by Kew and others proved that typical Modelo contains beds=Topanga fm. (middle Mio.), but U. S. Geol. Survey follows Kew's 1924 definition, which restricted Modelo to upper Mio. beds, believing that that usage will be more useful, and that the Topanga may eventually be separated from type Modelo.

Modin formation.

Lower Jurassic: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). An extensive succession of tuffaceous beds, overlain by a greater mass of compact, fine gray shaly sss. and shales, with a few small lenses of ls. At base an extensive bed of volcanic cgl., having max. thickness of about 400 ft. in Bear Mtn. Estimated thickness of fm. 3,000 ft. Rests uncon. on Brock sh. The relation of *Modin fm.* to overlying Potem fm. appears to be one of conformity, though Modin epoch closed at a time of vigorous volcanic activity, especially in vicinity of Bagley Mtn. [See *Bagley andesite.*] Named for exposures on Modin Creek, near mouth of which, in NE. part of Redding quad., the fm. has yielded most of its fossils.

Modoc limestone.

Mississippian (lower): Southeastern Arizona (Clifton-Morenci region).

W. Lindgren, 1905 (U. S. G. S. P. P. 43). *Modoc ls.*—Coarse blue or gray lss., exceptionally pure, with subordinate strata of qtzite and dol.; the gray ls. is characteristic part and recurs at many places. Thickness 170± ft. South of Modoc Mtn the fm. consists of (descending): (1) Coarse blue fossiliferous ls. in benches 2 to 3 ft. thick, 4 to 10 ft.; (2) *"Gray Cliff" ls.*, consisting of 75 to 85 ft. of light-gray coarse ls. with crinoid stems, in 2-ft. benches; (3) light grayish-brown dolomitic ls., 60 ft.; (4) white or reddish calc. qtzite, 15 to 17 ft.; (5) massive bench of gray coralliferous ls., 8 to 10 ft. Rests conformably on Morenci sh. and is uncon. overlain by Pinkard fm. (Cret.).

Modoc quartz monzonite.

Eocene: Central northern Colorado (Boulder County).

P. G. Worcester, 1921 (Colo. Geol. Surv. Bull. 21, pp. 30–31). *Modoc quartz monzonite porphyry.*—Occurs in a single dike, which is found in Modoc mine, about ½ mi. due N. of Ward. The dike extends E. for about a mile.

Modoc lavas.

Tertiary (?): Northwestern Nevada (Washoe County).

R. W. Chaney, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 162–163). *Modoc lavas* overlie Davis Creek beds in Washoe Co., Nev. The Davis Creek beds contain plants that seem to establish their Mio. age. [Derivation of name not stated.]

Modoc basalt.

Recent: Northern California (Modoc lava-bed quadrangle).

H. A. Powers, 1932 (Am. Min., vol. 17, No. 7, pp. 253, 273, map). *Modoc basalt.*—A group of Recent basalt flows and cones the eruption of which began after the glaciation and continued to present time. The youngest of these is certainly not over 500 yrs old. Most of these flows and cinder cones are found in 2 areas, one the Modoc Lava beds on NE. slope of Medicine Lake Highland and the other on southern slope of the Highland. A few flows are scattered along eastern and western flanks of the Highland, and a few eruptions took place at top of the Highland in vicinity of Medicine Lake. Little Mount Hoffman is a Modoc basalt cone containing small irregular intrusives. The rock of most of the flows is dark gray, usually aphanitic, variably vesicular, and rarely visibly porphyritic.

†Modoc porphyry.

Name locally applied to a rhyolite porphyry, of Mio. or Plio. age, in Butte, Mont., dist.

Moduria limestone series.

Misprint (on p. 273 of U. S. G. S. Bull. 191) for *Maclurea ls.*

Moenkopi formation.

Lower Triassic: Arizona, southern Utah, southeastern Nevada.

L. F. Ward, 1901 (Am. Jour. Sci., 4th, vol. 12, pp. 401–413). *Moencopie beds.*—Consist of (descending) 200 ft. of dark chocolate-brown argill. and saliferous sh.;

100 ft. of soft dark-brown argill. sss.; 200 ft. of dark-brown argill. sh.; 100 ft. of white calc. sh.; and 100 ft. of saliferous argill. sh. Rest uncon. on Upper Aubrey [Kaibab ls.] (Carbf.) in Little Colorado Valley. Underlie Shinarump cgl.

In some subsequent repts Moenkopi fm. was defined as underlying De Chelly ss. In other repts De Chelly ss. was placed in lower part of Moenkopi. But true De Chelly ss. is now known to be of Perm. age, to be=uppermost part of Coconino ss., and to belong to Cutler fm. At De Chelly Canyon, Ariz., it is top memb. of Cutler fm. (Perm.), and is uncon. overlain by Moenkopi fm. (Triassic). At Fort Defiance, Ariz., some red beds of the Cutler separate the light-colored De Chelly ss. from the uncon. overlying Moenkopi, which is, in turn, uncon. overlain by Shinarump cgl. At places in Ariz. (Grand Canyon, Lees Ferry, Red Canyon, Little Colorado River, etc.) and Utah (Circle Cliffs, San Rafael Swell, etc.) the Moenkopi rests on Kaibab ls. (See A. A. Baker and J. B. Reeside, Jr., A. A. P. G. Bull., vol. 13, No. 11, pp. 1413-1448, 1929.) This is present approved definition of Moenkopi fm.

Named for Moenkopi Wash, Grand Canyon, Ariz.

†Moenkopian series.

A term employed by C. [R.] Keyes to designate the Lower Triassic Moenkopi fm.

Mogollon andesite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). *Mogollon andesite.*—Dominantly andesitic flows, but includes dacite flow near top and possibly other dacite flows. Underlain by a few ft. of red ss. Thickness 250 to 600 ft. Uncon. overlain by Dog Gulch fm.

Named for prominent outcrops near town of Mogollon.

†Mohave formation.

Tertiary (probably Eocene): Southern California (Mohave region).

J. H. Smith, 1900 (Jour. Geol., vol. 8, pp. 455-456). *Mojave fm.*—A fm. in SE. Calif. described [but not named] by H. W. Fairbanks (Am. Geol., vol. 17, 1896, p. 63 [also 67-68]), as consisting of a series of beds of clays, ss., volcanic tuffs, and interbedded lava flows, probably 1,000 ft. or more thick, occurring on N. slope of El Paso Range, btw. Mojave and Owen's Lake, and probably extending over considerable area btw. El Paso Range and Sierra Nevada. Finely exposed in Red Rock Canyon and about Black Mtn; tilted northward at angle of 15-20°. Fossil plants identified by F. H. Knowlton as without doubt Tert. and as probably Eo.

†Mohawk limestone.

Middle Ordovician: Eastern New York.

T. A. Conrad, 1839 (Phila. Acad. Nat. Sci. Jour., vol. 8, pt. 1, pp. 228-235; N. Y. Geol. Surv. 3d Ann. Rept., pp. 57-66). *Mohawk ls.*—Underlies Trenton ls. and overlies Birdseye [Lowville] ls. Characterized by *Orthostonia communis*. Included in Mohawk system. [Applies to post-Lowville part of Black River group, or to beds now called *Amsterdam ls.* Some succeeding early N. Y. repts gave following succession (downward): Trenton ls., Birdseye ls., Mohawk ls., Calciferous sandrock. Other repts state that Mohawk ls. is base of Trenton ls.]

Named for development in Mohawk Valley.

†Mohawk system.

Silurian, Ordovician, and Upper Cambrian: New York.

T. A. Conrad, 1839 (Phila. Acad. Nat. Sci. Jour., vol. 8, pt. 1, pp. 228-235). *Mohawk system or Lower Silurian group.*—Includes (descending) Clinton group [exclusive of Rochester sh.], Niagara ss., shales of Salmon River, unnamed black sh.

that is—Trenton ls., Mohawk ls., Birds-eye ls., Calciferous ss., and Potsdam ss. Is overlain by Niagara [Rochester] sh. "The Cambrian, which was supposed to underlie the Silurian system, having proved to be composed of members of the latter group, I include in our Silurian."

†Mohawk slate group.

Upper Ordovician: Eastern New York.

W. W. Mather, 1841 (N. Y. Geol. Surv. 5th Ann. Rept., pp. 91–94, 98–101, 129). *Mohawk sl. group (Black sl. of Vanuxem)*.—More or less fissile and interstratified with thin layers of ss. and ls. Passes into underlying Trenton ls. by gradual interstratification of thin bands of sl. in the ls. Overlain by Frankfort sl. group.

Now replaced by Utica sl.

†Mohawk group.

Middle and Lower Ordovician: New York (Mohawk Valley).

J. Hall, 1842 (Am. Jour. Sci., 1st, vol. 42, p. 52). The ls. along Mohawk valley, the principal memb. of which is termed by Mr. Vanuxem the "Mohawk ls.," a name which with much propriety might be applied to the whole mass, forming the *Mohawk group*. This would include Mohawk, Birdseye, and Trenton lss.; and calciferous sandrock [Beekmantown] might also be included as lower memb. of the group.

Mohawk lake beds.

Miocene (upper): Northern California (Plumas County).

H. W. Turner, 1891 (Wash. Phil. Soc. Bull. 11, pp. 385–410). *Mohawk lake beds*.—Lake beds of fine stratified material deposited in Mohawk Valley and vicinity, in Plumas Co., during Plio. and Pleist. time. Rest on Tert. igneous rocks (andesites and rhyolites) and are overlain by recent alluvium.

According to J. P. Smith (Calif. State Min. Bur. Bull. 72, p. 37, 1916) these beds are of upper Mio. age.

Mohawkian series (or **epoch**).

Provincial series of Middle Ordovician rocks as developed in Eastern States and the time covered by their formation. Includes Trenton and Black River time. Defined by J. M. Clarke and C. Schuchert (Sci., n. s., vol. 10, pp. 876, 877, 1899). Rocks typically developed in valley and watersheds of Mohawk River, N. Y. For definition see U. S. G. S. Bull. 769, pp. 86–87.

Mohegan granite.

Pre-Cambrian: West Point quadrangle, southeastern New York.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, pp. 29, 35, 40, 42, 43, 64). *Mohegan granite*.—Same as Peekskill granite, which is quarried about 4 mi. E. of Peekskill and also a little E. of road running S. from Mohegan Lake. The product is known in the trade as *Mohegan granite*.

Named for exposures about Mohegan Lake.

†Mohegan Bluff beds.

†Mohegan Bluff series.

Pleistocene: Block Island, Rhode Island.

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, p. 978 and table opp. p. 988). *Mohegan Bluff series*.—At Mohegan Bluffs, on Block Island, consists of blue clays with ice-scratched bowlders above, underlain by sands and gravels, to which succeed clayey beds resting on bluish carbonaceous clays probably of Cret. age. Belongs to Tisbury subepoch. Preceded Vineyard interval.

J. B. Woodworth, 1897 (Geol. Soc. Am. Bull., vol. 8, p. 210). *Mohegan Bluff beds*.—Nearly horizontal sands and clays, with boulders and cobbles. Equiv. to Tisbury beds on Marthas Vineyard. Typically exposed in upper part of Mohegan Bluffs. Uncon. overlain by glacial drift of last glacial stage. Uncon. overlies Sankaty beds.

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52), divided the beds exposed at Mohegan Bluffs, Block Island, that are uncon. overlain by last Wisconsin glacial drift and uncon. underlain by Weyquosque fm. (=Sankaty sand), into (descending): Manhasset fm. (including all 3 of its members—Hempstead gravel memb., Montauk till memb., and Herod gravel memb.), Jacob sand, Gardiners clay, and Jameco gravel.

Moheganter shales and sandstones. (In Hamilton group.)

Middle Devonian: Eastern New York (Schoharie Valley).

A. W. Grabau, 1930 (Sci. Quart. Nat. Univ. of Peking, China, vol. 1, No. 4, p. 14). *Moheganter shales and sss.*—Represent all of Hamilton group in Schoharie Valley, that is the beds which in the section of Ulster Co. are represented by the Ashokan, Mount Marion, and probably part of so-called Marcellus shales. In Schoharie Valley these beds contain typical Hamilton fossils from top to bottom. Thickness 1,500 ft. They are abruptly capped by Sherburn ss., the base of which represents horizon of Tully ls. farther W.

G. A. Cooper, 1933 (Am. Jour. Sci., 5th, vol. 26, p. 551). Grabau proposed *Moheganter shales and sss.* for the fossiliferous Hamilton beds which Prosser and others thought represented all of the Hamilton. It is now known that Prosser failed to recognize the upper Hamilton in Schoharie Valley, and therefore the Moheganter beds do not represent the complete Hamilton but a little more than half of it. The name *Panther Mtn*, here proposed, is preferred to Grabau's name, because Moheganter Mtn does not furnish an adequate type section for interval writer wishes to define, and the limiting Portland Point memb. is not known to occur there.

Mohnian stage.

Tertiary: California.

See under *Zemorrian stage*, R. M. Kleinpell, 1934.

H. G. Schenck and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 224). *Mohnian stage* includes Briones fm., middle Monterey, Tice, and Rodeo shales, etc.

Moingona till.

A term introduced by C. [R.] Keyes to cover an early Pleist. deposit in Iowa. (See Pan-Am. Geol., vol. 58, p. 203, 1932.)

Moingonan glacial epoch.

A term introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 44, pp. 139–142, 1925) to cover the time of deposition of an old glacial till encountered in deep excavations in city of Des Moines, Iowa, which he considers to be of pre-Nebraskan age. Named after the old pre-glacial Moingona River (Iowa Acad. Sci. Proc., vol. 25, pp. 551–559, 1920), in a tributary deep gorge of which the till remnant is now revealed.

Moira granite.

Pre-Cambrian (Huronian): Western Ontario (Hastings County).

W. G. Miller and C. W. Knight, 1914 (Ontario Bur. Mines Rept., vol. 22, pt. 2, p. 4). Intrusive.

†Mojave formation.

See *Mohave*.

Mokapu basalt.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Mokapu basalt.*—Included in lower part of Honolulu volcanic series [q. v.]. Named for Mokapu Peninsula.

Mokulea basalt.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Mokulea basalt.*—Included in lower part of Honolulu volcanic series [q. v.]. Composes Mokulea Rock, in Kailua Bay.

Moku Manu volcanics.

Pleistocene (late): Hawaii (Moku Manu).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Moku Manu volcanics.*—Lithic tuff, basalt, and cinders composing Moku Manu, which consists of two islands, one 202 ft. and the other 132 ft. high. Included in lower part of Honolulu volcanic series [q. v.].

Molas formation.

Pennsylvanian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120, and Geol. Soc. Am. Bull., vol. 16, pp. 470–496). *Molas fm.*—Red calc. shales and sss. with chert, ls., and qtzite pebbles and thin fossiliferous ls. lenses. The ls. lenses contain Penn. fossils. The chert and ls. pebbles often contain fossils from Miss. part of underlying Ouray ls., with which it is uncon. Thickness 75 ft. Is conformably overlain by Hermosa fm. The Molas is absent in area where Hermosa fm. was first defined, and therefore was not included in original Hermosa.

The Miss. part of Ouray ls. as first defined is now called Leadville ls., and *Ouray ls.* is restricted to the Upper Dev. part.

Named for exposures on Molas Lake, Needle Mtns quad.

Mollie Miller sand.

A subsurface sand in South Ponca field, central eastern Okla., which is reported to correspond to Sylamore ss. memb. of Chattanooga sh. (Dev.?). Named for Mollie Miller lease, where first recognized.

Mollman sand.

A subsurface sand, of Ord. age, in Okla. City oil field, central Okla., that has been correlated with a lower part of Simpson fm. It is said to be basal 30 ft. of *School Land ss.*, q. v.

Momable slates.

Pre-Cambrian: Newfoundland.

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 219).

Mona schist.

Pre-Cambrian (Keewatin): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 490+). *Mona schists.*—Nonconglomeratic greenstone schists, many of which are probably altered tuffs, while others are squeezed basic lavas. Some of schists are banded, others aphanitic, others resemble epidiorite, others might be called amphibolites, others strongly resemble true crystalline schists. All are older than the granites of Basement Complex, and of about same age as the conglomeratic Kitchi schist. Exposed on Mona Hills, SW. of Marquette.

Later repts state that Kitchi schist may be younger than Mona or may be of same age.

Mona limestone. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1917 (W. Va. Geol. Surv. Rept. Braxton and Clay Counties, p. 191). The ls. immediately at base of Lower Connellsville ss. in Mona section, as described in Monongalia-Marion-Taylor Co. rept, is not Clarksburg ls., which overlies Lower Connellsville ss., but represents an unclassified ledge which could appropriately be referred to as *Mona ls.*, from Mona, Monongalia Co. [This ls. is described in Monongalia, Marion, and Taylor Co. rept as consisting of 10 to 30 ft. of dark-gray hard ls. with interbedded limy shales.]

Mona shale.

Oligocene: Panama and Costa Rica.

D. F. MacDonald et al., 1919 (A. A. P. G. Bull., vol. 3, p. 364).

†Monarch formation.

Upper and Middle Devonian: Central northern Montana (Fort Benton quadrangle).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Monarch fm.*—Rocks readily distinguished by color and crystalline granular texture from lss. above and below. Includes both Jefferson and Threeforks fms, to S. Greater part of total thickness of 130 ft. consists of Jefferson lss. (dark-colored, usually chocolate-brown or bluish-black, finely crystalline lss. that weather with pitted surface, carry Dev. fossils, and often show a fine striping, due to slight color variations). The upper 30 ft. consists of reddish shaly lss., also carrying Dev. fossils. Underlies Madison ls. and overlies Barker fm. [Mapped at and around village of Monarch, in SW. corner of Fort Benton quad.]

Monclova sandstone.

Lower Devonian: Northwestern Ohio.

E. Orton, 1888 (Ohio Geol. Surv. vol. 6, p. 20) and 1890 (Ohio Geol. Surv., 3d Organization, 1st Ann. Rept., p. 24). *Monclova or Holland ss.* occupies same position in the series as Sylvania ss.

Named for Monclova, Lucas Co.

Monclova shale.

Cretaceous: Mexico.

E. Ordóñez, 1908 (Min. and Sci. Press, vol. 96, p. 363).

Moneague.

Tertiary: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 75).

Moneta biotite-hornblende gneiss.

Pre-Cambrian: Central western Virginia (Bedford County).

A. A. Pegau, 1932 (Va. Geol. Surv. Bull. 33, pp. 22-26, 83, pl. 4). *Moneta biotite-hornblende gneiss.*—Occurs in area mapped as *Lynchburg gneiss* (*pre-Camb.*) on 1928 map of Va. It is described as mica gneiss and mica schist, in part garnetiferous. The gneiss in Moneta-Bells area differs so much from general character of Lynchburg gneiss that writer has named it *Moneta gneiss*, from Moneta, Bedford Co., where it is best known. It is prevailing type in Moneta-Bells area. Consists of two distinct lithologic types, biotite gneiss and hornblende gneiss, so intimately associated that they cannot be mapped separately. The two types may (1) represent different beds in original sediments, (2) both be of igneous origin, or (3) one may be igneous and the other sedimentary.

Monitor sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1915 (W. Va. Geol. Surv. Rept. Boone Co.). The name of the massive, bluish gray, medium grained, hard, micaceous ss., 20 to 40 ft. thick, lying 0 to 5 ft. below Alma coal and 1 to 5 ft. above Little Alma coal, is now changed from *Logan ss.* (preoccupied) to *Monitor ss.*

Named for exposures at Monitor, Logan Co.

Monitor (Lower) sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co., p. 274). The name *Lower Monitor ss.* is suggested for the ledge in Logan and Mingo Counties that was erroneously correlated with Peerless ss. on pp. 103 and 183 of Logan and Mingo Co. rept. [For description see Hennen and Reger, 1914, under *Peerless ss.*]

Monitor Mountain limestone member.

Mississippian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 48 and passim). *Monitor Mtn ls. memb.*—Top memb. of Madison ls. (lower Miss.), nearly every good exposure of which in this area contains typical Madison fauna. Most striking feature of this memb. is its large amount of argill. matter. Lower 26 ft., fine-grained white argill. ls., which breaks with conchoidal fracture and weathers white gray. Near base is 2½ ft. of gray fine-grained sandy qtzite. Overlying 54 ft. is argill. fine-grained cream-colored ls. and some crumbly argill. ls. Overlying this are 182 ft. of white, slightly sandy argill. ragged lss. that weather clayey but of more white-gray color than underlying. Upper 20 ft., very massive thick-bedded pale buff-gray argill. ls., which exhibits an occasional pinkish cast on fresh surfaces and weathers white buff. Thickness of fm. 0 to 282 ft. Only known occurrence is in NE¼ sec. 18, T. 17 N., R. 7 W., on upper ridge and top of Monitor Mtn, where it is 282 ft. thick. Overlies Rooney chert memb.

Monk formation.

Pre-Cambrian: Southeastern British Columbia, northwestern Idaho, and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 6 and 7). *Monk fm.*—Alternating phyllites and metamorphosed (schistose) grits, sss., and cgls., of gray colors.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 147, 178, 194). *Monk fm.*—Qtzite, phyllite, cgl., and schist, 5,500± ft. thick. Conformably underlies Wolf fm. and conformably overlies Irene volcanics—all included in Summit series of Selkirk Mtns at 49th par. Exposed on summits just N. of Monk Creek, B. C., for which it is named.

Monkey Hill formation.

Oligocene: Panama.

E. Howe, 1908 (Am. Jour. Sci., 4th, vol. 26, p. 228).

Monkton quartzite.

Lower Cambrian: Northwestern Vermont (Addison County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 106). *Monkton qtzite.*—Oldest fm. in central sequence. Base not known, because lowest red beds rest on Ord. rocks along a thrust-fault plane. Named for town of Monkton, 20 mi. nearly S. of Burlington, where relations to overlying beds are well shown. Is almost wholly qtzite, in layers from a few inches to 3 ft. thick. A few seams and beds of reddish or purplish sh. most of them only a few inches thick, are interbedded with the qtzite in lower part of fm. The qtzite has a decided reddish color, varying from reddish brown through brick red and purple to light shades of red, pink, buff, and white; the white beds are more numerous at top, especially N. of Burlington, where they are as important as the vari-colored beds. In upper part of fm. a few thin layers of gray or pink dol. form transition to overlying Winooski marble. Quartz cgl. in thin layers has been reported from a few places by several geologists but has not been observed by writer. Full thickness of fm. unknown, but 300 ft. are seen in sections in Colchester Twp. Contains Lower Camb. fossils.

Mon Louis formation.

Pleistocene: Southwestern Alabama.

See description under †*Mobile fm.*

Name derived from Mon Louis Island, on W. coast of Mobile Bay.

Monmouth group (also **formation**).

Upper Cretaceous: New Jersey, Delaware, and northeastern Maryland.

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 315, 331). *Monmouth fm.*—Name is now proposed for first time, from Monmouth Co., N. J. Underlies Rancocas fm. [group] and overlies Matawan fm. Thickness 60 to 150 ft. Divided into (descending) Redbank sands, Navesink marls, and Mount Laurel sands.

The Monmouth is now classified as a group in N. J., and its subdivisions (Redbank sand, Navesink marl, and Mount Laurel sand) as fms. In Md., where the subdivisions are not recognized, it is called *Monmouth fm.*

Mono limestone.

Mississippian (upper): Central northern Utah (Ophir district).

S. G. Olmstead, 1921 (Econ. Geol., vol. 16, pp. 438, 452, 453). Great Blue ls. fm. is locally known as *Mono* in Ophir dist.

Evidently named for Mono mine, which is in Deseret ls., Humbug fm., and †Great Blue ls., according to J. Gilluly (U. S. G. S. P. P. 173, p. 154, 1932).

Mono series (also Monon series).

Terms applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 51, 53, 79), to 2,600 ft. of lss. in Nev. and Calif., said to be of early Camb. age and to be older than Prospect Mtn qtzite. "Term derived from Mono Co., Calif."

Mono shale.

Eocene (?): Southern California (southern part of Santa Ynez quadrangle, Santa Barbara County).

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 10, pp. 350, 352, pl. 46, and map). At type loc. the *Mono sh.* consists of a series of sandy gray shales, in beds up to 4 inches thick, interbedded with light-gray, medium fine-grained micaceous sss, varying in thickness from 1 to 4 inches. In lower part some of softer shales are locally contorted. Oval concretions occur locally. Toward top are impure ls. ledges 1 to 2 ft. thick. At base is a rather hard massive coarse-grained ss. about 50 ft. thick. Total thickness of fm. 700 ft. Rests conformably on Indian cgl. and is conformably overlain by Sierra Blanca ls. No fossils, but believed to be of marine origin. Extends from Mono Creek to Santa Cruz Creek; also occurs on SE. side of Big Pine Mtn. Named for exposure in canyon of Mono Creek, at mouth of Roble Creek, Santa Barbara Co.

M. F. Keenan, 1932 (San Diego Soc. Nat. Hist. Trans., vol. 7, No. 8, pp. 53–84). Paleontologic evidence points to Cret. (Chico) age of *Mono sh.* and Indian cgl., instead of Eo.

Monon series.

A term employed by C. [R.] Keyes to cover 2,000 ft. of shales, of early Camb. age, in Utah, to which he has applied name *Timpanogos*.

Monongahela formation.

Pennsylvanian: Western Pennsylvania, eastern Ohio, West Virginia, and western Maryland and Virginia.

H. D. Rogers, 1840 (Pa. Geol. Surv. 4th Ann. Rept., p. 150). *Monongahela series*.—The Upper Coal Measures. Exposed in valley of Monongahela River. Includes the beds entitled Pittsburg series in my last annual rept. and rests on Allegheny series, the bdy btw. the two being marked by final outcrop of the shales which are exposed just above Ohio River at Pittsburg.

J. J. Stevenson, 1873 (Am. Phil. Soc. Trans., vol. 15, n. s., pp. 15–32). *Upper Coal Group* (*Monongahela River series*), extends from top of Waynesburg ss. to base of the 3 ft. of fireclay that underlies Pittsburg coal. [This definition corresponds with current definition of *Monongahela fm.* (the shorter name) except that top of Waynesburg coal has for many years been accepted as top of the Monongahela, the succeeding 1 to 15 ft. of Cassville sh. and overlying Waynesburg ss. being included in Washington fm.]

The present Pa. Geol. Survey classifies the Monongahela as a *group*. The U. S. Geol. Survey classifies it as a *fm.*

Named for exposures along Monongahela River, Pa.

Monongahela group.

Monongahela series.

See under *Monongahela fm.*

Monongahela system.

A term applied by F. Platt (2d Pa. Geol. Surv. Rept. L, 1876) to Monongahela fm. of present nomenclature.

†Monongahela River series.

See J. J. Stevenson, 1873, under *Monongahela fm.*

†Monongahela River coal series.

Permian and Pennsylvanian: Western Pennsylvania and northern West Virginia.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_5, p. xxiii). *Monongahela River coal series* includes Upper Barren Measures (divided into Greene County group above and Washington County group below) and the Upper Productive Coal Measures [Monongahela fm.] overlying the Allegheny River coal series.

W. G. Platt, 1878 (2d Pa. Geol. Surv. Rept. H_4). [Used same definition as above, and stated that base of Monongahela River coal series was base of Pittsburg coal.]

Monroan.

A time term applied by A. W. Grabau, 1909 (Sci., n. s., vol. 29, pp. 351–356), to upper part of Cayuga group (Sil.) of N. Y. and contemp. deposits elsewhere. As defined included (descending) Manlius, Rondout, Cobleskill, and Bertie fms. of N. Y., Sylvania ss. of Mich. and Ohio (now assigned to Lower Dev.), and the so-called "Lower Monroe" of old repts, which is now known as *Bass Islands dol.*

See under †*Monroe group.*

†Monroe beds.

†Monroe formation.

†Monroe group.

Lower Devonian and Silurian: Michigan (Lower Peninsula) and northern Ohio.

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, p. 66). *Monroe beds*, 100 to 220 ft. exposed, underlie Dundee ls. and rest on 600 to 2,000 ft. of dol., salt, and anhydrite.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2, p. 26). *Monroe beds.*—Underlie Dundee ls. and overlie Niagara fm. Thickness 650 to 2,000 ft. Only 100 to 120 ft. exposed. Consist of (1) aren., thin argill. dark-colored ls. or dol., 40 to 100 ft. thick; underlain by (2) buff ls., 100 to 220 ft. thick; and (3) thick gyp. deposit.

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30). *Monroe beds* include near top the Sylvania ss., which extends persistently across Monroe Co.

In subsequent repts the beds above Sylvania ss. were called "Upper Monroe" (later named *Detroit River dol.*) and the beds below Sylvania ss. were called "Lower Monroe" (later named *Bass Islands dol.*). The Detroit River dol. and Sylvania ss. were later proved to be Lower Dev. and Bass Islands dol. to be Sil. The names "Monroe fm." and "Monroe group" have therefore been discarded.

Named for exposures in Monroe Co., Mich.

†Monroe shales.

Middle Devonian: Northern New Jersey and southeastern New York.

N. H. Darton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 367, 373). *Monroe shales.*—Dark-gray to black fissile to slaty shales, 200 to 900 ft. thick. Underlie Bellvale flags and overlie Oriskany qtzites or cgl. Contain typical lower Hamilton fossils, according to James Hall. Are 200 ft. thick at Monroe, Orange Co., N. Y.

Replaced in N. Y. by *Cornwall shale* (C. A. Hartnagel, N. Y. State Mus. Bull. 107, 1907), because of preoccupation of Monroe in Mich. Replaced in N. J. by *Pequanac sh.*, in 1908 (U. S. G. S. Franklin Furnace folio, No. 161), but "Pequanac" was discarded in 1914 (U. S. G. S. Raritan folio, No. 191) in favor of prior name *Cornwall sh.*, which is now commonly used in both States.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

†Monroe beds.

†Monroe slates.

Pre-Cambrian(?): Southern central North Carolina (Union County).

H. B. C. Nitze and G. B. Hanna, 1896 (N. C. Geol. Surv. Bull. 3, pp. 36–37). *Monroe slates.*—Bedded but little indurated or metamorphosed slates at Monroe, Union Co., very similar to slates at Parker mine, at town of Albemarle, Stanley Co., and at San Christian mine, Montgomery Co. In fresh condition the sl. is black, weathering to dark and light drab, greenish, and even reddish. At railroad station at Monroe it lies in a low, gently undulating anticlinorium. Of sed. origin and of later age than the slates and schists to W. and N. No fossils. Provisionally placed in Algonkian.

L. C. Graton, 1906 (U. S. G. S. Bull. 293, pp. 23–24, 29, 31), described (under heading "*Monroe*" *beds*) rocks to SW. of Monroe, Union Co., N. C., as consisting of horizontal or slightly tilted beds of fine-grained material, well stratified, considerably decomposed, and having the appearance of a tuff. No fossils. Age uncertain, but pre-Triassic. "It is difficult to believe that these soft rocks could have been present when the metamorphism of the schists took place."

On 1932 geol. map of U. S. these rocks are mapped as pre-Camb.

†Monroe beds.

Pennsylvanian: Central southern Iowa.

S. W. Beyer and L. E. Young, 1903 (Iowa Geol. Surv. vol. 13, p. 366). *Monroe beds.*—Shales and sss., with coal, constituting bulk of Coal Measures in Monroe Co. Overlain by Appanoose beds and underlain by Miss.

Preoccupied. Comprises most of Cherokee sh.

Named for Monroe Co.

†Monroe beds.

An abbreviated form of Monroe Creek beds (Miocene) that has been used by some geologists.

Monroe gas rock.

A subsurface porous sandy ls., thin to 75 ft. thick, in upper part of Upper Cret. of Richland gas field, NE. La. (See D. Gordon, A. A. P. G. Bull., vol. 15, No. 8, 1931.)

Monroe City gas sand.

A subsurface sand in Mansfield ss. (Penn.) of Ind. The Ind. geologists have also applied *Monroe City deep sand* to a sand of early Chester (Miss.) age that has been correlated with Paoli ls. of Cumings.

Monroe Creek beds.

Miocene (lower): Western Nebraska and eastern Wyoming.

J. B. Hatcher, 1902 (Am. Phil. Soc. Proc., vol. 41, p. 116). *Monroe Creek beds.*—Very light-colored fine-grained, not very hard but firm and massive sss., 300 ft. thick. Grade into overlying Harrison beds and overlie Gering sss. Scant fauna. Well shown in N. face of Pine Ridge, at mouth of Monroe Creek Canyon, 5 mi. N. of Harrison, Nebr. Assigned to Mio.

Is a part of Arikaree fm. Assigned to Mio. by most geologists, but H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5, p. 44), assigned it to upper Olig.

Mons formation.

Lower Ordovician (Beekmantown): Alberta and British Columbia.

C. D. Walcott, 1920 (Smithsonian Misc. Coll. vol. 72, No. 1, p. 15). *Mons fm.*, Camb., Alberta. [Walcott fully defined this fm. in Smithsonian Misc. Coll. vol. 67, No. 8, pp. 459–460, Mar. 5, 1923, when he assigned it to lower Ozarkian of Ulrich. Thickness 0 to 1,480 ft. Uncon. underlies Sarbach fm. and overlies Lyell fm.]

In 1923, 1924, and 1928 Walcott assigned this fm. to †Lower Ozarkian. In 1924 Kindle assigned it to Camb. In 1930 P. E. Raymond (Am.

Jour. Sci., 5th, vol. 20, pp. 300–307) assigned the Mons "as restricted by Walcott in 1928" to Lower Ord. (Beekmantown) and the underlying Sabine fm. (originally included in Mons) to Upper Camb., and stated that there is no occasion for the use of the term *Ozarkian*.

Monson granodiorite.

Late Carboniferous or post-Carboniferous: Central Massachusetts, southwestern New Hampshire, and northern Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 15, 18, 41–45, 57–65). *Monson gneiss* (also *Monson cgl. gneiss*).—A clear-gray friable biotite gneiss, medium- to fine-grained. Named for occurrence at Monson, Hampden Co., Mass.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 124), called this fm. *Monson granite gneiss*.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 241–243 and map). *Monson granodiorite*.—A clear-gray granite or granite gneiss of rather fine grain, generally purely biotitic but some of it slightly hornblendic or muscovitic. Although wholly massive and granitoid over large areas, it is generally foliated by concentration of biotite in darker bands, many of them rather broad, and tapering or set so as to simulate cross-bedding, faulting, corrugations, or in different complex patterns. In U. S. G. S. Mon. 29, 1898, this rock was believed to be an altered cgl.

W. G. Foye and A. C. Lane, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 137), regard this fm. as "probably Dev."

Montague group.

Devonian or Carboniferous (?): Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 27).

†Montalban.

Name applied in some early repts to a series of pre-Camb. (?) gneisses and mica schists in White Mtn region of N. H. and westward, which were supposed to be younger than Huronian series of Lake Superior region.

According to C. R. Van Hise and C. K. Leith (U. S. G. S. Bull. 360, 1909, pp. 87, 88) T. S. Hunt in 1888 stated that in 1871 [where?] he gave the name *Montalban* to the young gneisses, crystalline lss., and micaceous and amphibolic schists, because of their great development in White Mtns of N. H.

C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, No. 5, pp. 178–179, pls. 16, 17). [See 1884 entry under *White Mtn series*, which is essentially the same as Montalban group as first defined.]

This name (derived from the Latin for White Mtn) has been in disuse for many years. On the 1932 geol. map of U. S. these rocks in N. H. are mapped as *pre-Camb.*, but this age is now questioned by M. Billings. (See under *Berlin gneiss*.)

In 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, No. 3) M. Billings applied *Montalban schists* to rocks beneath Chatham granite in North Conway quad., N. H., and correlated the schists and granite with Montalban group of Hitchcock, which he assigned to pre-Camb. (?).

M. Billings, 1935 (letter dated Aug. 27). This summer some of our field parties are struggling with the "Montalban schist." Lithologically most of it is like the katazone facies of Littleton fm., and I believe there is little doubt that the Montalban is Dev. but we have not yet been able to prove this conclusively.

Mont Alto lignite.

Tertiary (?): Central southern Pennsylvania.

J. P. Lesley, 1864 (Mont Alto lignite and Appalachian erosion, 30 pp., 4 pls.). [Describes bed of lignite found recently in southern central Pa. Assigned to Tert. and correlated with Brandon lignite of Vt. See Am. Jour. Sci., 2d, vol. 40, p. 119, 1865.]

Montalto quartzite member (of Harpers schist).

Lower Cambrian: Central southern Pennsylvania.

G. W. Stose, 1906 (Jour. Geol., vol. 14, p. 207). *Montalto qtzite memb. (of Harpers fm.)*.—Hard qtzitic stratum, usually dark gray and veined with quartz. In South Mtn area it occurs near middle of Harpers fm. Forms Montalto Mtn.

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170), gave thickness of Montalto qtzite as 20 to 850 ft.

Montana group.

Upper Cretaceous: Montana, Wyoming, Dakotas, Colorado, Utah.

G. H. Eldridge, 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, p. 93, footnote). [See under *Fox Hills ss.*]

A more elaborate description of *Montana group* was given by Eldridge in 1889 (Am. Jour. Sci., 3d, vol. 38, pp. 313–321). The original subdivisions of Fox Hills ss. and Pierre sh. are still recognized in the Dakotas, eastern Mont., eastern Wyo., and eastern Colo. In southern Mont. the group is now divided into (descending) Bearpaw sh., Judith River fm., Claggett sh., and Eagle ss. In NW. Mont. it is divided into (descending) Horsethief ss., Bearpaw sh., Two Medicine fm., and Eagle ss. In central and southern Wyo. it is divided into (descending) Lewis sh., Mesaverde fm., and Steele sh. In eastern Colo. the group is overlain by Laramie fm. (Upper Cret.); in central southern Wyo. by Medicine Bow fm. (Upper Cret.); and elsewhere in Wyo. and in Mont. by Lance fm. (Upper Cret.).

Named for extensive development in Montana, especially in Upper Missouri River region.

†Montana breccia.

Tertiary: Central Nevada (Tonopah district).

J. E. Spurr, 1911 (Rept. on geol. of property of Montana-Tonopah Min. Co., Tonopah, Nev., published privately). *Montana breccia*.—Intrusive glassy rock that immediately preceded West End rhyolite intrusion. Named for Montana mine.

T. B. Nolan, 1930 (Univ. Nev. Bull., vol. 24, No. 4, p. 10). Tonopah fm. as here defined (for what has previously been called "Lower rhyolite") includes rocks that have previously been mapped as "Glassy trachyte" and "Montana breccia," but it does not include all exposures that have been so assigned by Spurr, Burgess, and others.

†Montana series.

Name proposed by G. H. Ashley (Eng. and Min. Jour.-Press, vol. 115, No. 25, pp. 1106–1108, 1923) to include Montana group and overlying Laramie fm.

Montanan series.

A term used by C. R. Keyes instead of *Montana group*.

†Montara granite.

Late Jurassic (?): Western California (San Francisco Peninsula and southward).

A. C. Lawson, 1895 (U. S. G. S. 15th Ann. Rept., p. 408, and Am. Geol., vol. 15, pp. 343–346). *Montara granite*, of undet. age, is intrusive into the crystalline ls. [Gabilan ls.] and constitutes the mass of Montara Mtn, San Francisco Peninsula.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193), mapped and described these rocks as *quartz diorite of pre-Franciscan age*, the name "Montara granite" being discarded.

Montauk till member (of Manhasset formation).

Pleistocene: Southeastern New York (Long and Fishers Islands) and islands of southern New England (Block Island, Nantucket, Marthas Vineyard, No Mans Land, and probably Cape Cod).

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367–390). *Montauk drift.*—Overlies Herod gravel (uncon. in places) on Fishers Island, N. Y.

M. L. Fuller, 1906 (Sci., n. s., vol. 24, pp. 467–469). *Montauk drift.*—Hard, compact dark-gray, often partly cemented till, 75 to 150 ft. thick; on Long Island, Fishers Island, and Cape Cod. Probably of Illinoian age. Overlies Herod gravels and underlies granitic gravels [Hempstead] which resemble Jameco and Herod fms. (See also U. S. G. S. Bull. 285, pp. 432–441.)

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). *Montauk till memb. of Manhasset fm.*—Consists of two beds of till separated by a gravel bed. Thickness 0 to 60 ft. on Long Island. Rests uncon. on Herod gravel memb. and is uncon. overlain by Hempstead gravel memb. of Manhasset fm. Time of deposition called *Montauk substage.*

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Montauk till memb. of Manhasset fm.* present on Block Island, Marthas Vineyard, Nantucket, No Mans Land, and probably on Cape Cod.

F. G. Wells, 1935 (Geol. Soc. Am. Proc. 1934, p. 121), regarded Manhasset fm. as of Wisconsin age.

Named for occurrence at Montauk Point, Long Island.

Montauk substage.

The time covered by deposition of *Montauk till memb.*

Montebello sandstone. (In Hamilton formation.)

Middle Devonian: Central Pennsylvania (Perry County).

E. W. Claypole, 1885 (2d Pa. Geol. Surv. Rept. F_2, pp. 67–68). *Hamilton (Montebello) ss.*—Ss., 500 to 800 ft. thick, separating Hamilton upper sh. from Hamilton lower sh. in Perry Co. Overlain by Montebello fossil ore, 2 ft. thick. The proportion of sand diminishes rapidly to N. and W., until the intermediate sh. becomes so thick that it forms most of fm., but is overlain and underlain by thin sss. Exposed at Montebello Narrows, on Little Juniata River. At its southernmost exposure, near Marysville, it is 800 ft. thick.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2). Selinsgrove upper ss.=Montebello upper ss. of Claypole.

Monte Cristo diorite.

Pre-Permian (?): Southeastern Alaska (Upper Tanana River region).

W. C. Mendenhall and F. C. Schrader, 1903 (U. S. G. S. P. P. 15, pp. 33–37). *Monte Cristo diorite.*—Medium- to coarse-grained granitoid rock belonging to diorite family. Named for exposure on Monte Cristo Creek, Nabesna and Chisana River region.

Monte Cristo limestone.

Mississippian (lower and middle): Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 9–10, 17, etc.). *Monte Cristo ls.*—Includes all Miss. rocks in Goodsprings quad. Divided into 5 members (descending): (1) Yellowpine ls. memb., 0 to 120 ft.; (2) Arrowhead ls. memb., 0 to 20 ft.; (3) Bullion dol. memb., 185 to 300 ft.; (4) Anchor ls. memb., 65 to 400 ft.; (5) Dawn ls. memb., 60 to 400 ft. Underlies (probably uncon.) Bird Spring fm. (Penn.) and overlies Sultan ls. (Dev.). Fossils [listed] are lower and middle Miss., according to G. H. Girty. [Mr. Hewett sent an advance copy of his Goodsprings section, and of the names he proposed to apply to the fms., to W. S. Glock, who in 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 326–339) described the *Monte Cristo ls.*, in east-central part of Spring Mtn Range, Goodsprings quad.]

Exposed near Monte Cristo mine, Goodsprings quad., but the mine itself is in Anchor ls. memb.

Monte de Oro formation.

Upper (?) Jurassic: Northern California (Oroville, Butte County).

H. W. Turner, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, p. 548). *Monte de Oro fm.*—Plant-bearing clay sl. with some cgl. The slates are very similar to those of Mariposa fm., from known areas of which they are, however, widely separated. Occur near Oroville, just S. of Monte de Oro, Butte Co.

Local name for sl. whose relations to Mariposa sl. still remain undet.

Montego formation.

Pleistocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 102).

Montell sandstone. (In Allegheny formation.)

Pennsylvanian: Western Maryland and northern West Virginia.

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Montell ss.*—Underlies Lower Freeport coal and overlies Montell rider coal; all included in Allegheny fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), showed *Montell* ss. as including, near its top, Montell rider coal, and as overlying Upper Kittanning (Montell) coal. On p. 50 he stated that it is 50 ft. thick, persistent over large areas, frequently forms cliffs, is found above Montell coal, is finer-grained and more argill. than the lower sss. of Allegheny fm. but is conglomeratic W. of Piedmont, W. Va., and that it is named for its position above Montell coal.

Montello granite.

Laurentian: Central southern Wisconsin (Marquette County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 521). *Montello granite.*—Pink granite outcropping in village of Montello. Assigned to Laurentian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). "May be supposed to be pre-Huronian."

This granite is known to the trade as *Montello granite.*

Monterey group (San Francisco region).

Monterey shale.

Miocene (upper, middle, and late lower): Western California.

W. P. Blake, 1856 (Phila. Acad. Nat. Sci. Proc., vol. 7, pp. 328–331). *Monterey fm.*, consisting of regular strata of light-colored, prevailingly white argill. and aren. material, the particles being very fine and firmly impacted, so that in some places the strata break with smooth curved surfaces, and have a semivitreous luster. Top 50 ft. very rich in diatoms, and the underlying beds may be equally rich. Thickness undet. Typical section is about 2 mi. SE. from center of town of Monterey, and it forms a portion of a hill 500 to 600 ft. high, which fronts the bay and rises on E. side of stage road to San Francisco. This hill is separated from bay by a broad sandy plain and a belt of sand hills along the beach. The detailed section approximates 81 ft., exclusive of basal memb., which "extends down for a long distance." The fm. is uncon. overlain by a rudely stratified or assorted mass of boulders and gravel like the accumulation along a beach, and it appears to be conformably underlain by Tert. strata that underlie part of town of Monterey and extend to and beyond the Mission of San Carlos. Is quarried near town of Monterey. [Blake's heading (p. 328) calls the beds *Tert. fm. of Monterey, Calif.* After describing the fm. he called it *Monterey fm.* on p. 331.]

Monterey sh. was approved by U. S. Geol. Survey in 1902, after correspondence with Calif. geologists.

A. C. Lawson, 1893 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 1, p. 7). The [Mio.] series was among the first which attracted attention of earlier writers—Trask (1854) also Blake (1856)—and it has since become famous for "infusorial" remains which it contains, being known to collectors as *Monterey fm.* This name, under form "*Monterey series*," will be adopted as local designation of the series. Thickness 1,000+ ft. around Carmelo Bay. Overlain by "terrace fms.," and rests, with erosion uncon., on Carmelo series (Tejon, Eocene?).

G. H. Ashley, 1895 (Jour. Geol., vol. 3, pp. 439–440). The Monterey series was long ago described and assigned to Mio., and later determinations have not modified that decision.

G. D. Louderback, 1913 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 7, pp. 191–241), proposed *Monterey series* to include all Mio. deposits as well as underlying Sespe fm.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Monterey group* is divided into (descending): Briones ss., 2,300 ft., containing Hercules sh. memb. near middle; Rodeo sh., 670 ft.; Hambre ss., 1,200 ft.; Tice sh., 460 ft.; Oursan ss., 600 ft.; Claremont sh., 800 ft.; and Sobrante ss., 400 ft. [Subsequent studies of B. L. Clark resulted in excluding Briones ss. from Monterey group.]

From 1913 to 1935 the U. S. Geol. Survey included Vaqueros ss. in Monterey group, because it was believed that basal ss. at Monterey (thin to 200 ft. thick) represented that fm. This basal ss. at Monterey, however, is now considered to be younger than Vaqueros. The Vaqueros was, therefore, in 1935 excluded from the Monterey, and *Monterey sh.* was adopted for a lithologic unit of variable Mio. age, consisting predominantly of hard silica-cemented shales and soft shales carrying siliceous micro-fossils. It includes, in different areas, beds of upper, middle, and even late lower Mio. age. In Palos Verdes Hills it ranges from middle Mio. into upper Mio.; in Kettleman Hills it includes only part of upper Mio. In Palos Verdes Hills it is divided into 3 members, named (descending) Malaga mudstone memb. (upper Mio.), Valmonte diatomite memb. (upper Mio.), and Altamira sh. memb. (upper and middle Mio.). As now defined the Monterey sh. is in places underlain by Vaqueros ss. or Temblor fm., and in other places by older rocks. In Palos Verdes Hills it rests uncon. on Franciscan (?) fm. In some regions it is overlain by Santa Margarita ss., and in other areas its upper part grades laterally into Santa Margarita ss. In still other areas it is overlain by San Pablo group, and in other places it includes time equiv. of the San Pablo. In San Francisco region the Monterey deposits (post-Vaqueros) are still called *Monterey group*. For details regarding present interpretation of Monterey sh. see report by W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell (A. A. P. G. Bull., vol. 20, No. 2, pp. 127–146, 1936).

†Monterey sandstone.

Lower Devonian: Northwestern Virginia and western Maryland.

N. H. Darton, 1892 (Am. Geol., vol. 10, pp. 13, 15–16). *Monterey ss.*—Coarse-grained light-colored ss. or moderately silicified qtzite, usually friable in weathered outcrops. Fossils mainly Oriskany forms, but Lower Helderberg and Hamilton fossils are intermingled to greater degree than in N. Y. Oriskany. Beds comprise not only Oriskany but in upper part representatives of the several coordinate members of Corniferous group. Thickness 0 to 300 ft. Uncon. underlies Romney sh. Overlies Lewistown ls.

Preoccupied. Replaced by *Ridgeley ss.*

Named for Monterey, Highland Co., Va.

†Monterey conglomerate.

Pennsylvanian: Northeastern Tennessee (Overton, Fentress, and Putnam Counties).

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 276, 277, 369–372, 374). *Monterey cgl.* (also *Monterey or Bonair cgl.*).—The cgl. at Monterey [Putnam Co.] is generally believed to be same as Bonair cgl. memb. of Lee fm. Massive pebble-bearing cgl., varying in thickness from 15 to 40 ft. To northward appears to be cut out or to thin out at Obey City, Overton Co., but is conspicuously developed to E. and across the line into southern Fentress Co. Overlies Whitwell sh. and underlies Vandever sh. A subdivision of Lee fm.

Same as Bonair ss., of Lee group.

†Monte Sano limestone (also †Montesano group).

Mississippian: Northern Alabama, Tennessee, Kentucky, and Illinois.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29). [On pl. 29 *Monte Sana* is used in "General time scale" to include Tribune, Cypress, and Ste. Genevieve. There is no other definition in book cited.]

E. O. Ulrich, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 157), casually referred to the *lower or Montesano group* of the Chester, but did not define term.

E. O. Ulrich, 1917 (Ky. Geol. Surv. Mississippian series in western Ky., pt. 2, pp. 25, 38, 45, 51, 52, 53, 59, 68, 100, 116, 125–141, 197, 199, 200, 206, pls. E and F), used *Montesano ls.* and *Montesano group* to include Gasper oolite, Aux Vases ss., Ste. Genevieve ls., and equiv. fms. in Ky. and Ill. "Underlies Cypress or Hartselle ss. and uncon. overlies St. Louis ls."

Corresponds to lower part of Chester group.

Named for exposures at Monte Sano, Madison Co., Ala. (The town and ridge are spelled with final *o* on U. S. G. S. topog. map.)

Montesano formation.

Miocene (upper): Southwestern and northwestern Washington.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). *Montesano fm.*—Largely massive coarse-grained light-brown sss., with many intercalated lenses of cgl. and grit; shales subordinate in lower part but common in upper part. Thickness 5,000 ft. Upper Mio. fauna. Uncon. overlies Chehalis fm. (Lower Mio.). Named for Montesano, Chehalis [Grays Harbor] Co.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). The upper Mio. marine invertebrate fauna of Wash. is called *Yoldia strigata* zone, from presence of this most characteristic species. Only 1 faunal horizon is recognized in the fm., and it is upper Mio. The strata containing this fauna are termed *Montesano horizon* or, more appropriately, *Montesano fm.* Is confined to 2 widely separated areas, the larger in Grays Harbor region, mostly S. of Chehalis River, and the smaller in SW. Clallam Co., in vicinity of junction of Soleduck and Bogachiel Rivers. Max. thickness 5,400 ft., in Grays Harbor region. Overlies Wahkiakum horizon uncon.

†Montevallo conglomerate.

Pennsylvanian: Northern central Alabama.

J. Squire, 1890 (Ala. Geol. Surv. Rept. Cahaba coal field, pt. 1, passim). *Cgl. group, the great Montevallo cgl.*, the cap rocks of our Alabama Coal Measures. Overlies Montevallo coal. Thickness 500 ft.

Is a cgl. at top of Pottsville fm.

Probably named for exposures at Montevallo, Shelby Co.

†Montevallo formation.

Lower Cambrian: Alabama.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, p. 148 and map). *Montevallo or Choccolocco shales.*—Sandy shales of variegated colors. Original material calc. sh., but at outcrops the calc. matter has been thoroughly leached out and only the more siliceous parts are left. Sometimes the shales are tough and hard and, especially toward E., assume characters of semicrystalline rocks. In upper part are beds of blue ls. and gray dol. which are often difficult to distinguish from similar rocks in overlying Knox dol. Underlies Knox dol. and overlies Coosa shales. Includes Weisner qtzite, usually interbedded in lower part. [Owing to faulting the relations of †Montevallo sh. to †Coosa sh., Conasauga sh., and Rome fm. were misunderstood. Now, however, typical Montevallo sh. is known to be same as Rome fm. (Lower Camb.) and to underlie Conasauga sh., which is same as †Coosa sh. Rome fm. is better established name. (See C. Butts, Ala. Geol. Surv. Spec. Rept. No. 14, p. 65, 1926.) As first defined, i. e., including rocks up to base of Knox dol., the Montevallo was of Middle and Lower Camb. age.]

Named for Montevallo, Shelby Co., and for Choccolocco, Calhoun Co.

Montezuma schist.

Pre-Cambrian: Western North Carolina.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 4). *Montezuma schist.*—Fine-grained epidotic and chloritic schists and amygdaloids, of very uniform appearance. Originally probably a basalt. Schists are bluish black, gray, or green when fresh, becoming more green and yellowish green on weathering. The amygdaloid beds occur chiefly along NW. areas of the fm., and consist of bluish-gray groundmass with cavities (the size of a pea) filled with quartz, feldspar, and epidote. Assigned to Algonkian (?).

Named for Montezuma, Cranberry quad., in Mitchell Co.

Montezuma quartz monzonite.

Eocene: Central northern Colorado (Montezuma region, Summit County).

H. B. Patton, 1909 (Colo. Geol. Surv. 1st Rept., pp. 125, 126, 128, map). *Montezuma granite.*—Pinkish-gray biotite granite with large porphyritic feldspar crystals. An intrusive rock, but does not occur in dikes. Town of Montezuma, Summit Co., is built on this rock. Is believed to be younger than Santa Fe granite. Is in contact with Idaho Springs fm. [pre-Camb.].

J. W. Vanderwilt, 1932 (16th Int. Geol. Cong. Colo. Guidebook), stated the *quartz monzonite* porphyries of this region are locally called *Montezuma granite*, and are of Eocene age. According to unpublished ms. by T. S. Lovering the Montezuma "granite" is quartz monzonite. It cuts the thrust fault that was formed during Laramide revolution and is older than Flattop peneplain, of late Eo. age.

Montezuma shales.

Jurassic: Southwestern Colorado and northeastern Arizona.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 65, No. 4, pp. 303, 306). Zunian series divided into (descending) McElmo shales, Lohali ss., Montezuma shales, and Arido sss. Latter 3 correspond to the LaPlata of Cross. For the middle shaly marine beds of the LaPlata the title *Montezuma shales* is suggested, the name being derived from Montezuma Co., in SW. Colo.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 66, No. 1, p. 72, and No. 3, p. 225). *Lohali ss.* is preoccupied and is here replaced with *Tyende ss.*

The Montezuma shales of Keyes appear to correspond to Kayenta fm. (See U. S. G. S. P. P. 183, 1936, table opp. p. 37.)

†Montgomery buhr.

†Montgomery grits.

†Montgomery sandstone.

Mississippian: West Virginia and Virginia.

W. B. Rogers, 1838 (Va. Geol. Surv. Rept. 1837, p. 17). In Floyd Co., Va., associated with the valley ls. occurs that interesting and valuable siliceous deposit, the *Montgomery Buhr.* Varies from grayish and yellowish white to deep orange brown, and presents a cellular texture and a great hardness and sharpness of grit. Is used for millstones.

W. B. Rogers, 1879 (Macfarlane's Geol. Ry Guide, p. 179). *Montgomery grits and coal measures*, of Lower Carbf. age, underlie Greenbrier ls. and overlie Catskill.

In some repts has been called "*Montgomery ss.*" Is same as Price fm., the name by which it is generally known. Probably named for Montgomery Co., Va., across which Price fm. occupies a wide belt. The Price fm. was named for Price Mtn, in Montgomery Co.

Montgomery limestone.

Silurian (Niagaran): Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Montgomery ls.*, of Niagara age, 10 to 60 ft. thick. Older than Taylor[s]ville slates and younger than Grizzly qtzite.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Montgomery ls.*—Light to dark bluish-gray ls. with occasional knots or benches of black chert. The form of the ls. is lenticular, and the largest lentil, which is on crest of N. end of Grizzly Mtns and is fossiliferous, has thickness of 60 ft. with length of about 200 ft. Five of these ls. lentils have been found. One is on S. bank of Montgomery Creek, where it forms prominent cliffs at an altitude of about 4,000 ft. Rests conformably on Grizzly fm. Believed to be uncon. with overlying Taylorsville fm.

Named for occurrence on Montgomery Creek, 2⅓ mi. S. of Taylorsville, Plumas Co.

†Montgomery formation.

Silurian: Southwestern Ohio, southern Indiana, and northern Kentucky.

A. F. Foerste, 1896 (Cincinnati Soc. Nat. Hist. Jour., vol. 18, pp. 189, 190). *Clinton or Montgomery fm.*—Very pure fossiliferous pink or red ls., becoming more siliceous eastward; 10 to 35 ft. thick. Overlain by white Dayton ls. in Ohio and by Osgood sh. in southern Ind.; underlain by Lower Sil. Belfast bed. Included in Niagara group. Formerly called Clinton fm., but perhaps more Niagara than Clinton.

Preoccupied. Replaced by Brassfield ls.

Named for Montgomery Co.

Montgomery bed. (In Jackson formation.)

Eocene (upper): Northwestern Louisiana (Grant County).

T. L. Casey, 1902 (Sci., n. s., vol. 15, p. 716). *Montgomery bed.*—Light blue-gray argill. marl, 6 ft. thick. Outcrops in well-known long low bluff at Montgomery, La. Older than Kimbrel bed, from which fossils indicate it is separated by a considerable lapse of time. Included in Jackson stage. Named for exposures at Montgomery, Grant Co.

Montgomery Creek formation.

Eocene: Northern California (Redding region).

H. Williams, 1932 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 21, No. 8, p. 215). Resting directly on Chico rocks in area W. of Lassen is a series of fresh-water sands and gravels, containing abundance of andesitic detritus, which Diller classed with "Ione" fm., as Mio. Recently these deposits have been restudied by [R. D.] Russell, by whom they have been termed *Montgomery Creek fm.*, provisionally assigned to Eo., and possibly the age equiv. of the Ione as redefined by Allen. Russell has also suggested that the Susanville gravels, lying SE. of Lassen and containing an admixture of rhyolitic tuff, may be tentatively correlated with Montgomery Creek fm.

N. E. A. Hinds, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, pp. 79, 114). *Montgomery Creek fm.*—Along SE. slopes of Klamath Mtns in Kosk Creek and Pit River Canyons, farther to S. on Montgomery Creek, and at a few other localities is a series of dominantly fluviatile brownish arkosic ss., sandy shales, and cgls. which Diller in Redding folio called "Ione" fm. and dated Mio. on determination of fossil leaves by Knowlton. These strata have recently been examined by R. Dana Russell, who was associated with me in the geologic studies of southern Klamath Mtns, and will be described by him as *Montgomery Creek fm.* in a rept now in preparation. Determination by R. W. Chaney of a flora discovered by Russell indicates a later Middle Eocene age for the fm. and Russell's field and laboratory studies prove that the fm. is not Ione fm. as Allen has recently redefined it along E. margin of Great Valley. The sediments appear to have come from the E. and NE., but actual source is not known. Only a limited area of this fm. appears along E. margin of Redding quad. S. of Little Cow Creek. Most of strata Diller mapped as Ione belong to the Plio. Tuscan and Tehama fms., which overlie Montgomery Creek fm. The Eocene deposits of Weaverville quad. are here named *Weaverville fm.*

Monticello rhyolites.

Pre-Cambrian: Central Virginia.

W. A. Lambeth, 1901 (thesis presented to Univ. Va., p. 11). *Monticello rhyolites*, of Keweenawan age, in Monticello area, Albemarle Co.

Monticello schist.

Pre-Cambrian: Central Virginia.

W. A. Lambeth, 1901 (thesis presented to Univ. Va., p. 9). *Monticello schists.*—Universally crystalline and fine-grained even when slaty; hard; break with splintery fracture; structure marked by joint planes and quartz veins from thickness of a hair to an inch or more; hornblende in flattened tabular crystals; scales of micaceous chlorite and epidote give rocks a green color. Assigned to Keweenawan epoch of Algonkian.

T. L. Watson and S. L. Powell, 1911 (Am. Jour. Sci., 4th, vol. 31, p. 36). *Monticello schist* is Catoctin schist of Keith. Derived chiefly from basic volcanic rock (basalt) of Algonkian age.

Monticello dolomite.

Silurian (Niagaran): Central eastern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 149, 150). *Monticello terrane.*—Dol., 60 ft. thick, forming top fm. of Niagaran series. Overlain by Goweran series and underlain by Hartwick dol., of Niagaran series. Separated from Hartwick dol. by its fauna.

Probably named for Monticello, Jones Co.

Montijo conglomerate.

Age (?): Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 241).

Mont Joli formation.

Devonian: Quebec.

See *Mount Joli fm.*

Montosa limestone.

See under *Mosca ls.* Is a part of Madera ls., Penn., N. Mex.

Montoya limestone.

Upper Ordovician: Western Texas and southern New Mexico.

G. B. Richardson, 1908 (Am. Jour. Sci., 4th, vol. 25, pp. 476, 478–479). *Montoya ls.*—Upper part, which carries Richmond fossils, according to E. O. Ulrich, is prevailingly gray ls., characteristically mag., in places seamed with conspicuous bands of chert a few inches thick; some beds are almost white, while others are dark. Lower part is commonly marked, in El Paso quad., Tex., by massive dark-colored ls., containing little or no chert and carrying characteristic Galena fossils, according to E. O. Ulrich. The two parts cannot always be distinguished lithologically. Thickness 250 ft. In Van Horn quad. the base of Montoya is commonly marked by presence of thin-bedded earthy yellow and reddish ls., but otherwise in both quads. the contact with underlying El Paso ls. is apparently conformable. Is overlain by Fusselman ls., of Niagara age.

Further studies of faunas contained in Montoya ls. resulted in assigning the *lower* fauna to pre-Richmond Upper Ordovician.

Named for Montoya station, on Santa Fe Ry., about 10 mi. above El Paso, Tex.

Montoyan series.

A time term employed by C. R. Keyes to cover a part of Montoya ls.

Montpelier sandstone.

Middle (?) Devonian: Southeastern Iowa.

C. R. Keyes, 1893 (Iowa Geol. Surv. vol. 1, pp. 40–46, pl. 2). *Montpelier ss.*—Considerable thickness of fossiliferous sss. developed at and near Montpelier, Iowa. Assigned to Middle Dev. Older than Lime Creek sh. and younger than Cedar Valley ls. [Some writers apparently include this in Cedar Valley ls.]

Named for Montpelier, Muscatine Co.

Montpelier.

Tertiary: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol 34, pp. 70–75).

†Montpelier slate.

Ordovician: Northeastern Vermont (Washington County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., p. 95). The terms *Montpelier sl.*, *Northfield sl.*, and *Montpelier and Northfield sl.* have been used interchangeably and indiscriminately in repts on geol. of Vt. If there has been any discrimination whatever, "Northfield sl." has been used more in a commercial sense than in the designation of a geological fm. I would propose, therefore, the single term *Montpelier sl.* for the terrane that has been formerly discussed under these different names. The name *Montpelier* is here applied for first time in a purely geological sense to the belt of sl. that flanks the pre-Camb. schist to E. of Green Mtn axis, lying conformably upon and often interstratified with Waits River ls. It is a highly metamorphic rock derived from beds of plastic clay. [On p. 115 he states that U. S. G. S. has adopted *Memphremagog sl.*, instead of Montpelier sl., preoccupied. Pl. 18 of 11th Rept. Vt. State Geol., 1918, maps this sl. as extending from Montpelier to Northfield.]

Montreal formation.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol 6, sec. 4, pp. 163, 224).

Montreal amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, fig. 28). *Montreal amygdaloid* belongs in Central Mine group. According to A. C. Lane (1911) it lies 150 to 224 ft. below Houghton cgl., and is fourth lode below that cgl. The mineralized part is the Montreal lode. Probably named for occurrence in Montreal mine, Keweenaw Co.

Montreal flow.

Includes Montreal amygdaloid and underlying trap.

Montrose sandstone.

Upper Devonian: Southern-central New York and northeastern Pennsylvania.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 381). *Montrose ss. or ss. of Oneonta.*—Many veins of gray ss. and sometimes red ss.; when weathered exhibits peculiar structure, to all appearance owing to manner in which it was deposited in water; often contains plant remains and thin coal. Is found in Otsego, Chenango, and Broome Counties, N. Y., and covers the whole of upper part of Susquehannah Co., Pa., where it surrounds town of Montrose. Younger than Chemung group and the last or upper rock of Third district.

See under *Oneonta ss.* also under *Honesdale ss. group.*

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 82). The nonmarine Oneonta ss. (1840 Vanuxem) is "Montrose ss., or ss. of Oneonta" of Vanuxem, and is of Portage age.

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7) and 1933 (Sci., n. s., vol. 77, pp. 86–87). *Montrose fm. of Vanuxem* is upper Chemung or Wellsburg ss. changed to red beds. The true Oneonta ss. is older and of Ithaca (lower Portage) age.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 4, p. 283). [I. C.] White (Rept. G5, 1881) devised some subdivisions for his "Catskill," including a "Montrose red sh." that fails to match his sanguine description of it; but Vanuxem had called this whole mass *Montrose* two score years before. Nor had Vanuxem's term lain idle, for Hall had frequently adverted to it in print and public. Hence to these Wellsburg, or true upper Chemung, red-beds, as a whole we must now restore Vanuxem's appropriate name *Montrose*, discarding White's fanciful restriction of it. The interfingering of the Wellsburg and Montrose may be well seen around Skinner's Eddy, Pa.

Montrose red shale. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 68, 115). *Montrose red sh.*—Underlies Honesdale ss. group and overlies Paupack ss. in Susquehanna and Wayne Counties. Thickness 180 ft. At least two-thirds of mass in Montrose county is red sh.; the rest is several intercalated beds of gray ss. Around Honesdale there is at least 150 ft. of red sh., the rest being intercalated gray sss. At Montrose [Susquehanna Co.], the type loc., 125 ft. of almost blood-red sh. is visible, and it contains very few sandy layers.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G6, pp. 94–101). *Montrose red sh.* is 1,500 ft. thick in Pike and Monroe Counties, where it underlies Honesdale ss. group and overlies Delaware River flags (the New Milford and Paupack ss. of Rept. G5). [Other repts give thickness of 2,000 ft.]

G. H. Chadwick, 1933. [See 1933 entry under *Montrose ss.*]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 584), renamed the Montrose red sh. of White the *Damascus red sh.*, the name *Montrose* being preoccupied in N. Y. "White's type loc. was not well chosen, for at town of Montrose, Susquehanna Co., the fm. is rather poorly exposed."

†Montrose chert. (In Osage group.)

Mississippian: Southeastern Iowa.

C. R. Keyes, 1895 (Iowa Geol. Surv. vol. 3, pp. 320, 341, 445). *Montrose chert.*—The flinty beds, 30 ft. thick, forming top part of Upper Burlington ls. in Lee Co., Iowa. Overlain by Keokuk ls.

These beds are now included in Keokuk ls. (See under *Keokuk ls.*) According to F. M. Van Tuyl, 1925 (Iowa Geol. Surv. vol. 30, p. 146), they are not now exposed at Keokuk, the type loc. of Keokuk ls., but were formerly visible in excavation beneath the bed of Miss. River for the Keokuk dam.

Named for exposures at Montrose, Lee Co.

Montrose moraine.

Pleistocene (Wisconsin stage): Southern Minnesota (McLeod and Wright Counties).

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 85–86). Included in Crow River morainic system. Village of Montrose, Wright Co., is on this moraine.

†Montville type.

Pre-Cambrian: Northern New Jersey.

F. L. Nason, 1889 (N. J. Geol. Surv. Ann. Rept. 1889, p. 31). *Montville type.*—White crystalline ls. of varying degrees of purity. Provisionally assigned to Archean, but Archean age not yet proved. Occurs at Montville, also at Franklin Furnace, where it is intimately associated with the Franklin type.

Same as Franklin ls.

Monument andesite.

Tertiary: Southwestern New Mexico (Sierra County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. 19, pp. 7–21). *Monument andesite*, Tert., 250 ft. thick. Type loc., Monument Peak, near Lake Valley [Sierra Co.].

†Monument Creek group.

Oligocene and Eocene: Eastern central Colorado (Denver Basin region).

F. V. Hayden, 1869 (U. S. Geol. Surv. Colo. and N. Mex. 3d Ann. Rept., pp. 39–40, 89). *Monument Creek group.*—Variegated sands, sss., and aren. clays, nearly horizontal, resting on upturned edges of older rocks. They range from coarse puddingstones to very fine-grained sands or sss.; very little lime in entire series; much ferruginous matter. Occurs 40 mi. S. of Denver, in region of South Platte Canyon to Colorado City. Occupies space about 40 mi. E. to W. and 50 mi. N. to S. Monument Creek [Castle Rock and Colorado Springs quads.] flows through this tertiary basin.

F. V. Hayden, 1876 (U. S. Geol. and Geog. Surv. Terr. 8th Ann. Rept., pp. 32, 36–37). The peculiar group of fresh-water strata which in 1869 I called the *Monument Creek group*, extends to a point within about 20 mi. of Denver, where the lignitic sediments return to their usual character. The group is 1,500 ft. thick and consists of (descending): (1) Variegated sss., brick red, white, and yellow, varying from fine-grained ss. to puddingstone; (2) rather massive ss., varying from puddingstone to fine-grained ss., usually of light color, sometimes a yellow or iron rust. It may be synchronous with upper part of White River group [Olig.].

G. H. Eldridge, 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, pp. 86–112). *Monument Creek beds.*—Embraces true Monument Creek group of Hayden Survey. Extends only short distance into SE. corner of Denver region, but occupies immense area beyond. Its manner of occurrence shows a break in continuity of its deposition sufficient in point of time for formation of a bed of rhyolitic tuff 40 ft. thick. This bed of lava does not extend into Denver field but is well exposed in vicinity of Castle Rock. Though the group is perfectly divisible into 2 distinct fms. it is for present better to retain name first given, more particularly to its lower memb., as a designation for entire group, especially in view of very meagre information. Age undet. Thickness 1,500 ft. Uncon. overlies Denver beds. In places rests on Laramie, showing absence of Denver beds and underlying Willow Creek beds. Eruptive material is prominent in upper part and absent in lower part.

S. F. Emmons, W. Cross, and G. H. Eldridge, 1896 (U. S. G. S. Mon. 27), applied *Monument Creek fm.* to Tert. beds overlying Denver fm. in Denver Basin.

W. T. Lee, 1902 (Am. Geol. vol. 29, pp. 96–109). *Monument Creek group of Hayden* is here divided, in Castle Rock region, into Castle cgl. above (90 ft. thick, and resting uncon. on the lava) and *Monument Creek fm. restricted* below. The name originally applied by Hayden is thus retained for the fm. which is best known, and the new and less cumbersome name *Castle cgl.* is given to the less extensive and little-known fm. The Monument Creek fm. restricted consists of cgls., breccias, sands, and clays which alternate, intermingle, and grade into each other in most lawless manner. It underlies the rhyolite and overlies Arapahoe fm.

G. B. Richardson, 1915 (U. S. G. S. Castle Rock folio, No. 198). "Monument Creek group" of Hayden included *Castle Rock cgl.* (Olig. and 300 ft. thick) and Dawson arkose (Eo. and 2,000± ft. thick). The Dawson is=Denver and Arapahoe fms. and some younger beds. These younger beds and the Castle Rock cgl. were included in "Monument Creek fm." of Emmons, Cross, and Eldridge.

Monument Hill bentonitic member (of Pierre shale).

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Monument Hill bentonitic memb. of Pierre sh.*—Impure bentonite and siltstone; some calc. and barite concretions. Marine fossils. Commonly forms a scarp. Thickness 150± ft. Top lies 150 to 250 ft. below Fox Hills ss. Separated from underlying Mitten black sh. memb. of Pierre sh. by 500 to 800 ft. of dark mudstone and sh. Named for exposures at Monument Hill, sec. 32, T. 56 N., R. 68 W., Crook Co., Wyo.

Monument Spring dolomite member (of Marathon limestone).

Lower Ordovician (Beekmantown): Southwestern Texas (Brewster County).

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1066–1069). *Monument Spring dol. memb. of Marathon ls.*—Dense massive dolomitic ls., mottled yellow and bluish, which on weathered surfaces changes to spongy brown chert. Thickness few ft. in N. part of Dagger Flat anticlinorium (to S. of which it disappears) to 75 ft. in Marathon anticlinorium. Lies near middle of Marathon ls. The beds are broken and shattered, as result of deformation, so that outcrop is characteristically a chain of disconnected boulders. Typically exposed ½ mi. W. of Monument Spring, Marathon uplift, Brewster Co.

†Monument Valley shale.

Permian: Southeastern Utah and northeastern Arizona.

D. Hager, 1924 (Min. and Oil Bull., vol. 10, No. 2, p. 137; No. 4, pp. 385, 423). *Monument Valley shales*, 1,000 ft. thick, formerly classed as Moencopie and

Upper Goodridge, belong to Supai fm. and are Perm. Older than Lower De Chelly ss. and younger than Upper Goodridge beds.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, p. 1441, etc.). "Monument Valley sh." of Hager, 1924, is lower part of Cutler fm., and is here divided into several units.

Named for exposures in Monument Valley, San Juan Co., Utah, and Navajo National Monument, NE. Ariz.

Moody shale member.

Oligocene: Northwestern Oregon (Lincoln County).

H. G. Schenck, 1927 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 455, 456, 457, 459). *Moody sh.*—Concretionary sh., about 1,200 ft. thick, overlying Burpee fm. and forming lower memb. of Toledo fm. Is overlain by about 1,000 ft. of sss. forming upper memb. of Toledo fm. Fossils rare, but fm. is assigned to lower Olig. Type loc., railroad cuts at Moody Station, on Southern Pacific Railroad, btw. Yaquina and Toledo, in Lincoln Co.

H. G. Schenck, 1928 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 18, pp. 22–31). *Moody sh. memb.* lies near base of Toledo fm.

Moody Ledge granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., Moosilauke map, p. 28). *Moody Ledge granite.*—Medium- to fine-grained pink granite of potash feldspar, quartz, oligoclase, and biotite. Late Dev. or late Carbf. Assigned to New Hampshire magma series. [Mapped on and around Moody Ledge.]

Moodys marl member (of Jackson formation).

Eocene (upper): Mississippi and southwestern Alabama.

O. Meyer, 1885 (Am. Jour. Sci., 3d, vol. 30, p. 435). [*Moody's Branch* used in Miss. column of table in parentheses after *Jackson* and opposite *Jacksonian*. No definition.]

G. D. Harris, 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 303–304). [*Moody's Branch Beds (substage)* used in table for upper part of Jackson stage, *Marks' Mills Red Beds (substage)* being used to cover lower part of *Jackson stage*.]

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12), described *Moodys Branch green marls* as a fm. of Jackson *group* and as overlying Yazoo clay marl.

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, No. 7, pp. 186–198). *Moodys calc. marl memb.*—Basal memb. of Jackson fm. Thickness 35 or 40 ft. in central and western Miss., 90 ft. in western Ala., a few mi. across Miss. line. At base is bed of shells enclosed in quartz, sand, and glauconite. Toward top becomes less sandy and much more calc. and in many places contains thin strata of indurated marl or impure ls. In eastern Miss. and western Ala. a deposit of fine incoherent yellow sand intervenes btw. the indurated ledges at top and the more argill. marl below. Although the individual indurated ledges are discontinuous, the zone in which they occur is quite persistent and has been traced from western Ala. across Miss. to Yazoo River. In Ala. it constitutes the principal horizon at which *Zeuglodon* occurs, and has therefore been called "Zeuglodon bed." The Moodys memb. rests conformably on Yegua fm. [=Gosport sand of Ala.] and is overlain by Yazoo clay memb. of the Jackson. [Later repts give thicknesses up to 220 ft.]

Later work led Cooke to transfer the *Zeuglodon*-bearing bed to Yazoo clay memb. (See A. A. P. G. Bull., vol. 17, No. 11, 1933, pp. 1387–1388.) He also applied *Cocoa sand memb.* to sandy beds in Ala. that represent lower part of Yazoo clay of Miss. and overlie Moodys marl memb. These are present approved definitions of Moodys marl memb., Yazoo clay memb., and Cocoa sand memb. The U. S. Geol. Survey does not now use *calc.* in connection with *marl.*

Named for exposures along Moodys Branch of Pearl River, in city of Jackson, Miss.

†Moodys Branch marl.

Eocene: Mississippi.

See *Moodys marl memb. of Jackson fm.*

Moon Lake diorite.

Pre-Cambrian: Northwestern New York (Jefferson County).

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, p. 62). *Moon Lake diorite.*—Quartz diorite; forms much of peninsula on S. side of Moon Lake, Antwerp quad. Intrudes Grenville series.

Moonshine conglomerate.

Middle Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81). [See under *Combe ss.*]

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 4, pp. 896, 900). *Moonshine fm.*—"New, of geographic origin." [Geographic feature not stated.] Lower part an ordinary cgl. bearing cobbles of granitic plutonic origin and ancient red porphyries, grading upward into red cgls., red sh., and finally red tuffs. Thickness 300 ft. Age middle Middle Jurassic. Underlies Hull aggl. and overlies Mormon ss. Occurs most abundantly on SW. slope of Mount Jura, just below 4,500 ft. elev.

Moorefield shale.

Mississippian: Central northern Arkansas and northeastern and central eastern Oklahoma.

G. I. Adams, 1904 (U. S. G. S. P. P. 24, p. 26). *Moorefield sh.*—Light-grayish or bluish friable sh., in places sandy. Thickness 50 to 75 ft. in vicinity of Moorefield. Overlies Boone ls. and chert and underlies Batesville ss.

E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 102–104). *Moorefield sh.*, 0 to 10 ft. thick, is=Fayetteville sh. in part of Branner. It overlies Boone ls. and grades into overlying Batesville ss. A few mi. NW. of Batesville there is a local deposit of highly fossiliferous ls. and limy sh. which H. S. Williams has called *Spring Creek ls.* Apparently this calc. fm. rests on Boone fm. and underlies Moorefield sh. The increase in argill. matter toward top of exposure probably indicates that the calc. beds grade upward into the sh. Though of small consequence areally, this calc. fm. is too important geologically to be entirely neglected in classification of Miss. rocks of Ark. Perhaps it is sufficiently accounted for by ranking it as a memb. of Moorefield fm.

According to G. H. Girty the Moorefield sh. is of pre-Chester (St. Louis?) age. Overlies Boone ls. and underlies Batesville ss.

Named for Moorefield, Independence Co., Ark.

Mooretown sandstone. (In Chester group.)

Mississippian: Southern Indiana and Meade and Breckinridge Counties, Kentucky.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, pp. 408, 515, and chart). *Mooretown ss.*—Sh. and ss., 10 to 60 ft. thick, locally very massive. Overlain by Beaver Bend ls. and underlain by Paoli ls. Of lower Chester age. Included in Gasper oolite of Butts. Name suggested by C. A. Malott.

Named for excellent exposures near village of Mooretown, Ind.

Mooreville tongue (of Selma chalk).

Upper Cretaceous: Northeastern Mississippi.

L. W. Stephenson, 1917 (Wash. Acad. Sci. Jour., vol. 7, pp. 243–250). *Mooreville tongue.*—A basal part of Selma chalk contemp. with and grading laterally into lower part of Coffee sand memb. of Eutaw fm. in E. part of Lee Co. and W. part of Itawamba Co. The material composing Mooreville tongue consists of argill. chalk and shaly chalky clay or marl. Is 215 ft. thick and 20 mi. long. Rests on Tombigbee sand memb. of Eutaw fm., and is overlain by Tupelo tongue of Coffee sand memb.

Named for development at Mooreville, Lee Co.

Moosalamoo phyllite.

Pre-Cambrian: Southwestern Vermont (Brandon quadrangle, Addison County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 362, 395). *Moosalamoo phyllite.*—A fine-grained black rock, mainly quartz and muscovite with a little biotite and disseminated iron ore. Ranges in thickness from 0 (at Lana Falls) to 500 ft. on S. and E. slopes of Moosalamoo Mtn, 1 mi. to N. Pinches out in general latitude of Middlebury but goes still farther to N. Uncon. underlies basal Camb. cgl. and is considered younger than Forestdale marble.

Moose meta-argillite.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 133). Included in Beltian system.

Moosebar formation.

Cretaceous: British Columbia.

F. H. McLearn, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 5).

Moose Creek beds.

Upper Ordovician: Northern New York (Black River Valley).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258). *Moose Creek beds* (zone of *Dalmanella emacerata* and *Plectambonites rugosus major*) are main zone in Lorraine gulf and well exposed along Moose Creek [Lewis Co.]. Of Lower Lorraine age, and top div. of Whetstone Gulf fm. Overlie Wood Creek beds and underlie Tremaines Bridge beds (basal part of Pulaski fm. or Upper Lorraine).

Moose Hide group.

Paleozoic (?): Canada (Yukon region).

R. G. McConnell, 1899 (Canada Geol. Surv. Ann. Rept., vol. 12, n. s., pp. 18A–20A).

Assigned to Camb. by H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 198).

Moosehide diabase.

Canada (Yukon region).

R. G. McConnell, 1905 (Canada Geol. Surv. Ann. Rept., vol. 14, pt. B, p. 22).

Moosehorn limestone.

Mississippian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 299–300). *Moosehorn ls.*—Lower part thinly bedded ls. with shaly partings, 545 ft. thick; upper part 645 ft. of coarse-grained, rather thinly bedded ls. Overlies Bedson ls. and underlies Rocky Mtn qtzite. Named for Moosehorn Creek, SW. of Bedson Ridge, but exposures on end of De Smet Range may be more conveniently used as type loc.

†Moose Island shale.

†Moose Island series.

Silurian: Southeastern Maine.

N. S. Shaler, 1886 (Am. Jour. Sci., 3d, vol. 32, pp. 51, 58). *Moose Island shales* (also *Moose Island series*).—A great thickness of black and dark-gray shales and slates comprising what appear to be uppermost beds of Cobscook series, and reminding one of Dev. black sh. of Ohio Valley and western N. Y., but rather thicker-bedded. Upper part is composed of dark siliceous flags, with occasional interbeddings of what will probably prove to be volcanic ash deposits. Thickness at least 1,000 or 1,500 ft., but neither superior or inferior limits seen. May represent the "Great Devonian shale."

Is a sedimentary facies of Eastport fm.

Named for development on Moose Island, SE. coast of Washington Co.

Moose River sandstone.

Middle and Lower Devonian (Schoharie and Esopus): Western Maine (Somerset, Penobscot, and Piscataquis Counties).

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21–22, 88–92). *Moose River ss.*—A belt of sss. and aren. shales, in some zones of which there is a fairly abundant fauna. It is generally a tough grayish ss. with some argill. layers, weathering brownish from iron oxides. Thickness runs up into hundreds and probably reaches several thousand ft. Called Oriskany ss. by C. H. Hitchcock.

H. S. Williams and C. L. Breger in 1916 (U. S. G. S. P. P. 89) assigned this fm. to epoch of Schoharie and Esopus grits of N. Y.

Named for exposures near Moose River and Moose River settlement, Somerset Co.

Moosic.

Upper Devonian: Eastern Pennsylvania.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 104–105). No Pocono fm. in Pocono Plateau. It is in Moosic Mtn, W. of Pocono Plateau, that we find the thousand ft. or more of "white" beds corresponding to Lehigh section, and here Lesley might have found the appropriate name.

G. H. Chadwick, 1935 (Am. Jour. Sci., 5th, vol. 29, No. 170, p. 139). If type section of Pocono is up the face of Pocono Knob, then, according to I. C. White, it is all "Catskill," Dev. If it is bottomed on Griswold Gap cgl. (as I. C. White thought in 1881) then there is none of it within miles of Pocono Plateau, and, as I have intimated, it should be called *Moosic*, which I will admit may be post-Chemung (Canadaway) from Griswold Gap cgl. up.

G. H. Chadwick, 1935 (letter dated Dec. 15). *Moosic* has no standing. It is not properly defined or introduced, and has no standing in strat. nomenclature.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 599), objects to *Moosic* or any other substitute for *Pocono*. (See 1936 entry under *Pocono fm.*)

Mooyie argillite.

Mooyie formation.

Pre-Cambrian: British Columbia (Idaho-Montana Int. Bdy).

R. A. Daly, 1905 (Canada Geol. Surv. Summ. Rept. 1904, pp. 96–100). *Moyie argillite.*—Thin-bedded red and gray argill. strata with subordinate thin beds of light-gray qtzite. Thickness 3,200 ft. in section along Int. Bdy from Port Hill, Idaho, to Gateway, Mont. Conformably overlies Kitchener qtzite and conformably underlies Yahk qtzite. Named for its situation on Moyie River [NE. Idaho and B. C.].

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 119–139), redefined *Mooyie fm.* to include Yaak qtzite. See 1913 entry under *Yaak qtzite.*

The U. S. Geog. Bd. has adopted *Mooyie* as the correct spelling of this river.

Mora sandstone.

Cretaceous: Central northern New Mexico.

C. R. Keyes, 1909 (Econ. Geol., vol. 4, pp. 368–369). *Mora ss.*, 500 ft. thick, named for Rio Mora, and refers to so-called Dakota ss. of Tuertos Mtns, S. part of Santa Fe Co., as described by Hayden, Newberry, and others; but does not include Lower Dakota ss. of Stevenson (Jour. Geol., vol. 16, p. 446, 1908).

Moraga formation.

Pliocene: Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Moraga fm.*—Chiefly flows of andesite and basalt, with which are associated some basic tuffs and beds of well-cemented rhyolite tuff. Between these volcanic rocks lie lenticular beds of cgl., clay, and ls. One of ls. beds contains fresh-water fossils, is 30 ft. thick, and has lavas above and below it. One of the cgl. lenses in places reaches thickness of about 200 ft. The first of the flows after an unusually long interval [btw. flows of Moraga fm.] was the andesite of Grizzly and Ruin Peaks. Max. thickness of fm. about 1,200 ft. Is basal fm. of Berkeley group. Underlies Siesta fm. and uncon. overlies Merced fm. Named for occurrence in Moraga Valley, Contra Costa Co.

Morales member (of Santa Margarita formation).

Miocene (upper): Southern California (Cuyama Valley).

W. A. English, 1916 (U. S. G. S. Bull. 621, pp. 191–215). *Morales memb.*—Upper memb. of Santa Margarita fm. Consists of about 2,000 ft. of clay, white sand, and gravel with, at base, 300 to 400 ft. of light-gray, poorly bedded soft clay sh. containing a few thin beds of white ls. which on weathering break up into small irregular fragments. Rests uncon. on Whiterock Bluff sh. memb. of Santa Margarita, which in places it overlaps. Is uncon. overlain by Cuyama fm. Named for development in vicinity of Morales Canyon.

Moran formation. (In Wichita group.)

Permian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Moran fm.*—Light-colored shales and reddish sands, marked, in upper part, by 3 thin lss. Top memb. is Moran ls. (yellow). About 160 ft. below top is Dothan ls. Thickness of fm. 220± ft. Top fm. of Cisco div. in north-central Tex. Overlies Pueblo fm. Includes at top Camp Colorado bed of Drake.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 40, etc.). *Moran fm.*—Sh. and ls., with Sedwick ls. memb. [Moran ls. of 1919 rept] at top, and, in Colorado River region, Watts Creek sh. memb. at base. Is 150 ft. thick to S. and 200 or more to N. Overlies Camp Colorado ls. memb. of Pueblo fm. and in north-central Tex. is conformably overlain by Santa Anna Branch sh. memb. of Putnam fm. Includes (descending) Sedwick ls., Santa Anna sh., Horse Creek ls. (= ? Dothan ls.), and Watts Creek sh., or all beds down to Camp Colorado ls. Named for Moran, Shackelford Co.

This fm. was transferred to Perm. Wichita group by E. H. Sellards in 1933 (Univ. Tex. Bull. 3232), and Perm. is present age designation of U. S. Geol. Survey.

†Moran limestone member (of Moran formation).

Permian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Moran ls.*, top memb. of Moran fm., is uppermost yellow bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 40), replaced this name with *Sedwick ls. memb.*

Named for Moran, Shackelford Co.

Morapos sandstone member (of Mancos shale).

Upper Cretaceous: Northwestern Colorado (Routt County).

E. T. Hancock, Oct. 1, 1923 (U. S. G. S. Press Memo. 16037, with map). In vicinity of Hamilton and Seeping Spring Gulch domes a thick lens of ss. (the Morapos ss. memb. of unpublished rept by E. T. Hancock) lies about 800 ft. below top of Mancos sh. This ss., which forms a conspicuous escarpment, has been removed by erosion from crests of both these domes.

E. T. Hancock, 1925 (U. S. G. S. Bull. 757). *Morapos ss. memb. of Mancos sh.*—Thin-bedded sss., 15 to 30 ft. thick, lying 800 ft. below top of Mancos sh. in Axial and Monument Butte quads. Outcrops in vicinity of Morapos Creek.

Morden beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 128).

†Moreau sandstone.

Lower Ordovician (Beekmantown): Central Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 370–375). *Moreau ss.*—Massive sss., 50 or more ft. thick, containing fragments and grains of chert. Underlies Jefferson City ls. and overlies Osage [Gasconade] ls. in central Mo.

Same as Roubidoux fm., older name.

Named for Moreau Creek, Cole Co.

Morehouse quartzite.

Ordovician and Silurian (?): Southwestern Utah (Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Morehouse qtzite.*—Fine-grained pink and white qtzite with some beds of red and reddish-brown sh. Near top a few beds of cgl. Thickness 2,000± ft. Overlain (uncon.) by Tert. intrusives and Quat. alluvium, and underlain (probably conformably) by Grampian ls. Contains Ord. fossils, but upper part is probably Sil. Type loc., Morehouse Canyon, NW. of Frisco.

E. Kirk, 1932 (Am. Jour. Sci., 5th, vol. 26, p. 38). Improbable *Morehouse qtzite* consists of other than Ord. sediments. It is approx.=Eureka qtzite.

Morena rhyolite.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 46, etc.). *Morena rhyolite.*—Gray or buff, somewhat darker than Sandstorm rhyolite, which it intrudes. Is older than Milltown andesite, from which it is probably separated by an erosion interval. Occurs on Morena Ridge.

Morenci shale.

Upper Devonian: Southeastern Arizona (Clifton-Morenci region).

W. Lindgren, 1905 (U. S. G. S. P. P. 43). *Morenci shales.*—Upper 100 ft. is clay shales mapped as *Morenci shales*; lower 75 ft. is compact and fine-grained argill. ls. mapped as *Morenci ls.* This lower part is missing in some parts of Clifton quad., and as it cannot conveniently be mapped separately on a small-scale map it has been grouped with the shales into one fm. on pl. 1, but on pl. 17 the two members have been separated. Rests conformably on Longfellow ls. and is conformably overlain by Modoc ls. Is present in vicinity of Morenci and at other places in Clifton-Morenci region.

Moreno formation (also **Moreno shale**).

Upper Cretaceous: Southern California (Diablo Range).

R. Anderson and R. W. Pack, 1915 (U. S. G. S. Bull. 603). *Moreno fm.*—Upper fm. of Chico group. Rests conformably on Panoche fm., the lower fm. of Chico group, and is uncon. overlain by Cantua ss. memb. of Martinez (?) fm. In southern area it consists of foraminiferal and diatomaceous maroon and chocolate-colored sh. and dark clay sh. with some interbedded ss., and has max. thickness of 1,600 to 1,800 ft. In northern area it contains less sh. of truly organic origin and more clay sh. and ss. and is uncon. overlain by Tejon fm. Typically exposed in Moreno Gulch, on E. flank of Panoche Hills, where it is 1,700 to 2,000 ft. thick and composed predominantly of thin-bedded, rather brittle brownish and lavender-colored shales that weather into small bits and flakes. In lower part of fm. are numerous beds of ss., locally containing poorly developed concretions and in general similar to the ss. of Panoche fm. Upper half of fm. is more nearly pure sh. and contains greater proportion of material of organic origin. Calc. sh., ls. nodules, and layers of semi-porcelaneous siliceous sh. occur locally, and near top of fm. is a zone of white platy diatomaceous sh. about 200 ft. thick, which is traceable most of way along face of Panoche Hills, Fresno Co. Line btw. Moreno and Panoche fms. is arbitrarily drawn at horizon where the ss. beds that form steep E. slope of Panoche Hills dip beneath the predominantly shaly beds.

Morgan formation.

Pennsylvanian: Northeastern Utah (northern Wasatch Mountains).

E. Blackwelder, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 519, 529–542). In upper canyon of Weber River [in which is located town of Morgan] the conspicuous Weber qtzite (Penn.) is separated from the dark Miss. lss by a fm. of red ss. and sh. with intercalated thin lss., having a total thickness of 500 to 2,000 ft. This fm. was noted by geologists of 40th Par. Surv. but not named. F. B. Weeks, in unpublished ms. on geol. of NE. Utah and adjacent regions, calls it *Morgan fm.*, and in present paper that name is adopted. Prevailing rock in Morgan fm. is earthy ss., relatively soft. Fresh surfaces are generally white or pink, but the rock weathers brick red. Some beds are distinctly shaly, and here and there thin layers of gray ls. with a few fossils are interbedded. The fm. passes upward through a transitional zone of alternate gray shales, lss., and sss., into the more or less calc. base of Weber qtzite. It rests uncon. on fossiliferous gray Miss. ls. Is of Penn. age. Has been traced from Weber Canyon northward 5 or 6 mi., where it disappears beneath the Eocene. Has not been recognized in other parts of region and is probably of local extent. Is probably of terrestrial origin. These beds were included in Weber qtzite as originally defined by King.

Morgan series.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed *Morgan series*, from Morgan Co., W. Va., as a geographic name for Lower Dev. series, to include Oriskany and Helderberg groups of N. Y.

Morgan Corners formation.

Name applied by H. W. McGerrigle (17th Rept. Vt. State Geol., 1931, pp. 182, 185) to *upper* part of A3 of Logan's section of Philipsburg series of Quebec. McGerrigle mapped his Morgan Corners fm. (Ord.) in small area in St. Albans quad., Vt., and stated that it consisted of 150 ft. of dol. He applied *Wallace Creek fm.* to *lower* part of Logan's A3, and described it as an interstratified series of thin-bedded shaly lss., with thicker bedded lss., gave its thickness as 200 to 250 ft., and mapped it in St. Albans quad. (See 1931 entry under *Philipsburg series*.)

Morgantown sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania, eastern Ohio, western Maryland, and northern West Virginia.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Morgantown ss.*—Named for Morgantown, W. Va. Lies 140 to 160 ft. below Pittsburg coal, and 25 to 38 ft. above Crinoidal [Ames] ls. Thickness 30 to 70 ft.

W. G. Platt, 1878 (2d Pa. Geol. Surv. Rept. H4). *Morgantown ss.*, 40 to 50 ft. thick, overlies Elk Lick coal, and consists of an upper and a lower ss. each 10 to 15 ft. thick, separated by 7 ft. of red sh.

Morgantown red bed. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania and western Maryland.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6), applied *Morgantown red bed* to beds shown as=lower part of Morgantown ss. at Pittsburgh, Pa., and to beds underlying Morgantown ss. in Upper Potomac Basin of Md.

Morgantown member. (In Conemaugh formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include (descending) Clarksburg ls., Clarksburg red bed, Morgantown ss., and Wellersburg coal.

Moriah marble.

F. J. H. Merrill, 1895 (N. Y. State Mus. Bull. 3, No. 14). The ophiolite of the crystalline lss. of Moriah and Westport Twps, Essex Co., N. Y., is widely familiar under trade name "Moriah marble." Assigned to Archean.

Morien series.

Pennsylvanian: Nova Scotia.

A. O. Hayes and W. A. Bell, 1923 (Canada Geol. Surv. Mem. 133, pp. 15, 95).

Morin limestone.

Pre-Cambrian (Laurentian): Canada.

W. E. Logan, 1863 (Canada Geol. Surv. 15th Rept. Prog., pp. 837–838+).

Morita formation.

Lower Cretaceous (Comanche): Southeastern Arizona (Bisbee region) and northern Mexico.

F. L. Ransome, 1904 (U. S. G. S. P. P. 21, pp. 56, 63–65). *Morita fm.*—Alternating beds of dull-red aren. sh. and red or tawny sss. with occasional layers of grit and lenses of impure ls. In upper part the red sh. becomes calc. One bed of reddish-brown grit, 10 to 15 ft. thick, occurs 1,200± ft. above base of fm. Some strata are 10 to 15 ft. thick, but usually are less than 4 ft. thick. Is a shallow-water deposit. Grades into overlying Mural ls. and rests conformably on Glance cgl., all of which are included in Bisbee group (of Comanche age). Named for Morita Hills, just S. of Int. Bdy. btw. longitudes 109°45′ and 109°50′, in Sonora, Mexico.

Morley coal group.

Local name for a group of coal beds in Raton fm. of Elmoro and Spanish Peaks region, Colo. Exposed at several places in vicinity of Morley. See U. S. G. S. Elmoro folio, No. 58, 1899.

Mormon sandstone.

Middle Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Mormon ss.*—Fine-grained compact gray ss. with several small beds of cgl. Thickness 500 ft. Older than Bicknell ss. and younger than Thompson ls.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Mormon ss.*—Prevailingly fine-grained gray compact ss., passing on one hand into greenish or reddish cgl. and on other hand into more shaly beds. Thickness 550 ft. Rests conformably on Thompson ls. and is overlain, probably conformably, by Bicknell ss. Extends across Mount Jura from lower slopes of Grizzly Mtns to North Arm.

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81), showed *Mormon ss.* of Mount Jura as underlying Moonshine cgl. and overlying Thompson red sh.

Named for exposures at Mormon Station, on old stage route near Taylorsville, Plumas Co.

Morne l'Enfer formation.

Tertiary: Trinidad.

G. A. Macready, 1920 (Am. Inst. Min. and Met. Engrs. Trans. [preprint 1017], p. 8).

Morning Glory limestone member (of Gold Hill formation).

Cambrian? (Upper Cambrian?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Morning Glory ls. memb.*—White to blue-gray crystalline ls. with mixture of silicates. Thickness 15 ft. Lies near middle of Gold Hill fm., nearly 200 ft. below White Cap ls. memb. and 140 ft. above Pine Nut ls. memb. Exposed near Morning Glory mine.

Morphy.

Middle Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Morphy* is introduced for lowest Canajoharie or zone of *Mesograptus mohawkensis* in Mohawk Valley.

Morrill limestone. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 234, 235, 237). *Morrill ls.* (in Garrison sh. memb. of Council Grove fm.) consists of 1 to 3 ft. of hard gray massive ls., irregular above, weathering grayish, basal portion weathering brownish and cavernous. Overlies Florena sh. (which rests on Cottonwood ls.) and underlies Stearns sh. Named for exposures 2 mi. NW. of Morrill, Kans.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 17). *Morrill ls.* consists of 2 dark-gray granular lss. separated by thin gray calc. sh. Thickness usually about 4 ft. in northern occurrence but becomes 7 to 13 at places in central and southern Kans. Type loc. W. and ½ mi. N. of Morrill, Kans. When named was well exposed at type loc., in gutter below the road cut in which Eiss ls. is shown, but is now covered here by a new road grade. But it is shown in a small bench, first above the Cottonwood, about ¼ mi. N. of type loc. and E. of N.-S. road in NW. corner of sec. 27 and SW. corner of sec. 22.

G. E. Condra, 1935. (See under *Beattie fm.*)

See also Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Morris granite.

Pre-Cambrian: Long Lake quadrangle, Adirondack Mountains, New York.

H. P. Cushing, 1907 (N. Y. State Mus. 60th Ann. Rept., pt. 2, pp. 482, 510, 525, and map). *Morris granite.*—Quite uniform red, very acid granite, constituted almost wholly of red feldspar and quartz; other minerals not visible to eye. More commonly fine-grained, but there is also a coarse phase.

H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95). *Morris granite*, intrusive into Grenville rocks and Saranac fm. Is latest granite of region. Consists almost wholly of alkali feldspar and quartz. Named for occurrence on W. slopes of Mount Morris, Franklin Co.

Morris sand.

A subsurface sand, of early Penn. (Cherokee) age, in central eastern Okla., which is said to correspond to upper Dutcher sand. In type area (Morris pool, Okmulgee Co.) it lies at 1,600 ft. depth, the second Booch sand at 1,300 ft. depth, the so-called Glenn sand at 1,725 ft., and the Fields sand at 1,800 ft.

Morris Ferry greensand.

Upper Cretaceous (Gulf series): Southwestern Arkansas and southeastern Oklahoma.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, p. 89). *Morris Ferry greensands.*—Hard massive rock, composed of fine grains of greensand, calcite, and siliceous sand, outcropping near low-water line of river at Morris' ferry on Little River, in N. edge of Little River Co., Ark. Underlies alluvial and Quat. deposits. Relations to other Cret. rocks undet.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 114, 302). The *Morris Ferry greensands* are most eastern outcrop of Woodbine fm.

According to studies of L. W. Stephenson and C. H. Dane these beds are part of Woodbine sand.

Morris Mountain shaly member (of Logan formation).

Mississippian: Northeastern Kentucky (Powell County).

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, p. 46). *Morris Mtn shaly memb.*—Mostly sh., but includes subordinate amounts of ss. and ls. or calc. and fossiliferous layers. At Carter, Carter Co., it has a bed of red sh. at top. Thickness 15 to 100 ft. Is top memb. of Logan fm., and probably same as Rushville group of Andrews in Ohio, but proof is lacking. Named for Morris Mtn, about 4 mi. N. of Stanton, Powell Co.

Morrison formation.

Upper Jurassic: Colorado, northern New Mexico and northeastern Arizona, eastern Utah, Wyoming, western South Dakota, central southern Montana (Stillwater-Rosebud Counties region), western Oklahoma, and western Kansas (?).

G. H. Eldridge, 1896 (U. S. G. S. Mon. 27). [The fm. was named by Eldridge in this Mon., within the area of which is its type loc.; but Pikes Peak folio, by W. Cross, in which the fm. was also described was published in 1894, before publication of the Mon.] *Morrison fm.*—Throughout Denver region and for much of distance along E. base of Rocky Mtns in Colo., the Jura is essentially a fm. of fresh-water marls, of average thickness of 200± ft. Its upper limit is sharply defined by Dakota ss., while the brown and pink ss. closing the Trias as clearly marks its lower limit. To this fm. has been assigned the name *Morrison*, from the town [near Denver] near which it is typically developed. The marls are green, drab, or gray, and carry in lower two-thirds numerous lenticular bodies of ls. of characteristic drab color and a texture compact and even throughout. About 20 ft. above base occurs a persistent band of alternating lss. and sss., or all sss., 10 to 15 ft. thick. At Morrison the top memb. of underlying Wyoming fm. consists of 15 to 25 ft. of persistent ss., fine-grained, often massive, pink and brown. The clays of lower two-thirds are remarkable for their reptilian remains and from the dominating form have been designated "*Atlantosaurus* clays." The upper third is generally a succession of sss. and marls, of which the sss. predominate. The most important ss. occurs just above the *Atlantosaurus* clays, is very persistent, and from contained Saurian remains has been called *Saurian ss.* It varies in thickness btw. 5 and 35 ft., and in its distance below the Dakota from 10 to 125 ft., although usually from 50 to 80 ft. The Morrison appears to be uncon. with underlying Wyoming fm. [now divided into (descending) Lykins fm., Lyons ss., Ingleside fm., and Fountain fm.].

In western So. Dak., Wyo., and as far S. in eastern Colo. as Loveland, the Morrison fm. is underlain by marine Sundance fm., of Upper Jurassic age. The age of the Morrison was long questioned, some geologists considering it Upper Jurassic, others considering it Lower Cret. The U. S. Geol. Survey now classifies it as Upper Jurassic, although for many years it classified it as Lower Cret. (?).

†Morrison sandstone.

Middle Jurassic: Northern California (Trinity and Shasta Counties).

O. H. Hershey, 1904 (Am. Geol., vol. 33, pp. 356-360). [*Morrison ss.* as used on pages above cited is, according to J. S. Diller (unpublished note), a misprint for *Mormon ss.*]

Morrison sand.

A subsurface sand in Morrison 3-No. 1A well, of Westbrook field, Mitchell Co., Tex., which lies near base of Clear Fork fm.

Morrisonian series.

A term employed by C. R. Keyes to cover Morrison fm. and supposedly contemp. deposits.

Morristown dolomite member.

Upper Cambrian: Eastern Tennessee.

C. R. L. Oder, 1934 (Jour. Geol., vol. 42, No. 5, pp. 476-478, 493, 496). *Morristown dol. memb.*—Lower memb. of Conococheague-Copper Ridge fm. Consists of 800 to 1,250 ft. of thin- to heavy-bedded dark- to light-gray dense to fine and medium crystalline, fine to coarsely laminated dol. and ls., with subordinate aren. and shaly zones. In W. outcrops very little ls. is present and characteristic rock is blackish to brownish-gray dol. with saccharoidal texture and fetid odor. Btw. Jefferson City and Morristown this memb. is almost wholly dol. of western type. Intraformational ls. cgls., somewhat silicified, occur at various levels. Chert usually plentiful in upper half, especially along western outcrops, and varies from grayish white and steel gray to grayish black, the darker colors more abundant in eastern areas; dense, compact, conglomeratic, and oolitic textures are all common. Fossils rare (listed). [Details.] Belongs to Ozarkian series of Camb. system. Rests uncon. on Maynardville ls. Underlies Bloomingdale ls. memb. of Conococheague-Copper Ridge fm., which contains thick aren. zone at base. Type loc. is along U. S. Highway 25E., about 2 mi. NW. of Morristown.

Morrow group (Arkansas).

Morrow formation (Oklahoma).

Pennsylvanian (Pottsville): Southeastern Arkansas and central eastern and northeastern Oklahoma.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 28, 109-113). *Morrow fm.*—Variable fm. of shales with some thin lss. and occasional sss. Basal portion usually ss. or sandy sh. Includes (ascending order) the following divisions of Ark. Survey: Washington sh. and ss.; Brentwood (Pentremital) ls.; coal-bearing sh.; Kessler ls.; and unnamed bed of shales and sss., 5 to 20 ft. thick, the upper limit of which is rather indefinite but at many places is marked by presence of heavy sss. carrying quartz pebbles. Underlies Winslow fm. or Millstone grit. Overlies Pitkin ls.

A. H. Purdue, 1907 (U. S. G. S. Winslow folio, No. 154). *Morrow group.*—Divided into two fms., the lower one, consisting of ss. and sh., called *Hale fm.*, and the upper one, consisting of carbonaceous sh. with two ls. lentils (Brentwood and

Kessler), called *Bloyd sh.* Underlies Winslow fm. and overlies Pitkin ls. Of Pottsville age.

In NE. Okla. is uncon. overlain by Cherokee sh.

Named for Morrow, Washington Co., Ark.

Morrow pay sand.

A subsurface sand in Woodbine fm. of Navarro Co., Tex. Lies 250 ft. below Main pay sand in Currie field.

Morrow Creek member (of Green River formation).

Eocene: Southern Wyoming (Rock Springs uplift).

W. H. Bradley, 1926 (U. S. G. S. P. P. 140, p. 123, map, chart, etc.). *Morrow Creek memb.*—A distinct lithologic unit of plant-bearing lacustrine beds that form upper part of Green River fm. and are easily traceable from N. part of Sweetwater Co. southward along top of White Mtn to Union Pacific R. R. and thence W. to Green River. Largely buff sandy ls. and buff ss., contrasting sharply with underlying bluish-white Laney sh. memb. of Green River fm. Also contains small amount of light-brown paper sh. and an occasional alga reef or pisolite. Exposures characterized by poor bedding and chippy fragments. Thickness 100 to 500 ft. Lower part appears to replace Tower ss. lentil of Green River fm., which occurs farther S. Underlies Bridger fm. Named for exposures in valley of Morrow Creek.

Morse Creek limestone.

Middle Devonian: Western New York (Lake Erie region).

A. W. Grabau, 1917 (Geol. Soc. Am. Bull., vol. 28, p. 946). *Morse Creek ls.*—Has been called "Encrinal ls." Is similar to the younger Tichenor ("Encrinal") ls. Is widespread in western N. Y. Well exposed on shore of Lake Erie, N. and S. of Eighteen-Mile Creek and in gorge of that stream. This ls., for which I propose name *Morse Creek ls.*, from Morse Creek, near Athol Springs, Erie Co., lies in reality below horizon of Ludlowville sh. and is=Centerfield ls. of Cayuga Lake region.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, p. 227). *Morse Creek ls.* of Grabau is same as true Tichenor ls. [See 1930 quotation under *Tichenor ls.*]

†Mortar beds.

A descriptive term applied in early repts to Ogallala fm. (Plio. and Mio.) of Kans. So named because in appearance the beds resemble rough mortar. (See also under *†Plains marl* and *Ogallala fm.*)

Moruga series.

Miocene: Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geology of Trinidad, pp. 45–53).

Mosby sandstone member (of Warm Creek shale).

Upper Cretaceous: Central northern Montana (Fort Benton-Little Rocky Mountains region).

C. T. Lupton and Wallace Lee, 1921 (A. A. P. G. Bull. 5, p. 263). Several distinct and easily recognized datum planes occur in exposed part of Colorado sh. in region of Musselshell River. The lowest of these, called *Mosby ss.*, from Mosby P. O., is 1,065 ft. above base of the Colorado. It is 3 to 4 ft. thick, and divided into two approx. equal parts by a dirty fossiliferous ls. bed about 6 in. thick. Along the Musselshell it forms a conspicuous rim rock at top of the bluffs bordering the river and has a uniform and unvarying character. A somewhat similar but noncalc. bed 2 ft. thick, usually less conspicuous, occurs 17 ft. above Mosby memb. on Musselshell River and at some localities closely resembles it.

A. J. Collier and S. H. Cathcart, 1922 (U. S. G. S. Bull. 736F, p. 172), treated the Colorado deposits of Little Rocky Mtn region as a group, divided into (descending) Warm Creek sh., Mowry sh., and Thermopolis sh., the Warm Creek sh. including the *Mosby ss. memb.* about 360 ft. above its base and 775 ft. below overlying Eagle ss. They described the Mosby as a rather thin calc. ss. (5 ft. thick) containing many periwinklelike fossils.

Mosca limestone.

Pennsylvanian: New Mexico.

C. R. Keyes, 1906 (Jour. Geol., vol. 14, pp. 147–154), divided his *Manzanan series* [not same as Manzano group, but older] into (descending) *Mosca lss.*, Coyote sss., *Montosa lss.*, and Sandia shales. Derivation of names not given.

Is a part of Madera ls.

Moscow shale. (In Hamilton group.)

Middle Devonian: Western and central New York.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 298–300). *Moscow shales.*—Fossils and sh. change considerably from those below. Chiefly bluish, sometimes olive, and in certain localities portions near upper part are black. Very little of mass is slaty. Named for occurrence at Moscow, Livingston Co. Underlies Tully ls. and overlies Encrinal ls.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, p. 229). *Moscow fm.*—Top fm. of Hamilton group. Hall (1839) described Moscow fm. from exposures along Little Beards Creek near village of Leicester (formerly Moscow). He limited the fm. at base by an "Encrinal" ls. which he believed to be="Encrinal" of Cayuga Lake region at Ludlowville. But the lower "Encrinal" at Moscow has now been traced eastward to Canandaigua Lake and proved to be Tichenor ls., while the "Encrinal" of Cayuga Lake region, when traced westward from Ludlowville, is found at horizon of Menteth ls., 55 ft. above type Tichenor. The Menteth can be traced to Genesee Valley, where it occurs 9 ft. above the Tichenor. There is thus an overlapping of the original Ludlowville and Moscow, both of which were defined so as to include the interval btw. Tichenor and Menteth lss. *It is therefore proposed to redefine the Moscow* to include Menteth ls. and all beds above it up to base of the "Pyrite," or to base of Tully ls. in localities where it is present. The Moscow as thus redefined can be traced at least as far E. as Unadilla Valley and W. to shore of Lake Erie. Hall's locality will serve as a type section, although the fm. is not exposed completely there. It is here subdivided into (descending) Windom memb., Kashong memb., and Portland Point memb., the latter including Menteth ls. at base. The Moscow as here redefined overlies Deep Run memb., top memb. of Ludlowville fm.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). Menteth ls. is basal bed of Moscow sh. and overlies Ludlowville sh.

The U. S. Geol. Survey now treats Moscow sh. as top fm. of Hamilton group, and draws its base at base of Menteth ls. memb.

Mose Carr sand.

A subsurface sand in Okmulgee Co., Okla., which is said by some geologists to belong to Dutcher sand series (early Penn.) and by other geologists to correlate with Tyner fm. (Ord.).

Moseley limestone lentil.

Eocene (Claiborne group): Eastern central Texas (Burleson and Robertson Counties).

B. C. Renick and H. B. Stenzel, 1931 (Univ. Tex. Bull. 3101, pp. 78, 91). *Moseley ls. lentil.*—From 25 to 35 ft. above Sparta sand memb. of Cook Mtn fm. in Burleson Co. and 15 to 25 ft. above the Sparta in Robertson Co., there is, in Crockett clay memb. of Cook Mtn fm., an argill. ls., sometimes very glauconitic, which is abundantly fossiliferous. In places this ls. grades into an argill., glauconitic shell marl, and at the old Moseley's ferry site on the Brazos (bridge on the Giddings to Hearne branch of Southern Pacific R. R.) it is of latter type. This ls. is persistent across these counties. The Moseley is underlain by sticky blue, gray, and buff clays containing beds of fossiliferous glauconitic sand, and is overlain by 24 to 30 ft. of gray and buff clays.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 612), showed *Moseley ls.* as lying higher in the Crockett than Eaton lentil and lower than Little Brazos ls.

H. B. Stenzel, 1935 (Univ. Tex. Bull. 3501, pp. 267–279), restricted *Crockett* to beds above Moseley ls., and included latter in his Stone City beds (new name).

Mosheim limestone. (Of Stones River group.)

Lower Ordovician: Eastern Tennessee, western Virginia, and northern Alabama.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 413, 414, 538, 543, 544, 557, 636, pl. 27). *Mosheim ls.*—Fine-grained ls. [mentions one locality where it is 84 ft. thick] uncon. overlying Knox dol. In Knoxville and Athens troughs uncon. underlies Lenoir ls.; in Pearisburg trough uncon. underlies Holston ls. In Pearisburg and Knoxville troughs uncon. overlies Upper Knox. In Athens trough uncon. overlies Jonesboro ls., of Beekmantown age. Is of lower Stones River age and older than Murfreesboro ls.

The beds designated Mosheim ls. by Ulrich are present at type loc. of Lenoir ls. and may have been included in original definition of Lenoir by Safford. According to Ulrich and Butts they differ in lithology, color, and fauna from overlying Lenoir and uncon. underlie it, also uncon. overlie Knox dol. According to A. Keith (personal communication) all of the chertless lss. were excluded from the Knox by Safford in his definition and in his mapping. The Mosheim ls. as identified by Butts in Ala. (Ala. Geol. Surv. Spec. Rept. No. 14, 1926, and U. S. G. S. Bessemer-Vandiver folio) uncon. overlies Odenville ls. and underlies, in places uncon., the Lenoir ls. The Mosheim ls. is now treated by E. O. Ulrich and C. Butts as middle fm. of Stones River group of E. Tenn. and western Va., where it underlies Lenoir ls. and overlies Murfreesboro ls.

Named for exposures in railroad cut at Mosheim Station, Green Co., Tenn.

Moshup till member (of Jameco formation).

Pleistocene (Kansan): Southeastern Massachusetts (Marthas Vineyard).

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Moshup till memb.*—Top memb. of Jameco fm. Consists of about 10 ft. of upturned stony blue clay till containing boulders as large as 8 ft. in diam. Known only on No Mans Land and at Nashaquitsa Cliffs, on S. shore of Marthas Vineyard, where it rests uncon. on Weyquosque fm. and is uncon. overlain by Gardiners clay. Gravel of typical Jameco type may underlie the Moshup, but it is not exposed. Is considered = at least upper part of Jameco gravel of other parts of Marthas Vineyard. Named for "a local god finding a place in aboriginal folk-lore concerning the origin of Gay Head."

Mosinee conglomerate.

Pre-Cambrian (upper Huronian): Central northern Wisconsin (Marathon County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 364). *Mosinee cgl.*—Mainly cgl., but in one area is mainly a fine-grained brittle sl. or chert. Occurs in scattered exposures on upland area E. and SE. of Mosinee. Thickness can only be surmised, but is believed to be great. Is either upper or middle Huronian. Rests uncon. on igneous rocks.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this fm. to upper Huronian.

Mosquito porphyry.

Eocene: Central Colorado (Leadville-Alma region).

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230) and 1886 (U. S. G. S. Mon. 12, p. 83). Light-gray fine-grained dike rock, formed of quartz, orthoclase, and plagioclase feldspars and biotite. [Petrographic description by W. Cross on p. 327 of Mon. 12.]

In U. S. G. S. P. P. 148, pl. 2, 1927, mapped with the other masses of diorite porphyry, without a distinctive name.

Named for occurrence in North Mosquito Amphitheater, on N. face of Mount Lincoln, N. of Alma, Park Co.

Moss porphyry.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). *Moss porphyry.*—Quartz monzonite porphyry. Intrudes Alcyone trachyte, and is believed to be younger than Oatman andesite. May be intrusive equiv. of Gold Road latite. The Moss mine is wholly within this rock.

Mott Haven limestone.

Pre-Cambrian: Southeastern New York (Manhattan Island).

J. D. Dana, 1881 (Am. Jour. Sci., 3d. vol. 21, pp. 431–432). The western or *Mott Haven ls. band* outcrops on New York [Manhattan] Island btw. 118th and 124th Streets. The ledge of ls. with intercalated gneiss, N. of 122d St. and E. of and adjoining Lexington Ave., is principal locality remaining. It is about 125 ft. in breadth.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 23). The W. belt of *Inwood ls.* in New York City in vicinity of Mott Haven has been called *Mott Haven ls.* (1881 Dana).

Mottville member (of Skaneateles shale).

Middle Devonian: Central New York (Onondaga and Cayuga Counties).

B. Smith, 1916 (Acad. Nat. Sci. Phila. Proc., vol. 67, pp. 561–566). *Mottville memb.*—Limy crinoidal band and associated fossiliferous shales above and below, which are exposed along Skaneateles outlet S. of Mottville, and form basal part of Skaneateles sh. in Tully quad. Thickness 15 to 25 ft. The sh. beneath limy band is gray, thin bedded, fossiliferous, and 10 to 25 ft. thick. The sh. above limy band is rather coarse, thick-bedded, and very fossiliferous. To E. the Mottville memb. rests on Cardiff sh.; to W. on underlying Marcellus sh. Named for occurrence at Mottville, Onondaga Co.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 216, 219). *Mottville memb. of Skaneateles fm.*—Smith carefully traced his Mottville memb. E. and W. of type loc. at Mottville and found that to W. it approached in strat. position the beds here named *Oatka Creek sh. memb. of Marcellus fm.*, and finally, at Criss Creek, Cayuga Lake, actually rested directly on Oatka Creek memb. This placed the Mottville in exact position of Stafford ls. Sufficient exposures cannot be found to permit accurate lateral tracing of the Mottville into the Stafford, but all evidence, faunal and strat. (Smith, 1916), points to continuity of these members. Both Clarke and Luther (1909) point out similarity of Stafford fauna to that of the Mottville of Cayuga Lake. The Mottville carries a distinctive Hamilton fauna.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). Skaneateles sh. includes *Mottville ls.* at base. [On p. 391 she says Stafford ls. has recently been proved to be = *Mottville ls.*]

Moulder sand.

A subsurface sand, of Middle Dev. age, in western Ky.

Moulton diorite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Littleton and Moosilauke quadrangles).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., maps and p. 27). *Moulton diorite*, typically exposed on Moulton Hill, in NW. corner of Moosilauke quad. Intrudes Littleton fm. and is therefore post-lower Dev. Assigned to New Hampshire magma series. [On maps assigned to late Dev. or late Carbf.]

Moulton sand.

A subsurface sand in upper part of Kootenai fm. (Lower Cret.) in Cutbank dist., Glacier Co., NW. Mont. According to J. G. Bartram (Geol. of nat. gas, A. A. P. G., 1935, pp. 257, 267) this sand is now called *upper Sunburst sand*.

†Mound limestone.

A term applied by J. G. Percival (Wis. Geol. Surv. 2d Ann. Rept., pp. 23, 65-70, 1856) to Niagara dol. and Burroughs dol. of southern Wisconsin. According to J. D. Whitney (Wis. Geol. Surv. Rept. 1, 1862) this descriptive term was appropriate only in lead region of SW. Wis.

†Mound group.

Pennsylvanian: Central western Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Prel. rept. on iron ores, pt. 2, pp. 169, 196). *Mound group*.—Sss. and shales, with some lss. and thin coals, 133 ft. thick, including beds 64 to 77 of detailed section of lower Coal Measures from Sedalia to Kansas City. Underlies upper Coal Measures and overlies Holden group.

Includes lower part of Kansas City fm. and upper part of Pleasanton fm. Named for occurrence in mounds of Johnson and Cass Counties.

Mound City shale.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). [See under *Swope fm.*]

J. M. Jewett, 1932 (pp. 99, 100, 103 of book cited above). *Mound City sh.*—Yellow fossiliferous sh. containing local beds of ls. a few inches thick. Thickness of memb. generally less than 5 ft. Underlies Sniabar ls. and overlies Critzer ls.

J. M. Jewett, 1933 (Kans. Acad. Sci. Trans., vol. 36, p. 136). Type loc. of *Mound City sh.* is near Mound City, Linn Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), dropped this name from his classification, without explanation of its fate. But, as he restricted his *Swope ls.* to beds above base of Middle Creek ls., this sh. appears to have been included in his underlying Ladore sh. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

Mounds sand.

A subsurface sand, of early Penn. (Cherokee) age, in central and northern Okla., which has been reported to correlate with Dutcher sand series, also with the ss. at base of Chattanooga sh. (Dev.?), and with Wilcox sand (Ord.). In its type loc. (town of Mounds, Creek Co.) the sand is now called Dutcher sand.

Moundsville sand.

A subsurface sand, 15 to 38± ft. thick, in Conemaugh fm. (Penn.) of W. Va., that is believed to lie at horizon of Saltsburg ss. memb. and to correspond to Little Dunkard sand of SW. Pa. Named for Moundsville, Marshall Co., W. Va.

†Mound Valley limestone.

Pennsylvanian: Eastern Kansas.

G. I. Adams, 1896 (Kans. Univ. Geol. Surv., vol. 1, p. 23). *Mound Valley ls.*—Heavy ls., thin to 15 ft. thick, capping row of hills, 120 ft. high, NW. of Mound Valley [Labette Co.] and passing under surface at Cherryvale.

Discarded by U. S. Geol. Survey many years ago, for Bethany Falls ls., the older name. R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 86), discussed Adams' miscorrelations and gave synopses of Mound Valley ls. as used by other writers. On p. 88 he stated: Bethany Falls ls. was called †Mound Valley by early Kans. Geol. Surv., but *Bethany Falls* has priority.

†Mound Valley shale.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 47, 102). *Mound Valley shales.*—Heavy bed of light ashy-gray to jet-black sh. carrying some ss. and constituting escarpment to NW. of Mound Valley.

Same as Ladore sh., later but well-established name adopted by Kans. Geol. Survey. Mound Valley sh. was dropped years ago.

Named for Mound Valley, Labette Co., Kans.

Moundville quartz porphyry.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Marquette County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 520). *Moundville quartz porphyry.*—Outcrops at head of Lake Buffalo, on line btw. secs. 8 and 5, T. 14, R. 9 E., Moundville, Marquette Co. Differs from Marcellon quartz porphyry in showing throughout traces of crystalline structure and thickly scattered large brownish feldspar surfaces.

†Mountain limestone.

Nongeographic term replaced by local geographic names in different parts of country. In Mo. it included most of Mississippian fms. In E. Tenn. and western Va. it is same as Newman and Greenbrier lss. In southern Tenn. and Ala. it is divided into several fms. (See Ala. chart.) The rocks generally form the sides of mtns. In Appalachian region the name *Mountain lime* has been applied (1) to subsurface rocks lying btw. Mauch Chunk sh. and Catskill fm.; (2) to Greenbrier ls. memb. of Mauch Chunk fm.; (3) to Loyalhanna ls.; (4) to Greenbrier and Loyalhanna lss. combined; and (5) to Newman ls. Also to Maxville ls. of Ohio.

Mountain sand.

A drillers' term for sands in NW. Pa. oil region, which according to J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_5, Atlas), are 375 ft. thick and include Homewood ss. at top. The term has also been applied by drillers to Burgoon ss. memb. of Pocono fm. of western Pa. and to other sands in Pottsville, Allegheny, and Conemaugh fms. J. P. Lesley (2d Pa. Geol. Surv. Rept. L, p. 221, 1876) also used, in a section at Pittsburgh, Pa., *Pocono Vespertine or Mountain sss.* for beds underlying Mauch Chunk sh. and overlying Catskill.

Mountain bed.

A name applied by J. A. Taff (Tex. Geol. Surv. 2d Ann. Rept., pp. 730-731, 1891) to 4,060 ft. of sandy beds in upper part of Washita group (Lower Cret.) of El Paso Co., Tex.

Mountain shales.

Cretaceous: Mackenzie.

E. J. Whittaker, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. B, p. 54).

Mountain Creek rock.

Cambrian: Central southern Pennsylvania (Franklin County).

J. P. Lesley and R. H. Sanders, 1881 (2d Pa. Geol. Surv. Rept. D_5, Atlas, map of Franklin Co.).

As mapped includes the following Camb. fms.: Tomstown ls., Antietam ss., Harpers schist, and Weverton ss.

Mountain Creek formation.

Pre-Middle Devonian: British Columbia.

M. Y. Williams and J. B. Bocock, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 199).

Mountain Girl conglomerate-quartzite.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group*. Derivation of name not stated.]

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). *Mountain Girl cgl.-qtzite.*—Apparently a persistent fm. consisting of 10 to 25 ft. of reddish brown cgl. with well-rounded pebbles up to 14 inches diam. of qtzite and rarely of ls., grading into rather massive rock containing allothigenous quartz grains in a cementing medium of sericite, chlorite, muscovite, biotite, and ferruginous material. Thickness 65 to 100 ft. Conformably underlies Wildrose fm. and discon. (?) overlies Middle Park fm., all of which belong to Telescope group (lower Paleozoic?) of S. part of Panamint Range. [Derivation of name not stated and not apparent from his maps.]

Mountain Glen shale.

Upper Devonian: Southwestern Illinois.

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 169–178). *Mountain Glen sh.*—Hard black laminated sh. having band of iron pyrites in basal part and containing numerous spores of *Sporangites huronensis* and shells of linguloid *Barroisella spatulata*. Thickness 25 to 45 ft. Uncon. underlies Springville sh. and uncon. overlies Alto fm. Probably=upper part of New Albany black sh. of Ind. and Chattanooga black sh. of Tenn. Is usually considered late Dev., but Ulrich is convinced it is early Miss. Named for occurrence near Mountain Glen, Union Co. Assigned to Chautauquan series, Dev.

Mountain Home shale.

Pennsylvanian: Southwestern New Mexico (Santa Rita district).

H. Schmitt, 1933 (Am. Inst. Min. and Met. Engrs. Contr. 39, pp. 2, 4, 13). [See under *Humboldt fm.*]

This is lower 100 to 130 ft. of Syrena fm. (Penn.) of Santa Rita dist.

Mountain Park formation.

Lower Cretaceous: Alberta.

B. R. MacKay, 1930 (Canadian Min. and Met. Bull. 222, p. 1312).

Mount Alto quartz monzonite.

Tertiary (Eocene): Central northern Colorado (Boulder County).

P. G. Worcester, 1921 (Colo. Geol. Surv. Bull. 21, pp. 34–35). *Mount Alto quartz monzonite porphyry.*—This rock occurs as a single dike about ¼ mi. N. of Mount Alto Park and about 1 mi. E. of Gold Hill Station.

Mount Ascutney granite.

Carboniferous: Southeastern Vermont (Windsor County).

C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, pp. 178–179). *Mount Ascutney granite or syenite* occurs only at Mount Ascutney [Claremont quad.].

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned *Mount Ascutney nordmarkite* to Carbf.

Mount Athos formation.

Pre-Cambrian: Central Virginia (along James River).

A. S. Furcron, 1931 (Pan-Am. Geol., vol. 55, p. 317). *Mount Athos fm.*—About 200 ft. of qtzite and schist. Principal qtzite memb., usually less than 100 ft. thick, occurs generally near middle of fm. and is enclosed by micaceous and talcose schists. Overlain by Cockeysville marble and rests on epidote-hornblende greenstone. [Derivation of name not stated.]

A. S. Furcron, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 232–233). Btw. Lynchburg and Howardsville the oldest exposed rocks are basaltic lava flows of unknown thickness, now altered to epidote-chlorite-hornblende greenstone. Over these flows occur about *200* ft. of qtzite and schist here called *Mount Athos fm.* The principal qtzite memb., usually less than 100 ft. thick, occurs generally near middle of fm. and is enclosed by micaceous and talcose schists. Cockeysville marble rests on this fm. and is overlain by Wissahickon schist and phyllite. It outcrops in narrow synclinal belts which are frequently interrupted by normal faults. The fm. is at least *600* ft. thick, and consists of interlayered blue-white and pink marbles, talcose and micaceous schists. Marble composes a large part of the fm. in some localities and in other places it is greatly subordinate to schist. [Derivation of name not stated, but there is a village called Mount Athos, which receives its mail at Lynchburg.]

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, pp. 6, 24). In region E. of Lynchburg basic volcanic rocks occur under *Mount Athos qtzite* and are oldest rock exposed in that area. The Mount Athos qtzite, which may be=Setters qtzite, underlies marble that is probably=Cockeysville marble. [In table on p. 6 author divides Glenarm series (pre-Camb.) of "Piedmont and Blue Ridge provinces, Va." into (descending) Wissahickon fm., Cockeysville marble, Mount Athos qtzite, and greenstone volcanics.]

Mount Athos quartzite.

See under *Mount Athos fm.*

Mount Athos greenstone.

Pre-Cambrian: Southeastern Virginia (James River region).

A. S. Furcron, 1935 (Va. Geol. Surv. Bull. 39, pl. 1), mapped *Mount Athos greenstone,* at base of pre-Camb. of James River iron and marble belt, extending over several counties E. of Lynchburg, and described it on map as consisting of basaltic lava flows at base of Mount Athos fm., altered to greenstone schist.

Mount Auburn concretionary shale member (of McMillan formation).

Upper Ordovician: Southwestern Ohio, northwestern Kentucky, and southeastern Indiana.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, p. 85). *Mount Auburn or Platystrophia lynx beds.*—Sh., chiefly blue but in places yellowish, with some irregularly bedded ls.; thickness 20 ft. Overlain by Warren beds [Arnheim fm.] and underlain by Corryville or *Chiloporella nicholsoni* beds.

Upper memb. of McMillan fm.

Named for Mount Auburn, Cincinnati, Ohio.

Mount Baker lava.

Quaternary: Central northern Washington.

G. O. Smith and F. C. Calkins, 1904 (U. S. G. S. Bull. 235, p. 35). *Mount Baker lava.*—Mount Baker, like most of the higher peaks of the Cascades, is an extinct volcano built up of andesitic lavas of comparatively recent age. Although fragmental materials probably form part of the cone, all volcanic materials from Mount Baker observed at close range are lava. The more crystalline varieties are generally gray, but the more glassy phases are black, or, less commonly, red.

Mount Bennett rhyolite.

Tertiary (Oligocene?): Southwestern Idaho.

I. C. Russell, 1902 (U. S. G. S. Bull. 199, p. 42). Extensive sheet of rhyolite forming Mount Bennett. Provisionally termed *Mount Bennett rhyolite.*

According to C. P. Ross (personal communication) this rhyolite flow belongs to his Challis volcanics.

†Mount Bohemia conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1906 (Mines and Minerals, vol. 27, pp. 204–206).

Same as Bohemia or No. 8 cgl.

Mount Cap formation.

Cambrian (Middle): Mackenzie.

M. Y. Williams, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. B, p. 59).

Mount Carmel sandstone.

Pennsylvanian: Southeastern Ill. See under *Hanging Rock ss.*

Mount Champion quartz monzonite.

Probably pre-Cambrian: Central Colorado (Chaffee and Lake Counties).

J. V. Howell, 1919 (Colo. Geol. Surv. Bull. 17, p. 43). *Mount Champion quartz monzonite.*—A light-gray crystalline rock of medium texture. Typically exposed on Mount Champion, Lake Co. Probably pre-Camb.

Mount Charles formation.

Devonian: Mackenzie.

M. Y. Williams, 1924 (Geol. Soc. Am. Bull., vol. 35, p. 96).

Mount Clark formation.

Lower Cambrian: Mackenzie.

M. Y. Williams, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 76).

Mount Clark granite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 128, map). *Mount Clark granite.*—Very siliceous light-colored granite or alaskite, composed almost wholly of feldspar and quartz. Moderately coarse-grained and even-textured. Is practically devoid of ferromagnesian minerals, such as biotite and hornblende.

Named for fact it composes Mount Clark, Yosemite Nat. Park.

Mount Clemens moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (fig. 7) in U. S. G. S. Detroit folio (No. 205), p. 9; also on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Mount Clemens.

Mount Deception granite.

Pre-Cambrian (?): Northern New Hampshire (Mount Washington quadrangle, White Mountains).

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, p. 124). Mount Deception is built up of a coarse Concord granite.

C. H. Hitchcock, 1878 (Geol. N. H., pt. 3, pp. 241–242), mentioned, casually, *Mount Deception granite.*

J. W. Goldthwait, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 281, 283, 285), referred to gray muscovite granite "of type known to Hitchcock as 'Mount Deception granite.'"

Mount Eagle series.

Upper Cretaceous: Virgin Islands.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 478).

Mount Ebel sandstone member.

Mississippian: Southern Indiana.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 251, 253, 258, 261, 270, 272, 274, 281+, etc.). *Mount Ebel ss. memb. of Edwardsville fm.*—A bed of ss., 0 to 1 ft. thick, lying 5 to 15 ft. below top of Edwardsville fm., characterized by (1) bright yellowish-brown color often mottled with gray; (2) greater resistance to weathering than other beds in upper part of fm.; and (3) fauna of brachiopods, including *Orthotetes keokuk* and *Syringothyris textus*. [On p. 274 he described it as 10 ft. of ss. beds with alternating shaly ss. resting on 80 ft. of gray to drab siltstone (argill. ss.).] Named for Mount Ebel church, NE.¼NW.¼ sec. 23, T. 7 N., R. 1 W., 3 mi. S. and slightly E. of Smithville and from the surrounding Mount Ebel community. Type exposure is along Smithville-Fairfax road a short distance S. of Mount Ebel church, where it is 1 ft. 3 in. thick.

Mount Eden formation.

Pliocene: Southern California (San Jacinto Mountains).

D. M. Fraser, 1931 (Mining in Calif., vol. 27, No. 4, pp. 511–514). *Mount Eden fm.*—Frick's name *Eden beds* being preoccupied, he suggests that it be replaced by *Mount Eden*, which is herein substituted and used to designate the Lower Plio.

sss. and shales which occupy region about Beaumont. The name is taken from Mount Eden, a rather large hill of schist lying just W. of San Jacinto quad., upon slopes of which the sediments were deposited and are now well exposed. Upper part of fm. consists of 1,500± ft. of nonmarine sh. and sss., only moderately indurated. The sss. are grayish to buff, with occasional green and blue tints, are coarse- to medium- to fine-grained, and arkosic layers are not uncommon. The interbedded shales, having gray, tan, and blue tinges, vary in texture from sandy shales to silt shales. These beds rest conformably on the lower, or *Mount Eden Red Beds memb.*, which consists of 1,800± ft. of massive arkosic red beds, grading up into massive gray ss. and sh.; near top the strata change to finer grits and sss. of gray or greenish-gray color. Upper memb. contains Plio. vertebrate fossils. Lower memb. is unfossiliferous, distinctly more indurated and more resistant than overlying beds, and may possibly be Mio. The Mount Eden fm. uncon. underlies Bautista beds (Pleist.) and overlies the metamorphic series of Paleozoic or older age.

Mount Eden Red Beds member.

See under *Mount Eden fm.*

Mount Forster formation.

Devonian (?): British Columbia.

J. F. Walker, 1926 (Canada Geol. Surv. Mem. 148, p. 34).

Mount Garfield formation. (In Mesaverde group.)

Upper Cretaceous: Western Colorado (Book Cliffs coal field).

C. E. Erdmann, 1934 (U. S. G. S. Bull. 851, pp. 22, 33). *Mount Garfield fm.*—Upper part, or "barren measures," consists of an assemblage, 405 to 665 ft. thick, of ss., sh., and carbonaceous sh., the ss. averaging about 33 percent, the sh. 51 percent, the sandy sh. and shaly ss. 10 percent, and the carbonaceous sh. 6 percent; the sss. not so thick as those of overlying Hunter Canyon fm. Lower part, or "coal measures," consists of an assemblage (305 to 666 ft. thick) of ss., sh., and carbonaceous sh. containing thick beds of bituminous coal, the rocks being of fluviatile, swamp, estuarine, and littoral environment, the coal being 5.4 percent of this memb., the carbonaceous sh. 14.8 percent, the sh. 25.5 percent, and the ss. 40 percent. The lower part contains Palisade coal (at base), Cameo and Carbonera coals at top, and Rollins ss. memb. below Cameo coal. Included in Mesaverde group. Underlies Hunter Canyon fm. and overlies Sego ss. Named for Mount Garfield, which has been carved from these rocks.

Mount Garfield porphyritic quartz syenite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Franconia quadrangle).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., p. 15; map). *Mount Garfield porphyritic quartz syenite.*—Coarse- to medium-grained, usually green. Named for Mount Garfield, Franconia quad. Extends from just N. of Mount Hale southwesterly to Hardwood Ridge. Is younger than both Kinsman quartz monzonite and Mount Lafayette porphyry, and either late Dev. or late Carbf. Assigned to White Mtn magma series.

Mount Gilead sandstone. (In Henshaw formation.)

Pennsylvanian: Western Kentucky (Webster County).

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 120). *Mount Gilead ss.*—Soft ss., 15 to 30 ft. thick, believed to be highest part of Penn. in Webster Co. Top memb. of Dixon fm. Overlies Mount Gilead shales and underlies Lafayette fm. (Plio.). Occurs around and on ridge W. of Mount Gilead School.

Mount Gilead shale. (In Henshaw formation.)

Pennsylvanian: Western Kentucky (Webster County).

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 120). *Mount Gilead shales.*—Shales very similar to older Bald Hill shales. Become sandier in upper 25 to 50 ft. and weather rusty yellow, as in immediate vicinity of Mount Gilead School, but middle and lower parts are argill. and calc., with thin lss. in places; 2 mi. SW. of Mount Gilead one of lss. becomes 20 to 30 ft. thick. Total thickness of beds 150 to 200 ft. Underlies Mount Gilead ss. and overlies Vanderburg ss., all being included in Dixon fm.

Mount Glen terrane.

A term applied by C. [R.] Keyes to *Mountain Glen sh.* of Savage (1920), Upper Dev., Ill. (See Keyes, 1923, Pan-Am. Geol., vol. 39, No. 4, table on p. 320.)

Mount Harris formation. (In Mesaverde group.)

Upper Cretaceous: Northwestern Colorado (Yampa coal field).

M. R. Campbell, 1931 (Tentative correlation of named geologic units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Mount Harris fm.*—Mostly sh., but contains some beds of ss. and Wadge and Wolf Creek coal beds—two of most important coals in Yampa field. Thickness 950 ft. Underlies Twentymile ss. and overlies Trout Creek ss. Included in Mesaverde group. Outcrops at Mount Harris, a coal-mining town on Yampa River.

Mount Herman sandstone.

Devonian or Carboniferous: Southwestern New York.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, p. 525). *Mount Herman or Salamanca cgl.* [also calls it *Mount Herman ss.*].—Overlies red and green Cattaraugus beds and is separated from the younger Olean cgl. by 200 ft. of sh.

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, p. 974). The ss. phase of Salamanca cgl. lentil is well exposed in a number of small quarries on Mount Herman, just S. of Olean, where it is locally known as *Mount Herman ss.*

Mount Holly conglomerate.

Pliocene (?): Southern New Jersey (Burlington County).

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc., vol. 32, pp. 271, 288). On top of the hill at Mount Holly, N. J., is an identical cgl. and gravel, composed of same materials as Bryn Mawr gravel in Pa. This cgl., which is named *Mount Holly cgl.*, has the peculiar ferruginous glaze of Bryn Mawr gravel. It overlies Cret. marls and sands. From its abundance at Mount Holly, and in order to show its connection with the Pennsylvania deposits, we shall call the cgl. of the Bryn Mawr gravel *Mount Holly cgl.*

Mount Holly gneiss.

Pre-Cambrian: Southwestern Vermont (Rutland County).

C. L. Whittle, 1894 (Am. Jour. Sci., 3d, vol. 47, pp. 347–355). In paper soon to appear in Jour. Geol. writer will call the upper metamorphosed Algonkian clastics (schists, qtzites, cgls., and lss.) *Mendon series*, and the older metamorphics of gneisses, schists, lss., and qtzites the *Mount Holly group*, upon which the Mendon series is believed to lie discordantly.

C. L. Whittle, 1894 (Jour. Geol., vol. 2, pp. 396–429). *Mount Holly series.*—More metamorphosed and more variable [than overlying Mendon series] series of stratified rocks of Algonkian age, together with gneisses and schists of unknown origin, and abundant metamorphic equivalents of old basic igneous rocks. Consists of gneiss, qtzites, lss., and schists. Named for development in town of Mount Holly [Wallingford quad., Rutland Co.].

L. M. Prindle and E. B. Knopf, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 264–269, etc.). *Mount Holly gneiss.*—Oldest known rock in Vt. Highly metamorphosed complex of sed. and igneous rocks, called *Mount Holly "series"* by Whittle. The rocks of probable sed. origin are schists, white gneisses carrying abundant blue quartz, and scattered irregularly shaped ls. deposits largely altered to impure marbles or serpentine. In addition there is a series of banded gneisses that may be mainly orthogneisses. The whole complex is cut by igneous rocks ranging in composition from rather massive amphibolites to granitic rocks commonly characterized by notable content of striking blue quartz. Later intrusions are unmetamorphosed gabbro and dunite. Greatly twisted and contorted. According to present definition of U. S. Geol. Survey it would be called Archean, as it is characterized by exceedingly intricate and variable structure, in which it contrasts strongly with the overlying rocks. Is overlain by Mendon schist (younger pre-Camb.) and is cut by Stamford granite gneiss, a concordant intrusion. Underlies greater part of Green Mtns from Glastenbury Mtn, Vt., southward to Mass. line. [This name was approved by U. S. G. S. instead of the preoccupied name †Woodford gneiss, originally suggested by these authors for use in this rept.]

†Mount Holyoke diabase.

A name applied in some early repts to Holyoke diabase. (See B. K. Emerson, U. S. G. S. Mon. 29, p. 17, etc., 1898.)

†Mount Hope type.

Pre-Cambrian: Northern New Jersey.

F. L. Nason, 1889 (N. J. Geol. Surv. Ann. Rept. 1889, p. 30). *Mount Hope type.*—Country rock of Mount Hope iron mines. Is in part the feldspathic gneiss of Prof. Smock and in part the hornblende gneiss of Dr. Britton. Always underlies Oxford type.

In U. S. G. S. Raritan folio (No. 191) the rocks around Mount Hope, Morris Co., are mapped as Byram gneiss, and the use of *Mount Hope* as a geographic name for a facies of that fm. is considered unnecessary.

Mount Hope shale member (of Fairview formation).

Upper Ordovician: Southwestern Ohio, central northern Kentucky, and southeastern Indiana.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, pp. 75, 76). *Mount Hope or Amplexopora septosa beds.*—Heavy, rather irregularly bedded lss. interbedded with shales; thickness 50 ft. Overlain by Fairmont or *Dekayia aspera* beds and underlain by Upper Utica or *Dekayella ulrichi* beds [McMicken memb. of Bassler].

Lower memb. of Fairview fm.

Named for an exposure on SE. slope of Price Hill, known as Mount Hope, at Cincinnati, Ohio.

†Mount Hope marl.

†Mount Hope phase.

Eocene (Jackson): Southern South Carolina (Berkeley County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 17, 18). *Mount Hope phase.*—Overlying Santee marls the Mount Hope marl is exposed along a narrow belt extending from Eutaw Springs by Pond Bluff and Mount Hope (on Santee River to point on Santee Canal near Pooshee. It consists of a matted mass of spines of echini, fragments of corals, and a few oyster and other shells (80 to 90 percent carbonate of lime). In vicinity of Eutaw Springs, and thence along Santee River from Pond Bluff to Mount Hope this phase appears; a marl described by Tuomey as capping the Cooper marl near Stoney Landing on Biggin Creek (1 mi. NE. of Moncks Corner), possibly represents another limited area. It has not been observed elsewhere in State. The material consists of marl, about 11 ft. thick, in alternate hard and soft layers.

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, p. 462). The *Mount Hope marl* consists of a matted mass of spines and plates of echini, coralline fragments, occasional shells of *Ostrea sellaeformis* and other forms. The color is yellow white; it exhibits ledges which are very hard and partly crystalline, with thick intermediate zones of somewhat softer and more porous, but otherwise similar material. Its thickness as exhibited by borings at Pond Bluff is 16 ft., of which 13.2 ft. extend above zero water level (24.8 ft. M. L. T.); the underlying material comprises 11 ft. of sands and then "rock" (report of well borer); this "rock" is probably the hard Santee marl. Mount Hope marl underlies Cooper marl and overlies Barnwell phase.

Name is preoccupied. Is a synonym of Santee ls., according to C. W. Cooke, 1936 (U. S. G. S. Bull. 867).

Named for exposures at Mount Hope, on Santee River, Berkeley Co.

Mount Hope formation.

Pleistocene: Panama.

A. P. Brown and H. A. Pilsbry, 1913 (Phila. Acad. Nat. Sci. Proc., vol. 65, p. 493).

Mount Houghton felsite.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 83, 175–750 passim, especially p. 190).

According to B. S. Butler (personal communication) Mount Houghton felsite and Mount Houghton quartz porphyry are different facies of same fm., and if intrusive are probably of upper Keweenawan age. They compose Mount Houghton, Keweenaw Co.

Mount Houghton quartz porphyry.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, p. 106).

See *Mount Houghton felsite*.

Mount Jefferson formation.

Pliocene: Central northern Oregon (Cascade Mountains).

E. T. Hodge, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 163). The Plio. *Mount Jefferson fm.*, composed of andesitic and trachytic rocks, cuts the older fms., especially near the divide, and fills in the older valleys. It forms the line of high peaks at 121°45′ long., and covers the eastern surface for at least 12 miles. [The older fms. mentioned are (descending) Columbia River basalt and John Day and Clarno fms.]

E. T. Hodge, 1928 (Pan-Am. Geol., vol. 49, pp. 341–356). Stocks and dikes of granodiorite and syenite cut Columbia basalts at many widely scattered places on W. side of Cascade Mtns. Flows of andesite and trachyte are discovered which fill valleys cut in Columbia basalts to W. of Mount Jefferson and the Three Sisters. Together they are called *Mount Jefferson fm.* and are considered to be Plio. They form Mount Jefferson, 10,523 ft. A. T., and other mtns. Underlie Black Crater and Madras fms.

Mount Joli formation.

Lower Devonian (Helderbergian): Quebec (Percé).

J. M. Clarke, 1908 (N. Y. State Mus. Mem. 9, p. 59). *Mount Joli massive*, Sil., Quebec.

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 170+). Clarke held *Mount Joli fm.* to be late Sil. Writer has collected from these fossiliferous beds many times, and his evidence and that of Clarke are here brought together to show that *Mount Joli fm.* is unmistakably Helderbergian (Lower Dev.), and younger than Coeymans of N. Y.

Mount Kindle formation.

Silurian: Mackenzie.

M. Y. Williams, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. B, p. 60).

Mount Lafayette granite porphyry.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Franconia quadrangle).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., p. 13; map). *Mount Lafayette granite porphyry.*—Hard massive gray or green rock, occupying much of Franconia quad. and typically exposed on summit of Mount Lafayette. Main body is 10 mi. long and 3 mi. wide and extends in SW. direction from Mount Hale to Mount Flume. Cuts Kinsman quartz monzonite and is older than Mount Garfield quartz syenite and Mount Osceola granite. Is late Dev. or late Carbf. Assigned to White Mtn magma series.

See *Lafayette granite porphyry*, the original name.

Mount Laurel sand. (In Monmouth group.)

Upper Cretaceous: New Jersey.

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 315, 333). *Mount Laurel sands.*—Coarse red sands, often indurated by iron content. More or less glauconitic, especially to S. Thickness 5 to 80 ft. Underlies Navesink marls [restricted] and overlies Matawan fm. [group]. Is basal div. of Monmouth fm. Named for Mount Laurel, Burlington Co.

The Monmouth of N. J. is now classified as a *group* and Mount Laurel sand as a fm. See concluding statement under *Navesink marl.*

†Mount Lebanon formation. (In Claiborne group.)

Eocene: Northwestern Louisiana.

H. K. Shearer, 1930 (A. A. P. G. Bull., vol. 14, No. 4, pp. 439–441). *Mount Lebanon fm.*—Marine beds of brown or green sh. and glauconitic sand, with characteristic fauna. Near middle a bed of hard glauconitic, more or less sandy ls. that forms characteristic boulder outcrops. Thickness 350 ft. Replaces St. Maurice fm. as restricted by Spooner in 1926. At St. Maurice only a small part of upper Mount Lebanon beds is visible at low-water periods. Named for Mount Lebanon, Bienville Parish, which is surrounded by good fossiliferous exposures. The name "*Minden fm.*" has also been proposed, but is not as satisfactory as Mount Lebanon, because the typical exposures are several mi. from Minden, and the fm. there is not as characteristic as in Bienville Parish. Underlies Cockfield fm. and overlies Sparta fm. Includes Saline Bayou memb., Milams ls. and marl memb., and Crockett memb. of Wendlandt and Knebel and Ellisor. Either *St. Maurice, Mount Lebanon,* or *Minden* should be considered a La. local name. According to C. L. Moody and others who have done detailed work in E. Tex., the exposure at Cook Mtn, Houston Co., Tex., is definitely on same fm. If this is true, *Cook Mtn* should be used as the fm. name, because of priority over all other names.

This name has been discarded in favor of Cook Mtn fm., the older name.

Mount Lowe granodiorite.

Late Jurassic or early Cretaceous: Southern California (San Gabriel Mountains, Los Angeles County).

W. J. Miller, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 149, abstract). White to light-gray massive to moderately foliated granodiorite, which may be called *Mount Lowe granodiorite,* because of typical occurrence on Mount Lowe and vicinity. Younger than Mount Wilson quartz diorite. [Age not stated.]

W. J. Miller, 1930 (Geol. Soc. Am. Bull., vol. 40, p. 150) and 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 162). Writer has mapped [does not say where published] *Lowe granodiorite (late Jurassic)* in San Gabriel Mtns, Calif.

W. J. Miller, 1934 (Univ. Calif. at Los Angeles Pub. Math. and Phys. Sci., vol. 1, No. 1, map, pp. 62–63). [Mapped *Lowe granodiorite* and assigned it to late Jurassic or early Cret.]

†Mount Marcy anorthosite.

See under *Marcy anorthosite.*

Mount Marion beds.

Middle Devonian: Eastern New York (Ulster County).

A. W. Grabau, 1917 (Geol. Soc. Am. Bull., vol. 28, p. 954). I propose to name the lower fossiliferous Hamilton beds of Ulster Co. region the *Mount Marion beds.* Underlie Ashokan beds, the terminal phase of the Hamilton in Ulster Co. region.

A. W. Grabau, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 468–470). *Mount Marion beds.*—Marine shales and ss., 400 to 500 ft. thick. Underlie, without break, Ashokan fm., and overlie "Marcellus" shales [named *Bakoven sh.* by Chadwick, 1933]. Well exposed at Mount Marion, W. of Saugerties.

G. H. Chadwick, 1933 (16th Int. Geol. Cong. Guidebook 9A, p. 4), divided the Marcellus W. of Catskill into (descending) *Mount Marion ss.,* 800 ft., and Chittenango black sh., 200 ft.

Mount Mesnard quartzite.

Pre-Cambrian: Northern Michigan.

M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. State Bd. 1891, 1892, pp. 64–65), mentioned, in one or two places, "the Mt. Mesnard qtzite and dolomitic series" and "the Mount Mesnard qtzite," of which he asked: "Is it a part of Republic fm. or does it overlie it?" He concluded: The evidence seems so strong that the

2 fms. are distinct and uncon. that the qtzite, dol., and associated rocks belonging with them will be designated here as *Mesnard fm.*, from Mount Mesnard, where the fm., is well exposed.

Mount Moat conglomerate.

Devonian(?): Northern New Hampshire (North Conway quadrangle, White Mountains).

C. H. Hitchcock, 1873 (Boston Soc. Nat. Hist. Proc., vol. 15, pp. 304, 307). *Mount Mote cgls.*—At base of Mounts Pequawket and Mote is the common horizontal granite of Labrador series capped by perhaps 200 ft. of spotted granite. Upon Mount Pequawket there are 2 fragments of sl., neither 1 mi. long. The conical summits of both mtns consist at base of a cgl. composed almost exclusively of fragments of sl. Upon Mount Mote there are also andalusite sl., red feldspar, and labradorite pebbles in it. The proportion of pebbles diminishes in ascending Mount Pequawket, and they are small and few at summit. The paste is feldspathic granite. Upon Mount Mote there is a large amount of greenish granite connected with the cgl. The character of embedded pebbles proves these cgls. to be more recent than the clay slates, and they are certainly the newest rocks about White Mtns. Included in "mostly Camb.?" [See also *Pequawket breccia.*]

The approved spelling of this Mtn is *Moat.*

Mount Moriah formation.

Eocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol. No. 7, p. 44).

Mount Morris limestone member (of Washington formation).

Permian: Southwestern Pennsylvania and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 39–40). *Mount Morris ls.*—Lies 2 to 5 ft. below Waynesburg "A" coal and 2 to 5 ft. above Waynesburg ss. Well exposed on N. bank of Dunkard Creek at Mount Morris, Greene Co., Pa. Seldom seen S. of Pa. line. Thickness 0 to 5 or more ft.

Mount Morris sand.

A subsurface sand in Pocono fm. (Miss.) of SW. Pa. and W. Va. Said to correspond to Big Injun sand (Burgoon ss. memb.). Named for Mount Morris, Greene Co., Pa., where it is 101 ft. thick in wells.

Mount Mote breccia.

See under *Pequawket breccia* and *Moat volcanics.* The geographic name is now spelled *Moat.*

Mount Mote conglomerate.

See *Mount Moat cgl.*, the spelling now used on N. H. maps.

Mount Murray diabase.

Jurassic (?): British Columbia.

W. L. Uglow, 1922 (Canadian Inst. Min. and Met. Monthly Bull. 127).

Mount Nelson formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1926 (Canada Geol. Surv. Mem. 148, p. 10).

Mount Olympus granite.

Pre-Cambrian: Central northern Colorado (Larimer County).

M. B. Fuller, 1924 (Jour. Geol., vol. 32, pp. 51–63). *Mount Olympus granite.*—Fine-grained gray biotite granite cutting Longs Peak granite and Big Thompson schist on Big Thompson River.

Named for peak and quad., over much of whose surface it is exposed.

Mount Olympus sand.

A subsurface sand in Cypress ss., of Chester (Miss.) age, in SW. Ind.

Mount Osceola granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Franconia quadrangle).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., p. 15, map). *Mount Osceola granite.*—Group of granites characteristically exposed on Mount Osceola and Scar Ridge, Franconia quad. Characteristically coarse- to medium-grained granite, weathered to white or gray rock. Writers believe this granite is older than Conway granite and either late Dev. or late Carbf. Assigned to White Mtn magma series.

Mount Pequawket breccia.

See under *Pequawket breccia.*

Mount Pisgah sand.

A subsurface sand, of Miss. age, lying at about horizon of Keokuk ls. in Wayne Co., Ky.

†Mount Pleasant beds.

Middle Ordovician: Southwestern Ohio and northern Kentucky.

See 1st entry under *Point Pleasant beds.*

Mount Pleasant conglomerate.

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 58–59). *Mount Pleasant cgl.*—Massive grayish-white sandrock, through which are scattered quartz pebbles, in places in such abundance as to constitute a cgl. There is always a pebbly portion, 3 to 6 ft. thick, near bottom, whose pebbles are reddish or rose-colored. A calc. cgl. 2 to 3 ft. thick forms base of Mount Pleasant cgl. Thickness of fm. 20 to 25 ft. [50 ft. in Rept. G_6, p. 76]. Caps summit of hill at village of Mount Pleasant, Wayne Co. Seems to become coarser toward Lackawanna Co. line. Is basal div. of Elk Mtn transition group (Sub-Pocono transition measures). Rests on Mount Pleasant red sh. memb. of Catskill fm.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 89–91). Mount Pleasant cgl. is basal memb. of Pocono fm.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7). *Mount Pleasant cgl.* is base of Pocono-Catskill transition group, which underlies Pocono ss.

C. S. Prosser, 1894 (U. S. G. S. Bull. 120, p. 78). *Mount Pleasant cgl.* of eastern Pa. belongs to the Pocono.

For later views see under *Pocono fm.*

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 575, 600), stated this cgl. seems rather local, and he included it in his "redefined" *Mount Pleasant red sh.*, q. v. "White thought he recognized Mount Pleasant cgl. along Lehigh River (Rept. G_6, p. 79), but that bed (No. 6) is probably Griswolds Gap cgl."

Mount Pleasant red shale. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 59, 63). *Mount Pleasant red sh.*—Sh. of uniform dull dark red color; no ss. layers. Thickness 150 ft. [300 in Rept. G_6, p. 76]. Top memb. of Catskill fm. Underlies Mount Pleasant cgl. and overlies Elk Mtn lower sands. Well exposed along road descending from village of Mount Pleasant, Wayne Co.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 94–95). Mount Pleasant red sh. is topmost memb. of Catskill series.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 574–576). *Mount Pleasant red sh.*—White used *Mount Pleasant* for more than one unit, for a cgl. and for a red sh. It is here used more inclusively and redefined to embrace the beds btw. base of Pocono and top of Elk Mtn fm. In Wayne Co. this will include 350± ft. of beds below Griswolds Gap cgl. (basal Pocono), which White thought probably were transitional Dev.–Miss. strata. There seems good reason to assign these to Dev. and abandon the idea of transitional strata. The cgl. seems rather local. The fm. is dominantly intensely red sh. and ss. plus some gray beds. Well exposed along United States Highway 6, in region of Waymart, Wayne Co., and thence W. up grade toward State Hospital. Here thickness is near 500 ft. Thins out to NW. in a Dev.–Miss. discon. Its identity S. of Wayne Co. has been determined on Pocono Plateau, but beyond that it cannot with certainty be distinguished from red Cherry Ridge, because intervening green Elk Mtn ss. is missing. There may be some question as to Dev. age, but until further evidence is produced it will be treated as highest div. of Dev. The village for which this unit was named is now known as *Pleasant Mount*, but the Twp retains the older name. [This "redefinition" appears to include Mount Pleasant cgl. of White and some overlying beds. On p. 600 he stated: Eastward from McKean and western Potter Counties the marine Oswayo becomes fresh-water Elk Mtn, which is separated from basal Pocono by an eastward-thickening wedge of red beds, the Mount Pleasant fm. Latter reaches as far E. as Pocono Plateau, but beyond that it has been eroded.]

Mount Pleasant phosphate.

Middle Ordovician: Central Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 105, 127–128, 209–211). *Capitol ls. or Mount Pleasant phosphate.*—Granular current-formed laminated ls., of blue or light-blue color. Thicker laminae alternate with thin darker laminae, the latter richly phosphatic. Included in Nashville (Trenton) fm. Overlies *Orthis* bed [Hermitage fm.] and underlies Dove ls.

Is part of Bigby ls.

Named for Mount Pleasant, Maury Co.

Mount Pleasant shales and sandstones. (In Chester group.)

Mississippian: Southwestern Indiana and central western Kentucky.

W. N. Logan, 1924 (Ind. Dept. Cons. Pub. 42, pp. 11, 125; taken from unpublished rept on Perry Co., by C. A. Malott). *Mount Pleasant shales and sss.*—Next to top fm. of Chester group. Underlie Negli Creek ls. and overlie Bristow sh. and ss. Thickness 20 ft. in well log in Knox Co., Ind.

C. A. Malott, 1925 (Ind. Acad. Sci. Proc., vol. 34, pp. 112–132). *Mount Pleasant ss.*—Hard quartzitic ss., similar to Bristow ss., and like it occurring in upper Chester deposits. Consists of one or more beds, and in places some of lower beds are separated by sh. Thickness 2 to 35 ft. Lies approx. 245 ft. above Glen Dean ls., 15 to 35 ft. above Bristow ss., and 15 to 53 ft. below Negli Creek ls. Extends from near latitude of Branchville and Bristow, Perry Co., southward into Ky. Named for development at Mount Pleasant, Perry Co., Ind.

M. A. Harrell, 1935 (Ind. Dept. Cons. Pub. 133, p. 78), listed (but did not define) *Gennet Creek fm.*, 10 to 35 ft. thick, as underlying Mount Pleasant ss. and overlying Bristow ss.

Mount Princeton quartz monzonite.

Tertiary: Central Colorado (Sawatch Range).

J. T. Stark and F. F. Barnes, 1935 (Colo. Sci. Soc. Proc., vol. 13, No. 8, p. 475, map). [Map shows Mount Princeton in midst of mass mapped as *Mount Princeton quartz monzonite.*]

Mount Rainier lavas.

A term that has been applied in a formational sense to the lavas of Mount Rainier National Park, Wash. (See H. C. Culver, State of Wash. Dept. Cons. and Develop., Div. Geol. Bull. 32, 1936, p. 21.)

Mount Roberts formation.

Carboniferous: British Columbia.

O. E. Le Roy, 1913 (12th Int. Geol. Cong. Guidebook 9, p. 84).

Mount Rosa granite.

Pre-Cambrian: Eastern Colorado (Colorado Springs region).

G. I. Finlay, 1916 (U. S. G. S. Colorado Springs folio, No. 203). *Mount Rosa granite.*—Fine-grained nonporphyritic bluish-gray rock made up chiefly of microcline, quartz, and riebeckite. Most extensively developed on slopes of Mount Rosa. Intrudes Pikes Peak granite in irregular masses, sheets, and dikes.

On 1935 Colo geol. map included in Front Range granite group.

Mount Savage fire clay. (In Pottsville formation.)

Pennsylvanian: Central southern Pennsylvania and western Maryland.

C. A. Ashburner, 1878 (2d Pa. Geol. Surv. Rept. F). [See under †*Mount Savage group*.]

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 201). The famous *Mount Savage fire clay* of Pa. and Md. occurs within limits of Mercer group, and directly underlies Mount Savage coal, which it occasionally replaces.

Most geologists include Mount Savage coal and fire clay in Pottsville fm., correlating the coal with the Upper Mercer, but some geologists include them in Allegheny fm.

Named for occurrence at Mount Savage, Allegany Co., Md.

†Mount Savage group. (In Pottsville formation.)

Pennsylvanian: Central southern Pennsylvania and western Maryland.

C. A. Ashburner, 1878 (2d Pa. Geol. Surv. Rept. F). *Mount Savage group*.—Middle memb. of Pottsville cgl. in S. part of Huntingdon Co., Pa. Thickness 40 ft. Consists of (descending): 14 ft. of ss. and sh.; Mount Savage coal bed, 2 ft.; fire clay; 17 ft. of gray false-bedded ss.; and 7 ft. of dark-gray and black sl. and slaty ss. Underlies Piedmont ss. memb. and overlies Congl. proper memb. [Connoquenessing ss.].

Corresponds to Mercer sh. memb. of Pottsville fm. of established nomenclature.

Mount Savage sandstone. (In Allegheny formation?)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Mount Savage ss.*—Underlies Lower Kittanning (Ellerslie) fire clay and overlies Upper Mount Savage rider coal (Scrubgrass coal?); all included in Allegheny fm.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 43, 45, 116, pl. 6). *Mount Savage ss.*—Very massive and persistent, white, hard, locally conglomeratic. Underlies Ellerslie (Lower Kittanning) fire clay and overlies Upper Mount Savage Rider coal. Thickness 21 ft. in Castleman Basin. Occupies position of Kittanning ss. of western Pa. [On p. 43 it is correlated with Clarion ss.]

Mount Selman formation. (In Claiborne group.)

Eocene: Southern and eastern Texas.

W. Kennedy, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 45, 52–54). *Mount Selman series*.—Marine beds consisting of brown sands, blue sands, greensands, altered greensands, glauconitic ss., and laminated iron ore, more or less fossiliferous throughout. The general section given of the Mount Selman, from Jacksonville to Bullard, shows (descending): (1) Sands with a little interbedded iron ore, 115 ft.; (2) pale-blue and brown clay, 15 ft.; (3) interbedded sands and iron ores, 55 ft.; (4) brown sand and altered green sand, 40 ft.; (5) dark-green sand containing fossil shells and a few shark teeth, 24 ft.; (6) lignite, 2 ft.; (7) lignitic clay, 5 ft.; (8) brown clay at bottom of well near Bullard, dug into 2 ft. Underlies Cook's Mtn beds (also marine) and overlies Queen City beds, uppermost memb. of Lignitic group. Thickness 260 ft. Named for typical development in Cherokee Co. [in which is town of Mount Selman].

E. T. Dumble, 1893 (Tex. Geol. Surv., Brown coal and lignite of Texas), defined *Mount Selman beds* as above, except that he gave thickness as 700 ft.

E. T. Dumble, 1898 (Phys. geog., geol., and res. Tex.) and 1902 (Sci., n. s., vol. 16, pp. 670–671), stated that Queen City beds are same as Carrizo ss. and included them in †*Lignitic* [*Wilcox*]. In 1911 (Tex. Acad. Sci., vol. 11, pp. 52–53) he repeated the correlation of Carrizo ss. with Queen City sand, but included it in Claiborne group.

A. Deussen, 1914 (U. S. G. S. W. S. P. 335). *Mount Selman fm.*—Palustrine and marine deposits, consisting of red ferruginous indurated and probably altered greensand, with casts of shells, lenses of lignite and clay, beds and concretions of limonite; as a whole is conspicuously ferruginous. Thickness 350 ft. in Texas Coastal Plain E. of Brazos River. Underlies Cook Mtn fm. and overlies Wilcox fm., the top unit of which consists of littoral deposits comprising Queen City sand memb.

E. T. Dumble, 1915 (Jour. Geol., vol. 23, pp. 481–498), repeated correlation of Carrizo ss. and Queen City sand and included them in Claiborne group, as a distinct fm.

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 83–84). The *Mount Selman* underlies the Cook Mtn and overlies the Queen City-Carrizo, which is here included in Claiborne group, but which is by some geologists classed as Wilcox. The Mount Selman is at least in part marine. Thickness 225 to 475 ft.

T. W. Vaughan, 1917 (Smithsonian Pub.), treated the Mount Selman as basal fm. of Claiborne group, as did W. G. Matteson, 1918 (Am. Inst. Min. Engrs. Bull. 134), who treated Queen City as top memb. of the Wilcox, and J. A. Udden, 1919 (Tex. Univ. Hdb. series, No. 1).

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869). *Mount Selman fm.* conformably underlies Cook's Mtn fm. and overlies the Carrizo, which in East Tex. is called *Queen City beds*. The Queen City is eastern equiv. if not direct extension of the Carrizo. It is here included in Claiborne group.

E. W. Berry, 1922 (U. S. G. S. P. P. 131A). The plants found in Carrizo ss., as well as those found above and below it near the Rio Grande, definitely settle its upper Wilcox age, but show that it is in nature of a lens which becomes thinner toward Rio Grande, where its upper part is replaced with more typical and more argill. Wilcox, also carrying characteristic fossil plants.

A. C. Trowbridge, 1923 (U. S. G. S. P. P. 131D), treated *Mount Selman* as basal fm. of Claiborne group in Rio Grande region, and divided the underlying Wilcox group into (descending): (1) Bigford fm., 0 to 470± ft. of clay of various colors, with subordinate amounts of gray, green, and brown ss. and many lignite beds; chiefly contemp. with Carrizo ss. but in part younger; contains Wilcox flora; rests with possible uncon. on (2) Carrizo ss., 118 to 400± ft. thick; contains Wilcox plants; rests uncon. and with overlap on (3) Indio fm., 648 to 700 ft.

E. T. Dumble, 1924 (A. A. P. G. Bull., vol. 8, No. 4, pp. 424–436), included Carrizo ss. in Claiborne group, but not in the Mount Selman.

A. C. Trowbridge repeated his 1923 classification of Wilcox group in Geol. Soc. Am. Bull., vol. 37, pp. 455–462, 1926.

T. L. Bailey, 1926 (Tex. Univ. Bull. 2645), treated the Mount Selman as basal fm. of Claiborne group of SW. Coastal Plain of Tex., and as resting uncon. on Carrizo ss.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, No. 10). Queen City sand (0 to 400 ft. thick) is younger than Carrizo sand (10 to 80 ft. thick), from which it is separated by Reklaw memb. (40 to 180 ft. thick in Tex.) and the underlying Cane River memb. (0 to 40 ft. thick in Tex.). The Carrizo is treated as basal memb. of Claiborne series because "it differs lithologically from the Wilcox and is separated from it by an uncon."

A. C. Trowbridge, 1932 (U. S. G. S. Bull. 837, pp. 28, 81+), described the Mount Selman as basal fm. of Claiborne group and as overlying Bigford fm. of Wilcox group, but with the statement (footnote 8 on p. 52) that "both the Carrizo and Bigford will probably prove to be of Claiborne age, instead of Wilcox, and on the new geol. map of Tex. will be so classed."

L. W. Stephenson, Julia Gardner et al., 1932 (geol. map of Tex.), treated Bigford as basal memb. of Mount Selman fm. and Carrizo sand as basal fm. of Claiborne group, as did F. B. Plummer, 1933 (Univ. Tex. Bull. 3232). This is present classification of U. S. Geol. Survey.

A. Deussen, 1934 (A. A. P. G. Bull., vol. 18, No. 4, p. 501), and A. Deussen and E. W. K. Andrau, 1936 (A. A. P. G. Bull., vol. 20, No. 5, p. 540), included Carrizo sand in Mount Selman fm.

Named for Mount Selman, Cherokee Co., Tex.

Mount Selwyn formation.

Cambrian (?): British Columbia.

M. Y. Williams and J. B. Bocock, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 200).

Mount Sicker formation.

Jurassic: British Columbia.

C. H. Clapp, 1909 (Canada Geol. Surv. Summ. Rept. 1908, p. 56) and 1911 (Summ. Rept. 1910, p. 105).

Mount Simon sandstone.

Upper Cambrian: Southwestern Wisconsin and Minnesota.

C. D. Walcott, 1914 (Smithsonian Misc. Coll. vol. 57, p. 354). *Mount Simon.—Ulrich ms., 1914.* Series of coarse sss. and grits 235+ ft. thick. Underlies Eau Claire ss. and overlies pre-Camb. granite. About 225 ft. shown in bluffs at Eau Claire and 50 ft. of base at Chippewa Falls. No fossils except *Scolithus* borings.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 553). *Mount Simon ss.*—In central Wis. mainly coarse- to medium-grained gray or yellow ss. with a few layers of green, blue, and red sh.; farther S. it is less coarse-grained; locally there are pink layers, the color being deepest in the fine-grained sands. Max. thickness is 778 ft. at Platteville, Wis.; 368 ft. at Madison. Outcrops have thus far been studied only near Eau Claire, the type loc., where it forms an escarpment [called Mount Simon] which is capped by [10 ft. of] Eau Claire shaly ss. It must be the basal Camb. over a large area in central Wis.

Some recent repts include this ss. in Dresbach fm. (see 1934 and 1935 entries under *Dresbach ss.*), but the U. S. Geol. Survey at present treats it as a distinct fm., uncon. overlying red clastic series. The 1935 repts cited above give thickness at Mount Simon 234 ft.

See 1935 entry under *Hinckley ss.*

Mount Stevens series.

Mount Stevens group.

Pre-Cambrian (?): Yukon, Canada.

D. D. Cairnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 50).

Originally assigned to lower Paleozoic, but later Canada repts indicate probable pre-Camb. age.

Mount Stuart granodiorite.

Pre-Tertiary: Central Washington (Mount Stuart region).

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137, map). Central part of Wenache Mtns is composed of granite, which forms all of higher peaks, including Mount Stuart, and hence may conveniently be designated *Mount Stuart granite*. Intrusive light-colored biotite granite carrying hornblende.

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Mount Stuart granodiorite* is pre-Tert. and post-Carbf., and later than Peshastin fm.

Mount Toby conglomerate. (In Newark group.)

Upper Triassic: Central southern Massachusetts.

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 452). *Mount Toby cgl.*, or the coarse schist and qtzite cgl. (shoreward Triassic rocks) of Mount Toby.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; see also U. S. G. S. Mon. 29). [See 1898 entry under *Longmeadow ss.* As mapped this cgl. occurs only in NE. corner of Holyoke quad.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 91–100). *Mount Toby cgl.*—Coarse materials ranging from pebbles 2 inches long to masses 2 to 4 ft. in size. Very largely and in many localities wholly made up of comminuted argillites, quartz schist, and vein quartz, with larger cobbles of same material. Westward from ½ mi. S. of old Mount Toby railroad station this cgl. composes whole mass of main ridge of Mount Toby. Several bands of Longmeadow ss. from the W. penetrate the horizontal beds of Mount Toby cgl., indicating successive oscillations of level or of flood violence, during which the finer-grained ss. extended E. across the cgl. several times and then gave place to the coarser material again. Is basal fm. of Newark group, to E., and synchronous with all except possibly basal part of Sugarloaf arkose to W.

Mount Tom hornblende gneiss.

Age (?): Western Connecticut.

W. M. Agar, 1927 (Conn. Geol. and Nat. Hist. Surv. Bull. 40). *Mount Tom hornblende gneiss.*—Dark-green or green and white hornblende gneiss. Forms Mount Tom, Little Mount Tom, and Mount Rat. Occurs as dikes in Hartland schist [Ord.] along NW. slope of Mount Rat.

†Mount Vernon series.

Lower Cretaceous: Eastern Virginia.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., p. 324). *Mount Vernon series* (also *Mount Vernon clays*).—Stratified clay of dark chocolate-brown color, fine texture, very little sand, highly charged with carbonaceous matter. Thickness 0 to 25 ft. Contains unique flora, differing decidedly from that of uncon. underlying Rappahannock series and from that of uncon. overlying Aquia Creek series, all of which are included in Potomac fm. First discovered about 1 mi. below Mount Vernon mansion, directly underneath high bluff known as Rose's Delight, within former Mount Vernon estate.

W. B. Clark and B. L. Miller, 1912 (Va. Geol. Surv. Bull. 4). Patapsco fm. includes Mount Vernon series and part of Aquia and Rappahannock series.

†Mount Vernon beds.

Silurian (Niagaran): Central eastern Iowa.

W. H. Norton, 1895 (Iowa Geol. Surv. vol. 4, pp. 130–135). *Anamosa stage or Mount Vernon beds*.—Soft even-bedded granular noncrystalline buff or drab ls. 0–70 ft. thick. Included in Sil. Underlain by LeClaire beds and overlain by Bertram beds. [In table on p. 127 of vol. 4 *Anamosa* "is substituted for *Mount Vernon* as used in text, at suggestion of Dr. Calvin." The book containing Calvin's name *Anamosa* was distributed in June 1895, and vol. 4 of Iowa State Surv. was distributed in December 1895.]

Named for Mount Vernon, Linn Co.

Mount Victory moraine.

Pleistocene (Wisconsin stage): Northern Ohio. Named for Mount Victory, Hardin Co. Merges with Wabash moraine. See U. S. G. S. Mon. 41, p. 543.

†Mount Washington series.

Ordovician and Cambrian: Southwestern Massachusetts and northwestern Connecticut.

W. H. Hobbs, 1893 (Jour. Geol., vol. 1, pp. 717–736, 780–802). *Mount Washington series* [SW. Mass.].—Includes (descending) Everett schist, correlated [erroneously] with Greylock schist of NW. Mass.; Egremont ls., correlated [erroneously] with Bellowspipe ls. of NW. Mass.; Riga schist, correlated [correctly] with Berkshire schist; and Canaan dol., correlated [correctly] with Stockbridge ls. Named for occurrence on Mount Washington.

The †Everett schist is now known to be Berkshire schist, and the †Egremont ls. to be Stockbridge ls.; the younger Greylock schist and Bellowspipe ls. of NW. Mass. are now considered not to be represented in SW. Mass. (See B. K. Emerson, U. S. G. S. Bull. 597, 1917, map, etc.)

Mount Whyte formation.

Lower Cambrian: British Columbia and Alberta.

C. D. Walcott, 1908 (Smithsonian Misc. Coll. vol. 53, No. 1804, pp. 2, 4). *Mount Whyte fm.*—Alternating bands of ls. and siliceous and calc. sh., underlying Cathedral fm. and overlying St. Piran fm. in Canadian Rocky Mtns. Thickness 386 ft. on N. slope of Mount Whyte, 390 ft. on S. slope of Mount Bosworth, 315 ft. on Mount Stephen, and 248 ft. on SE. slope of Castle Mtn. Contains Lower Camb. fossils. Type loc. is Mount Whyte, above Lake Agnes, and E. slope of Popes Peak, SW. of Mount St. Piran.

L. D. Burling, 1916 (Am. Jour. Sci., 4th, vol. 42, pp. 469–472), modified definitions of Cathedral and Mount Whyte fms. See 1916 entry under *Cathedral ls.*

C. D. Walcott, 1917 (Smithsonian Misc. Coll. vol. 67, No. 1, Pub. 2444, pp. 1–5). The name *Ptarmigan fm.* is proposed for a series of Middle Camb. lss. and interbedded shales that occur above Mount Whyte fm. (Lower Camb.) and beneath Cathedral fm. (Middle Camb.) in Alberta and B. C. The Ptarmigan fm. includes the Middle Camb. *Albertella* fauna about 100 ft. below its top.

C. D. Walcott, 1917 (Smithsonian Misc. Coll. vol. 67, No. 2, Pub. 2445), stated that his recently named Ptarmigan fm. was formerly included in Cathedral ls.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 67, No. 9, pp. 487, 549), assigned *Mount Whyte fm.* to Lower Camb.

Mount Wilson quartzite.

Devonian: Alberta.

C. D. Walcott, 1923 (Smithsonian Misc. Coll. vol. 67, No. 8, pp. 464–465), and 1928 (Smithsonian Misc. Coll. vol. 75, p. 208).

Mount Wilson quartz diorite.

Late Jurassic or early Cretaceous: Southern California (San Gabriel Mountains, Los Angeles County).

W. J. Miller, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 149, abstract). The most typical and extensively developed of the diorites of San Gabriel Mtns, southern Calif., may be called *Mount Wilson quartz diorite*, because of fine exposures on and near Mount Wilson. A hornblende-rich diorite, occurring in smaller masses, may be older than Mount Wilson diorite or may be only a facies of it. A pinkish-gray, more or less foliated granite, which occupies a considerable area, is younger than the diorite. The diorite is older than Mount Lowe granodiorite.

W. J. Miller, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 149–150). *Wilson diorite* is cut by Lowe granodiorite. [Age not stated.]

W. J. Miller, 1934 (Univ. Calif. at Los Angeles Pub. Math. and Phys. Sci., vol. 1, No. 1, map of western San Gabriel Mtns, pp. 62–63). [*Wilson diorite* mapped and tentatively assigned to late Jurassic or early Cret.]

Mount Wissick group.

Devonian (?): Quebec.

H. W. McGerrigle, 1934 (Quebec Bur. Mines Ann. Rept. 1933, pt. D, p. 120).

Mount Zion porphyry.

Eocene: Leadville district, Colorado.

S. F. Emmons, 1883 (U. S. G. S. Atlas of Leadville dist., Colo.) and 1886 (U. S. G. S. Mon. 12, p. 76). *Mount Zion porphyry.*—A gray porphyry, consisting chiefly of quartz, orthoclase, and biotite, occurring on Mount Zion and Prospect Mtn. [Petrographic description of W. Cross on p. 323 of Mon. 12.]

Belongs to Gray porphyry group. Contains more quartz and less biotite than Evans Gulch porphyry.

Named for development on Mount Zion, N. of Leadville.

Moutray sand.

A subsurface sand, of Penn. age, in Moutray and Hatchett fields of Callahan Co., north-central Tex., lying at 450 ft. depth in Hatchett field and at 730 ft. depth in Moutray field.

Mowitza shale.

Upper Devonian: Southwestern Utah (southeast of Frisco region).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Mowitza sh.*—Calc. sh. interstratified with thin beds of ls. Thickness 50 ft. Underlies (conformably) Topache ls. and overlies (conformably) Red Warrior ls. Type loc., Mowitza shaft, Star dist., SE. of Frisco dist.

Mowry shale. (Of Colorado group.)

Upper Cretaceous: Wyoming (rather widespread), western South Dakota, and Montana (rather widespread).

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 394–401). *Mowrie beds.*—Hard lighter-gray shales and thin-bedded sss. that weather light gray and form ridges. Contains large numbers of fish scales and occasional fish teeth and bones. Thickness 150 ft. on E. side of Bighorn Mtns. Distinctive Benton fossils occur above it, and in other parts of E. Wyo. Its relations indicate that it occurs below middle of the Graneros. Is included in Benton fm. of this area (E. side of Bighorn Mtns). Separated from older Cloverly fm. by several hundred ft. of dark sh. underlain by dark-gray sh. in part sandy and of rusty-brown color, with occasional thin beds of brown ss., all of which are here included in Benton fm., although it is possible part of the dark-gray beds may represent Dakota ss. Named for Mowrie Creek, NW. of Buffalo [Johnson Co.], Wyo.

Mowry has been approved spelling of this name since 1906.

In 1916 (U. S. G. S. Bull. 621, p. 168) C. T. Lupton applied *Thermopolis sh.* to the 700± ft. of beds conformably underlying Mowry sh. and conformably overlying Greybull sand of drillers (the top memb. of Cloverly fm.). This is present approved definition of U. S. Geol. Survey, except that in Black Hills region the 10 to 50 ft. of dark-gray sh. and sandy sh. to which Collier applied name *Nefsy sh. memb. of Graneros sh.*, and which represents upper part of Thermopolis sh., is now included in Mowry sh. and *Nefsy* has been abandoned. In latter region the Mowry as thus redefined rests on Newcastle ss. memb. of Graneros, and the beds overlying the Mowry and underlying the Greenhorn are the Belle Fourche memb. of Graneros sh. In western Wyo. the beds separating Mowry sh. from the younger Carlile sh. (of late Benton age) have long been known as *Frontier fm.* In parts of Wyo. *Mowry sh.* is now treated as a distinct fm.; in some other places (where Carlile, Greenhorn, and Graneros can be differentiated) the Mowry is locally called *Mowry hard memb. of Graneros sh.* or, locally, *Mowry siliceous memb. of Graneros sh.* In areas where the Mowry is the only subdivision of the Benton that can be differentiated it has been treated as a memb. of Benton sh.

Moxahala clay. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio (Perry County).

E. Orton, 1884 (Ohio Geol. Surv., vol. 5). *Moxahala clay*, 0 to 8 ft. thick, underlies Lower Freeport coal (No. 6A) in N. part of Perry Co. and at Zanesville and vicinity, Muskingum Co. Is=Lower Freeport clay.

Named for Moxahala, Perry Co.

Moydart formation.

Silurian: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 203).

Moyer gas sands.

Occur about 290 ft. below top of Penn. section in Graham field, NW. part of Carter Co., southern Okla., and 320 to 400 ft. above Kirk gas sand.

Moyie argillite.

See *Mooyie argillite*.

Moyie sill (gabbro).

See under *Kitchener qtzite*.

Muav limestone. (Of Tonto group.)

Middle Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Muav ls.*—Impure thin-bedded bluish-gray ls. having characteristic mottled appearance imparted by numerous thin bands or lenses of buff or greenish shaly material. Thickness 450 to 475 ft. Consists of (descending): (1) mottled ls., more shaly, 65 ft.; (2) fine-grained white ss., 4 ft.; (3) mottled ls., 208 ft.; (4) mottled ls., more shaly, 45 ft.; (5) mottled ls., 23 ft. Uncon. underlies Redwall ls. and conformably overlies Bright Angel sh. Is top fm. of Tonto group. Named for Muav Canyon, Grand Canyon dist., in lower part of which the fm. is well exposed. Is "mottled ls." of Walcott.

L. F. Noble, 1922 (U. S. G. S. P. P. 131B), transferred from Muav ls. to Bright Angel sh. 58 [68?] ft. of shaly beds containing near base a few beds of mottled ls. similar to mottled lss. of Muav ls.

Mud sandstone. (In Bluestone formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 294, 320–321). *Upper Mud ss.*—Brown shaly micaceous ss., 0 to 5 ft. thick, underlying Lower Belcher sb. Rests on *Upper Mud sh.*, which consists of 20 to 50 ft. of red sh. overlying *Lower Mud ss.* The latter ss. consists of 0 to 5 ft. of greenish-gray or brown ss., resting on *Lower Mud sh.* (red and variegated or dark-green and sandy sh. 15 to 40 ft. thick, which rests on Glady Fork ss.). All are members of Bluestone group [fm.], and all are exposed on Mud Fork of Bluestone River in Tazewell Co., Va., about 1 mi. N. of Bailey Station, also in Mercer Co., W. Va.

Mud shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926. [See under *Mud ss.*]

Muda limestone.

Cretaceous (?): Puerto Rico.

D. R. Semmes, 1919 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, p. 74).

Muddy sand.

Drillers' name for a sand (or sands) in Thermopolis sh. (Upper Cret.) of Bighorn Basin and other areas in Wyo. F. F. Hintze, Jr., who described the sand as occurring in lower part of Benton sh., stated (Wyo. State Geol. Bull. 10, 1915, pp. 20–21) that it is almost pure white on outcrop, but that probably in drilling the soft shales above and below it are so mixed with the white sand grains that the mixture has a muddy appearance, hence the name. In the Basin and Greybull fields the sand is said to lie 210 to 330 ft. above base of the Thermopolis; in Rex Lake and other domes W. of Laramie, Wyo., the sand called *Muddy* is said to lie 90 ft. above base of the Thermopolis. The name has also been applied by drillers to sands in strata that have been identified by geologists as lying in Cloverly fm., which underlies Thermopolis sh. In Rock Creek oil field, south-central Wyo., the name *First Muddy sand* has been applied by drillers to a sand in Thermopolis sh., *Second Muddy sand* to a sand in what is said to be top of Cloverly fm., and *Third Muddy sand* to a sand in lower part of the Cloverly. There are at least 8 Muddy Creeks in Wyo., but, although the sand outcrops, it is not known to be exposed on any Muddy Creek.

Muddy Creek formation.

Tertiary (Pliocene?): Southeastern Nevada and northwestern Arizona.

C. Stock, March 1921 (Geol. Soc. Am. Bull., vol. 32, p. 147). Approx. 80 mi. S. of Panaca, in Meadow Valley, a second series of mammal-bearing deposits is exposed. These beds are mapped by Spurr as Plio. Between villages of Overton and Logan, Lincoln Co., Nev., and on SW. side of Muddy River, the deposits consist of well-indurated sands and clays, red or light brown in color. They rest uncon. on a series of beds that are presumably of early Tert. age. Are also terraced, and yielded a small collection of mammalian remains, which differ from those in Panaca beds and suggest that northern and southern deposits are not of same age. Possibly the mammal-bearing beds of Muddy Valley, which may be designated *Muddy Creek beds*, are earlier in age than the Panaca deposits.

The Muddy Creek fm. rests uncon. on Horse Spring fm.

Muddy Peak limestone.

Middle Devonian and possibly older: Southeastern Nevada (Muddy Mountains).

C. R. Longwell, 1921 (Am. Jour. Sci., 5th, vol. 1, pp. 46–53) and 1928 (U. S. G. S. Bull. 798). *Muddy Peak ls.*—Dense hard lss.; many beds with siliceous appearance; beds heavy and regular, 2 to 20 ft. thick; in color either distinctly carbonaceous and dark or decidedly light, beds of the two colors alternating; lenses and thin layers of ss. at frequent intervals, especially near top. Includes all rocks btw. the overthrust and the Mississippian, all of which are of same general nature and no break in them. Thickness 1,300+ ft. Underlies Rogers Spring ls. (Miss.) with suggested discon. No dependable fossil evidence in lower 1,000 ft. Very probably several hundred ft. at base are Camb. Best exposed in vicinity of Muddy Peak Basin, especially on N. side of Muddy Peak.

†Muddy Valley beds.

Tertiary (Pliocene?): Southeastern Nevada.

C. Stock, November 1921 (Am. Jour. Sci., 5th, vol. 2, pp. 254–257). The sed. deposits of Muddy Valley, SE. Nev., in which mammalian remains were found, may be known as *Muddy Valley beds*, as distinguished from Panaca deposits of Meadow Valley. The beds consist of well-indurated sands and clays, red and light brown, and uncon. overlie the early Tert. deposits in region. A small vertebrate fauna, including camels and a horse, was collected in the fine ss. approx. 3 mi. W. of Overton.

Same as **Muddy Creek fm.**, which has priority.

Mud Hill series.

Miocene to Pleistocene (?): Southern California (Riverside County).

E. E. Free, 1914 (Carnegie Inst. Wash. Pub. 193, pp. 22–23). *Mud Hill series.*—Consists of an upper memb. of very variable sss. and clays, mostly thinly bedded and showing many probable unconformities; underlain by a thick memb. of coarse arkose ss., usually of reddish color and quite uniform texture; at base a basal cgl., resting normally upon eroded surface of schists and granites such as make up core of the range. Thickness 3,000 ft. No fossils at type loc. at Mecca, but in Carrizo Creek Valley Blake found Mio. fossils in lower beds. Very probably includes beds of all ages from Carrizo Creek Mio. into early Pleist. Named for occurrence in Mecca Mud Hills, Mecca, Riverside Co.

J. P. Buwalda and W. L. Stanton, 1930 (Sci., n. s., vol. 71, pp. 104–106). *Mud Hill series* of Free includes Indio and Carrizo fms.

Mud Lake granite.

Pre-Cambrian (Laurentian): Western Ontario (Rainy Lake region).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 54).

Mugford series.

Pre-Cambrian: Labrador.

A. P. Coleman, 1921 (Canada Geol. Surv. Mem. 124, p. 25).

Mukwa granite.

Pre-Cambrian (Laurentian): Central northern Wisconsin (Waupaca County).

T. C. Chamberlin, 1877 (Geol. Wis., vol. 3, p. 248). *Mukwa granite.*—An isolated outlier in SE¼NE¼ sec. 26 and NW¼SW¼ sec. 25, town of Mukwa, Waupaca Co.

Mulatto tongue (of Mancos shale).

Upper Cretaceous: Northwestern New Mexico (Gallup region).

J. D. Sears, 1934 (U. S. G. S. Bull. 860A). The lower tongue of Mancos sh. (marine) that grades laterally into Mesaverde fm. (nonmarine) of part of area from Gallup eastward toward Mount Taylor, is named by C. B. Hunt (U. S. G. S. Bull. 860B,

1934) *Mulatto tongue of Mancos sh.*, from its excellent exposures at mouth of Canyon Mulatto, in T. 14 N., R. 9 W. It in part underlies and in part grades laterally into Dalton ss. memb. of Mesaverde fm., both of which are of Colorado age.

C. B. Hunt, 1934 (U. S. G. S. Bull. 860B, p. 44). *Mulatto tongue of Mancos sh.*—Lies btw. Dilco coal memb. and Dalton ss. memb. of Mesaverde fm. The name is here given for exposures at S. end of Canyon Mulatto, 9 mi. NW. of San Mateo. Best exposures are in southward-facing scarp extending NW. from San Mateo. Toward S. part of Mount Taylor coal field the tongue is largely light-tan marine sandy sh. with some thin sss. and very local grits. Northward the proportion of sh. increases until, where Gallup and Dilco members of the Mesaverde thin out, the Mulatto tongue is entirely dark-gray sh. and cannot be distinguished lithologically from main body of Mancos and is there mapped with rest of Mancos. Thickness of Mulatto tongue ranges from 250 ft. (in S. part of field) to 400 ft. (in N. part of field).

Mule sandstone.

Lower Cretaceous: Southeastern Arizona.

C. [R.] Keyes, 1935 (Pan-Am. Geol., vol. 64, No. 2, pp. 125 to 140). *Mule ss.*, proposed for the ss. stratum in Mural ls. fm. of Ransome. Thickness 50 ft. Name derived from Mule Mtns, in which Bisbee mining camp is situated, with type section in Mural Hill, E. of town.

Muleros sandstone.

Lower Cretaceous (Comanche): Southeastern Arizona and western Texas.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 247, 250, 337). *Muleros sss.*, the capping memb. of Cerro de Muleros, W. of El Paso, Tex. Thickness 800 ft. Represent lower part of Cintura fm. of Ransome.

Mulford formation.

Pennsylvanian: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Mulford fm.*—Shales, 146 to 250 ft. thick in Webster Co., with thin ls. in upper part, and, in S. part of Webster Co., a prominent ss. near base. Includes coals Nos. 9, 10, and 11. Uncon. underlies Lisman fm. (Penn.) and uncon. overlies De Koven fm. (Penn.).

Seems to be named for Mulfordtown, Webster (?) Co.

Mumm limestones.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll. vol. 57, No. 12, pp. 334, 337).

Muncie Creek shale.

Pennsylvanian: Northeastern Kansas and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). [See under *Iola ls.* On p. 45 *Muncie Creek sh.* is described as consisting of (descending): (1) calc. sh. with *Conularia* and concretions, 0.2 ft.; (2) black fissile sh., 1.2 ft.; (3) gray sh. 0.7 ft.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 51–55). *Muncie Creek sh. memb.*—Middle memb. of Iola ls. Consists of sh., carbonaceous where thick, argill. buff or gray where thin, with spherical phosphatic concretions. To S. replaced by 6-inch bed of clay. Thickness 3 to 5 inches. Underlies Raytown ls. memb. and overlies Paola ls. memb. Named for Muncie Creek, in S. part of Wyandotte Co., Kans., E. of town of Muncie.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 115). If it were not for geographic persistence and significance of this unit in terms of cyclic sedimentation, differentiation of such a thin sh. as a distinct memb. would hardly be justified. Despite its thinness, it is by no means the least important element of Iola fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Munising sandstone.

Upper Cambrian: Northern Michigan.

A. C. Lane and A. E. Seaman, 1907 (Jour. Geol., vol. 15, pp. 680, 692). *Munising ss.*—White or light-colored ss., 200 to 250 ft. thick, composing uppermost part of Lake Superior ss. of previous repts. [See further explanation under *Jacobsville ss.*]

Named for exposures in bluffs back of Munising, Alger Co.

Munson's granite.

See under *Mapleton granite*.

Murailles formation.

Lower Devonian: Quebec.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 67).

Mural limestone.

Lower Cretaceous (Comanche): Southeastern Arizona (Bisbee region).

F. L. Ransome, 1904 (U. S. G. S. P. P. 21, pp. 56, 65+). *Mural ls.*—Upper memb. consists of 350± ft. of relatively thick-bedded and pure lss. Lower memb. consists of 300± ft. of thin-bedded impure lss. with 25± ft. of buff sss. at top. Underlies (conformably) Cintura fm. and overlies (conformably) Morita fm., all of which belong to Bisbee group, of Comanche age. Caps Mural Hill, Bisbee quad.

C. [R.] Keyes, 1935 (Pan-Am. Geol., vol. 64, No. 2, pp. 125–140), proposed that these rocks be called *Muralian series* and be divided into the units listed under that name.

Mural limestone.

Cambrian: British Columbia.

L. D. Burling, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 109).

Muralian series.

Name proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 64, No. 2, 1935, pp. 125–140) to replace *Mural ls.* of Ransome, which Keyes divided into (descending): Comanche lss., 350 ft.; Mule sss., 50 ft.; and Glenrose lss., 300 ft.

†Murat limestone.

Lower Ordovician: Central western Virginia.

H. D. Campbell, 1905 (Am. Jour. Sci., 4th, vol. 20, pp. 445–447). *Murat ls.*—Massive gray crystalline ls.; lower part often contains chert nodules. Thickness 100 to 150 ft. Underlies Liberty Hall ls. and overlies Natural Bridge ls. About 125 ft. exposed along Buffalo Creek at Murat, Va.

Same as Holston ls., older name.

Murchison formation.

Middle Cambrian: Alberta and British Columbia.

C. D. Walcott, 1920 (Smithsonian Misc. Coll. vol. 72, No. 1, p. 15). *Murchison fm.*, Camb., Alberta. [Walcott fully defined this fm. in Smithsonian Misc. Coll. vol. 67, No. 8, pp. 462–463, Mar. 5, 1923, when he assigned it to Middle Camb., gave thickness as 497 ft., showed it uncon. below Arctomys fm. and younger than Cathedral fm.]

Murdock breccia.

Tertiary: Northwestern Arizona (Oatman district, Mohave County).

C. Lausen, 1931 (Ariz. Bur. Mines Bull. 131). *Murdock breccia.*—A detrital deposit near Murdock mine. Largely granitic detritus with angular fragments and boulders of granite, gneiss, schist, vein quartz, and some dark rocks, perhaps diorite. Matrix is composed of angular grains of quartz and feldspar derived from disintegration of exposures of granite. More or less red mud in matrix was probably formed from decomposition of feldspar. Age uncertain, but probably Tert., perhaps early Tert. Underlies Alcyone trachyte and overlies pre-Camb. granite.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Murdockville sand.

A subsurface sand in Pocono fm. (Miss.) of Washington Co., SW. Pa., that lies at horizon of Burgoon ss. memb.

Murfreesboro limestone. (Of Stones River group.)

Lower Ordovician: West-central and eastern Tennessee and western Virginia.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 105, 125). *Murfreesboro ls.* (*Central ls.*).—Light-blue heavy-bedded and often cherty ls. Lowest ls. of Central Basin; 70 ft. exposed. Basal fm. of Stones River (Chazy). Underlies Pierce ls. and overlies Knox dol.

In eastern Tenn. and western Va. the Stones River group is now divided by E. O. Ulrich and C. Butts into (descending) Lenoir ls., Mosheim ls., and Murfreesboro ls.

Named for Murfreesboro, Rutherford Co., Tenn.

†Murfreesboro stage.

Miocene (upper and middle?): Northeastern North Carolina and eastern Virginia.

A. Olsson, 1917 (Bulls. Am. Pal., vol. 5, No. 28). *Murfreesboro stage.*—New name for lower Upper Miocene deposits. Consists of blue sandy clays, typically exposed at Murfreesboro, N. C., and along Meherrin River in immediate vicinity of Murfreesboro. Throughout its areal distribution the stage is uniform and in many respects represents most typical expression of our east coast or cold-water Mio. to which the name Chesapeake is generally given. After its close, and during Yorktown stage, changes toward the warmer Plio. were inaugurated and new faunal elements introduced. Rests on crystalline rocks, on Cret., on Eo., and on some memb. of Mio. series. Known to extend from central Va. to central N. C. The whole series of blue clays beneath Yorktown stage on James River belong to the Murfreesboro. This stage has in general been misinterpreted and different parts correlated with different portions of Mio. series. Clark and Miller (Va. Geol. Surv. Bull. 4, 1919) referred part of these beds to Calvert stage and remainder to the St. Marys. Both Calvert and St. Marys are well represented in northern or NE. Va. Fossils of the Murfreesboro indicate much closer relationship with overlying Yorktown than with underlying St. Marys or older beds.

W. C. Mansfield, 1929 (Wash. Acad. Sci. Jour., vol. 19, p. 266). The "Murfreesboro stage" of Olsson belongs in reality to lower part of Yorktown fm.

W. C. Mansfield, 1931 (Geo. Wash. Univ. Bull, Summaries of Doctoral Theses, 1925–28, p. 94). There are 2 faunal horizons at type loc. of "Murfreesboro stage" (preoccupied) of Olsson. The lower horizon I have assigned to zone I of Yorktown fm. and the upper horizon to zone II of the Yorktown.

Murky conglomerate.

Pre-Cambrian: Northwest Territory, Canada.

C. Lausen, 1929 (Canadian Min. and Met. Bull. 202, p. 378).

Murphy marble.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 5). *Murphy marble.*—Entirely marble, rather fine-grained and wholly recrystallized from original condition. Predominant color white, but a large portion is dark gray or blue, and many layers consist of banded or mottled blue and white; some layers btw. Nantahala and Red Marble Gap have a beautiful rose-pink color. Base is exposed near Nantahala River, where it passes downward into Valleytown fm. by interbedding with the slates of the latter. Upward it passes into Andrews schist through several ft. of interbedded marble and schist. Thickness 150 to 500 ft.

Named for fact that town of Murphy, Cherokee Co., N. C., is partly located on this marble.

Murphy sand.

A subsurface sand in Conemaugh fm. (Penn.) of western Pa. and W. Va. that is believed to correspond to Morgantown ss. memb.

Murphy's Creek formation.

Cambrian (Upper): Quebec (Gaspé Peninsula).

C. H. Kindle, 1936 (Eastern Geol., No. 1, April 1936, p. 1). *Murphy's Creek fm.*—Dark sh. and interbedded layers of sh. and dark ls., also lighter-colored lss. and intraformational breccia. Fossils found on bank of Murphy's Creek are Upper Camb. [See also Kindle, Geol. Soc. Am. Proc. 1934, June, 1935, p. 354.]

Murray slate (also **Murray shale**). (In Chilhowee group.)

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Murray sh.*—Grayish-blue sandy, micaceous, and calc. sh., 300 ft. thick. Overlies Nebo ss. Underlies Hesse ss.

Named for Murray Branch of Walden Creek, Sevier Co., Tenn.

Murrysville sand.

A subsurface sand in western Pa. that probably corresponds to Berea ss. of Ohio. Named for village in Westmoreland Co., Pa.

Muscogee.

See *Muskogee*.

Muskingum conglomerate. (In Washington formation.)

Permian: Southeastern Ohio.

J. P. Lesley, 1856 (Manual of coal, p. 105). *Muskingum cgl.*—Cavernous sandrock, 60 ft. thick, quarried at Marietta, Ohio. Forms cliffs 60 ft. high btw. Hockhocking and Muskingum Rivers and up the Muskingum. Underlain by 1½ ft. of coal and overlain by 25 ft. of argill. ss.

Compare Marietta ss.

Named for Muskingum River.

†Muskogee group.

Pennsylvanian: Central eastern and central Oklahoma.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, pp. 6, 7). *Muskogee group.*—Chiefly sss. and shales, 450 to 9,550 ft. thick, extending from uncon. at top of Miss. series on E. to base of Claremore fm. and its approx. equiv., Calvin ss., on W. In N. part of State is represented by Cherokee sh. To S. includes rocks btw. base of Atoka fm. and top of Calvin ss.

Has also been spelled *Muscogee*.

Named for Muskogee Co.

Muskogee sand.

A subsurface sand, 12 to 20 ft. thick, in Muskogee Co., central eastern Okla., which is said by some geologists to correlate with one of the sands of Dutcher sand series, but according to p. 17 of Okla. Geol. Surv. Bull. 40Q, 1928, the Muskogee sand of Beland pool, Muskogee Co., lies at 1,270 ft. depth and the first or upper Dutcher at 1,650 ft. In Muskogee pool it lies at 1,400 ft. depth and the underlying and overlying sands are not correlated. In Timber Ridge pool it lies at 1,480 to 1,510 ft., the Bad Hole sand lying at 1,385 to 1,407 ft. and the Timber Ridge sand at 1,540 to 1,560 ft. C. W. Wilson, Jr., says (A. A. P. G. Bull., vol. 19, No. 4, 1935, p. 515) this sand corresponds to Pope Chapel ss. memb. of Atoka fm.

Muskogee lime.

A subsurface unit, of Penn. age, in NE. Okla. lying lower than Burgess sand and higher than Dutcher sand.

Mussellem sand.

See *Musselman sand.* The correct spelling is *Mussellem.*

†Musselman sand.

A subsurface sand, of Penn. age and 25± ft. thick, in central and northern Okla. Correlated with a part of Ochelata fm. In Oilton pool, Creek Co., this sand lies at 700 ft. depth and Layton sand at 1,480 ft. This sand was named for its occurrence in wells on land owned by M. S. Mussellem (a Syrian), lying along Cimarron River 1½ mi. S. of Oilton. The name of the sand has been spelled *Musselman* and *Mussellem.* The latter is the correct spelling.

Muttleberry limestone.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 80). *Muttleberry lss.*—Calc. beds (lss.), 500 ft. thick, underlying Oreana shales and composing lower fm. of Lovelockian series (Early Jurassic) of Nev. Named for exposures in Muttleberry Canyon, E. of Lovelock, Humboldt Co., NW. Nevada.

Myers shale.

Mississippian: Northeastern West Virginia and western Maryland.

G. W. Stose and C. K. Swartz, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Myers sh.*—Largely bright-red crumbly sh. and thin argill. sss., with, at base, thick cross-bedded dirty-gray gritty ss. 60 ft. thick. Thickness 800+ ft. Underlies Pinkerton ss. and overlies Hedges sh.; all included in Pocono group. Named for exposures on the Myers place, in Meadow Brook Valley, Berkeley Co.

Myers Hill sandstone.

Upper Cambrian: Wisconsin.

C. E. Resser, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 4, p. 738), in a table of Camb., divided his Trempealeau fm. (Upper Camb.) into several members, the upper 3 of which he designated (descending) Norwalk ss., *Myers Hill ss.*, and Lodi sh. He did not define these members.

†Myrick formation.

Eocene: Southern Texas.

T. W. Vaughan, 1900 (U. S. G. S. Uvalde folio, No. 64, p. 2). *Myrick fm.*—Coarse- and fine-grained soft yellowish or brownish sss. and clays, 800 to 850 ft. thick in Uvalde quad., but upper limit not determined. Underlies Neocene Uvalde fm. and overlies Upper Cret. Pulliam fm.

According to Julia Gardner, Myrick fm. of Vaughan included beds later mapped as Midway, Indio, Carrizo, Bigford, and Mount Selman fms. Named for Myrick's lower apiary (on map), on Frio River, Uvalde Co.

Myrtle formation.

Lower Cretaceous: Southwestern Oregon.

J. S. Diller, 1898 (U. S. G. S. Roseburg folio, No. 49). *Myrtle fm.*—Lss., cgls., sss., and shales, the lss. mapped separately as *Whitsett ls. lentils.* Thickness 6,000± ft. in valley of Myrtle Creek. Contains Horsetown and Knoxville fossils. Uncom. underlies Umpqua fm.

See also under *†Dillard series.*

Myrtle Creek formation.

Upper Cretaceous: Alberta.

J. A. Allan, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 12).

Mysterious Creek formation.

Upper Jurassic: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissert. 1924–26, vol. 1, p. 132).
C. H. Crickmay, 1930 (Geol. Mag., vol. 67, p. 487 and map). *Mysterious Creek fm.*—Argillite, 2,500 ft. thick, carrying *Cadoceras schmidti* and *Lilloettia lilloetensis*. Underlies Billhook fm. (Upper J.) and overlies Echo Island fm. (Middle J.). Assigned to Upper J.

Mystic.

Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 6).

Myton member.

Eocene (uppermost): Northeastern Utah (Uinta Basin).

H. E. Wood, 2nd, 1934. [See under *Blacks Fork memb. of Bridger fm.* The beds to which this name is applied comprise the Uinta fm. of U. S. Geol. Survey and other writers—the "true Uinta" or *Diplacodon* zone of H. F. Osborn and others.]

Nabesna limestone.

Carboniferous: Southeastern Alaska (Upper Tanana River region).

W. C. Mendenhall and F. C. Schrader, 1903 (U. S. G. S. P. P. 15, pp. 33–37). *Nabesna ls.*—Provisional name for series of lss. occurring on upper Nabesna and Chisana Rivers, whose exposures, so far as seen, are almost entirely restricted to Wrangell Mtns. Is more or less freely associated with diabasic intrusives and apparently also with older effusives. Is probably part of Nutzotin series of Brooks farther E. In general the ls. is heavy bedded, much of it white and crystalline, but darker gray or bluish layers, apparently dolomitic, are also present. No fossils found in the lss. on Nabesna and Chisana Rivers, but from fossils from similar lss. in pass btw. Jack Creek and head of Platinum Creek the Nabesna is regarded as Perm.

Nacatoch sand. (In Navarro group in Texas.)

Upper Cretaceous: Southwestern Arkansas, northwestern Louisiana, and northeastern Texas.

A. C. Veatch, 1905 (La. Geol. Surv. Bull. 1, pp. 84, 85, 87–88, and U. S. G. S. W. S. P. 114, pp. 180, 183). *Nacatoch* (*Washington*) *sand.*—Name taken from typical exposures at Nacatoch Bluff, on Little Missouri River in Clark Co., Ark., and includes the sandy beds btw. the Marlbrook below and the Arkadelphia above. Called Washington Greensands by Hill, which name is preoccupied. Thickness 150 to 200 ft.
A. C. Veatch, 1906 (U. S. G. S. P. P. 46, pp. 26–27). *Nacatoch sand.*—A series of sandy beds overlying Marlbrook marl and underlying Arkadelphia clay. Outcrop at Nacatoch Bluff, on Little Missouri River, Clark Co., Ark., measures 64 ft. in thickness, and includes a minor amount of sandy ls. and calc. ss. In W. part of region the sands are of rather light color. About Hope they are 100 to 160 ft. thick in wells. Toward Arkadelphia the sand grows darker and thinner. In well of Arkadelphia Ice & Fuel Co. it appears to extend from 100 to 160 ft., and is therefore about 60 ft. thick. Nearly="Washington greensand" or "Washington or High Bluff greensand" of Hill.
C. H. Dane, 1929 (Ark. Geol. Surv. Bull. 1). *Nacatoch sand* as now interpreted is a complex unit of cross-bedded yellowish and gray fine-grained unconsolidated quartz sand, hard crystalline fossiliferous sandy ls., coarse, richly glauconitic sand, fine argill. dark blue-black sand, and pure light-gray clay and marl, resting uncon. on Saratoga chalk, also on the older Marlbrook marl restricted and the still older Ozan fm. There is no doubt that most of the beds included by Hill in "Washington or High Bluff greensand beds" as well as the underlying "Blue sands of High Bluff and of Pate's Creek" were included by Veatch in upper part of his Marlbrook fm. From point W. of Washington, Hempstead Co., Ark., E. to Dobyville, Clark Co., the Nacatoch is divisible into three gradational lithologic units (descending): (1) Unconsolidated gray fine-grained quartz sand which weathers yellowish and reddish. (2) Dark-greenish sand containing 20 to 80 percent of coarse glauconite grains and weathering to lighter shades of green; generally fossiliferous where strongly glauconitic; contains hard irregular concretionary beds cemented

with calcite and subordinate beds of dark blue-gray argill. massive fine-grained sand. Most extensive exposures in vicinity of Washington, where 30 ft. is shown. (3) Bedded gray clay, sandy clay, and marl; dark clayey, very fine-grained sand and harder irregular concretionary beds; contains lenses of calc. fossiliferous, slightly glauconitic sand. Nacatoch Bluff exposes about 50 ft. of upper part of fm. Thickness 150 to 400 ft.; in vicinity of Arkadelphia not much over 150 ft.

The Navarro deposits of NE. Tex. are now called a *group*, divided into (descending) Kemp clay (restricted), Corsicana marl (restricted), Nacatoch sand, and Neylandville marl. (See Univ. Tex. Bull. 3232, 1933, L. W. Stephenson and W. S. Adkins, and U. S. G. S. geol. map. of Tex., 1937.)

Naches formation.

Eocene: Central Washington (Snoqualmie quadrangle).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139). *Naches fm.*—Interbedded gray sss. and olive sh. with basalt lava flows, chiefly in upper part. A heavy flow of in part contemp. Kachess rhyolite is interbedded with it. Thickness of fm. 4,000± ft. Overlain uncon. by Roslyn fm. (Eocene), also by Kachess rhyolite and by Keechelus volcanics. Uncon. overlies Peshastin fm. (Carbf.?). Believed nearly contemp. with Swauk fm. (Eocene). Named for Naches River, in whose basin it is most extensively developed. No known occurrence outside of Snoqualmie quad.

Nacimientan series.

See first 2 entries under *Nacimiento group*.

Nacimiento group.

Eocene: Northwestern New Mexico.

C. R. Keyes, 1906 (Sci., n. s., vol. 23, p. 921; Am. Jour. Sci., 4th, vol. 21, pp. 298–300). *Nacimientan series.*—Shales, 800 ft. thick, underlying Wasatchan series and overlying Cret. Laramian series in N. Mex.

C. R. Keyes, 1907 (Iowa Acad. Sci. Proc., vol. 14, pp. 223–228). *Nacimientan series* of N. Mex. is Eocene and includes Torrejon sands (300 ft.) above and Puerco marls (500 ft.) below.

J. H. Gardner, 1910 (Jour. Geol., vol. 18, No. 8, p. 713). *Nacimiento group* (Cope's original Puerco) includes Torrejon fm. and Puerco fm. as restricted.

J. B. Reeside, Jr., 1924. [See 1924 entry under *Puerco fm.*]

Named for town of Nacimiento (better known as Cuba), Sandoval Co.

Naco limestone.

Permian and Pennsylvanian: Southeastern Arizona (Bisbee-Tombstone region).

F. L. Ransome, 1904 (U. S. G. S. P. P. 21). *Naco ls.*—Chiefly light-colored, regularly stratified fossiliferous beds, consisting essentially of calcium carbonate; compact, nearly aphanitic, breaking with splintery fracture; granular crinoidal beds not uncommon. Beds range in thickness from a few inches to 10 ft., but are usually thinner than those of Escabrosa ls. Chert not uncommon; occurs in irregular bunches and nodules. Rests conformably on Escabrosa ls. Is uncon. overlain by Glance cgl., basal Cret. Composes Naco Hills, near W. edge of Bisbee quad., where it is at least 1,500 and probably 2,000 ft. thick. Original thickness, before erosion, probably 3,000+ ft.

Nacogdoches beds. (In Claiborne group.)

Eocene: Eastern Texas (Nacogdoches County).

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869, pp. 57, 65, 67, 79–101, 255). *Nacogdoches beds.*—Marine and palustrine transition beds btw. Cook's Mtn greensands and the massive gypsiferous clays of Yegua fm. Regarded as distinct lithologic unit. Consists of alternating sands and clays with a few layers of greensand; much cross-bedding; frequent alternation of sand, clay, sh., and gravel; in places gypsiferous; sand is mottled in places but mainly reddish brown; 35 ft. above base at Ortons Hill is a layer of medium-coarse and for most part angular cgl. with boulders up to 6 in. diam. Thickness 25 to 60+ ft. Rests uncon. on Cook's Mtn fm. Difficult to separate from overlying Yegua fm., but top is placed where last marine fossil is found. The Nacogdoches beds are well exposed at Nacogdoches, also along streams flowing southward into Angelina River, in Nacogdoches Co., and in some of river bluffs, also in lower reaches in tributaries on S. side of river.

B. C. Renick, 1928 (A. A. P. G. Bull., vol. 12, p. 531). *Nacogdoches memb. of Cook Mtn fm.*—Mostly brown sand, locally containing some glauconite and some beds of brown clay; weathers red and tan gray. Thickness 275 to 375 ft. Underlies Lufkin memb. of Cook Mtn fm. and overlies San Augustine memb. of Cook Mtn.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 651). Dumble's name Nacogdoches appears to be a synonym for Vaughan's older name Sparta as restricted by Spooner. Since some doubt exists as to just what Dumble intended to include in his "transition beds," and since *Sparta* was in good usage in La., Miss Ellisor and Wendlandt and Knebel have been justified in dropping *Nacogdoches*.

Naese sandstone member (of Lee formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 35, 86). *Naese ss. memb.*—Massive cliff-making ss., probably 256 ft. thick, forming top memb. of Lee fm. in Cumberland Gap coal field.

Named for Naese Cliff, on Cumberland River, Bell Co., Ky.

Nagle sand.

A subsurface sand lying at horizon of lower ss. bed of Connoquenessing ss. memb. of Pottsville fm. in Willowwood field, Lawrence Co., SE. Ohio.

†Nahant schist.

Lower Cambrian: Eastern Massachusetts (Nahant).

N. S. Shaler, 1889 (U. S. G. S. 9th Ann. Rept., pp. 577–578). West of Lynn, in region called southwestern extremity of Boston Bay syncline, we have an extensive series of more or less metamorphosed rocks, including Cambridge slates, Roxbury cgls., *Nahant schists*, and Braintree fossiliferous slates.

The rocks referred to above as "Nahant schists" are mapped by B. K. Emerson (U. S. G. S. Bull. 597, 1917) as part of Weymouth fm.

†Nahant limestone.

Lower Cambrian: Eastern Massachusetts (Nahant).

J. H. Sears, 1891 (Essex Inst. Bull., vol. 22, p. 32). *Nahant lss.*—Much metamorphosed into bands of light and dark lydite. Occur on S. side of Nahant Head, at the Shag Rocks, and extend about 300 yds. to just beyond Bennett's Head on N. Contain *Olenellus* Lower Camb. fossils.

Belong to Weymouth fm., and are of too small extent to map.

†Nahant gabbro.

Early Paleozoic: Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.), used *Nahant gabbro*.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 181–182 and map). *Gabbro at Nahant* was mapped as a distinct fm.

L. LaForge, 1932 (U. S. G. S. Bull. 839), treated the isolated area of gabbro at Nahant as a part of Salem gabbro diorite.

Naheola formation. (In Midway group.)

Eocene (lower): Southern Alabama and eastern Mississippi.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 57–60). *Naheola and Matthew's Landing series.*—Mostly gray sandy clays alternating with cross-bedded sands, with a bed (3 to 6 ft. thick) at base of section containing marine fossils and consisting of glauconitic sands and dark-gray, nearly black sandy clays. Uncon. underlies Nanafalia series and overlies Black Bluff series [Sucarnoochee clay]. Thickness, 130 to 150 ft. [In descriptions in rept cited and in subsequent repts the basal marl bed, 3 to 6 ft. thick, is called *Naheola marl*, also *Matthew's Landing marl*.]

In present usage the Naheola is top fm. of Midway group, and is underlain by Sucarnoochee clay and overlain by Wilcox group. It is of marine origin. C. W. Cooke, 1933 (A. A. P. G. Bull., vol. 17, No. 2, pp. 192-195), restricted Nanafalia fm. to its upper two members, the lower memb. (†Coal Bluff beds of early repts) having proved to be an eastern extension of Ackerman fm., basal fm. of Wilcox group of Miss. The beds that overlie the Naheola fm. are therefore now called *Ackerman fm.*

Named for exposures at Naheola, on Tombigbee River, in Choctaw Co., Ala.

†Naheola marl.

Eocene (lower): Southwestern Alabama.

E. A. Smith, 1887 (U. S. G. S. Bull. 43, pp. 57-60).

For definition, see under *Naheola fm.*, of which this bed is basal memb. and with which the name conflicts.

Named for exposures in lower part of section at Naheola, on Tombigbee River, in Choctaw Co.

Naiad limestone.

Silurian (?): Southwestern New Mexico (Silver City region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257-259; Conspectus of geol. fms. of N. Mex., pp. 3, 10). *Naiad ls.*—Main ore-bearing fm. at Georgetown, Silver City, and elsewhere in these districts. Thickness 250 ft. Overlies Cibola ls., both of which comprise Santa Ritan series. Assigned to Sil. [Derivation of name not given.]

Naish limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 87, 97). *Naish ls.*—Basal memb. of Stanton ls. along Kansas River. Absent in SE. Nebr. Underlies Linwood sh. memb. [Derivation of name not stated. On p. 46 *Naish ss.*, at base of Stanton ls., is described as consisting of 1.8 ft. of hard gray calc. ss.]

R. C. Moore and G. E. Condra also used this name in their Oct. 1932 revised classification of Penn. of Kans. and Nebr., but there is no other record of the name. R. C. Moore in his 1936 classification of Penn. rocks of Kans. (Kans. Geol. Surv. Bull. 22) dropped this name, without explanation, and defined *Captain Creek ls.* as basal memb. of Stanton ls., underlying Eudora sh. memb. and overlying Vilas sh. The bed appears to be included in his Captain Creek ls.

Nakimu limestone.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 137). Included in Beltian system.

Nakimuan series.

A term employed by C. [R.] Keyes to cover rocks of Cordilleran region interpreted by him as having been formed during interval btw. the Keweenawan and upper Huronian epochs. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Naknek formation.

Upper Jurassic: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 169-171, 179, 181). *Naknek series.*—Great thickness of granitic arkoses and cgls., which generally contain granite pebbles. Cut by later basaltic lava. Outcrops about halfway from mouth of Naknek Lake to head of Savonoski. Westernmost rock of Naknek series is an augite andesite that outcrops on Naknek Lake. Not certain this rock represents a flow contemp. with the sed. rocks of the series. Fossils indicate Upper Jurassic.

G. C. Martin, 1905 (U. S. G. S. Bull. 250, p. 44), in description of Enochkin Bay, identified *Naknek fm.* (=Naknek series of Spurr) as consisting of 583 ft. of dark sandy shales overlain by an alternating series of andesite flows and beds of aggl. 270 ft. thick, and as separated from the older Enochkin sh. by 290 ft. of aggl. The beds originally defined as *Enochkin fm.* were later divided into 2 fms. (Chinitna sh. above and Tuxedni ss. below), and Enochkin fm. was discarded.

In 1912 (U. S. G. S. Bull. 485, pp. 68+) G. C. Martin and F. J. Katz applied the name *Chisik cgl.* to the cgl. ("aggl." of Martin, 1905) overlying the Chinitna sh. and underlying the Naknek fm. Later (G. C. Martin, U. S. G. S. Bull. 776, 1926) Chisik cgl. was treated as basal memb. of Naknek fm., and this is present definition of U. S. Geol. Survey.

†Nampa beds.

A term loosely applied by S. F. Emmons (Boston Soc. Nat. Hist. Proc., vol. 24, pp. 432–433, 1890) to the deposits called *Idaho* and *Payette fms.* in U. S. G. S. Nampa folio, No. 103, 1904.

†Nanafalia marl. (In Wilcox group.)

Eocene (lower): Southwestern Alabama.

E. A. Smith, 1883 (Ala. Geol. Surv. Prog. Rept. 1881–82, pp. 256, 318–321). *Nanafalia marl.*—Marl containing a large percentage of greensand, and characterized by *Gryphaea thyrsae;* thickness 50 ft. Included in lower part of Lagrange or Lignitic.

Conflicts with Nanafalia fm., better-established name, of which it is a memb.

Named for exposure at Nanafalia Landing, on Tombigbee River, in Marengo Co.

Nanafalia formation. (In Wilcox group.)

Eocene (lower): Southern Alabama.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 51–57). *Nanafalia series.*—The series of strata to which the Nanafalia marl has given the name, broadly considered, is susceptible of threefold division upon basis of lithological and paleontological characters: (1) 40 to 50 ft. of indurated gray clays and sandy clays, in part glauconitic; (2) 75 to 80 ft. of yellow, reddish, and whitish sands, alternating with green-sand beds, and highly fossiliferous, *Gryphaea thirsae* being characteristic fossil; near base a bed 20 ft. thick literally packed with these shells; (3) 70 to 80 ft. of sandy clays and sands, variously interstratified, cross-bedded sands passing near base into greensands, which overlie the Coal Bluff lignite, 4–7 ft. thick. Uncon. overlies Matthew's Landing and Naheola series and uncon. underlies Bell's Landing series. [E. A. Smith had in 1886 (Ala. Geol. Surv. Bull. 1, p. 12) described these same rocks under heading *Nanafalia and Coal Bluff section*, and he also used that term in his description in Ala. Geol. Surv. Bull. 2, p. 48, 1892.]

C. W. Cooke, 1933 (A. A. P. G. Bull., vol. 17, No. 2, pp. 192–195), restricted Nanafalia fm. by removing its basal memb. (†Coal Bluff beds of early repts), 80± ft. thick, which he stated is an E. extension of Ackerman fm. of Miss. Basal fm. of Wilcox group in Ala. is therefore now called *Ackerman fm.*

See also 1932 entry under *Salt Mtn ls.*

Named for exposures at Nanafalia Landing on Tombigbee River, in Marengo Co.

Nanaimo group.

Upper Cretaceous: Southwestern British Columbia.

G. M. Dawson, 1886 (Canada Geol. Surv. Rept. 1886, p. 10B) and 1890 (Am. Jour. Sci., 3d, vol. 39, pp. 181–183). [See under *†Vancouver fm.*]

C. H. Clapp, 1912 (Canadian Mg. Inst. Trans., vol. 15, pp. 337–338). *Nanaimo series*, Cret., B. C., includes Gabriola, Northumberland, DeCourcy, Protection, Newcastle, Cranberry, Extension, East Wellington, Haslam, Departure Bay and Benson fms.

Nanjemoy formation. (Of Pamunkey group.)

Eocene: Eastern Maryland and Virginia.

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Nanjemoy fm.*—Generally highly argill. greensand, particularly in lower part. Characterized by well-marked fauna, representing a clearly defined paleontological stage. Top fm. of Pamunkey group. Divided into Woodstock memb. or substage above and Potapaco memb. or substage below. Uncon. underlies Chesapeake group and overlies Aquia fm. Named for Nanjemoy Creek, Charles Co., Md.

Now classified by U. S. Geol. Survey as of Claiborne and Wilcox age.

Nannie Basin limestone.

Middle (?) Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 6, 36, and passim). *Nannie Basin ls.*—At type loc. (where it forms the lower cliffs which are the rim of physiographic feature known as Nannie Basin) consists of homogeneous gray-white, very massive thick-bedded, rather fine-grained ls. with a few beds of chocolate-gray ls. in upper part; in lower 28 ft. there is also drab-gray nodular ls. with much buff clay in thin bands. The ls. weathers dull gray, and clay in lower part weathers buff. In nearly all other places Nannie Basin ls. is more tan than gray and has much more buff clay than at type loc. Thickest (203 ft.) in Nannie Basin; thinnest (111 ft.) on Wall Creek-Juliet Creek Ridge. Underlies Dearborn ls. and overlies Damnation ls.

Nantahala slate.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 4). *Nantahala sl.*—In the main black and gray banded slates and schists distinguished by mica, garnet, staurolite, or ottrelite. Most of schists are near base of fm. and strongly resemble the sl. and schist beds in Great Smoky cgl. The slates and ottrelite schists are as a rule somewhat darker than the other beds, the color being due to very minute grains of iron oxide. The slates are banded light and dark gray and bluish gray and cannot be distinguished from the slates in other fms. In N. half of quad. sl. makes up nearly all of fm., but forms only the upper beds at S. Many ss. and cgl. beds are interstratified with the sl. near its base and form a transition into underlying Great Smoky cgl. Unimportant layers of graywacke or cgl. are also found higher up in the sl. Thickness 1,400 to 1,800 ft. Overlain by Tusquitee qtzite.

Named for fine exposures along Nantahala River in Nantahala quad., Macon and Swain Counties, N. C.

Nantucket moraine.

Pleistocene: Southeastern Massachusetts (Nantucket Island, Marthas Vineyard) and southeastern Rhode Island (Block Island).

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Nantucket moraine* occurs on Nantucket and Block Islands and Marthas Vineyard and No Mans Land. Is a corrugated moraine, submarginal, mainly folded pre-Wisconsin beds, overlain by thin Wisconsin drift, and is not a true moraine but a pseudomoraine of Nantucket outwash plain.

Nantucket substage.

The time during which the Nantucket moraine was deposited.

Nanushuk formation.

Upper Cretaceous: Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 247). *Nanushuk series.*—Mainly thin-bedded gray and brown ss., generally fine-grained and sometimes friable; slate-colored aren. and impure fossiliferous ls.; dark sh. or mud rock; soft uncleaned slates; fine-grained gray qtzite; drab chert; and bituminous coal. Upper Cret. fossils. Uncon. overlies Anaktoovuk series on N. and underlies Tert.

Named for Nanushuk River.

Naparima marl.

Miocene: Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geol. of Trinidad, pp. 36–37).

†Naples shale.

†Naples group.

Upper Devonian: Western to central New York.

J. M. Clarke, 1885 (U. S. G. S. Bull. 16). *Naples beds or Naples shales* (Cashaqua and Gardeau beds of previous repts, which are abandoned, because there seems no paleontological evidence for their separation, and for which I have substituted *Naples beds*, from town of Naples, Ontario Co., where the sections are very perfect and where the beds have been carefully studied).—Author does not mean to assume, in absence of complete evidence, applicability for this subdivision outside of dist. here discussed [Ontario Co.]. Underlies Portage [Nunda] sss. and overlies Genesee beds. [The blocks on Clarke's map of Ontario Co., published in 1885 (N. Y. State Geol. Rept. for 1884) are (descending) High Point Chemung; Lower Chemung (Portage) sss.; Naples ("Portage") shales; Transition shales; Genesee shales with Styliola layer; Tully ls. * * *]

J. M. Clarke, 1894 (N. Y. State Mus. 47th Ann. Rept., p. 750), correlated the Naples of *Naples* section with Ithaca or middle Portage and lower Portage to E. In 1897 (N. Y. State Geol. 15th Ann. Rept., pp. 33–62) Clarke described the *Naples fauna*, or "the fauna of the typical Portage series," as an exotic fauna derived from the W. and having little relation to the contemp. Ithaca or eastern fauna of the Portage; and stated (p. 57) that the name *Naples beds* is "a local name for the strata which carry the *Intumescens* fauna." The beds consist of shales and flags. In 1902 (N. Y. State Mus. Bull. 52, pp. 420–421) Clarke stated that Naples fauna occupies all the ground from meridian of Cayuga Lake to shores of Lake Erie, and persists to W. much longer than to E., where it became replaced by the Ithaca and in part by the Chemung fauna. In 1903 (N. Y. State Mus. Hdb. 19, pp. 23–24) Clarke divided *Naples beds* into several units, the Middlesex black sh. being the basal one and the Wiscoy sh. (or Westhill ss.) the topmost one, the overlying High Point ss. being said to carry a Chemung fauna. In several subsequent repts the High Point ss. and overlying Prattsburg sh. were excluded from the Chemung.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), included in *Naples* all beds btw. base of Middlesex sh. and top of Wiscoy sh. (=Prattsburg ss.).

This name seems to have fallen into disuse until revived by G. H. Chadwick in 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 313–318, 352). His classification is: *Naples group*, divided into Enfield or Attica memb. above (which includes Hatch and Rhinestreet) and Ithaca or Sonyea memb. below (which includes Cashaqua and Middlesex shales). See also Chadwick, Am. Mid. Nat., vol. 16, No. 6, Nov. 1935, pp. 858, 862. W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 369, 405), included *Naples fauna* in *Portage group*. The U. S. Geol. Survey has discontinued the use of *Naples*.

Napoleon sandstone.

Mississippian: Michigan (Southern Peninsula).

W. H. Taylor, 1839 (Mich. Geol. Surv. Rept. State Geol. in re improvement of State salt springs, Mich. Leg. H. R. Doc. 2). *Napoleon ss.* is source of brine.

A. Winchell, 1861 (Mich. Geol. Surv. 1st Bien. Rept. Prog., pp. 88, 90, 139). *Napoleon group*.—Consists of (descending): (1) Shaly micaceous ss., 15 ft.; (2) *Napoleon ss.*, highly saliferous in many places, 78 ft.; (3) shaly micaceous ss., 15 ft.; (4) clay or sh., 10–64 ft. [In several places he speaks of No. 4 as "the separating sh. lying between the Napoleon and Marshall groups." In some places he seems to call the whole "group" the *Napoleon ss.*] Thickness 173 ft. "There is no reason, except its negative paleontological characters, for separating the Napoleon group from the Marshall group." "If correctly separated from Marshall group it has no distinct equivalent in surrounding States." Outcrops at Napoleon, Jackson Co. Tentatively included in Carbf. Underlies Michigan salt group and grades into underlying Marshall group, which contains Chemung Dev. fossils.

A. C. Lane, 1904 (Mich. Acad. Sci. 5th Ann. Rept., pp. 189–193). *Upper Marshall or Napoleon* is 130 ft. thick, and underlies Lower Grand Rapids or Michigan, and overlies Lower Marshall.

In some subsequent repts these beds were called "Upper Marshall," and they are now commonly included in *Marshall ss.*, as the Marshall deposits are now designated.

Napoleon group.

See under *Napoleon ss.*

†Narcissa sandstone. (In Cherokee shale.)

Pennsylvanian: Northeastern Oklahoma (Ottawa County).

S. Weidman, 1932 (Okla. Geol. Surv. Bull. 56, p. 24). *Little Cabin ss. memb.* (of Cherokee sh.), named by D. W. Ohern in unpublished ms., consists of 10 to 15 ft. of medium- to coarse-grained ss. grading into shaly beds. It lies 50± ft. above base of Cherokee sh. in Ottawa Co., and is well exposed in vicinity of Narcissa, Ottawa Co. Its approx. distribution is indicated on the geol. map, pl. I, under name *Narcissa ss.* No fossils except plants. [The name *Little Cabin ss.* was published in 1928, and "Narcissa ss." is therefore an unnecessary synonym.]

Nariva series.

Eocene: Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geol. of Trinidad, pp. 35–36).

†Narragansett series.

A term that has been used in some repts to include same rocks as †Narragansett Basin series.

†Narragansett Basin series.

Pennsylvanian and Permian (?): Rhode Island.

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, Geol. ser., vol. 8, No. 4, p. 99, etc.). *Narragansett Basin series.*—Arkoses, coarse and fine cgls., shales, and interbedded sss., some ls. Thickness 12,000 ft. In general appearance resemble the rocks of Boston and Norfolk Basins, but are more highly fossiliferous and of more pronounced red color. The Dighton cgl. is upper memb. of series.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks of Narragansett Basin as (descending) Dighton cgl. to N. and Purgatory cgl. to S.; Rhode Island fm.; Wamsutta fm.; and Pondville cgl.

Narrows chert. (In Beekmantown limestone.)

Lower Ordovician: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 641–643). *Narrows chert.*—Dol. or dolomitic ls. carrying abundant quantities of chert, which appears to be usually gray at top but black toward base. Thickness 200 to 283 ft. Forms top memb. of Beekmantown ls. Type loc. in Giles Co., Va., on low spur of Wolf Creek Mtn, W. of Mill Creek, S. of Wolf Creek and about 2.2 mi. SW. of Narrows. Also observed in Mercer and Monroe Counties, W. Va.

†Nash group.

Upper and Middle Ordovician: Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 160, 260).

Abbreviated form of †Nashville group.

Nash marble series.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 636). *Nash marble series.*—Chiefly dense marble, massive to thin-bedded, white to pink or gray, alternating with beds of jasper, chloritic phyllite, striped ferruginous metadolomite, and thin biotitic schists. Some beds contain structures believed to be fossil algae.

Lower part largely massive slaty gray metargillites. Thickness 2,400 ft. Underlies Anderson phyllite with probable conformity and overlies Sugarloaf metaqtzite, but contact with latter not seen. Exposed on west branch of Nash Fork. Assigned to early Algonkian.

†Nashaquitsa series.

Pleistocene: Southwestern Massachusetts (Marthas Vineyard).

N. S. Shaler, 1888 (U. S. G. S. 7th Ann. Rept., pp. 303–363), casually called the deposits of Nashaquitsa the *Nashaquitsa series*, but mapped them as Weyquosque series.

N. S. Shaler, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 536–539). *Nashaquitsa series.*—Gray and reddish sands and clays in general character like those formed during last glacial period, but on account of greater age they have been more changed in texture. Of Plio, or post-Tert. age. No fossils. In part at least laid down in salt water.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). At Nashaquitsa Cliffs, on S. shore of Marthas Vineyard, the Wisconsin drift, Manhasset, Jacob, Gardiners, Jameco, and Weyquosque fms. are present and no Tert. has been recognized.

†Nashua marl.

Pliocene (lower): Northeastern Florida.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50, and pp. 128–133). *Nashua marl.*—Light-colored marine sand beds alternating with shell marl. Although matrix is usually calc., it is always more or less sandy and sometimes consists of nearly pure sand. Bears strong lithologic resemblance to Caloosahatchee marl. Thickness 6 to 32 ft. Is thought to rest uncon. on Mio. and is uncon. overlain by Pleist. sand. Occupies St. Johns Valley, where it underlies a broad terrace bordering the stream. It probably occurs beneath the plain E. of St. Johns River.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept. and Geol. Soc. Am. Bull., vol. 40, p. 92). "*Nashua*" *marl* abandoned for Caloosahatchee marl, which is so nearly of same age that two names are not needed.

Named for exposures on St. Johns River near Nashua, Putnam Co.

†Nashville group.

Upper and Middle Ordovician: Western, central, and eastern Tennessee.

J. M. Safford, 1851 (Am. Jour. Sci., 2d, vol. 12, pp. 353, 356–357). *Nashville group.*—Lower 60 to 80 ft. a well-characterized memb. of siliceous or sandy ls.; remaining 260 ft., not affording grounds for positive division, has simply been divided equally into Upper and Lower Nashville beds, consisting of thick-bedded blue and blackish-blue ls., running up into thinner layers separated by seams and, rarely, beds of sh., generally granular, often gritty and impure, and prone to disintegrate. Older than Harpeth and Tenn. River group. Overlies Stones River group.

J. M. Safford, 1856 (Geol. reconn. Tenn.), called these beds *Nashville memb. of Central ls. and sh. group.*

Includes (descending) **Fernvale fm.**, **Arnheim ls.**, **Leipers ls.**, **Catheys ls.**, Bigby ls., and Hermitage ls., which range in age from early Trenton to late Richmond. Some repts have excluded Richmond at top. In Ga. the Rockmart sl. has been called "Nashville sl."

Named for Nashville.

†Nashville slate.

Ordovician: Northwestern Georgia.

J. W. Spencer, 1891 (Ga. Geol. Surv. 1st Rept. Prog., p. 112). *Nashville (or Rockmart) sl.* [Described. See under *Rockmart sl.* Same as Rockmart sl., which has priority, and *Nashville* conflicts with other uses of that name.]

†Nashvillean.

A time term proposed by A. W. Grabau in 1909. See explanation under *Trentonian.*

†Nasina series.

†Nasina group.

Pre-Cambrian and Paleozoic: Eastern Alaska.

A. H. Brooks, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 465-467, 478, 483). *Nasina series*.—Largely clastic rocks, essentially quartz schists and white crystalline ls., with some slates and some intrusive sheets and dikes. Occurs only on lower White River up to about mouth of Ladue Creek. Seems to correspond to Birch Creek schist and Fortymile series of Spurr; but I could not differentiate. It seems likely it includes Tanana schists. Assigned to pre-Sil. [*Nasina* is Tanana native name for *White River*.]

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, p. 60). *Nasina "series"* (which preferably should be *Nasina group*) includes Spurr's Birch Creek and may also include Fortymile "series" [Paleozoic and pre-Camb.].

According to J. B. Mertie, Jr., the Nasina series of Canadian geologists is same as Birch Creek schist as now restricted to sed. rocks, and *Nasina series* and *Nasina group* are no longer useful terms for rocks in Alaska.

†Nass formation.

Jurassic or Triassic: Northwestern British Columbia (Salmon River Valley region).

R. G. McConnell, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 65), 1912 (Canada Geol. Surv. Summ. Rept. 1911, pp. 53, 58), 1914 (Canada Geol. Surv. Mem. 32, p. 17); no age assignment. S. J. Schofield and G. Hanson, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. A, p. 8), assigned these rocks to Jurassic, as did Schofield, 1922 (Canada Geol. Surv. Mem. 132, p. 13). G. Hanson, 1921 (Canada Geol. Surv. Mem. 159, p. 9), assigned them to Jurassic or Triassic. Late Canadian repts say the name should be dropped. (See Canada Geol. Surv. Summ. Rept. 1923, pt. A, p. 34.)

Nassau beds.

Lower Cambrian: Eastern New York (Rensselaer County) and western Vermont (?).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 69-70). *Nassau beds*.—Divisions A to E of [T. N.] Dale's series in Rensselaer Co. Consists of 150 to 800 ft. of alternating reddish and greenish shales and qtzites, underlying Bomoseen grit—all of Lower Camb. age. Named for exposures in Nassau, N. Y.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, No. 2, p. 414), placed *Nassau beds* above Schodack beds and both in Lower Camb., with Middle and Upper Camb. absent.

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285). [See 1930 entry under *Schodack fm.*]

Nass River argillite.

Age (?): British Columbia.

W. V. Smitheringale, 1928 (Econ. Geol., vol. 23, p. 193).

Nastapoka series.

Pre-Cambrian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 197).

Natapoc formation.

Eocene: Central Washington (central part of Chelan County).

E. Houghland, 1932 (Northwest Sci., vol. 6, No. 2, p. 68). *Natapoc fm.* is here used to designate the ss. series about 11 mi. N. of Leavenworth, Wash., and about 15 mi. E. of crest of Cascade Mtns. It is Tert., and uncon. overlies metamorphic rocks. Mr. Parrott has shown this fm. as about 15,000 ft. thick. It has been folded into at least 2 anticlines and 2 synclines with av. dip of 40°. The major fold is an anticline btw. 7 and 8 mi. wide at base. From unmetamorphosed character of beds and light shearing effects it is inferred this series was not subjected to intensive stresses during the folding. In two places the underlying rock has been exposed by erosion.

E. Houghland, 1932 (Pan-Am. Geol., vol. 58, No. 4, pp. 263–270). Natapoc Mtn is 15± mi. E. of crest of the Cascades, near Great Northern Railway, 10 mi. N. of Leavenworth. It is composed almost wholly of broadly folded aren. strata of Eo. age and of great thickness, resting upon a foundation of metamorphics and igneous masses. The section consists of cgl., pebbly sss., some layers of sh., and an interstratified basaltic plate and some felsites. Appears to correlate with the Eo. fms. of Mount Stuart area, namely, Swauk fm., Teanaway basalt, Roslyn ss., and Manastash fm.

Natchez formation.

Early Pleistocene: Mississippi.

T. C. Chamberlin, 1896 (Am. Geol., vol. 17, pp. 108–109). *Natchez fm.*—Alternating stages of deposition and erosion of Pleist. stratified gravel, sand, and fine silt of immediate valley of Mississippi River in vicinity of Natchez. The Natchez fm. and associated deposits and stages of erosion are of special interest on account of their probable relationship with Kansan, Aftonian, and Iowan stages of Glacial period in upper and more northern part of Mississippi Basin.

T. C. Chamberlin and R. D. Salisbury, 1906 (Textbook geol., vol. 3, pp. 386–388). *Natchez fm.*—At Natchez, Miss., a section of assorted material chiefly made up of derivatives from Lafayette fm., upon which it rests uncon. Also contains crystalline pebbles and calc. clays assignable to wash from the glacial regions. Marked interval btw. its deposition and that of overlying loess. Probably of either Aftonian or sub-Aftonian age. Thickness 200± ft.

E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14) and 1925 (Miss. Geol. Surv. Bull. 20). *Natchez fm.*—In river bluffs at Natchez is 75 to 80 ft. of reworked gravels and sands which overlie Citronelle fm. and seem to be of early Pleist. age. The materials are derived in part from older Plio. deposits and in part from glacial drift from the north. Uncon. underlies the loess.

L. W. Stephenson, W. N. Logan, and G. A. Waring, 1928 (U. S. G. S. W. S. P. 576, p. 61). As described by E. W. Shaw in an unpublished ms. the *Natchez fm.* is a very early Pleist. stream deposit consisting of 150 to 175 ft. of gravels, sands, and clays. Only good exposure known is at Natchez, where it lies considerably above position of highest floods of present day and is well exposed in bluff. It appears to be much older than the loess.

Natick granite.

A name mentioned in some early repts. (See W. O. Crosby, Boston Soc. Nat. Hist. Occ. Papers No. 3, 1880.) The granite at Natick, Mass., was mapped as Dedham granodiorite by B. K. Emerson in U. S. G. S. Bull. 597, 1917.

Natick arkose.

Carboniferous: Eastern Rhode Island (Kent County).

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 253–256, 375–376, 383–385). *Natick arkose.*—Largely detrital quartz derived from decayed granite, and usually found near those localities where the immediately underlying pre-Carbf. rocks consist chiefly of granite. Exposed along steep hill face from Natick [Kent Co.], R. I., for 2½ mi. northward into Cranston. Underlies Kingstown series.

Is part of Wamsutta fm. as mapped by B. K. Emerson, U. S. G. S. Bull. 597, 1917.

National sandstone.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. with map, Phila., 1863; map and p. 21). North of Minesota traps is a belt of ss. 50 ft. wide. It is well exposed in a creek on the National Location and is known as *National ss.* [Is shown as overlying Minesota traps and underlying Toltec traps.]

According to B. S. Butler (U. S. G. S. P. P. 144, 1929) this is probably cgl. No. 12.

Nation River formation.

Carboniferous (Pennsylvanian?): Central eastern Alaska (Nation River region).

A. H. Brooks and L. M. Prindle, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 294, etc.). *Nation River fm.*—Cgls., sss., and shales, 3,700± ft. thick, containing plant fragments. Assigned to Upper Carbf. Overlies (uncon.) Calico Bluff fm., and underlies (uncon.?) heavy lss. of Upper Carbf. age. Exposed on Yukon River at mouth of Nation River.

The fossils of the ls. overlying Nation River fm. are now classified by G. H. Girty as Perm., and the Nation River is now classified as Penn. (?). Its max. thickness is now stated to be 6,000 ft. J. B. Mertie, Jr., 1933 (U. S. G. S. Bull. 836, p. 423), stated that he believed a group of intermediate or transitional rocks, 1,000 to 2,000 ft. thick, exists btw. Nation River fm. and Calico Bluff fm. in Tatonduk-Nation dist., but that this remains to be proved. He classified Nation River fm. as *Penn.* (?) and Calico Bluff fm. as *upper Miss.*

Natural Bridge limestone.

W. W. Mather, 1843 (Geol. N. Y., vol. 1, pl. 45). [This geologic cross section (from Monticello, Sullivan Co., to Croton River near Bulls Bridge, Westchester Co., N. Y.) shows *Natural Bridge ls.*]

†Natural Bridge limestone.

Middle and Upper Cambrian and Lower Ordovician: Central western Virginia.

H. D. Campbell, 1905 (Am. Jour. Sci., 4th, vol. 20, pp. 445–447). *Natural Bridge ls.*—Chiefly heavy-bedded gray and light-blue mag. lss. with thin siliceous laminae conspicuous. Beds of white and pinkish dol. occur now and then. Calc. sss. from few in. to 8 ft. thick are occasionally prominent. Black chert nodules more or less abundant throughout, and heavy chert beds are usually very conspicuous near top. Thickness 3,500+ ft. Beekmantown fossils found 300 to 400 ft. below top and Camb. fossils lower down. Underlies Murat ls. and overlies Buena Vista sh.

Now divided into (descending) Beekmantown group, Conococheague ls., and Elbrook ls.

Natural Corral member.

Lower Cretaceous (Comanche series): Central Kansas.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9, pp. 31–32). *Natural Corral memb.*—The basal strata of Belvidere fm., underlying Windom memb. Exposed at Natural Corral, a box canyon about 5 mi. SW. of Marquette (NW¼ sec. 5, T. 18 S., R. 5 W.), McPherson Co.

See also 1924 entry under *Mentor fm.*

Naugatuck sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 163). *Naugatuck ss.*—Massive grayish-white medium-grained, 15 to 40 ft. thick. Lies 1 to 5 ft. below Hernshaw coal and overlies Dingess coal. Named for Naugatuck, Mingo Co.

†Naugus Head series.

Age (?): Eastern Massachusetts (Boston region).

W. O. Crosby, 1877 (Geol. map of eastern Mass.), mapped as *Naugus Head series* (1) the rocks of Naugus Head (on NW. shore of Marblehead); (2) the rocks of Salem, Salem Neck, and S. shore of Beverly and some adjacent islands; and (3) the rocks of Nahant. The rocks of Naugus Head and S. shore of Beverly and adjacent islands are mapped by B. K. Emerson (U. S. G. S. Bull. 597, 1917) as Beverly syenite; the rocks of Salem Neck as in part nephelite syenite and in part Salem gabbrodiorite; and the rocks of Nahant as granite.

W. O. Crosby, 1880 (Boston Soc. Nat. Hist. Occ. Papers, No. 3, with map). The oldest of these crystalline series [of eastern Mass.] is smallest in extent. I propose to designate it, provisionally, *Naugus Head series*, in allusion to promontory of this name on Marblehead shore, where the rocks of this series are best developed and were first observed. Rocks are chiefly feldspar and pyroxene.

M. E. Wadsworth, 1883 (Boston Soc. Nat. Hist. Proc., vol. 21, pp. 288-294), discussed the "so-called Naugus Head series," but "did not assent to the views which led to its establishment."

†Naushon series.

Pleistocene: Southeastern Massachusetts (Marthas Vineyard).

N. S. Shaler, 1888 (U. S. G. S. 7th Ann. Rept., pp. 303-363 and map). *Naushon series.*—Yellowish and reddish stratified sands, containing occasional water-rounded pebbles, occurring on island of Naushon [N. of Marthas Vineyard]. Also occurs at several places on Marthas Vineyard. Not of strict glacial origin. Appears to antedate ice sheet, though it may represent deposits of one of the interglacial periods. Uncon. underlies till and kame deposits.

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). Shaler recognized beneath the surface moraine of Naushon Island a thick series of fine sands to which he gave the name "Naushon series," comparing it with beds now referred to the older Pleist. [probably Weyquosque fm.] of Marthas Vineyard.

Navajo sandstone. (In Glen Canyon group.)

Jurassic (?): Northern Arizona, southeastern Utah, western Colorado, and extreme northwestern New Mexico.

H. E. Gregory, 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 102, 112). *Navajo ss.*, upper memb. of La Plata group in Navajo Ind. Res., Ariz., consists of light-red massive cross-bedded ss., 30± ft. thick. Underlies McElmo fm.

H. E. Gregory, 1916 (U. S. G. S. W. S. P. 380). *Navajo ss.*—Red ss., massive exceedingly cross-bedded; locally thin-bedded and greatly reduced in thickness. Thickness 400 to 1,000 ft. Underlies McElmo fm. and overlies Todilto fm. Is top fm. of La Plata group.

H. E. Gregory, 1917 (U. S. G. S. P. P. 93, pp. 57+). [Detailed description.] Is widely displayed in Navajo country and is appropriately termed *Navajo ss.* Nearly complete section is exposed in walls of Navajo Canyon and other canyons.

The beds that overlie Todilto ls. in NW. N. Mex. are now known to be younger than true Navajo, and they, as well as Todilto ls., are now included in Morrison fm., while the beds that separate Navajo ss. from underlying Wingate ss. in Utah and Ariz. are now known as *Kayenta fm.* (See U. S. G. S. P. P. 183, 1936, by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.)

†Navajo shales.

Name applied by C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 22, p. 257, 1915, and Conspectus of geol. fms. of N. Mex., pp. 2, 10, 1915) to 1,000 ft. of sh. overlying Pictured Cliffs ss. and underlying Tert. in San Juan region, N. Mex. Now divided into several named fms. of Upper Cret. age. (See J. B. Reeside, Jr., U. S. G. S. P. P. 134, 1924.)

Navarro group.

Upper Cretaceous (Gulf series): Eastern Texas.

B. F. Shumard, 1862 (Boston Soc. Nat. Hist. Proc., vol. 8, p. 189). *Navarro beds.*—Fossiliferous blue and gray aren. clays in Navarro Co., not hitherto recognized in Tex. but believed to occupy strat. position above Austin ls.

R. T. Hill, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 298). *Navarro beds* (*Exogyra ponderosa marl*).—Marls, clays, and lss. of varying hardness and in beds of limited extent. Overlie Dallas ls. and underlie basal Tertiaries. [As thus defined included Taylor marl.]

R. T. Hill, 1889 (Am. Jour. Sci., 3d, vol. 37, p. 290). *Navarro beds.*—Calc. sands overlying *Exogyra ponderosa* [Taylor] marls. Top fm. of Upper Cret. in Tex.

Adopted in well-established sense, for aren. glauconitic deposits overlying nonglauconitic Taylor marl and underlying Eocene. (See also *Taylor* *marl.*) The Navarro deposits of NE. Tex. are now treated by U. S. Geol. Survey as a group, divided into (descending) Kemp clay (restricted), Corsicana sand (restricted), Nacatoch sand, and Neylandville marl. See U. S. G. S. 1937 geol. map of Tex. and Univ. Tex. Bull. 3232, 1933. In Medina River region Navarro group is now divided by L. W. Stephenson into (descending) Escondido fm. and Corsicana marl. In Rio Grande region it is now divided into (descending) Escondido fm. and Olmos fm.

Named for development in Navarro Co.

†Navasota beds.

Miocene and Pliocene: Eastern Texas.

W. Kennedy, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 9–15, 43–44). *Navasota beds.*—Upper div., 75 ft. of blue and yellow, sometimes red clays, occasional strata of gray calc. sands containing Cret. shells, and thin-bedded coarse-grained soft calc. ss.; lower div., 350 ft. of gray and yellow calc. sss. interstratified with coarse yellow sand containing worn Cret. shells and beds of tufaceous yellow siliceous ls. Overlies Eo. beds corresponding to Fayette div. and underlies Quat.

Includes Lagarto clay and Oakville ss., according to U. S. G. S. P. P. 126, 1924.

Named for Navasota, Grimes Co.

Navesink marl. (In Monmouth group.)

Upper Cretaceous: New Jersey.

W. B. Clark, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, pp. 336–337, and Jour. Geol., vol. 2, pp. 161–177). *Navesink fm.*—Distinguishing feature is greensand. Lower part frequently quite sandy. Upper part highly argill., and at top frequently aren. and so oxidized that it is difficult to separate from Redbank fm. Highly fossiliferous. Thickness 40 to 60 ft. Is Lower Marl Bed of previous repts. Overlies Matawan fm. conformably. Extensively developed throughout region of Navesink Highlands, in vicinity of village of Navesink and along N. bank of Navesink River. [As thus defined the Navesink fm. included the beds separated, in 1897, under the name *Mount Laurel sands.*]

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 315, 333–334). *Navesink marls.*—Typically glauconitic sands, 12 to 50 ft. thick, which admit of subdivision throughout much of Monmouth Co. Underlie Redbank sands and overlie Mount Laurel sands. Is middle div. of Monmouth fm. [group].

The Navesink and Mount Laurel are generally treated as distinct lithologic units, but according to S. Weller and G. N. Knapp, 1907 (N. J. Geol. Surv. vol. 4, pp. 25, 137, 154), they are in part contemp.

Navosaigame formation.

Age (?): Mexico.

E. O. Hovey, 1907 (Am. Mus. Nat. Hist. Bull., vol. 23, pp. 401–442).

Naylor ledge.

Lower Ordovician (Beekmantown): Quebec (Philipsburg region).

E. O. Ulrich, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, p. 348). *Naylor ledge.*—So called by Dr. H. W. McGerrigle, who is mapping the area adjacent to town of Philipsburg, Quebec. Upper Canadian [upper Beekmantown] marine ls. in upper part of Philipsburg series. Corresponds essentially to div. D of Brainerd and Seely's section of "Calciferous" in Champlain Valley. Max. thickness 30 ft. Is div. B5 of Logan. Contains Upper Canadian fossils in the matrix. Fills caverns in Upper Ozarkian fms. [Derivation of name not stated.]

Naylor Ledge formation.

Name applied by H. W. McGerrigle (17th Rept. Vt. State Geol., pp. 182, 185, 1931) to summit bed (30 ft. thick) of B2 (lss.) of Logan's section of Philipsburg series of Quebec. McGerrigle mapped his Naylor Ledge fm. in small area in St. Albans quad., NW. Vt. (See 1931 entry under *Philipsburg series.*)

Nazareth cement rock.

Middle Ordovician: Eastern Pennsylvania (Lehigh Valley district).

E. T. Wherry, 1909 (Sci., n. s., vol. 30, p. 416). *Nazareth cement rock* (lower Trenton), 0 to 500+ ft. thick. Underlies Martinsburg sh. and overlies Nisky fm.

Probably named for occurrence at or near Nazareth, Northampton Co.

Btw. 1910 and 1927 this name was used in several Pa. Geol. Survey and other repts. In 1928 (letter dated March 26) B. L. Miller stated: (See quotation under *Coplay ls.*) Has also been called *Nazareth ls.*

Nazlini shales.

Upper Triassic: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 337). *Nazlini shales* is proposed for median and main body of shales of Doloresian series in Apache Co. [NE. Ariz.], and typically exposed on Nazlini Creek, S. of Chinle and NW. of Fort Defiance. Thickness 450 ft. Underlies Ventana sss. [This name was later (Pan-Am. Geol., 1924) applied by him in Utah and Colo. In his table for latter State he spelled the name *Noxlini*.]

Neabsco Run diorite.

Pre-Cambrian (?): Northeastern Virginia.

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). *Neapsco Run diorite.*—Outcrops 1 mi. NE. of Minnieville P. O. and 5 mi. NW. of Dumfries, along Neapsco Run. Assigned to pre-Camb. or Camb. [Neabsco is spelling of the stream on Va. maps.]

Neahga shale.

Silurian (Niagaran): Western New York (Niagara Gorge).

J. T. Sanford, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 194). The term *Neahga sh.* is proposed for the lower Clinton green sh. of Niagara Gorge. [All.]

J. T. Sanford, 1935 (Jour. Geol., vol. 43, No. 2, pp. 169–183). [Under heading *Neahga fm.* he stated:] At Niagara Gorge the lower Clinton green sh. is 6 ft. thick; thins to E. and is nearly or completely missing at Lockport, where about 3 in. of green sh. occur btw. underlying Thorold ss. and overlying Reynales ls. Originally correlated by Hall with green sh. below *Pentamerus ls.* at Rochester (Maplewood sh.), to which it corresponds in strat. position. Fossils (listed) seem more closely related to overlying fms. Btw. the Neahga and underlying Thorold ss. is a bed of calcitic sandy rock, with possibly a small uncon. at its base. The bed of green sh. may be of Furnaceville age, or may correspond, at least approx., to Maplewood sh., but laid down in separate basin or embayment or under different environment. The term "Neahga" (meaning Niagara River), which can be used as a local name implying no correlation, is proposed to designate this fm. [On p. 169 he stated relationships of Neahga fm. not certainly known except in Niagara Gorge. On p. 183 he stated the Neahga and Maplewood occur at same strat. horizon and are of approx. same age.]

Neapsco Run diorite.

See *Neabsco Run diorite.*

Nebo quartzite. (In Chilhowee group.)

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Nebo ss.*—Massive fine white ss., containing only grains of fine white sand and small quartz pebbles. Thickness 500 ft. Overlies Nichols sh. Underlies Murray sh.

Named for Mount Nebo Springs, on Mount Nebo, Blount Co., Tenn.

†Nebo.

Ordovician (Lower): Southern Oklahoma (Arbuckle and Wichita Mountains).

C. E. Decker, 1930 (A. A. P. G. Bull., vol. 14, No. 12, p. 1495), published a ms. chart that was prepared by E. O. Ulrich in 1928 and shown by him at Geol.

Soc. Am. meeting in N. Y. in Dec. 1928, in which he divided the Simpson of Okla. into (descending) Bromide, Criner, Tulip Creek, McLish, Falls, *Nebo*, and Joins Ranch fms.

In 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73) Ulrich published a list of his subdivisions of the Simpson, in which he substituted *Oil Creek* for the preoccupied name *Nebo*.

Named for village in Murray Co.

†Nebraska beds.

Miocene: Nebraska.

W. B. Scott, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 594–595). *Nebraska or Loup Fork proper.*—Second or middle horizon of Loup Fork. Covers a vast area from Nebr. to Mexico. Characterized by *Cosoryx*. Underlies Palo Duro horizon and is younger than Deep River horizon of Loup Fork of Mont.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 65, 79), assigned these beds to upper Mio. and to lower part of Ogallala fm., and stated (footnote p. 79): Under misapprehension of Scott's definition of "Nebraska," both Hatcher [Am. Phil. Soc. Proc., vol. 41, p. 117, 1902] and Peterson [Carnegie Mus. Annals, vol. 2, p. 473, 1904] first applied this term to part of the lower Arikaree or lower Mio.

Named for State of Nebraska.

†Nebraska conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, p. 588, fig. 52). *Nebraska cgl.* is same as Caledonia cgl. [which is same as Bohemia (No. 8) cgl., top fm. of Bohemian Range group].

Probably named for occurrence in old Nebraska mine (which later became the Caledonia mine), Ontonagon Co.

Nebraska City limestone.

Pennsylvanian: Southeastern Nebraska, northeastern Kansas, and northwestern Missouri.

G. L. Smith, 1919 (Iowa Acad. Sci. Proc. 1918, vol. 25, p. 526). *Nebraska City ledge.*—Ledge of ls. and ss. that weather into irregular slabs with a rough granular surface. Not named in Condra and Bengston's [1915] Nebr. rept. I suggest name *Nebraska City ledge* for this double ledge. Upper 2 ft. is dark-bluish ls. of fine texture along some layers and along other seams almost wholly made up of very small and thin shell fragments, lying flat; this is underlain by 1 ft. of shaly silt; followed below by ¾ ft. of dark-gray ls., in places brownish; basal 2½ ft. is aren. and calc. rock of fine texture and bluish color, consisting of a siliceous, well-assorted silt or sand embedded in calc. material. Type section is upper strata in brickyard sh. pit ¼ mi. S. of Missouri River bridge at Nebraska City, Nebr. This ledge is not a constant horizon. In passing S. it grades into ss. and cannot be recognized a few mi. S. of State line in Mo.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 116). *Nebraska City ls.*—Dark bluish-gray massive, hard, somewhat sandy and pebbly, in large rectangular blocks, weathering buff to brownish and slabby, 2 ft. 10 in. thick in bluff and clay pits SE. of Nebraska City. Fossils. Top bed of Pony Creek sh., which is top unit of McKissick Grove sh.

R. C. Moore and G. E. Condra, Oct. 1932 (Kans. and Nebr. revised classification chart). *Nebraska City ls. memb. of McKissick Grove sh.* underlies Pony Creek sh. and overlies Frenck sh. (redefined).

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 9–10), changed last definition, as explained under *Jim Creek ls.*

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), treated this ls. as basal memb. of his Caneyville ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Nebraskan stage of glaciation, also **Nebraskan drift** (Pleistocene).

Nebraskan drift is name applied to oldest Pleistocene drift of western or Keewatin part of Laurentide ice sheet; *Nebraskan stage* being applied to the time during which this drift was deposited. The drift was named for its occurrence in Nebr., where, however, it is poorly exposed. The name was originally proposed by B. Shimek (Geol. Soc. Am. Bull., vol. 20, p. 408, 1909; Sci., n. s., vol. 31, pp. 75–76, 1910). This drift has also been called *sub-Aftonian* (from fact it underlies the Aftonian interglacial deposits) and *pre-Kansan* (from fact it is an older drift than the Kansan). See also *Jerseyan drift*.

Necedah quartzite.

Pre-Cambrian (Huronian?): Central southern Wisconsin (Juneau County).

R. D. Irving, 1877 (Geol. Wis. vol. 2, pp. 523–524). *Necedah qtzite.*—A qtzite hill at foot of which stands village of Necedah. The rock is glassy, translucent, subgranular, grayish qtzite, much of it dark gray. Much more nearly allied to qtzite of Rib and Mosinee Hills, Marathon Co., than to that of Baraboo ranges.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 724). Age of qtzite at Necedah is unknown, but its lithologic similarity is with the lower Huronian.

Necessity shale member (of Graham formation).

Pennsylvanian: Central northern Texas.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 113, 114). *Necessity sh. memb. of Graham fm.* replaces South Bend sh., which is preoccupied. [Derivation of name not stated. On p. 113 he called it *Necessity sh. and ss.*]

Nechacco series.

A local facies of Kootenai fm. See G. M. Dawson, 1878 (Canada Geol. Surv. Rept. 1876–77, p. 72).

Necoxtla formation.

Cretaceous: Mexico.

J. deD. Villarello and E. Böse, 1902 (Mexico Inst. geol. Bol. 16, p. 16).

Neda formation (iron bearing).

Upper Ordovician (Richmond): Southeastern Wisconsin (Dodge and Door Counties) and northeastern Iowa.

T. E. Savage and C. S. Ross, 1916 (Am. Jour. Sci., 4th, vol. 41, pp. 187–193). The iron-ore bed in old ore pit near Neda, Wis., heretofore correlated with and called Clinton iron ore, is here named *Neda iron ore*, because it is now known to be much older than the Clinton of N. Y., Maquoketa (Richmond) fossils having been found in it. It consists of a hard nonoolitic iron-ore band ⅗ to 1⅕ ft. thick, underlain by 25 to 32 ft. of horizontally and regularly stratified beds of reddish-brown oolitic iron ore, with a thin band of iron-coated fragments of shaly material and iron pebbles near bottom. It uncon. underlies Mayville ls. in ore pit near Neda, and also at Cascade Falls, near Green Bay, and at both places it rests uncon. on Maquoketa sh. Occurs in several [listed] isolated patches or lenses in SE. Wis. It is "*Mayville ore bed*" of Chamberlin, but he applied Mayville more definitely to the ls. immediately overlying the ore.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 536). *"Clinton" or Neda fm.*—Oolitic hematite with subordinate red sh. layers and sh. pebbles. Greatest known thickness 55 ft. (at Manitowoc, Wis.). Occurs only in local lenses. Outcrops in Dodge and Door Counties.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21). *Neda fm.*, of eastern Wis., 0 to 55 ft. thick, is of Richmond age. Uncon. underlies Mayville dol. Included in Maquoketa group.

Needle Mountains group.

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). During survey of this quad. it was found that the main Algonkian qtzites and slates were like those of Uncompahgre section, but from structural complexities the portion represented was less, and, as in Uncompahgre Canyon, the upper and lower parts were not seen. In Vallecito Canyon, however, at S. margin of quad., a heavy cgl. was discovered and traced to E., where it was found in such relations with Uncompahgre qtzites and slates as to appear unquestionably to be lower part of the group. To this cgl. the name *Vallecito cgl.* is given, and to the group which includes it and the *Uncompahgre*, together with higher fms. that may hereafter be recognized, the name *Needle Mtns group* is applied. Total thickness of group unknown. Vallecito cgl. is 2,000 or more ft. thick 2 mi. E. of this quad., and overlying Uncompahgre qtzites and slates are 5,000+ ft. thick in Grenadier Range.

For many years this group was classified as Algonkian, but the terms "Algonkian system" and "Archean system" having been discarded by U. S. Geol. Survey the group is now classified as *pre-Camb.*

Neeley lake beds.

Pliocene? (lower Pliocene?): Southern Idaho (Power County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Neeley lake beds.*—Flesh- to brown-colored sandy lacustrine deposits consisting largely of reworked tuffs. Thickness 100+ ft.; base not exposed. Older than Eagle Rock tuff and younger than Pillar Falls mud flow. Exposed in bluffs of Snake River in vicinity of village of Neeley, 5 mi. SW. of American Falls.

Neelytown limestone.

Upper Cambrian: Eastern New York (Orange County).

W. Horton, 1839 (N. Y. Geol. Surv. 3d Rept., p. 148), mentioned a ls. associated with argillite in Orange Co., which "is called the *Neelytown ls.* in the neighborhood where it lies."

W. W. Mather, 1843 (Geol. N. Y., vol. 1, p. 367). *Neeleytown ls.* is a synonym of Black River ls.

H. Ries, 1897 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 442–443). In woods S. of Neely station is a small area of light-blue granular ls. which is sometimes brecciated in its upper layers. The ls. first crops out in the cross road a few hundred ft. E. of Neelytown station. A short distance to S., on W. side of road in a field, is a small ls. quarry. The rock is massive and irregularly bedded, with brecciated structure and very indistinct traces of fossils in its upper layers. Chert nodules are very abundant. [Mentions some other outcrops. This ls. is mapped as *blue Cambrian ls.*]

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 12). The Cambric or *Neelytown lss.* of Orange Co., which constitute a part of Kittatinny ls. series of N. J., are deeper-water deposits of similar character [to Greenfield ls. which overlies Potsdam ss. in Saratoga Co. The chart of Hdb. 19 shows Neelytown ls. as older than Schaghticoke sh.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 31). *Neelytown ls.* (*1839 Horton*).—This is a small outlying area surrounded by "Hudson River" shales near Neelytown, in central Orange Co. In lithologic features it resembles upper part of the Cambric lss. farther S. and is therefore provisionally considered as of same age. In early repts this ls. was doubtfully referred to Hudson River group.

†Nefsy shale member (of Graneros shale).

Upper Cretaceous: Northeastern Wyoming.

A. J. Collier, 1922 (U. S. G. S. Bull. 736, table opp. p. 76, p. 82, etc.). *Nefsy sh. memb. of Graneros sh.*—Soft dark sh. interbedded with lenses of sandy sh. Thickness 25 to 50 ft. Overlies Newcastle ss. memb. of Graneros and underlies Mowry sh. memb. of Graneros. Named for fact that large part of Nefsy townsite at Osage is underlain by this sh.

This soft sh. is now included in base of Mowry sh. memb., into which it grades, and *Nefsy* has been abandoned. (See W. W. Rubey, U. S. G. S. P. P. 165, 1930, p. 4.)

Negaunee iron-formation.

Pre-Cambrian (middle Huronian): Michigan (Upper Peninsula).

M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, pp. 65–66). *Negaunee fm.*—Schist, qtzite, and graywacke. Overlies Holyoke fm., apparently uncon., in Marquette dist. Is highest fm. of Azoic or Archean system of Mich. [As thus defined it apparently includes Negaunee fm. and overlying upper Huronian.]

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 561+). *Negaunee fm.*—The Lower Marquette iron-bearing fm. Consists of sideritic slates, grünerite-magnetite schists, ferruginous slates and cherts, and jaspilite. Thickness 1,500 ft. Rests conformably on Siamo sl. or Ajibik qtzite and uncon. underlies Goodrich qtzite. [This is present commonly accepted definition of Negaunee, although R. C. Allen (Am. Inst. Min. and Met. Engrs. Bull. 153, pp. 2579–2594, 1919) correlated Negaunee fm. with lower part of Michigamme sl., Vulcan fm. and Ironwood fm., and assigned all to middle Huronian.]

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), adopted the name *Negaunee iron-fm.*

J. L. Adler, 1935 (Jour. Geol., vol. 43, No. 2, pp. 113–132), divided Negaunee fm. of part of Marquette Co. into (descending) Jasper Knob zone, Corning Creek zone, North Lake zone, and Makasin Hill zone.

Named for exposures at and S. of Negaunee, Marquette Co.

Negli Creek limestone. (In Chester group.)

Mississippian: Southern Indiana and central western Kentucky.

W. N. Logan, 1924 (Ind. Dept. Cons. Pub. 42, pp. 11, 125. Taken from unpublished rept on Perry Co., Ind., by C. A. Malott). *Negli Creek ls.*, top subdivision of Chester group, overlies Mount Pleasant shales and sss. Thickness 20 ft. in well log in Knox Co.

C. A. Malott, 1925 (Ind. Acad. Sci. Proc., vol. 34, pp. 112–132). *Negli Creek ls.*—Uppermost fm. of upper Chester of Ind. Consists of ls., usually quite massive, but on weathered faces bedding is well brought out, the beds being from a few in. to a few ft. thick. Ranges in color from rusty yellow to white or dove color. Very fossiliferous. Thickness 2 to 20 ft. Lies at or near base of Mansfield ss. and 15 to 53 ft. above Mount Pleasant ss. Named for excellent exposures along Negli Creek, a tributary of Little Deer Creek, 4 or 5 mi. E. of Tell City, Perry Co., Ind. At Buffalo Wallow, Ky., 1½ mi. W. of Cloverport, Breckinridge Co., it is separated from Mansfield ss. by 5 ft. of upper Chester sh. and from underlying Mount Pleasant ss. by 53 ft. of sh.

Negra clay.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 61, 80). *Negra clays* is name locally used in Death Valley region for upper borax silts exposed in fine section in E. wall of Furnace Canyon, beneath Mesa Negra [E. of Death Valley, in Inyo Co., Calif.]. [On p. 61 Keyes says these clays are known as *Mesa Negra beds*, and that they are tentatively considered as Miocene.]

Nehant limestone.

Misprint (on p. 284 of U. S. G. S. Bull. 191) for *Nahant ls.*

Nehawka limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 6, 33). *Nehawka ls.*—Hard gray bedded ls. forming base of Andrew (Lawrence) sh. in Weeping Water section, Nebr. Exposed in bed of North Branch of the Weeping Water 2 mi. N. of Nehawka. Best shown in sec. 6, T. 10 N., R. 13 E. Largest exposures show thickness of 4 ft. 6 in. (under wagon bridge just N. of center of sec. 6, T. 10 N., R. 13 E.), but correlated neighboring exposures indicate total thickness of 10 ft. or more.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 34). *Nehawka ls.* is Iatan ls. memb., and latter name is now used.

Neihart quartzite.

Pre-Cambrian (Belt series): Central western (Philipsburg region) and central southern (Little Belt Mountains) Montana.

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Neihart qtzite and ss.*—Coarse reddish sss., with interbedded dark-greenish layers of fine-grained ss. and sh., 300 ft.; underlain by 400 ft. of pinkish-gray massive, sometimes cross-bedded qtzite, in some parts a compact hard ss. Basal fm. of Belt series. Underlies Chamberlain shales. Named by W. H. Weed, for its occurrence on

Neihart Mtn, where the qtzites and sss. are in contact with the gneiss. Thickness measured by Weed 700 ft. [The compiler has been unable to find any Neihart Mtn, and assumes that Walcott referred to mtn slightly NE. of Neihart, which is called Long Mtn on Little Belt Mtns topog. map, as in Little Belt Mtns folio (No. 56) Neihart qtzite is mapped over S. part of Long Mtn and over large area to S. and E. of village of Neihart.]

Neihart porphyry.

Cretaceous (?): Central Montana (Little Belt Mountains).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Neihart porphyry.*—Rhyolite porphyry, pale yellowish or earthy-colored. Intrudes Archean rocks. Is probably Cret. Occurs on divide above Neihart and on slopes drained by Snow and Mackey Creeks.

P. A. Schafer, 1935 (Mont. Bur. Mines and Geol. Mem. 13). *Snow Creek (Neihart) rhyolite or quartz porphyry* is the rock called *Neihart porphyry* by Weed. It is probably early Tert.

†Nelagoney sandstone.

Pennsylvanian: Central northern Oklahoma.

L. C. Snider, 1911 (Okla. Geol. Surv. Bull. 7, p. 221). *Nelagony ss.*, 40 ft. thick, underlies Elgin ss. in Pawhuska quad., and is separated from underlying Bigheart ss. by 85 ft. of sandy and clay shales. Included in upper part of Sapulpa group, in beds approx.=Buxton fm. of Kans.

Upper part only of unit for which name Nelagoney fm. was later adopted, and is approx.=Wynona ss. memb.

Named for Nelagoney, Osage Co.

Nelagoney formation.

Pennsylvanian: Central northern and northeastern Oklahoma.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 75). *Nelagoney fm.*—Named by D. W. Ohern, in unpublished ms. Consists of shales and sandy shales interstratified with sss. and with ls. lentil, 20 ft. thick, near middle. Thickness averages 500 to 600 ft. in Osage Co. Basal bed is Bigheart ss. memb. Underlies Elgin ss. and overlies Ochelata fm. Type loc., Nelagoney, Osage Co.

Nelchina limestone.

Lower Cretaceous: Central southern Alaska (Matanuska district, Cook Inlet region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 313–315, table opp. p. 474). *Nelchina ls.*—Massive dark-colored fine-grained unaltered ls. separated by thin laminae of gray sh.; some beds so highly siliceous they probably should be called calc ss. Thickness 100 to 300 or 400 ft. Occurs in several isolated areas, mostly small, on hilltops at headwaters of Nelchina River and of Billy Creek. Overlies, with apparent conformity, Lower Cret. tuff and cgl.; at some places is uncon. overlain by Tert. cgl. The Upper Cret. strata that crop out on Billy Creek were not observed in contact with the ls. Almost unfossiliferous, but assigned to Lower Cret.

Nellie gas sand.

A subsurface sand, of Penn. age, in Stephens Co., Okla., lying at a depth of 1,840 ft. in Nellie pool.

Nellie Bly formation.

Pennsylvanian: Northeastern, central northern, and central Oklahoma.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 74). *Nellie Bly fm.*—Named by D. W. Ohern in unpublished ms. Alternating shales and hard gray sss., the latter ranging in thickness from a few in. to several ft., from 15 ft. on Kans. line to 200 ft. in SE. Osage Co. Is middle fm. of Drum group. Rests on Hogshooter ls. and underlies Dewey ls. Named for Nellie Bly Creek, southern Washington Co. Enters Okla. in NW. Nowata Co., and extends SW. across Nowata, Washington, SE. Osage, and Creek Counties as far as northern Okfuskee, where it merges with Francis fm. [Later repts give thickness up to 400± ft.]

Drum group is no longer used to include these rocks.

Nellie Juan granite.

Mesozoic (?): Southeastern Alaska (Prince William Sound region).

U. S. Grant and D. F. Higgins, 1910 (U. S. G. S. Bull. 443, pp. 37, 46). *Nellie Juan granite*.—Typical biotite granite, chiefly light pink; the porphyritic facies is light gray. Occurs in W. part of Prince William Sound, on S. shore of Port Nellie Juan. Cuts Valdez group.

Nelson granodiorite.

Jurassic: British Columbia.

C. W. Drysdale, 1915 (Canada Geol. Surv. Mem. 56, p. 48).

Nelson limestone.

Ordovician: Manitoba.

A. F. Foerste and T. E. Savage, 1927 (Denison Univ. Bull. Sci. Lab. Jour., vol. 22, pp. 4, 8).

Nelson Hill facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons. Div. Geol. Pub. 98, pp. 77, 145, etc., 1931) to lithologic development of his Locust Point fm. in a part of southern Ind.

Nelson Mountain quartz latite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). The upper flow, 0 to 350 ft. thick, of Piedra group (in Potosi volcanic series) in Creede dist. Is a quartz latite of uniform character. Named for fact it is cap rock on Nelson Mtn, where it is less than 200 ft. thick. Younger than Rat Creek quartz latite.

Nelson River limestone.

Ordovician: Canada.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 342, 344).

Nemaha formation.
Nemaha member. (In Wabaunsee group.)
Nemaha subgroup.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 8, 14, 26). *Nemaha fm.*—A fm. of lss. and shales, 110 to 130 ft. thick, underlying McKissick Grove shales and overlying City Bluffs (Scranton) shales. Includes (descending) Tarkio ls., Preston ls., Fargo ls., Burlingame ls., and Rulo ls. members and the separating shales. Best developed in Big Nemaha Valley, with exposures btw. Tecumseh and Humboldt and btw. Union and Nebraska City, N. of Rulo, and at mouth of the Big Nemaha.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 62, 71). The *so-called Nemaha memb. or fm.* is reduced by excluding at base the Rulo ls. and overlying Silver Lake sh., which some geologists would assign to Scranton sh. The "Preston" ls. is the Emporia; the "Fargo" ls. is the Wakarusa, both of which have priority. Nemaha fm. is dropped provisionally, to be revived if it is decided by State and Federal Geol. Surveys that Wabaunsee beds represent 2 fms., and bdy of lower one is placed at Rulo ls. or at Silver Lake coal.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 4, 10). *Nemaha subgroup* is adopted to include Tarkio ls. fm. at top, down to base of Burlingame ls. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 215). In Nebr. Geol. Surv. Bull. 5, 1932, table C, p. 18, by G. E. Condra, R. C. Moore, and C. O. Dunbar, strata from base of Burlingame ls. to top of Tarkio are called "*Nemaha ls.*" Moore was not consulted on this usage and has never adopted it. [Nemaha is discarded by Kans. Surv., being preceded by dagger in this 1936 Bull.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Nemenjish series.

Pre-Cambrian: Quebec.

H. C. Cooke, 1919 (Jour. Geol., vol. 27, pp. 75, 188, 374).

Nemire sand.

A subsurface sand, of Penn. age, in northern Okla., lying lower than Red Fork sand and higher than Glenn sand.

Nemo series.

Pre-Cambrian: Southwestern South Dakota (northern Black Hills).

J. J. Runner, 1926 (Chicago Univ. Abstracts of Theses, Sci. ser., vol. 2, pp. 229–234). *Nemo series.*—Pink to gray qtzites, quartz and graywacke schists, and iron fms. occupying interior of oval-shaped area of about 5 sq. mi. extent to W. of village of Nemo [Lawrence Co.]. The iron fms. consist of beds containing alternating bands of crystalline quartz with specular hematite and magnetite, and grade into qtzite above, below, and laterally. Believed to be uncon. with overlying series of thick cgls. alternating with qtzite and quartz schist, siliceous ls. and sl., with iron fms. near base.

In 1934 (Am. Jour. Sci., 5th, vol. 28, p. 355) Runner called the rocks *Nemo system;* divided them into qtzites (above) and some iron fm. (below); and stated that they uncon. underlie Estes system.

Nenana gravel.

Tertiary (Eocene or later): Central Alaska (Nenana River region).

S. R. Capps, 1912 (U. S. G. S. Bull. 501, pp. 30–34). *Nenana gravel.*—Widespread series of elevated gravels which cover a large area in foothill belt of Bonnifield region. Named for exposures on Nenana River near mouths of Lignite and Healy Creeks. Greatest known thickness 1,760 ft., on lower Healy Creek. No determinable fossils. Underlain by Eo. coal-bearing series, probably uncon.; overlain by glacial deposits of probable Pleist. age. May be Mio.

Nenzel rhyolite breccia.

Triassic (Middle?): Northwestern Nevada (Rochester district).

A. Knopf, 1924 (U. S. G. S. Bull. 762). *Nenzel rhyolite breccia.*—Explosive outbursts of (descending): (1) Massive breccia, no trace of bedding, fragmental origin obvious, especially in basal part, 325 ft.; (2) stratified tuff and breccia, in bed 3 inches to 3 ft. thick, 25 ft.; (3) cgl. breccia or subangular cgl., 0 to 10 ft.; (4) well-stratified breccias carrying abundance of euhedral quartz crystals, 50 ft. Total thickness 30 to 600 ft. Lies 0 to 70± ft. below Weaver rhyolite. Forms summit of Nenzel Hill. Is of Triassic (Middle? Tr.) age.

Neocene.

A term that had considerable usage in early geol. repts to cover the Plio. and Mio. series, but is now used in repts of U. S. Geol. Survey in a quotational sense from early repts.

Neodesha sandstone.

Pennsylvanian: Southeastern Kansas.

Robt. Hay, 1887 (Kans. Acad. Sci. Trans., vol. 10, p. 7 and cross section). *Neodesha ss.*—Ss., 30 to 40 ft. thick, exposed at Neodesha. Separated from overlying Dun ls. by 80 to 100 ft. of sh.

There is no other record of this name. It appears to apply to the whole or part of Chanute sh.

Named for Neodesha, Wilson Co.

Neogene.

A term employed by European geologists to include the Miocene and Pliocene series of American geologists. (See also *Eogene* and *Paleogene.*)

Neosho shale member (of Garrison shale).

Permian: Eastern Kansas, southeastern Nebraska, and northern Oklahoma (?).

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 764–771, 799–800). *Neosho fm.*—Gray lss. alternating with varicolored shales. Thickness 130 ft. Underlies Strong flint [Wreford ls.] and overlies Cottonwood shales [Florena sh.].

Named for excellent outcrops in Neosho Valley, near Council Grove, Morris Co., Kans.

For the many units into which this sh. has been divided in recent years, see Kans.-Nebr. Perm. chart compiled by M. G. Wilmarth, 1936. The name appears to have recently been discarded by Kans. Geol. Survey.

Neosho limestone.

Pennsylvanian: Central eastern Kansas (Lyon County).

A. J. Smith, 1903 (Kans. Acad. Sci. Trans., vol. 18, p. 99). *Neosho ls.*—Ls., 30 to 40 ft. thick, in Lyon Co., characterized by rough weathering, many cavities filled with calcite crystals, a conglomeratic appearance, and clusters of *Fusulina cylindrica*. Separated from overlying Burlingame ls. by 54 ft. of sh. containing a thin ls. and some ss. Underlain by 40 ft. of sh.

Appears to be same as Topeka ls.

Named for Neosho Rapids, Lyon Co.

Neozoic.

A term employed by some European geologists to include Tertiary system of American geologists.

Nepigon group.

Same as Nipigon.

†Neponset conglomerate.

Carboniferous or Devonian: Eastern Massachusetts.

W. W. Dodge, 1882 (Boston Soc. Nat. Hist. Proc., vol. 21, pp. 210–213), applied *Neponset cgl.* to cgl. mapped as Roxbury cgl. by B. K. Emerson in U. S. G. S. Bull. 597, 1917.

†Nerinaea flags (also †Nerinea flags).

A paleontologic name applied by R. T. Hill (Biol. Soc. Wash. Proc., vol. 8, pp. 10–15, 1893) to lss. and marls locally forming top bed of Glen Rose ls. of Tex.

Nerola.

See *Neroly*.

Neroly formation. (In San Pablo group.)

Miocene (upper): Central western California (Mount Diablo region).

B. L. Clark and A. O. Woodford, 1927 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 17, p. 69). Uncon. on San Lorenzo deposits is San Pablo group, divided into two fms., the Cierbo and the *Nerola*. Uncon. on the San Pablo is a series of tuffs and sss.; the tuffs have generally been referred to Pinole tuff, the sss. to Orinda fm.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 764–767, 774, pls. 15, 20). *Neroly fm. or Astrodapsis tumidus zone.*—Ss. cgl., sh., 4,000 ft. thick W. and S. of Mount Diablo; 250 ft. thick N. of Mount Diablo. On S. side of Mount Diablo it uncon. underlies 1,000± ft. of sss. and cgls., mostly marine, correlated by writer with Jacalitos fm., and it overlies Cierbo fm. Is of upper Mio. age, and included in San Pablo group. [This is present approved definition of U. S. Geol. Survey.]

Neruokpuk schist.

Paleozoic or older: Northern Alaska (Canning River region).

E. D. Leffingwell, 1919 (U. S. G. S. P. P. 109, pp. 103–105, map). *Neruokpuk schist.*—Chiefly qtzite schist. Oldest exposed fm. Both upper and lower contacts believed to be fault contacts. Metamorphism so great that it is unquestionably pre-Carbf. Typically developed on 3 sides of Lake Peters, also near forks of Canning River. *Neruokpuk* is Eskimo name for Lakes Peters and Schrader.

Neslen coal-bearing member (of Price River formation).

Upper Cretaceous: Central eastern Utah (Book Cliffs).

D. J. Fisher, 1936 (U. S. G. S. Bull. 852). Series of relatively light-colored alternating sss. and shales, in about equal proportions. A rather heterogeneous unit of brackish-and-fresh-water origin. Thickness 250 to 410 ft. Underlies Farrer non-coal-bearing memb. and overlies Sego. ss. memb. of Price River fm. Includes Chesterfield coal zone, Bluecastle ss. bed, Sulphur Canyon ss. bed, Thompsons Canyon ss. bed, and Ballard and Palisade coal zones. Named for Neslen Canyon, in which town of Sego is located.

Nespelem silt.

Pleistocene: Northeastern Washington (Colville Indian Reservation).

J. T. Pardee, 1918 (U. S. G. S. Bull. 677). *Nespelem silt.*—Largely very light-colored silt but includes small amount of gravel. Unconsolidated lake and stream deposits of glacial origin, deposited on terraces that line Columbia River Valley and the correlated flats that fill the mouths of tributaries at elevations btw. 1,700 and 1,800 ft., including the well-developed flat below Nespelem village. Max. thickness, equiv. to vertical distance btw. Columbia River and the Nespelem flat, is about 750 ft. Thickness gradually lessens upstream to 500 or 600 ft. near N. bdy of Colville Indian Res. Near mouth of Nespelem River this silt overlies glacial drift of earlier epoch, and along Columbia River above mouth of the Spokane it is deposited on the latest drift. With little doubt it is=White Silt fm. of Dawson in southern B. C.

Nester ground moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan.

W. A. Ver Wiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 164). Lies in SE. part of Nester Twp. (T. 21 N., R. 1 W.)

Neudeckian stage.

A term applied by W. Upham (Am. Geol., vol. 16, p. 104, 1895) to a stage of the Pleist. "Included in Champlain epoch."

Neva limestone. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

J. W. Beede, Sept. 1902 (Kans. Univ. Sci. Bull., vol. 1, p. 180). *Neva ls.* proposed in unpublished mss. of C. S. Prosser and J. W. Beede. Consists of gray ls., 6 to 8 ft. thick, in two beds separated by sh. layer. Weathers rough, which caused Swallow to call it "drybone" ls. Underlies Eskridge shales and overlies Elmdale fm. [See also Prosser, Jour. Geol., vol. 10, p. 709, Oct.–Nov. 1902, and U. S. G. S. Cottonwood Falls folio, No. 109, p. 2, 1904.]

Some authors have treated the Neva as basal fm. of Perm. Later repts give thicknesses up to 28 ft., and state that the sh. separating the two lss. is 15 to 20 ft. thick. G. E. Condra and C. E. Busby (Nebr. Geol. Surv. Paper No. 1, p. 30, 1933) stated that different members or combinations of members of their Grenola fm. (defined in rept cited) have been correlated as the Neva at places in Nebr. and Kans. They restricted *Neva* to top bed (12½ ft.) of their Grenola fm., q.v. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), placed Perm.-Penn. bdy at top of his Brownville ls. fm., which threw Neva ls. and several underlying fms. into Perm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 50), showed *Neva ls.* of "old classification" is same as Grenola ls. of "revised classification," which he divided into (descending) Neva ls. [restricted], Salem Point sh., and Burr ls., and showed it as underlying Eskridge sh. and overlying Roca sh. (top bed of Elmdale sh. of "old classification"). He assigned it to Perm.

N. W. Bass (Kans. Geol. Surv. Bull. 23, in press). At type loc. of Neva ls. (near Neva Station, Cottonwood River Valley [Chase Co., Kans.]), it is a prominent ledge-forming rock 11 ft. thick; light gray with light-buff hue; weathers to pitted, sharply rough surface; many fossils. About 4½ ft. above main ledge in this vicinity is a light-gray ls. 1 ft. or less thick, separated from main ledge by calc. gray sh. To S. this upper thin ls. thickens, becomes massively bedded, crops out with a slightly pitted, sharply rough surface, and closely resembles the main ls. of type loc. Early Kans. repts restricted Neva ls. to main ledge-forming ls. of type loc., but rept on Cowley Co., by writer, placed in Neva ls. both these lss. and the intervening sh. In southern Kans. and northern Okla. these two lss. merge into one thick ls. The Neva as expanded by Moore and Condra included all beds btw. Roca sh. below and Eskridge sh. redefined above. Subsequent to preparation of this rept the expanded Neva was named *Grenola fm.* by Condra and Busby [1933 rept cited above], and they restricted Neva to the ls. originally named by Prosser.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

The U. S. Geol. Survey has not yet had occasion to consider, for its publications, these recent innovations in classification.

Nevada limestone.

Upper and Middle Devonian: Eastern Nevada (Eureka region).

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, map 4, of NE. Nev.). "Nevada (Chemung to Upper Helderberg)." [Shown as upper part of Dev., and younger than Ogden qtzite.]

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 264–266). *Nevada ls.*—Lower horizons indistinctly bedded, saccharoidal texture, gray color, passing up into strata distinctly bedded, brown, reddish brown, and gray, frequently finely striped, producing a variegated appearance. Upper horizons are massive, well bedded, and bluish black, highly fossiliferous. The fm. is mainly ls., although intercalated beds of sh. and qtzite occur. Thickness 6,000 ft. Grades into underlying Lone Mountain ls. and is conformably overlain by White Pine sh. Named for great development in State of Nev.

C. W. Merriam, 1936 (Geol. Soc. Am. Proc. 1935, p. 92), restricted *Nevada fm.* to lower part of Nevada ls. of previous repts, which he divided into 5 paleontologic zones, the lowest of which he assigned to Oriskany (?) and the next younger one to Onondaga. The beds of Upper Dev. age he assigned to a new (unnamed) fm. This restriction of Nevada ls. has not been considered by U. S. Geol. Survey for its publications.

†Nevadan series.

A name applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 55, 80), to Nevada ls. (Dev.) of Nev., and to supposedly contemp. deposits in other States. *Nevadan* has also been applied to a series of late Jurassic intrusives in northern Calif. (Redding, Weaverville, and Red Bluff quads.). (See N. E. A. Hinds, Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, pl. 3, p. 104.)

Nevadian revolution.

A term applied by C. Schuchert and C. O. Dunbar (1933 Textbook geol., p. 64) to diastrophic movements in early Lower Cret. and late Jurassic time. Is called *Nevadan* by some geologists.

Newala limestone.

Lower Ordovician (Beekmantown): Northern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 95, etc.). *Newala ls.*—Much ls. and proportionately little dol. Most of ls. is thick-bedded, compact or noncrystalline or textureless, dark gray, pearl gray (which predominates), and bluish gray. Yields very little or no chert. Thickness 1,000 ft. in Cahaba Valley. Contains Beekmantown fossils. Underlies Odenville ls. and overlies Longview ls. (both of Beekmantown age). Named for Newala P. O. [Shelby Co.], which is located upon a broad belt of the fm. Best exposures are about ½ mi. NW. of Pelham.

New Albany shale.

Upper Devonian: Indiana and north-central Kentucky.

W. W. Borden, 1874 (Ind. Geol. Surv. 5th Ann. Rept., pp. 150, 152, 158, 172). *New Albany black sl.*—Geographic name applied to fm. which in previous Ind. repts has been called "Dev. black sl." and "Dev. black sh." Thickness 50 to 120 ft. Usually jet black, and occurs in thick beds, but after exposure exhibits thin laminated cleavage and becomes of pink, drab, or mottled color. Invariably capped by ferruginous ls. Rests on the blue crinoidal [Sellersburg] ls., which overlies the Hydraulic ls. [Jeffersonville ls.].

W. S. Blatchley and G. H. Ashley, 1898 (Ind. Dept. Geol. and Nat. Res. 22d Ann. Rept.), and G. H. Ashley, 1899 (Ind. Dept. Geol. and Nat. Res. 23d Ann. Rept., p. 74), defined *New Albany sh.* as overlain by Rockford ls. and underlain by 25 to 47 ft. of brown sh.; but in all other repts the brown sh. is included in New Albany sh., which is defined as overlying Sellersburg ls. and underlying Rockford ls. Exact relations to Ohio sh. and Chattanooga sh. undet.

The New Albany sh. has been classified by most authorities as Upper Dev., but Schuchert, Ulrich, and Bassler have considered it partly Dev. and partly Miss. J. W. Huddle has made special study of conodonts of New Albany sh. of Ind., and concludes (Bulls. Am. Pal., vol. 21, No. 72, Nov. 5, 1934) that its deposition in Ind. began in Genesee time and that upper 5 or 10 ft. afford only likelihood of Miss. age of any part of fm. Most of conodonts from this upper part are new sp., but aspect of entire fauna indicates all of fm. is Dev.

Named for exposures at New Albany, Floyd Co., Ind.

New Arcadian amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs near base of Central Mine group and is older than Arcadian amygdaloid. The mineralized part is the New Arcadian lode. Named for occurrence in New Arcadian mine, Houghton Co.

New Arcadian flow.

Includes New Arcadian amygdaloid and underlying trap.

Newark group.

Triassic (Upper): Connecticut to North Carolina.

W. C. Redfield, 1856 (Am. Jour. Sci., 2d, vol. 22, p. 357; Am. Ass. Adv. Sci. Proc., vol. 10, p. 181). I propose latter designation [*Newark group*] as a convenient name for these rocks [the red sss. extending from N. J. to Va.] and to those of Connecticut Valley, with which they are thoroughly identified by footprints and other fossils, and I would include also the contemp. sss. of Va. and N. C.

In Mass. the Newark group includes (descending) the following sed. fms. and interbedded flows: Chicopee sh., Granby tuff, Hampden diabase, Longmeadow ss., Holyoke diabase, Talcott diabase, Mount Toby cgl., and Sugarloaf arkose. In N. J. and SE. Pa. it includes (descending): Brunswick sh., Lockatong fm., Stockton fm., and Watchung basalt (a flow; the diabase dikes and intrusives not being a part of the Newark, but younger). In southern Pa. it is divided into Gettysburg sh. above and New Oxford fm. below. In Va. it has been divided into several units (see Va. chart I). In Deep River coal field, N. C., it includes (descending) the Sanford, Cumnock, and Pekin fms.

Named for development of rocks at and around Newark, N. J.

The fauna and flora of Newark group of Connecticut Valley are described in U. S. G. S. Bull. 597, 1917, pp. 105–132.

Newark granite.

Devonian: Northeastern Vermont (Caledonia County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Quarried in E. part of Newark Twp, in NE. part of Caledonia Co., according to pl. 18, 11th Rept. Vt. State Geol., 1918.

Newaukum series.

Pre-Tertiary (?): Southwestern Washington.

H. E. Culver, 1919 (Wash. Geol. Surv. Bull. 19, pp. 18–33). *Newaukum series.*—Oldest rocks in Thurston, Cowlitz, Gray Harbor, and Lewis Counties. Consists of (descending): (1) Breccia of red volcanic fragments in dense black matrix, absent in places; grades down into (2) graywacke, in places replaced by dense siliceous sh., nearly black sl., with, in places, interbedded ls. lenses; (3) dense resistant cgl. at base, with, in places, interbedded ls. lenses. Total thickness unknown; max. exposed not more than 100 ft. Underlies Puget series (Eocene) with possible uncon. Is probably pre-Tert. Typically exposed in channel of North Fork of Newaukum River, in sec. 19, T. 14 N., R. 1 E. Possibly correlates with Peshastin fm.

†New Bedford gneiss.

Early Paleozoic (pre-Devonian): Southeastern Massachusetts.

E. Hitchcock, 1833 (Rept. geol., min., bot., and zool. of Mass., pp. 389–390). *New Bedford gneiss.*—At New Bedford this gneiss is schistose, passes into mica sl., and contains a beautiful variety of porphyritic gneiss in boulders.

Included in Dedham granodiorite as mapped by B. K. Emerson in U. S. G. S. Bull. 597, 1917.

Newberger sand.

A subsurface sand in lower part (Hiawatha memb. of Nightingale) of Wasatch fm. of Vermilion Creek gas area, on Wyo.-Colo. State line in Sweetwater Co., SW. Wyo., and Moffat Co., NW. Colo. Lies lower than Wilson gas sand. (See W. T. Nightingale, A. A. P. G. Bull., June 1935.)

Newbern shale (In Sumner group.)

Permian: Northeastern Kansas.

R. C. Moore, 1936 [See under *Donegal ls.*]

Newberry sand.

Permian (?): Central southern Oklahoma (Garvin County).

A. R. Denison, 1923 (A. A. P. G. Bull., vol. 7, No. 6, pp. 627–644). *Newberry sands.*—Occur around edges of Robberson buried hills [SW. part of Garvin Co.], at depth varying from 1,375 to 1,877 ft. Named for the discovery well. Are of Perm. age, but older than Garvin and Mauldin beds.

R. Roth, 1927 (Okla. Geol. Surv. Bull. 40K). In old ravines and gullies of these buried hills, and also spread over the hills themselves at a depth varying from 1,375 to 1,877 ft., is a sand series called in Denison's rept the *Newberry sands*, after the discovery well, Newberry No. 1. These sands are undoubtedly an erosional residue and probably represent an overlap of the last of the Penn. seas in the area, prior to Perm. deposits, as they may be correlated with the Pontotoc cropping out to SE. There can be little doubt they represent a fm. older than Perm.

According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 179, these sands are of Penn. age.

Newberry.

Name applied to a Pleist. glacial lake in central N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, p. 614, 1932.)

New Brighton fire clay.

See under *Kittanning fire clay.*

Newburg limestone.

Pennsylvanian: Western Kentucky (Henderson County).

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pl. showing geol. section of Henderson Co.). *Upper Newburg ls.*—Hard gray rock with some lime, 4 ft. 1 in. thick, about 66 ft. below top of Upper Coal Measures; separated from *Lower Newburg ls.* (hard gray heavy rock 3½ ft. thick) by Little coal (4 ft. 5 in. thick at Newburg) and by 3 ft. 7 in. of sh. or fire clay.

Newburg sand.

A subsurface sand, 0 to 30 ft. thick, that occurs about 200 ft. above base of Niagara ls. in Cleveland region of northern Ohio. It has been most successfully prospected in SW. part of Cleveland, which is known as Newburg and Brooklyn. W. Stout et al. state (Geol. of nat. gas, A. A. P. G., 1935, p. 907) that it lies near contact btw. Salina fm. and underlying Niagara.

Newburgh limestone.

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept. of 1st dist., p. 257). The range of ls. described in 2d ann. rept under name of *Barnegat ls.*, and in 3d rept under the name *Newburgh ls.* occupies a small area in the dist. under examination this year. [The compiler has been unable to find *Newburgh ls.* in 3d rept. but on pp. 151–152 of that rept, in rept of W. Horton on geol. of Orange Co., is the following: "On the whole our blue ls. formation is abundant for useful purposes, and conveniently distributed. It is found at Newburgh." (He mentions several other places, also the "superior lime" that is burned from the *ls. at Newburgh.*) "There is little if any good ls. in the county, except at Newburgh, and as a consequence the *Newburgh lime* has comparatively excluded all other from use."]

W. W. Mather, 1843 (N. Y. Nat. Hist. Surv. vol. 1, pp. 367, 410, pls. 45, 46). *Newburgh ls.* is same as Barnegate ls.

Newbury volcanic complex.

Probably early Devonian: Northeastern Massachusetts (Essex County).

B. F. McDaniel, 1884 (Essex Inst. Bull., vol. 16, p. 165), in describing the geol. of Newbury, Mass., casually applied *Newbury felsite* to the rocks lying btw. the granite and the diorite of that area. In U. S. G. S. Bull. 597, 1917, B. K. Emerson named the felsitic fm. referred to the *Newbury volcanic complex*, and L. LaForge described it (pp. 161–164) as consisting of flows (of rhyolite, andesite, dacite, basalt, etc.), breccias, tuffs, and sh. and as occupying Newbury and Parker River basins in towns of Rowley and Newbury, Essex Co.

On basis of the few fossils obtained, E. O. Ulrich has classified the fm. as probably early Dev.

Newbury granite gneiss.

Cambrian: Northeastern Vermont (Orange County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Camb. of eastern Vt., but without definition. Probably named for village or twp in Woodsville quad., E. part of Orange Co.

Newburyport quartz diorite.

Early Paleozoic (pre-Devonian): Northeastern Massachusetts (Essex County and Boston Basin) and southeastern New Hampshire.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 177–178 and map). *Newburyport quartz diorite.*—A medium-grained, somewhat gneissic rock, consisting essentially of andesine-labradorite, orthoclase, quartz, and hornblende, with accessory biotite, augite, ilmenite, magnetite, apatite, rutile, and titanite. Named for occurrence at Newburyport, Essex Co., Mass. Assigned to Dev. (?).

L. LaForge, 1932 (U. S. G. S. Bull. 839), changed age to *early Paleozoic*. He regards it as "certainly pre-Dev."

Newcastle formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canadian Min. Inst. Trans., vol. 15, p. 338). Included in Nanaimo series.

Newcastle sandstone member (of Graneros shale).

Upper Cretaceous: Northeastern Wyoming.

E. T. Hancock, 1920 (U. S. G. S. Bull. 716, pp. 39, 42, 96). *Newcastle ss. memb. of Graneros sh.*—Reddish to light-yellow ss. associated with black carbonaceous sh. In Lance Creek field, Wyo., it is divisible into upper ss., 20 ft.; middle sh., 15 ft.; lower ss., 15± ft. In Mule Creek field, Wyo., the Newcastle memb. is 3 to 15 ft. thick. In both fields it is separated from underlying Dakota ss. by 175 ft. of dark-gray to black sh., and from overlying Mowry sh. memb. of Graneros by 25 ft. of dark sandy sh. [Nefsy sh. memb. of Collier's 1922 rept. but now included in Mowry sh. and Nefsy discarded]. Named because it is conspicuously developed at Newcastle, Wyo.

E. F. Schramm and H. J. Cook, 1921 (Kanoka Pet. Co., Geol. Dept., Bull. A, pp. 12, 14). In Agate, Nebr., anticline [Sioux Co., NW. Nebr.] *Newcastle ss. memb. of Graneros sh.* is 3 to 50 ft. thick.

Newcastle Creek formation.

Pennsylvanian: New Brunswick.

W. S. Dyer, 1926 (Canada Geol. Surv. Mem. 151, p. 8).

New Chapel chert bed. (In Silver Creek limestone.)

Middle Devonian (Hamilton): Southeastern Indiana (Clark County).

G. I. Whitlatch and J. W. Huddle, 1932 (Ind. Acad. Sci. Proc., vol. 41, pp. 363–371). *New Chapel chert bed.*—A bed in uppermost part of Silver Creek ls. in Clark Co., which normally contains abundance of chert, often in distinct horizontal bands, embedded in a matrix of drab fine-grained ls. lithologically similar to Silver Creek ls. Is characterized in basal part by distinctly bedded character and extreme abundance of chert as compared with that found in lower part of Silver Creek fm. In literature has been called "bastard rock" and "cement rock." Since this chert bed is a fairly persistent and distinct lithologic unit, and since earlier writers have seen fit to discriminate btw. the chert bed and the "cement rock," it is proposed that the bed be called *New Chapel chert bed of Silver Creek ls.*, from a small country church in SW¼SE¼ sec. 37, Clark Grant, Clark Co. Well exposed near top of hill in a road cut a few yds E. of church. Better exposed at Watson and Charleston, where overlying and underlying fms. are present. Thickness a few ft. to 14 ft.; absent in few places only. In a few places an inch or so of sh. separates the cement rock from New Chapel chert bed.

New Corydon limestone.

Silurian (Niagaran): Northeastern Indiana.

E. R. Cumings and R. R. Shrock, 1928 (Ind. Dept. Cons., Div. Geol. Pub. 75, pp. 53, 54, 113–117). *New Corydon ls.*—A series of irregularly bedded brown cherty layers of impure ls. with intercalated carbonaceous partings. Has conspicuous blocky nodular appearance on weathered surfaces. Thickness few ft. to possibly 20 ft. Fossils listed. Fauna, with its Lockport affinities, may indicate brief return of Lockport fauna at close of Niagaran, or the New Corydon may represent closing phase of Guelph deposition, in which practically all typical Guelph forms had disappeared. Conformably overlies Huntington fm. Is probably overlain by Kokomo ls. or its eastern equivalent. We know of no fm. like the New Corydon in Ohio, and so far as we have observed it is not present in western Ind. Is exposed at but 3 localities—in vicinity of New Corydon [Jay Co.]; at and near Linn Grove; and 2½ to 3 mi. E. of Huntington, along Little River. In vicinity of New Corydon the fm. crops out in old bed of the Wabash, just N. of Jay City, and in the Karsch and the Smith & Baker quarries. Is 15 ft. thick in Karsch quarry.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 159). *New Corydon fm.* is not exposed S. of NE. corner of Jay Co.

Newett limestone member (of Weber? formation).

Pennsylvanian: Central Colorado (Park and Chaffee Counties).

D. B. Gould, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 973–1009). *Newett ls. memb. of Weber (?) fm.*—Resistant lss., light gray to dark gray, in layers less than 1 in. to 2 ft. thick; dense; with conchoidal fracture. Thickness 20 ft. Lies 330± ft. above Leadville ls. (upon which it rests uncon.) and about 1,375 ft. below top of Weber (?) fm. in Salt Creek area, Park and Chaffee Counties. Named for abandoned town of Newett, in sec. 3, T. 14 S., R. 77 W., near which it is exposed.

Newfoundland coal formation.

Age (?): Newfoundland.

J. B. Jukes, 1839 (Rept. on geol. of Newfoundland, p. 4).

†Newfoundland quartzite.

†Newfoundland grit.

Middle Devonian (Onondaga): Southeastern New York and northern New Jersey.

E. C. Eckel, 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 1, p. r148). *Newfoundland qtzite.*—Usually a light-colored qtzite but locally conglomeratic. At some localities carries fossils which correlate it with basal Dev. Oriskany qtzite. The fm. name here proposed is in allusion to the exposure of the qtzite at Newfoundland, N. J., where its lithologic and paleontologic characters are well shown and were described by Britton and Merrill in 1886 (N. J. State Geol. Rept.). Is exposed at several other points along margin of the Dev. outlier in both N. Y. and N. J. Underlies Monroe shales.

H. B. Kümmel and S. Weller, 1902 (N. J. Geol. Surv. Ann. Rept. State Geol. 1901, p. 18). *Newfoundland grit* consists of 115 ft. of rather thin-bedded hard greenish ss. underlain by 100 ft. of heavy-bedded fine-grained cgl. Contains a mixed Oriskany-Corniferous fauna. Grades into overlying Monroe shales. Overlies Decker Ferry ls., but nowhere seen in contact with that fm., so that intervening Helderbergian strata may be present. Ledges of this grit have been found at Newfoundland [Morris Co., N. J.].

This name was replaced by Kanouse ss. in 1908. The Kanouse is of Onondaga age.

Newfoundland series.

Cambrian: Newfoundland.

B. F. Howell, 1926 (Canadian Field Nat., vol. 40, pp. 53, 55).

New Galilee clay shale. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania (New Castle quadrangle).

F. W. DeWolf, 1929 (Topog. and Geol. Atlas Pa., No. 5, New Castle quad., pl. 6, pp. 30, 31, etc.). *New Galilee clay sh.*—Lies 10 to 20 ft. below Brush Creek coal and 70 to 90 ft. above base of Conemaugh group. Has characteristic rusty color of orange brown or ocher, but its hardness and flinty fracture are even more striking. Yellowish gray when fresh; weathers much deeper shade of yellow brown. Is a flint fire clay of possible value. Thickness 5 to 20± ft. Named for its occurrence 1 mi. E. of New Galilee, where it has been prospected on land of W. H. Anderson.

†New Germantown trap.

Name applied by N. H. Darton (Am. Jour. Sci., 3d, vol. 38, pp. 134–139, 1889) to the sheet of Watchung basalt, about 400 ft. thick, W. of New Germantown, Hunterdon Co., N. J. Interbedded in upper half of Brunswick sh. of Newark group (Upper Triassic).

New Glasgow conglomerate.

Carboniferous: Nova Scotia.

H. Fletcher and E. R. Faribault, 1887 (Canada Geol. Surv., n. s., vol. 2, pp. 93P to 94P).

New Hampshire magma series.

Late Devonian or late Carboniferous: Northwestern New Hampshire.

M. Billings, 1934 (Sci., Jan. 19, vol. 79, No. 2038, pp. 55-56). [See under *Highland Croft magma series.*]

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., pp. 9, 19, map). *New Hampshire magma series* is proposed for a group of intrusive igneous rocks which either accompanied the great period of folding in western N. H. or were intruded shortly thereafter but are separated from overlying Moat volcanics by pronounced uncon. Is characterized by muscovite in many members, a distinct foliation in some, and an abundance of pegmatites. Bethlehem granodiorite gneiss and Kinsman quartz monzonite are typical representatives. Also includes Scrag granite, intrusive breccia ("Franconia breccia" of Hitchcock), Bickford granite, and Priest Hill granite. Is definitely post-lower Dev. and may be either late Dev. or late Carbf., probably the former.

M. Billings, 1935 (letter dated July 19). If there must be a type loc. for *New Hampshire magma series* it is the Littleton and Moosilauke quads.

See also M. Billings, Geology of Littleton and Moosilauke quads., N. H., 1935.

New Haven limestone member (of McLeansboro formation).

Pennsylvanian: Southeastern Illinois.

A. H. Worthen, 1875 (Ill. Geol. Surv., vol. 6, p. 67). *New Haven ls.*—Hard, brittle ls., 3 to 4 ft. thick, weathering rusty brown, in lower part of upper Coal Measures of White and Hamilton Counties, Ill. Lies probably 100 to 150 ft. above coal No. 7.

G. H. Cady, 1916 (Ill. Coal Min. Invest. Cooperative Agreement Bull. 15). *New Haven ls.*, in McLeansboro fm. of SE. Ill. is 10 to 25 ft. thick. Appears to be a solid bed. Lies higher than coal No. 11 and 200 to 250 ft. above Carlinville ls., and considerably higher than Shoal Creek ls., which lies in interval btw. coals Nos. 9 and 10.

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, pp. 129-138). *New Haven ls.* is same as Shoal Creek ls.

Probably named for New Haven, Gallatin Co.

See also 1935 entry under *St. Wendell ss.*

New Haven clay.

Name applied by R. F. Flint (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 965-987, 1933) to a late Pleist. clay at and N. of New Haven, Conn.

Newington moraine.

Pleistocene (Wisconsin): Southwestern Maine, southeastern New Hampshire, and northeastern Massachusetts.

F. J. Katz and A. Keith, 1917 (U. S. G. S. P. P. 108, pp. 11-29). *Newington moraine.*—A recessional moraine consisting of several separate segments disposed along a sinuous course near Atlantic coast, and traced for 60 mi.—from Saco, Maine, to Newbury, Mass. Of Wisconsin (probably late Wisconsin) age. Deposited in the sea. Youngest strictly glacial deposit in immediate vicinity of coast of N. H. and SW. Maine. Named for development in Newington, Rockingham Co., N. H. Is contemp. with, in part older, and probably in part younger than the Pleist. marine clays (the so-called "Leda clay") of region.

Newkirk limestone.

Permian: Central northern Oklahoma (Kay County).

L. L. Hutchison, 1911 (Okla. Geol. Surv. Bull. 2, pp. 205-206). The surface ls. at Newkirk, Kay Co., is locally known as *Newkirk ls.*

C. N. Gould, 1930 (letter dated Oct. 30). The surface fm. at Newkirk is the Herington ls.; at least the Herington outcrops very close to the town.

Newkirk sand.

A subsurface sand, of Penn. age and 10 to 40 ft. thick, in central northern Okla., reported to correlate with a part of Pawhuska fm. and to lie 200-250± ft. higher than Hoover sand series.

Newland limestone.

Pre-Cambrian (Belt series): Central southern (Little Belt Mountains) and western central Montana (Helena-Big Belt Mountains region).

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Newland ls.*—Hard lss., dark bluish gray on fresh fracture, and buff to straw color on weathering. Thickness 2,000 ft. Underlies Greyson shales and overlies Chamberlain shales. Type loc. on Newland Creek, 10 mi. N. of White Sulphur Springs, Meagher Co., btw. Big Belt and Little Belt Mtns.

New Lisbon member.

Upper Devonian: Central New York (Butternut Valley).

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 809). *New Lisbon memb.* is proposed by writers for the *Leiorhynchus* beds of Tully fm. in Butternut Valley, extending from top of Hamilton up to first appearance of *Hypothyridina*. Well exposed along first S. tributary to Stony Creek, 1½ mi. E. of New Lisbon, where it consists of 60 ft. of shaly blue-gray thin-bedded fossiliferous ss. and is overlain by Laurens memb. of the Tully, which is 35 ft. thick and contains *Hypothyridina* at 3 known levels.

Newlon limestone and shale. (In Kanawha formation.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1918 (W. Va. Geol. Surv. Rept. Barbour and Upshur Counties, p. 281). *Newlon ls. and sh.*—Dark sandy sh. with numerous concretions and large siliceous ls. "turtlebacks." Thickness 0 to 25 ft. Underlies Eagle ss. and overlies Eagle coal. Just E. of Newlon, Upshur Co., in cut along Chemical & Helvetia R. R., it is a ls., but near village of Czar it is black sh. 5 ft. thick.

New London granite gneiss.

Late Carboniferous or post-Carboniferous (?): Southeastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 149, 152, and map). *New London granite gneiss.*—Distinctly granitic. Light-gray, rather fine-grained rock of uniform texture, composed largely of feldspar and quartz with subordinate brilliant black biotite and occasional hornblende crystals. Has been marked off from Mamacoke gneiss by rather arbitrary bdy. Is intruded by Westerly granite. Typical exposures in and about New London.

Newman limestone.

Mississippian: Southwestern Virginia and eastern Kentucky and Tennessee.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 38). *Newman ls.*—Interbedded lss. and calc. sh., with a few thin sss., covering entire Appalachian Basin except in Pa. and Ohio; 930 ft. thick in Bigstone Gap coal field of Va. and Ky., where it forms lower fm. of Miss. series. Overlies Grainger sh. and underlies Pennington sh. (Miss.).

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, pp. 125, 161, 168, 178). *Newman ls.* includes Glen Dean ls. at top and St. Louis ls. at base, but St. Louis ls. is absent at Newman type loc.—Newman Ridge, Hancock Co., Tenn.

The Warsaw ls. is now believed to be included at base of Newman ls.

†Newman sandstone lentil. (In Newman limestone.)

Mississippian: Northeastern Tennessee (Wartburg and Standingstone quadrangles).

A. Keith, 1897 (U. S. G. S. Wartburg folio, No. 40). *Newman ss. lentil.*—Grayish-white ss., 10 to 30 ft. thick, lying in midst of Newman ls.

The U. S. Geol. Survey does not apply the same name to a fm. and to a memb. of that fm. Therefore this name is no longer in use. The ss. is correlated by C. Butts with Cypress ss. of Ky. (See Ky. Geol. Surv., Mississippian series in western Ky., 1917, p. 90.)

New Mass amygdaloid.

Pre-Cambrian (Keweenawan) : Northern Michigan.

W. H. Weed, 1925 (The Mines Hdb., pp. 1008, 1049, as reported by Mass Consolidated Mining Co.). Lies about 120 ft. below Evergreen amygdaloid. Occurs on property of Mass Consolidated Mining Co., in Ontonagon Co. The mineralized part is the New Mass lode.

Belongs to Central Mine group.

New Mass flow.

Includes New Mass amygdaloid and underlying trap.

New Mayflower amygdaloid.

Pre-Cambrian (Keweenawan) : Northern Michigan.

Local name for an amygdaloid which is older than Old Mayflower (=Mayflower) amygdaloid, and which is probably slightly younger than New Arcadian amygdaloid. Belongs in Central Mine group.

New Milford group. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 68–70). *New Milford group.*—Consists of (descending): (1) *New Milford upper ss.*, 40 ft. (massive, grayish, current-bedded); (2) *New Milford middle sand and shales*, 300 ft. (greenish-gray current-bedded sss. 20 to 25 ft. thick, regularly alternating with shales, some red, 30 to 50 ft. thick); (3) *New Milford lower ss.*, 20 to 25 ft. (current-bedded); (4) *New Milford red sh.*, 100 to 120 ft. (deep red; occasional sandy layers covered by calc. breccia; along Starrucca Creek is almost wholly olive and greenish shales). The group is finely displayed in New Milford part of Susquehanna Co.; the basal red sh. is concealed at New Milford, but appears just S. of village. Overlain by Paupack shales and underlain by Starrucca gray and olive shales. All included in Catskill fm.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, p. 73). *New Milford group* along Delaware River from Narrowsburg to Shawangunk Mtn, N. Y., consists of (descending) 20 ft. of red shales; 40 ft. of green ss.; and 15 ft. of red sh. Underlies Delaware flags, 1,000 ft. thick, and rests on 600 ft. of greenish-gray ss. forming basal part of Catskill fm. [On pp. 94 and 99–101 of above rept he stated that New Milford and Paupack sss. of Rept G_5 cannot be followed in Pike and Monroe Counties, but are represented in the very thick Delaware River flags, which rest on New Milford red sh. and are overlain by Montrose red sh. See quotation under *Delaware River flags*.]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1205–1206). *Delaware River flags* (late Portage) are older (instead of younger) than New Milford red sh. in Monroe Co. At type loc. New Milford is upper Chemung. [Red sh. underlying Delaware River flags is here renamed *Analomink red sh.*]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571+). *New Milford fm.* included in Chemung group, but uppermost beds are post-Chemung, probably Canadaway. To E. they are continental and assigned to Catskill facies group. To W. they carry Luthers Mills coquinite near top. Remainder of New Milford is probably of Wellsburg age and partly continental and partly marine. Includes Lanesville memb. and underlying Kingsley red sh. Overlies Cayuta fm. and underlies Damascus red beds. In Susquehanna Co. the Cayuta includes at top the Starrucca sh. of I. C. White. The Paupack (upper) ss. memb. of Shohola fm. is=part or all of the New Milford. [On p. 589 he states the New Milford to E. becomes upper part of Shohola.] I. C. White mistook the much older Analomink red sh. for his New Milford, and hence placed New Milford beneath Delaware River flags, instead of above them. White considered the New Milford chiefly fresh-water, but D. S. Harding has found marine invertebrates at intervals in lower two-thirds at least, if not higher. Writer believes the fm. in type region consists of alternating continental and marine beds distinguishable only by fossils. The continental beds dominate at top in type region, but to W. pass over to marine facies.

New Milford sandstone.
New Milford shale.
See under *New Milford group*.

New Oxford formation. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania and western Maryland.

A. I. Jonas, 1928 (Md. Geol. Surv. Carroll Co. geol. map). *New Oxford fm.*—Arkosic ss. with quartz cgl. at base. Underlies Gettysburg red sh. (Triassic) and uncon. overlies Conestoga blue slaty ls. Assigned to Triassic.

G. W. Stose, 1929 (U. S. G. S. Fairfield-Gettysburg folio, No. 225). Red sh. and ss. containing many beds of light-colored micaceous ss., arkose, and cgl. Is distinguished from overlying Gettysburg sh. by these light-colored ss. and cgl. beds. In lower 3,000 ft. cgls. and arkosic beds are more common. Upper 4,000 ft. composed largely of soft red sh. and ss. with scattered light-colored ss. In 500 ft. near middle, gray to white micaceous ss. beds are thicker and more numerous than in rest of fm. Upper limit of fm. is drawn where the light-gray micaceous harder sss. cease to be prominent and softer beds predominate. Is basal fm. of Newark group in this region. The overlying Gettysburg sh. is upper fm. of Newark group. Occurs W. of Susquehanna River. Occupies same general strat. position as Stockton fm. E. of Susquehanna River, and has somewhat the same lithologic character.

Named for exposures at New Oxford, Adams Co., Pa.

New Paris moraine.

Pleistocene (Wisconsin stage): Northeastern Indiana. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for New Paris, Elkhart Co.

†Newport conglomerate.

Carboniferous: Southern Rhode Island.

E. Hitchcock, 1861 (Am. Jour. Sci., 2d, vol. 31, p. 377). The *Newport cgl.* is probably only a special variety of the extensive deposit of highly siliceous puddingstone found so abundantly btw. Boston and Rhode Island. Both have same geol. position, we believe, and were *Roxbury cgl.* to be brought into a plastic state, and the pebbles elongated and flattened by pressure, we think result would resemble Newport cgl.

W. B. Rogers, 1877 (Boston Soc. Nat. Hist. Proc., vol. 18, p. 100). The mass known as *Newport cgl.* has its typical loc. in Purgatory Rocks.

Replaced by Purgatory cgl., the better-defined and better-established name.

Newport shales and sandstones.

Upper Devonian: Central southern Pennsylvania (Perry County).

F. Platt, 1881 (2d Pa. Geol. Surv. Rept. T, p. 28), gives following subdivisions in Perry Co. (downward): Chemung olive shales on Juniata River, 4,384 ft.; *Newport (Portage?) sandy shales and sss.*, 835 ft.; Genesee sh.; * * *.

Newport limestone.

Upper Devonian: Central Pennsylvania (Perry County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, p. 1594). *Newport ls.* is at base of the Catskill or top of the Chemung in Perry Co. Is local deposit, 3 to 5 ft. thick; best exposed opposite the furnace at Newport and 1 mi. E., on bank of the Juniata, as a lenticular mass of fossil shell casts and siliceous matter; is blue and hard. Seen only in Howe and Oliver Twps, Perry Co.

Newport granite.

Devonian: Northeastern Vermont (Orleans County).

C. H. Richardson, 1908 (6th Rept. Vt. State Geol.). *Newport granite*, Dev., intrudes Waits River ls.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this granite to Dev. [Newport is in Memphremagog quad.]

Newport formation.

Pleistocene: Northwestern Oregon (Lincoln County).

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, p. 269). *Newport fm.*—Unconsolidated sands and gravels typically exposed at Newport. Of Pleist. age. Younger than Pleist. marine terraces, and=San Pedro of Calif.

Newport Neck shale.

Pre-Cambrian: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 316–318, 383). *Newport Neck shales.*—Shales with thin dol. layers occurring along W. shore of Newport Neck. May be Camb.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped the rocks of area described as Marlboro fm.

New Providence shale. (In Osage group.)

Mississippian: Southern Indiana and northern and eastern Kentucky.

W. W. Borden, 1874 (Ind. Geol. Surv. 5th Ann. Rept., p. 161). *New Providence sh.*—Fine greenish marly sh., 80 to 120 ft. thick. Basal fm. of Knobstone group. Near New Albany is capped by thin bed of ferruginous ss. In NW. part of Clark Co. is capped by thin bed of crinoidal ls., which is overlain by what I recognize as true Knob sh., 120 to 160 ft. thick. New Providence sh. rests on a thin bed of ferruginous ls. containing crinoid stems [Rockford ls.].

E. M. Kindle, 1899 (Bull. Am. Pal., vol. 3, No. 12). *New Providence sh.* of southern Ind. consists of 125 ft. of blue clay sh., overlain by Riverside ss. and underlain by Rockford ls.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, p. 137). *New Providence sh.*—Soft green clay sh., 150 to 160 ft. thick in Jefferson Co., Ky., where it underlies Kenwood ss. and uncon. overlies New Albany sh. Basal fm. of Osage group. Contains Burlington and Fern Glen fossils.

E. R. Cumings, 1922 (Hdb. Ind. Geol. pt. 4, Sep. Pub. 21, p. 489). *New Providence sh.*, 120 to 150 ft. thick, underlies Kenwood ss. for a short distance in southern Ind., and in places overlies Rockford ls., thin and local. Until recently the name has been used for lower and middle shaly part of Borden group, but Butts limits name to lower 120 to 160 ft. of green sh. below the lower sss., which is evidently what Borden had in mind when he proposed the name.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, pp. 29+). In *eastern Ky.* the *New Providence* becomes a *group*, more than 600 ft. thick, overlain in places by Rosewood sh. and in places by Fort Payne chert, and underlain in places by Sunbury sh. and in other places by Ohio sh.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 85, 93–94). New Providence sh. was named for village of New Providence, Clark Co., Ind., which has since been renamed Borden. The village is situated higher than top of New Providence fm., and lies upon and is surrounded by younger fms. Rocks that can be doubtfully ascribed to top part of the New Providence barely crop out in creek beds immediately S. and SE. of the village, although good "typical" exposures are not seen nearer than about 4 mi. E. of the town, in vicinity of Broomhill and Carwood. Observers have therefore been misled into thinking of the next overlying sandy sh. (here named *Locust Point fm.*) exposed in the bluffs about town of Borden as the fm. intended by Borden as New Providence fm. There are objections to the name, but it is firmly entrenched in the literature and is therefore used in this rept. Most of the fm. is argill. sh. bordering on claystone. It is here treated as basal fm. of Borden group. [On pp. 93–94 he proposes to include Kenwood ss. in the New Providence and names overlying beds Locust Point fm. He says:] Uppermost limit of New Providence fm. is nicely marked in east-central and south Floyd Co., Ind., and in Jefferson Co., Ky., because of presence of abrupt ss. layers (Kenwood ss. of Butts); but northward as far as Brown and Bartholomew Counties the upper limit is conjectural in most places as a consequence of a remarkably gradual transition into overlying rocks. To limit the fm. to "a thickness from 80 to 120 ft." (Borden, 1874, p. 161) above the Rockford is not sound nor justified because no significant strat. differences are observed at those horizons. Borden may have been in error in his calculations because of failing to take into consideration the W. dip of the strata. Interval btw. base of the New Providence and top of zone with ss. layers is 190 ft. in Kenwood-New Albany region, according to Butts; 10 mi. to N., in Floyd Co., it averages 200± ft., but the zone of ss. layers does not here extend as low in typical New Providence nor contain as many ss. beds. To N. of T. 2 S. the ss. beds disappear. Writer wishes to assign top of this zone—within which the sh. is highly argill. and shows traits common to the sh. below, and above which the sh. becomes gradually more sandy and begins to lose the characteristics of the rock beneath—as upper limit of New Providence fm. in this southern region, and to describe the New Providence fm. of this region as *Silver Hills facies*. In accordance with this interpretation the ss. layers of S. and east-central Floyd Co. and "Kenwood ss." of Butts in Jefferson Co., Ky., are part of New Providence fm. There seems lack of justification for assigning "Kenwood ss." the rank of a fm., but one may be justified in considering it as a local memb. of New Providence fm. In this rept the ss. layers will be referred to as the *Kenwood beds of New Providence fm.* [See also under *Kenwood ss.* Fossils listed on pp. 106–108.]

Named for New Providence, Clark Co., Ind., now known as Borden.

†New Red sandstone.

A name used in early repts to include, in some areas, Triassic system and part of Permian series of Carboniferous system. In Atlantic States it was applied to Newark group (Upper Triassic).

New Richmond sandstone.

Lower Ordovician (Beekmantown): Central western Wisconsin, southeastern Minnesota, and Iowa.

L. C. Wooster, 1878 (Wis. Geol. Surv. Ann. Rept. 1877, btw. pp. 36 and 41). In vicinity of New Richmond [St. Croix Co., Wis.] there appear to be bodies of ss. in upper part of Lower Mag., which may possibly represent horizon of Jordan ss. of Minn. These are penetrated by 3 wells in neighborhood. The wells in this part of St. Croix Co. quite uniformly penetrate the ls. 15 to 20 ft. for water, striking it at horizon of *New Richmond ss.* [Name used only once.]

L. C. Wooster, 1882 (Geol. Wis., vol. 4, pp. 106, 123–129, in a rept on the lower St. Croix dist.). The name Lower Mag. ls. covers a series of layers more uniformly dolomitic than the same strata on the east, there being no layers of any thickness to which the term ss. may be applied with the exception of one horizon. It is possible that the upper layers in NW. Wis. are not represented by ls. at the E., having been laid down after the deposition of St. Peters ss. commenced in those regions. In this rept these layers of ls. will be termed *Willow River beds* and the ss. btw. these layers and the Lower Mag. proper [Oneota dol.], the *New Richmond beds*, from the localities in which these strata are best exposed and most fully developed. [Page 106.] About 100 ft. from the base and about 80 ft. from the top of the Lower Mag. ls., in several localities, a varying amount of white quartzose sand is found that probably represents the horizon of Jordan ss. of Minn. [For many years known to be a miscorrelation. (Pages 124, 125.) Fig. 4, on p. 126, shows the ss. exposed at base of bluff of Willow River at Jewett's Mills, Wis.] Sandstone was penetrated at this same horizon in 3 wells in sec. 23, T. 30, R. 18 W. The presence of thin layers of ss. at the same horizon in other portions of the dist., and the character and thickness of the ls. above and below, indicate that in this ss. we have the eastern equiv. of the Jordan ss. of Minn. [Miscorrelation.] Along Kinnickinnick River the entire Lower Mag. ls. is shown, but presents no new features except a layer of white sand about 100 ft. above the Potsdam ss.

Wooster's name *New Richmond ss.* was introduced into Minn. repts as early as 1886, into Iowa repts as early as 1895, and into Ill. repts in 1910, for a sandy unit in the middle of Prairie du Chien group (†Lower Mag. ls. of early repts on upper Miss. Valley). This sandy unit has been recognized by many geologists in at least 20 repts on Wis. geology, 30 or more repts on Minn. geology, 30 or more repts on Iowa geology, and 18 or more repts on the unexposed rocks of northern Ill. In these published repts its thickness has been given as 1 to 40 ft. in Wis., 5 to 40 ft. in Minn., 10 to 170 ft. in Iowa, and 0 to 188 ft. in northern Ill. It has been identified in at least 22 counties in Iowa, 16 counties in SE. Minn., several counties in southern Wis., and 10 counties in northern Ill. Notwithstanding the identification by many geologists of these sandy beds as a distinct unit, some geologists have questioned the validity of the unit, as indicated in some of the citations that follow:

C. W. Hall and F. W. Sardeson, 1895 (Geol. Soc. Am. Bull., vol. 6, pp. 167–198). *New Richmond (Elevator B) ss.* consists of 20 ft. of pure-white quartz sand. It seems stratigraphically to belong to the Oneota. It may prove to be an area cap to the Oneota when further localities have been explored or fossils have been discovered.

C. W. Hall, 1905 (U. S. G. S. W. S. P. 114, pp. 226–228). The layer of ss. called *New Richmond ss.* appears to be basal cgl. of Canadian series of upper Miss. Valley.

U. S. Grant, 1906 (Wis. Geol. and Nat. Hist. Surv. Bull. 14, Econ. ser., No. 9). In Grant, Iowa, and Lafayette Counties, Wis., the Lower Mag. ls. contains a thinner middle div. known as *New Richmond ss.*, which is lacking or apparently lacking at many points.

S. Calvin, 1906 (Jour. Geol., vol. 14, pp. 571–574). *New Richmond ss.* when present divides the Lower Mag. of Owen into 3 units. It lies in thin beds, the surface of the beds being often ripple-marked. It differs from St. Peter ss.

H. F. Bain, 1907 (Wis. Geol. and Nat. Hist. Surv. Bull. 19, pp. 16–35). *New Richmond ss.* is not always well developed in outcrop, but is clearly defined in well records far to S. and W. of the outcrop, though not well exposed in lead and zinc dist. proper. Seems to be absent in places.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 640–641). *New Richmond ss.* is included in Shakopee dol. because it is thought to indicate an introductory clastic phase of the Shakopee rather than a distinct fm.

A. C. Trowbridge, 1914 (Iowa Acad. Sci. Proc., vol. 21, pp. 205–209). *New Richmond memb.* of Prairie du Chien fm. seems to be developed only locally, and it now appears unfortunate that the Minn. classification of that fm. has been followed in Iowa.

A. C. Trowbridge, 1917 (Iowa Acad. Sci. Proc., vol. 24, pp. 177+). The uncon. btw. St. Peter ss. and Prairie du Chien fm. explains discontinuity of *New Richmond memb.* of Prairie du Chien fm., which is missing where the Prairie du Chien is thin and present where it is thick.

F. W. Sardeson, 1924 (Pan-Am. Geol., vol. 41, pp. 113, 115). At Shakopee 50 ft. of Shakopee ls. is exposed, but wells there give 96 ft. It is there mainly ls., with eroded top, and base concealed below Minn. River water level. It contains ss. beds in lower part and overlies Oneota dol. There is no distinct unit of ss. btw. Shakopee and Oneota lss. in Minn. or elsewhere, but there are lenses and strata of ss. in top part of Oneota ls. and others in lower part of Shakopee ls., as at town of Shakopee. These sandy strata, when weathered out in SE. Minn., appear to be what gave Prof. N. H. Winchell the grounds for calling them the "Jordan" by error.

F. W. Sardeson, 1926 (Pan-Am. Geol., vol. 45, btw. pp. 29–48). Shakopee fm. includes Willow River beds (the upper ls. layers) and *New Richmond beds* (a ss. btw. Willow River beds and "Lower Magnesian proper"). It is faunally totally distinct from Oneota dol.

C. E. Needham, 1931 (Ill. State Acad. Sci. Trans., vol. 24, No. 2, pp. 363–368). At New Richmond, Wis., on S. bank of Willow Creek, at the dam, the *New Richmond fm.* is 1¼ ft. thick, consists of white to pale-yellow ss., friable, thin-bedded, irregular, fine-grained, and cross-bedded; is overlain by 10 ft. of Shakopee dol. and uncon. (?) underlain by Oneota (?) dol. In bluffs of Miss. River just E. of Prairie du Chien, Wis., the New Richmond is 5 ft. thick, and consists of pale-yellow friable, slightly dolomitic medium-grained cross-bedded ss., with smaller quantities of fine and coarse sand, overlain by 35 ft. of Shakopee dol. and underlain by 200 ft. of Oneota dol.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 73). Recent work by E. H. Powers (unfinished doctor's thesis, Univ. of Iowa) seems to show that although some variation may occur in strat. position of *New Richmond beds*, and although in some sections these ss. beds appear to be missing, there are so many sections in which they do occur at about same strat. position that the New Richmond may properly be considered as a memb. separating the Oneota and Shakopee.

The U. S. Geol. Survey treats *New Richmond ss.* as middle fm. of Prairie du Chien group, and assigns it to Lower Ord. This is generally accepted classification.

New River group.
New River series. } (In Pottsville group.)

Pennsylvanian: West Virginia and southwestern Virginia.

W. M. Fontaine, 1874 (Am. Jour. Sci., 3d, vol. 7, p. 463). The *New River system of coals*, "which for the sake of distinction we may call the Conglomerate series."

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxiii–xxx). The *New River Coal Measures* of Fontaine is middle or coal-bearing part of Pottsville cgl.; the name is preoccupied by J. P. Lesley's application of New River to a part of Pocono fm.; and Lesley has therefore replaced it by *Kenawha River Coal Measures*.

H. M. Chance, 1881. [See quotation under *Beaver River fm.*]

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 202–204). *New River coal group.*—The great development of coal in middle and lower half of Pottsville series along New River, W. Va., has given name to this group, which underlies Connoquenessing sss. and overlies Sharon cgl. Includes Sharon shales and Sharon coal.

I. C. White, 1899 (W. Va. Geol. Surv. vol. 1). *Pottsville cgl., No. XII (New River or Pocahontas coal series)*.—Underlies Lower or Allegheny River coal series and overlies Mauch Chunk red sh.

J. J. Stevenson, 1904 (Geol. Soc. Am. Bull., vol. 15). Lower Pottsville=*New River series* of Fontaine, and includes Sharon ss. at top, but not the overlying Sharon group of shales and coals.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A). *New River group (Middle Pottsville)*.—Underlies Connoquenessing ss. and overlies Pocahontas group or Lower Pottsville, which includes Flat Top Mtn ss. at top and all of Pocahontas coals (Nos. 1 to 9, inclusive).

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. on Wyoming and McDowell Counties). No. 8 Pocahontas coal is younger than Flat Top Mtn ss. and is basal memb. of *New River group*, which rests on Flattop Mtn ss. (top memb. of Pocahontas group) and extends upward to base of Gilbert coal.

W. Va. Geol. Surv. broadside sheet, 1917. *New River group* extends from base of Gilbert coal down to base of No. 8 Pocahontas coal.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co.). Top of *New River group* lies from a few inches to 15 ft. below Lower Douglas coal.

D. B. Reger, 1921 (W. Va. Geol. Surv. Rept. Nicholas Co.). Lower Douglas coal rests on *New River group*, which extends down to top of Flattop Mtn ss.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties). No. 8 Pocahontas coal is basal bed of *New River group*, and Flattop Mtn ss. is top memb. of Pocahontas group.

†New River coal series.

Mississippian: West Virginia.

C. A. Ashburner, 1877 (Am. Phil. Soc. Proc., vol. 16, pp. 519–560). Lesley was original proposer of *New River series*, "a number of years" prior to 1877. [The compiler is unable to ascertain, without expenditure of more time than matter merits, where *New River* was published by Lesley prior to 1877. In publication cited above Ashburner states that original *New River series* of Lesley is middle part of Pocono ss. and is 313 ft. thick, and that "New River series of Fontaine" is middle or coal-bearing part of Pottsville cgl.]

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxiii–xxx). *New River system (No. X)*.—Includes (descending) *New River Coal Measures* and Pocono ss.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_2, p. xxiii). *New River coal group* is included in Mountain ls., which rests on Pocono ss.

†New River system.

Mississippian: Pennsylvania and West Virginia.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxiii–xxx). *New River system (No. X)*.—Includes (descending) New River Coal Measures and Pocono ss. Underlies Mountain ls. and overlies Catskill Old Red ss.

New Rochelle serpentine.

Pre-Cambrian: Southeastern New York.

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). *New Rochelle serpentine*.—Occurs at Davenport's Neck at New Rochelle. Intrusive into Fordham gneiss, Inwood ls., and Manhattan schist.

†New Salem serpentine.

Late Carboniferous or post-Carboniferous: Northern central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 55). *New Salem serpentine.*—A lenticular mass of rather coarse biotite-granitoid gneiss on W. slope of Rattlesnake Hill, about 300 yds. NE. of A. A. Haskell's house.

Discarded by B. K. Emerson, as an unnecessary name, and New Salem adopted for the aplite described by him in U. S. G. S. Bull. 597, 1917.

New Salem aplite.

Late Carboniferous or post-Carboniferous: Northern central Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 244 and map). *New Salem aplite.*—A broad lobe of "ribbon gneiss," which extends up from Enfield through Prescott and New Salem. Is white, and all very fine-grained and aplitic, though uniformly biotitic. Is made up of quartz, orthoclase, and sodic plagioclase. In places it has a tourmaline-bearing border. [See also under *Dana diorite.*]

New Scotland limestone. (In Helderberg group.)

Lower Devonian: Eastern New York and Pennsylvania, western Maryland and Virginia, and northern West Virginia.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *New Scotland beds* (also *ls.*).—Is Catskill or Delthyris shaly ls. Exposed at town of New Scotland, Albany Co., N. Y. Underlies Becraft ls. and overlies Coeymans ls. Included in Helderbergian group. [For lithologic description see *†Catskill or Delthyris shaly ls.*]

In subsequent repts the thickness of New Scotland ls. has been given as 50 to 127 ft. Thickness of Kalkberg ls. (see next paragraph) has not been stated.

In 1908 (Sci., n. s., vol. 28, pp. 346–348) G. H. Chadwick introduced *Kalkberg ls.* "to cover certain layers heretofore included variously by writers with the beds above (New Scotland) or below (Coeymans)," and carrying a mixed fauna, highly developed and excellently silicified on Catskill Creek [Greene Co., N. Y.], where the beds show numerous thin parallel seams of black flint nodules.

Has also been called "*Shaly ls.*"

Chadwick's restricted definition of New Scotland ls. is generally accepted.

In central Pa. the Helderberg is treated as a fm. and these beds are designated as *New Scotland ls. memb. of Helderberg ls.*

Newsom shaly clay.

Silurian (Niagaran): Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 397, 402). *Newsom shaly clay.*—Overlies Whites Bend (Laurel) ls. and underlies Bledsoe (Louisville) ls. in Tenn. Thickness 0 to 8 ft. Included in Clifton ls. Same as Waldron shaly clay of Ind.

Named for Newsoms Station, Davidson Co.

Newton sandstone. (In Pottsville group.)

Pennsylvanian: Southeastern Tennessee (Cumberland, Grundy, Hamilton, Van Buren, White, Bledsoe, Sequatchie, Rhea, and Marion Counties).

W. A. Nelson, 1925 (Tenn. Dept. Ed., Div. Geol. Bull. 33A, pp. 50–51, and under county descriptions). *Newton ss.*—Top memb. of Bonair ss. Consists of 50 to 175 ft. of soft coarse white, yellow, or reddish-white micaceous ss., generally strongly cross-bedded. In places there are thin ripple-marked beds and one or two coal beds. In N. part of field this ss. rests on Eastland sh. lentil of Bonair ss. In S. part of field it rests on Whitwell sh. Named for fact that it occurs at Newton P. O., in SW. corner of Cumberland Co.

Newton sandstone member (of Everton formation).

Lower Ordovician: Northern Arkansas (Harrison, Eureka Springs, and Yellville quadrangles).

E. T. McKnight, 1935 (U. S. G. S. Bull. 853). *Newton ss. memb. of Everton fm.*—Thickness 0 to 20 ft. In Yellville quad. its base is estimated to lie 160 and 200 ft. above base of Everton. Shows, especially in Harrison and Eureka Springs quads., pronounced uncon. at base. In Eureka Springs-Harrison folio was erroneously called St. Peter ss. Named for prominence in northern Newton Co. Enters Yellville quad. from W. and wedges out in W. part of quad. [The Eureka Springs-Harrison folio, No. 202, 1916, describes this ss. as consisting of 0 to 150 ft. of massive, cross-bedded, and laminated saccharoidal ss., underlying [so-called] Joachim ls. (0 to 95 ft. thick) and uncon. overlying Everton ls. (0 to 115 ft. thick). The so-called Joachim ls. of this folio is now known to be older than true Joachim and to belong to Everton fm. The Newton ss. memb. of Everton fm., therefore, lies 95± ft. below top of Everton and 115± ft. above base of Everton in Eureka Springs-Harrison quads.]

†Newtonville limestone.

Mississippian (late): Central Ohio.

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 93). *Maxville or Newtonville ls.*—Is=Sub-Carbf. ls. of Ky. hills. Overlies Logan ss. group, and is overlain by cgls. [Pottsville fm.] on which Productive Coal Measures rest.

Same as Maxville ls.

Named for Newtonville (now called White Cottage), Muskingum Co.

†New Ulm quartzite.

Pre-Cambrian (Huronian): Southwestern Minnesota (Brown County).

N. H. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 2, pp. xxii, 35). *New Ulm qtzite.*—Red qtzite outcropping at New Ulm. Believed to be older than the several hundred ft. of red shales and red sandrock encountered in deep wells at Belle Plaine, Mankato, Hastings, and East Minneapolis.

N. H. Winchell, 1895 (Am. Geol., vol. 16, pp. 150–162). *New Ulm qtzite* is same as Sioux qtzite.

New Ulm conglomerate.

Cambrian (?): Southwestern Minnesota (Brown County).

F. W. Sardeson, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 221–242). *New Ulm basal cgl.*—The qtzite cgl. which outcrops on left side of Minn. River opp. New Ulm. 1½ mi. above Redstone. Mapped. Has heretofore been considered by geologists as basal part of Courtland qtzite, but it is Middle Camb. and contains pebbles of Courtland qtzite.

†New Vernon trap.

Name applied by N. H. Darton (Am. Jour. Sci., 3d, vol. 38, pp. 134–139, 1889; U. S. G. S. Bull. 67, 1890) to the extrusive sheet of Watchung basalt, 150 to 250 ft. thick, around New Vernon, Morris Co., N. J.

†New York system.

Devonian, Silurian, Ordovician, and Cambrian: New York.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, Geol. 2d dist., pp. 99, 429). *New York Transition System.*—The Transition rocks of New York constitute, as a whole, the most perfect system which has hitherto been described. The remarkable series which fill up the space btw. the Primary and the Old Red System constitute together the New York Transition System. It is composed of several groups. [Page 99.]

Tabular view of the sedimentary rocks of New York

Tertiary.***

New Red system.**

Old Red system. [Also calls it "Old Red ss." On other pp. of vol. cited L. Vanuxem included this in "New York system."]

New York system:
Erie group (Marcellus and Hamilton shales, Tully limestone, Genesee slate, Ithaca and Chemung shales and grits).
Helderberg series (Pentamerus limestone, Delthyris shaly limestone, Oriskany sandstone, Encrinal limestone, Cauda-galli grit, Schoharie grit, Helderberg limestone).
Ontario group (Medina sandstone, Green shales and Oolitic iron ore, Niagara limestone, Red shale, Onondaga salt and plaster rocks, Manlius water-lime).
Champlain group (Potsdam sandstone, Calciferous sand rock, Chazy and Birdseye limestone, Marble of Isle La Motte, Trenton limestone, Utica slate, Loraine shales, Grey sandstone, Conglomerate).
Taconic system (Taconic slate, Magnesian slate, Stockbridge limestone, Granular quartz). [Page 429.]

As above defined "New York system" comprises all rocks btw. base of Potsdam ss. and top of Chemung fm., and thus includes nearly all of Dev., all of Sil. and Ord., and part of Camb.

H. S. Williams, 1891 (U. S. G. S. Bull. 80, p. 60). See quotation under †*Appalachian group*.

Neylandville marl. (In Navarro group.)

Upper Cretaceous (Gulf series): Northeastern Texas.

L. W. Stephenson and W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 488, 516, etc.). [For definition see 1933 entries under *Corsicana fm. (restricted)*.]

See U. S. G. S. 1937 geol. map of Tex., where Navarro group is divided into (descending) Kemp clay (restricted), Corsicana marl (restricted), Nacatoch sand, and Neylandville marl. This is present approved classification.

†Niagara sandstone.

Silurian: Western New York.

T. A. Conrad, 1837 (N. Y. Geol. Surv. 1st Rept., pp. 166–172). Red and variegated sss. of Niagara River. [Called *Niagara ss.* on p. 172.] The only ss. developed in course of Niagara River. Probably not more than 200 ft. thick. Includes at top the "Gray Band" of Eaton, about 4 ft. thick. The red ss. is underlain by siliceous cgl. [Whirlpool ss. memb.?] which is either part of underlying or overlying fm.

T. A. Conrad, 1840 (N. Y. Geol. Surv. 4th Ann. Rept., p. 201). This name [Niagara ss.] I applied to the red ss. of Niagara and Oswego.

Essentially same as Albion ss.

†Niagara shale.

Silurian: New York.

T. A. Conrad, 1839 (Phila. Acad. Nat. Sci. Jour., vol. 8, pt. 1, pp. 228–235). *Niagara sh.*, at base of Helderberg system or Middle Sil. group, is underlain by Clinton group.

Replaced by Rochester sh. memb. of Clinton fm.

†Niagara limestone.

Silurian: New York.

L. Vanuxem, 1839 (N. Y. Geol. Surv. 3d Rept., p. 248). [Describes upper fm. of †Protean group as consisting of concretionary ls. and blue sh. and states that in some quarries of the ls. "we find that singular concretionary rock which forms the upper part of the *Lockport and Niagara ls.*, being the terminal mass in the Third District, and from which its name was in part derived."]

Same as Lockport dol., the established name.

Niagara group (also **limestone** and **dolomite** where not divisible).

Silurian: New York, Michigan, northern Ohio, Wisconsin, and Illinois.

J. Hall, 1842 (Am. Jour. Sci., 1st, vol. 42, pp. 52, 57–62). *Niagara group* includes Rochester sh. and Lockport ls., and rests on "Protean group" (green shales, Pentamerus ls., and iron ores and=Clinton fm. minus Rochester sh. memb.).

The foregoing definition of Niagara group persisted for several decades, although J. D. Dana as far back as 1857 used *Niagara period* to include Niagara group, Clinton group (excluding Rochester sh. memb.), Medina ss., and Oneida cgl. [Oswego ss. and not true Oneida, which is=upper Medina]; but Dana excluded "Galt ls." [Guelph] at top. The 1863, 1864, 1868, 1869, 1875, and 1895 editions of his Textbook of geol. employed the foregoing classification. In some early repts the Rochester sh. was called "Niagara sh." and the Lockport dol. was called "Niagara ls." In 1898 (Buffalo Soc. Nat. Sci. Bull., vol. 6, No. 1, p. xvii) A. W. Grabau applied *Niagara group* to all rocks btw. Onondaga group (as he called the middle Sil.) and Upper Ord. In 1899 (Sci., n. s., vol. 10, pp. 874–878) J. M. Clarke and C. Schuchert introduced *Niagaran period or group* to include Guelph dol., Lockport ls., Rochester sh., and Clinton beds. This is present commonly accepted definition of Niagara group, although Rochester sh. is now treated as a memb. of Clinton fm. and the beds carrying the Guelph fauna are included in Lockport dol. by U. S. Geol. Survey and others. G. H. Chadwick's 1908 classification, however (Sci., n. s., vol. 28, pp. 346–348), also A. W. Grabau's 1909 classification (Jour. Geol., vol. 17, pp. 209–252), included "upper Medina" (Albion ss.) in the Niagaran. In 1865 James Hall included the Guelph in Niagara group, and it is generally now included in that group, although the Canadian Geol. Survey (see M. Y. Williams 1914 and 1919) formerly excluded, and probably still excludes, the Guelph from the Niagara. In 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 560–561) E. O. Ulrich stated that Brassfield ls. is oldest Clinton known, and he included it in his *Niagaran series*. Later, however, he correlated the Brassfield with Albion ss. and excluded it from the Niagaran, as do other geologists. On pl. 28 of Bull., vol. 22, cited above, Ulrich classified Louisville ls. of Ky. as younger than the Guelph, but included it in his *Niagaran series*, as did R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 4), Ulrich and Bassler, 1923 (Md. Geol. Surv. Sil. vol., pp. 244, 267), and E. O. Ulrich, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 329, where he seems to correlate it with Guelph).

The Clinton fm. of Niagara group is a distinct unit as far S. as NE. Tenn. In Upper Mississippi Valley States the deposits of Niagara age are usually not divided, and are there called *Niagara ls.* or *Niagara dol.*, depending upon the lithology.

Named for exposures in Niagara Co., N. Y., all of the subdivisions, including those of Guelph age, being well exposed in gorge of Niagara River.

†Niagara period.

A term applied by some early writers (see early editions of J. D. Dana's Textbook of geology) to include the time during which Niagara group, Medina ss., and Oneida cgl. were deposited. The U. S. Geol. Survey applies the term *Niagara epoch* to the time covered by Niagara group, in which it includes Clinton fm. at base and Guelph at top.

†Niagara transition group.

A term applied by E. N. S. Ringueberg (Am. Nat., vol. 16, pp. 711–715, 1882, and Am. Geol., vol. 1, pp. 264–272, 1888) to 0 to 2 or more ft. of light-bluish ls. "heretofore included in the Clinton group," but "its fossils prove it is more closely allied to the Niagara." Characterized by abundance of Cephalopoda. "It forms the connecting link btw. the Clinton lss. beneath and the Niagara shales" [Rochester sh.].

Niagara series.

A term applied by some authors to Niagara group.

Niagara Falls moraine.

Pleistocene (Wisconsin stage): Western New York and southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17. Named for Niagara Falls, N. Y.

Niagara Gulch latite. (In Silverton volcanic series.)

Miocene: Southwestern Colorado (Silverton quadrangle).

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). *Niagara Gulch latite.*—The most widely distributed variety of the hornblendic latite of Burns latite complex. Named for Niagara Gulch, E. of Eureka, where it occurs in a massive flow several hundred ft. thick, which lies btw. two notable tuff bands.

Is a facies of Burns latite, of Silverton volcanic series.

Niagaran.

A time term covering the interval during which the rocks of the Niagara group were deposited. See under *Niagara group.*

Nicholas limestone. (In Cynthiana formation.)

Middle Ordovician: North-central Kentucky and southwestern Ohio.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, pp. 209, 210, 294, 297). *Nicholas bed.*—The coarse-grained ls., with relatively few fossils, forming top bed of Cynthiana fm.; 35 ft. thick in Nicholas Co., Ky., but decreases along Ohio River, where the lss. become more argill., fine-grained layers more frequent, and fossils more abundant. Underlies Fulton layer. [On pp. 209 and 210 author states it overlies Point Pleasant, "which term should be restricted to lower part of exposures at Point Pleasant, as intended by Prof. Orton." On pp. 295 and 297 the Point Pleasant seems to be divided into Greendale and Perryville beds, and the Nicholas bed is described as resting on Greendale. Foerste repeated latter classification in 1910 and 1912.]

A. M. Miller, 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 651–657) and 1919 (Dept. Geol. and Forestry of Ky., ser. 5, Bull. 2) applied *Point Pleasant ls.* to the beds overlying Greendale ls. in Ky.

A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, No. 121 geol. ser., chart opp. p. 58), divided Cynthiana fm. into (descending) Rogers Gap, Gratz, Bromley, and Greendale, and did not recognize Nicholas ls. as defined by him in earlier repts.

A. C. McFarlan and D. M. Young, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 12, p. 1977). *Nicholas ls.* is a quarry rock, and is not recognized in all sections in central Ky., in which case the Greendale is overlain by the Rogers Gap. The Nicholas is regarded as a ls. facies of the upper Greendale.

Named for Nicholas Co., Ky., where it is fully developed SW. of Pleasant Valley.

Nicholas sand.

A subsurface sand, 150 ft. thick, in SW. Okla., correlated with a part of Garber ss. (Perm.).

Nichols slate. (In Chilhowee group.)

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Nichols sh.*—Grayish-blue shales, sandy, micaceous, argill., and slightly calc.; of uniform composition throughout. Thickness 550 to 800 ft. Overlies Cochran cgl. Underlies Nebo ss.

Named for Nichols Branch of Walden Creek, at E. end of Chilhowee Mtn, Sevier Co., Tenn.

Nichols sand.

A subsurface sand assigned to upper part of McElroy memb. of Fayette ss. of eastern Tex., by O. L. Brace (A. A. P. G. Bull., vol. 15, No. 7, 1934, pp. 779–781).

Nickel Plate formation.

Carboniferous (?): British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 44, 54). [Assigned to Carbf. Later repts by other geologists assign this fm. to Triassic or Jurassic.]

Nickerson morainic system.

Pleistocene (Wisconsin stage): Northeastern Minnesota and northwestern Wisconsin.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Nickerson, Pine Co., Minn.

Nickwaket graywacke.

Pre-Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 362, 394). *Nickwaket graywacke.*—Entirely schistose rocks with large percentage of graywacke and feldspathic qtzite. The schists and schistose coarser beds consist of variable amount of quartz, muscovite, biotite, and chlorite, with local developments of magnetite. The graywacke beds at top of fm. are coarse and in many places conglomeratic, while at base there are important lenticular cgls., consisting of pebbles and boulders of the older rocks, largely quartz, granite, and gneiss. Best development of this cgl. is a few mi. SE. of Middlebury, in town of Ripton. The upper graywacke beds are seen in contact with overlying Forestdale marble at Forestdale. Overlies Archean granite and gneiss. In central Green Mtns is uncon. overlain by Cheshire qtzite.

According to A. Keith (personal communication) this graywacke is exposed on Nickwaket Mtn, in SW. corner of Rochester quad., in Rutland Co.

Nicola series.

Triassic: British Columbia.

G. M. Dawson, 1879 (Canada Geol. Surv. Rept. 1877–78, p. 74B).

Nicollet clay.

A term listed in U. S. G. S. Bull. 191, 1902, p. 292. The reference given simply refers to "Nicollett's great bed of clay."

Nicoyan series.

Miocene: Costa Rica.

J. Romanes, 1912 (Geol. Mag., dec. 5, vol. 9, p. 262).

Nigh sand.

A subsurface sand in Stephens Co., southern Okla., lying at 1,600 ft. depth in Empire pool, the Miller sand lying at 1,500 ft. and the Surber sand at 1,700 ft. According to Okla. Geol. Surv. Bull. 40Q, 1928, p. 179, this sand is Perm.; according to Okla. Geol. Surv. Bull. 40E, 1926, it is Penn.

Nikanassin formation.

Lower Cretaceous: Alberta.

B. R. MacKay, 1929 (Canada Geol. Surv. Summ. Rept. 1928, pt. B, p. 7).

Nikolai greenstone.

Permian and Triassic(?): Eastern Alaska (Nizina-Tanana region).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 425–432). *Nikolai greenstone.*—A series of greenstones that contain the Nikolai copper vein. Is a series of ancient basic volcanics. Underlies Chitistone ls.

Later work showed that typical Nikolai greenstone as defined by Rohn is of Perm. and possibly Triassic age, but that in many subsequent repts the name was used to include the Miss. tuffs, basalts, and interbedded sh., chert, and ls. which have been named *Strelna fm.* The name is now restricted to the Perm. (and possibly Triassic) rocks to which it was originally applied.

Nikomeki sand and silt.

Pleistocene: British Columbia.

E. M. J. Burwash, 1918 (The geology of Vancouver and vicinity, p. 81).

Nile sand.

A subsurface sand, of Dev. age, in western N. Y., lying lower than Bradford sand.

Nilkoka group.

Pre-Cambrian: Eastern Alaska.

A. H. Brooks, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 472, 480, 483). *Nilkoka beds.*—Fine quartz cgl. and sss., with red and green clay slates. Upper part of fm. seems in general more argill. and lower part more aren. Closely folded. Little evidence of metamorphism. No fossils. Tentatively assigned to Paleozoic. Exposed on bluffs of lower Tanana River btw. Nilkoka Creek and Baker Creek. Younger than Tanana schist, on which the beds probably rest uncon.

According to recent work by J. B. Mertie, Jr., the Nilkoka group is pre-Camb.

Nimrod limestone. (In Cisco group.)

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, p. 136), used *Nimrod* in section only, for what appears to be the ls. in Pueblo fm. which Plummer and Moore in 1922 called *Eolian ls.*, but it may be a younger ls.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), treated *Nimrod ls.* as younger than Eolian ls. and older than Camp Colorado ls., and stated that it was named for exposures near Nimrod, Eastland Co.

Nimrod shale. (In Pueblo formation.)

Pennsylvanian: Central northern Texas (Shackelford, Stephens, and Eastland Counties, Brazos River region).

F. Bradish, Feb., 1929 (Tex. Bur. Econ. Geol., geol. map of Stephens Co.). *Nimrod sh.*, 100± ft. thick, underlies Camp Colorado ls. and overlies Stockwether ls.

O. F. Hedrick, E. Owens, P. A. Meyers, May 1929 (Tex. Bur. Econ. Geol., geol. map of Shackelford Co.). *Nimrod sh.*, 50± ft. thick, overlies Stockwether ls. and lies below Camp Colorado ls.

W. G. Wender, 1929 (Tex. Bur. Econ. Geol., geol. map of Eastland Co.), shows *Nimrod sh.* occupying interval of about 50 ft. in Pueblo fm. btw. Camp Colorado ls. (at top) and Stockwether beds below.

This name is not listed by E. H. Sellards in Tex. Univ. Bull. 3232, 1933, and presumably has been discarded by Tex. Survey, being preoccupied by Nimrod ls. of Plummer.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197, 198, 249), named the shale lying below Camp Colorado ls. and above Stockwether ls. in McCulloch Co., Colorado River region, the *Salt Creek Bend sh.*

Nineveh limestone member (of Greene formation).

Permian: Southwestern Pennsylvania and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 22, 32–33). *Nineveh ls.*, 7 to 30 ft. thick. Several ls. layers separated by shales. Lies 75 to 100 ft. above Fish Creek ss. and 25 to 30 ft. below Nineveh coal. Included in Dunkard Creek series [Dunkard group].

Nineveh sandstone member (of Greene formation).

Permian: Southwestern Pennsylvania (Greene and Washington Counties).

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 22, 32). *Nineveh shales and ss.*, 25 ft. thick on Dunkard Creek, Greene Co.; lie 20 ft. above Nineveh coal and 230 ft. below Gilmore ss. Included in Dunkard Creek series [Dunkard group]. Also *Nineveh ss.* (massive yellowish-gray coarse-grained ss.), which lies 225 to 250 ft. below Gilmore ss. Named for exposures near Nineveh, Greene Co., Pa.

Nineveh.

A name applied by drillers to several sands of probable Upper Dev. age in western Pa., because first discovered to be productive at Nineveh, Greene Co. The Nineveh 30-foot sand lies btw. 100-foot sand above and Snee sand below.

Ninole basalt.

Tertiary or older: Hawaii (Kau district).

H. T. Stearns, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 150). *Ninole basalt*, Hawaii, assigned to Tert.(?).

H. T. Stearns, 1930 (U. S. G. S. W. S. P. 616). *Ninole basalt.*—Lava flows, chiefly massive gray pahoehoe, often in beds 75 ft. thick, interstratified with a few beds of aa. About 500 ft. below top occurs a bed of compact fine-grained dark-red to brown palagonitic tuff, usually 2 ft. thick but reaching a known maximum of about 15 ft. At Noguchi tunnel a lava flow is interbedded with the tuff. Thickness of Ninole basalt unknown, but 2,100 ft. of it is exposed at Makaalia Peak, at head of Hilea Valley. Type section is exposed in walls of Ninole Valley, at Puu Enuhe.

Ninos schist.

Pre-Cambrian: Central northern New Mexico (Las Vegas region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; also Conspectus of geol. fms. of N. Mex., pp. 4, 10). *Ninos schists.*—Lower and principal schistose section above Azoic gneisses in Solitario Mtn region NW. of Las Vegas. Thickness 1,000 ft. [Derivation of name not given.]

†Niobenton sandstone.

Drillers' name for a ss. that forms top bed of Carlile sh. memb. of Benton sh. (Upper Cret.) in NE. Colo. and Ellis and Hamilton Counties of western Kans. The top of this ss. is base of Niobrara fm. in that region. The term is a contraction of Niobrara and Benton, and has been replaced by *Codell ss.*

Niobrara formation (also **Niobrara limestone**). (In Colorado group.)

Upper Cretaceous: Nebraska, South Dakota, North Dakota, central southern and southeastern Montana, eastern Wyoming, eastern Colorado, northeastern New Mexico, Kansas, and southern Minnesota.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 419, 422). *Niobrara div.* (*Formation No. 3 of Cret.*).—Upper part is lead-gray calc. marl weathering to yellowish or whitish chalky appearance; lower part is light-yellowish and whitish ls. Total thickness 200 ft. [Fossils listed.] Occurs in bluffs along the Missouri below Great Bend to vicinity of Big Sioux River, also below there on hilltops. Overlies Fort Benton group [Benton sh.] and underlies Fort Pierre group [Pierre sh.].

Is upper fm. of Colorado group. In some repts on eastern Colo. the Niobrara deposits have been treated as a group, divided into Apishapa sh. above and Timpas ls. below. In some regions the deposits are chiefly or wholly sh. and are called *Niobrara sh.*

Named for exposures along Missouri River near mouth of Niobrara River, Knox Co., Nebr.

†Niobrara group.

Miocene, Pliocene, and later (?): Eastern Wyoming and Colorado, and western and northern Nebraska.

O. C. Marsh, 1875 (Am. Jour. Sci., 3d, pl. 9, pp. 51–52). At close of Mio. a subsidence took place E. of Rocky Mtns. A great Plio. lake was thus formed directly over the eastern Mio. basin, having nearly the same boundaries on N. and W., but extending much farther E., and stretching S. nearly to Gulf of Mexico.

It covered an area at least 5 times as great as the older lake, while its deposits attained a thickness of nearly or quite 1,500 ft. This lake basin may with great propriety be called the Niobrara Basin, since Niobrara River cuts through its typical strata for more than 200 mi. The beds in this basin lie nearly horizontal. They are light in color, and much more aren. than the Mio. below. The upper strata consist of hard sss. or calc. grits, which weather but slowly, and hence still form the great table-lands over much of the basin. Writer has traced these high plateaux and the intervening isolated buttes from near Black Hills S. to Arkansas River, and found them all of Plio. age. South of Smoky Hill River these strata rest directly on the Cret.

A. Hague, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, pp. 42, 67–71). *Niobrara beds.*—For the Plio. strata of Tertiary plains of Wyo., E. of Colorado Range, the name Niobrara, first suggested by Prof. O. C. Marsh, has been retained. The beds consist of marls, clays, coarse and fine sss., and cgls., with some nearly pure lss. The fine marly sss. are predominant and light-colored lss. exceptional. Thickness 1,200 to 1,500 ft. Uncon. overlies White River and older fms. Contains Plio. fossils.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 425, 458, 544). *Niobrara group.*—East of Colorado [Front] Range the great Plio. lake stretched from base of Rocky Mtn system eastward well toward Miss. Valley, and extended in N.-S. line from lowlands of Tex. to unknown distance into British Columbia. Deposited in lake named Cheyenne Lake. Correlated with North Park group and Humboldt group. Is older than Wyoming cgl. and younger than White River group.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 115). *Upper Miocene and (?) lower Pliocene.*—First phase (Arikaree fm.) in part. Includes *Fort Niobrara* (*"Nebraska fm."*), *Nebraska.*

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 23, 25). *Fort Niobrara fm.*—Upper Mio. or lower Plio. Name *Niobrara fm.* is preoccupied in Cret. Type loc. on Niobrara River near Fort Niobrara [Cherry Co.], Nebr. This is "Horizon F" of Hayden and Leidy, 1869, and lower part of "Loup Fork" of Hayden. [Fossils listed. On pp. 9, 23, 25, he calls the beds "Niobrara River."]

Includes Ogallala and Arikaree fms. (the former of Plio. and Mio. age and the latter of Mio. age) and possibly later deposits. The Niobrara River is cut in Arikaree fm., the Ogallala being absent in that area.

†Niobrara River formation.

See 1918 entry under †*Niobrara group* (Tertiary).

†Nipigon group.

Pre-Cambrian (Keweenawan): Canada.

Name introduced by R. Bell, 1875 (Canadian Nat. and Geol., 2d ser., vol. 7, pp. 49–51), for the rocks now known as *Keweenawan series*. Named for Nipigon Basin, where the rocks have their max. development in Canada.

Nipisiguit granite.

Devonian (?): New Brunswick.

G. A. Young, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 220).

Nipissing clay.

Pleistocene: Ontario.

A. P. Coleman, 1909 (Ont. Bur. Mines Ann. Rept., vol. 18, pt. 1, p. 297).

Nipissing diabase.

Pre-Cambrian (Keweenawan): Quebec and Ontario.

M. E. Wilson, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 278).

Nipissing.

Name applied to glacial lakes, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Nipple Mountain series.

Miocene: British Columbia.

L. Reinecke, 1915 (Canada Geol. Surv. Mem. 79, pp. 57, 60).

Nisconlith series.

Cambrian (?): British Columbia.

G. M. Dawson, 1890 (Canada Geol. Surv., n. s., vol. 4, pp. 31B–32B).

These rocks were assigned to Camb. until 1912, when R. A. Daly assigned them to pre-Camb., as did Drysdale in 1917.

Nisconlithian series.

A term applied by C. [R.] Keyes to rocks of Cordilleran region interpreted as having been formed during early part of pre-Animikie erosion interval. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Nishnabotna sandstone.

Upper Cretaceous: Southwestern Iowa.

C. A. White, 1867 (Am. Jour. Sci., 2d, vol. 44, pp. 27, 31). *Nishnabotany ss.*—Coarse-grained friable ferruginous ss., sometimes more than 30 ft. thick, lying uncon. on Coal Measures in Mills, Montgomery, Cass, and Pottawatomie Counties. Of supposed Cret. age and suspected to be part of Dakota group.

C. A. White, 1870 (Iowa Geol. Surv., vol. 1, pp. 26, 167+, 289, pl. at end), described fms. of Iowa and divided Cret. into (descending) *Inoceramus* beds, 50 ft.; Woodbury sss. and shales, 130 ft.; Nishnabotany ss., 100 ft.

Named for East Nishnabotna River.

Nisky limestone.

Middle Ordovician: Eastern Pennsylvania (Lehigh Valley district).

E. T. Wherry, 1909 (Sci., n. s., vol. 30, p. 416). *Nisky fm.* (*Black River*).—Gray, very shaly ls., 100 ft. max. Underlies Nazareth cement rock and uncon. overlies Coplay ls.

B. L. Miller, 1911 (Pa. Topog. and Geol. Surv. Rept. 4), called the fm. *Nisky ls.* "Is quarried near Nazareth."

Derivation of name not known.

Btw. 1910 and 1927 this name was used in several Pa. Geol. Survey and other repts. In 1928 (letter dated March 26) B. L. Miller stated: (See quotation under *Coplay ls.*)

Nitinat formation.

Jurassic or Triassic (?): British Columbia.

C. H. Clapp, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 88) and 1912 (Canada Geol. Surv. Mem. 13, p. 44).

Nittany dolomite. (In Beekmantown group.)

Lower Ordovician: Central Pennsylvania (Center and Blair Counties), western Maryland, and western Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 552, 658, pl. 27). *Nittany dol.*—At Bellefonte consists of (descending): (1) Massive light-gray, finely crystalline dol., 198 ft.; (2) alternating beds of light- and dark-gray crystalline dol. in beds of medium thickness, 313 ft.; (3) gray crystalline dol., some chert, and a little ss., 132 ft.; (4) mainly thick-bedded, in part probably slightly calc. dol., light to medium shades of gray, crystalline to compact, 624 ft. Underlies Axeman[n] ls. and overlies Stonehenge ls. [All these fms. belong to Beekmantown group.]

Named for exposures in Nittany Valley, Center Co.

[library stamp]

†Nittany Valley limestone.

Ordovician: Central Pennsylvania (Clinton County).

H. M. Chance, 1880 (2d Pa. Geol. Surv. Rept. G_4, pp. 17–24). Trenton, Birdseye, Black River, etc. are all exposed in Nittany Valley. [In several places he used *Nittany Valley ls.* and *Nittany Valley lss.*]

Niverton shale. (In Conemaugh formation.)

Pennsylvanian: Western Maryland and southern Pennsylvania.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 67, 114, pl. 6). *Niverton sh.*—A bed of dark to olive sh., 8 ft. thick, found at various places in Castleman Basin above lower bench of Clarksburg ls. Contains great profusion of a new sp. of *Pleurophorus* and a few *Estheria ortoni*. Well exposed on W. bank of Castleman River 1.3 mi. S. of Niverton, Pa. Rests on Lower Clarysville coal and lies 25± ft. below Upper Clarksburg ls.

Nixon sand.

A subsurface sand, of Chester (late Miss.) age, in southern Ind., that has been correlated with Sample ss. memb. of Gasper oolite.

Nizina limestone.

Upper Triassic: Eastern Alaska (Nizina-Tanana region).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 429, 431, 435, etc.), casually applied *Nizina ls.* to the ls. he named, in that rept, *Chitistone ls.*

G. C. Martin, 1916 (Geol. Soc. Am. Bull., vol. 27, p. 690), introduced *Nizina ls.* for the thin-bedded lss. forming upper conformable part (1,000 to 1,200 ft.) of Chitistone ls. as defined by Rohn, and restricted *Chitistone* to the massive lss. composing lower and major part (1,800 to 2,000 ft.) of the original Chitistone. The Nizina ls. is overlain by McCarthy sh. (See also G. C. Martin, U. S. G. S. Bull. 776, 1926.)

Noah Parker horizon.

Lower Cambrian: Northwestern Vermont (Franklin County).

G. E. Edson, 1906 (5th Rept. Vt. State Geol., pp. 133–155). *Noah Parker horizon.*—The type of the Lower Camb. terrane is represented by shales and sss. The fm., by a series of ledges, passes westward from and over W. part of Noah Parker farm, in town of Georgia, Vt. This is last exposure of this horizon in N. part of Georgia, although the fm. to W. continues northward.

G. E. Edson, 1908 (6th Rept. Vt. State Geol., pp. 210–220). *Noah Parker horizon.*—The *Olenellus* zone of Walcott. Type loc. in Georgia, Vt., on farm of Noah Parker, W. of highway passing Chase's corners, where the rocks are shales and sss.

Noatak formation.

Mississippian (upper and lower): Northern Alaska (Noatak-Kobuk region).

P. S. Smith, 1913 (U. S. G. S. Bull. 536, pp. 55, 69, 74, map). *Noatak ss.*—Chiefly ss. with subordinate qtzite, sh., and thin lss. Underlies Lisburne ls. (Miss.) and overlies Upper Dev. ls. Contains large fauna of Miss. age. Possibly some of lower beds may be very late Dev., but there is considerable reason for believing the fm. is all Miss. Occurs most extensively in central and W. parts of Noatak Basin, from the canyon as far E. as camp of Aug. 9.

P. S. Smith and J. B. Mertie, Jr., 1930 (U. S. G. S. Bull. 815, p. 153). *Noatak fm.*—At its type loc., in W. part of Noatak Valley btw. Nimiuktuk and Kugururok Rivers, was originally described by Smith in 1913, under designation *Noatak ss.*, but work of that date did not yield a complete section across the strike. For this reason, and also because other Miss. rocks have in present rept been assembled and treated collectively with original Noatak ss., it has seemed desirable to create a new and more comprehensive cartographic unit, to be known as *Noatak fm.* [Long description.] Underlies Lisburne ls. and includes all pre-Lisburne Miss. rocks in northern region. In some areas includes numerous cherty beds and, along Killik River, a peculiar chert cgl. All variations may be seen btw. chert cgl. and sed. chert breccia. Present available evidence seems to justify hypothesis that Noatak fm. is a group of rocks confined essentially to northern Alaska.

Noblesville dolomite.

Silurian (Niagaran): Central Indiana.

E. M. Kindle, 1904 (Ind. Dept. Geol. and Nat. Res. 28th Ann. Rept., p. 407). *Noblesville dol.*—Hard thin-bedded buff-colored dol., 100 ft. thick, containing an older Niagara fauna (Lockport fossils) than Huntington ls., which contains a Guelph fauna.

E. R. Cumings and R. R. Shrock, 1928 (Geol. Soc. Am. Bull., vol. 39, p. 585). Noblesville fm. of Kindle (1904) is based on the highly inclined beds in flank of a reef that may lie in the Liston Creek, or more likely in both the Liston Creek and Mississinewa fms. It is certainly not permissible to name a fm. from a reef facies that in no way represents the typical fm., either lithologically or faunally; and the name Noblesville is therefore regretfully abandoned.

Named for Noblesville Twp, Hamilton Co.

†Nodaway limestone. (In Shawnee formation.)

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., p. 53). *Nodaway ls.* contains *Fusulina* and Bryozoa, underlies Nodaway or No. 9 coal, and overlies coal No. 8.

Is a part of Deer Creek ls. memb. of Shawnee fm., older name, according to H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13). R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 181), cites Hinds and Greene and includes this ls. in synonymy of Deer Creek ls.

Named for exposures at Nodaway, Andrew Co.

†Noel shale.

Devonian (?): Southwestern Missouri and northwestern Arkansas.

G. I. Adams, 1904 (U. S. G. S. P. P. 24, p. 24). *Noel sh.*—Previously described by Ark. Surv. under name "Eureka sh." (preoccupied). Hence renamed from town of Noel [McDonald Co., SW. Mo.], where it is typically exposed. Often black, but not infrequently it has a greenish and sometimes a yellowish appearance. Thickness from a few in. up to 70 ft.; usually averages 15 to 30 ft. Thus far it has never been found lying on Polk Bayou ls., as does the Sylamore. It commonly rests on Key ss., or, where that is absent, on Yellville fm. In upper part it contains at some places thin limy layers, and when not abruptly succeeded by the even-bedded St. Joe memb. of Boone fm., it grades upward into that fm.

G. I. Adams and E. O. Ulrich, 1905 (U. S. G. S. Fayetteville folio, No. 119), stated that the 30 to 70 ft. of black carbonaceous fissile sh. forming upper memb. of Chattanooga sh. and overlying 0 to 75 ft. of light-colored ss. called Sylamore ss. memb. of Chattanooga sh., is the sh. exposed at Noel.

†Nogal formation.

Permian: Southeastern New Mexico (Roswell artesian basin).

A. G. Fiedler and S. S. Nye, 1933 (U. S. G. S. W. S. P. 639). *Nogal fm.*—A lithologic unit consisting chiefly of red beds, gyp., and anhydrite, but including interbedded ls. in thick beds, dolomitic ls., ss., sh., and salt. Thickness 1,000 to 2,000+ ft. Is 1,000± ft. thick in vicinity of Nogal Canyon, for which it is named. Underlies, apparently conformably, Picacho ls. and rests on Abo ss. In SE. part of basin it gives place laterally to a thick ls. section, which is tentatively included in Picacho ls. The Nogal fm. differs from the younger Pecos fm. in that it is usually much more thickly bedded and includes but a small proportion of red beds. The Nogal fm. is considered by geologists working in SE. N. Mex. to be Yeso fm. of Lee and Girty, and it forms lower part of Chupadera fm. of Darton in this region. The Picacho ls. of this rept is considered by geologists working in this region to be the San Andres ls. of Lee and Girty.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). Picacho ls. is here abandoned for San Andres ls. memb. of Chupadera fm., and Nogal fm. is here abandoned, being replaced by Hondo ss. memb. of Chupadera fm. (above) and Yeso memb. of Chupadera fm. (below). [As originally defined and heretofore used San Andres ls. rested on Yeso. The recognition of Hondo ss. involves slight redefinition of San Andres and Yeso.]

Nogales division.

A term applied by E. T. Dumble (Am. Inst. Min. Engrs. Trans., vol. 29, 1900, and vol. 31, 1902) to 1,000 ft. of "late Tertiary" [now assigned to Cret. or Tert.] lavas, aggls., and cgls., with some andesitic lavas and tuffs, in Sonora, Mexico, and Cochise Co., SE. Ariz. Probably named for Nogales, Santa Cruz Co., Ariz.

Noix oolite member (of Edgewood limestone).

Silurian (early): Northeastern Missouri and southwestern Illinois.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 62). *Noix oolite.*—Very white massive fossiliferous oolite, 4 to 7 or more ft. thick, lying on Buffalo shales (Ord.) at Louisiana, Mo., and vicinity, and extending over area of 100 sq. mi. in Pike and Lincoln Counties, Mo., and Calhoun Co., Ill. Underlies Bowling Green ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28). *Noix oolite* uncon. underlies Brassfield ls. and uncon. overlies Girardeau ls.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 351–376). *Noix oolite memb.* will refer to local oolite facies of Edgewood fm. that is=upper half to two-thirds of Cyrene memb. of Edgewood.

C. R. Keyes, 1914 (Am. Jour. Sci., 4th, vol. 37, pp. 254–256), included in *Noix ls.* the upper local oolitic ls. or Noix oolite of previous repts as well as underlying nonoolitic ls. resting on Girardeau ls., and discarded Cyrene memb.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 4). *Noix oolite* overlies Edgewood ls. and underlies Bowling Green dol.

E. B. Branson, 1918 (Univ. Mo. Bull., vol. 19, No. 15). *Noix oolite memb.* of Edgewood fm., 8 to 10 ft. thick, is a local phase of Cyrene ls. memb. of Edgewood, which wedges in btw. typical Cyrene and the Bowling Green. Occurs in Mo. only near Louisiana.

At present the U. S. Geol. Survey divides Edgewood ls. into Bowling Green ls. memb. above and Noix oolite memb. below, the underlying fm. being Girardeau ls.

Named for exposures along Noix Creek at Louisiana, Pike Co., Mo.

Nolans limestone. (In Sumner group.)

Permian: Northeastern Kansas.

R. C. Moore, Jan.–Feb. 1936 (Jour. Geol., vol. 44, No. 1, pp. 5–9), divided Sumner group into (descending) Wellington [restricted], Donegal, and Nolans fms., but did not define the new names *Donegal* and *Nolans*.

R. C. Moore, Sept. 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12). *Nolans ls.* underlies Pearl sh., overlies Odell sh., and includes (descending) Herington ls., Paddock sh., and Krider ls. [Derivation of name not stated.]

Nolichucky shale.

Upper Cambrian: Eastern Tennessee, western North Carolina, and southwestern Virginia.

A. Keith, 1896 (U. S. G. S. Morristown folio, No. 27, p. 2). *Nolichucky sh.*—Calc. shales and shaly lss., with beds of massive blue ls. in upper portion. When fresh the shales and shaly lss. are bluish gray and gray, but they weather readily to various shades of yellow, brown, red, and green. Over much of region the fm. is nearly uniform, and contains only yellow and greenish-yellow sh. Passing NE. to N. of Holston River the ls. beds become more prominent and the shales more highly colored and calc. Thickness 400 to 750 ft. Very fossiliferous. Overlies Maryville ls. and underlies Knox dol.

Foregoing is original definition in type region. The name, however, first appeared in print in 1894, in U. S. G. S. Estillville folio (No. 12), by M. R. Campbell, who accepted Keith's name and correlated the rocks of Estillville area with those of Nolichucky type loc. He described the fm. as consisting of 500 to 730 ft. of calc. sh. carrying lentils of blue ls., the center of fm. in Carter Valley consisting of a lentil of massive blue ls. 400 to 500 ft. thick. Underlain by Maryville ls. and overlain by Knox dol.

Named for exposures along Nolichucky River, Greene Co., Tenn.

Nome group.

Early Paleozoic or older: Northwestern Alaska (Seward Peninsula).

A. H. Brooks, G. B. Richardson, and A. J. Collier, 1901 (Reconn. Cape Nome and Norton Bay regions, Alaska, in 1900: U. S. G. S. Spec. Pub., p. 29, map). *Nome series.*—Lss., graphitic mica and calc. schists, with many greenstone intrusives and some chloritic schists of undet. origin; green schists common. Broadly speaking the rocks are calc. Thickness 5,000 to 6,000 ft. Overlies Kuzitrin series. Differs from Kuzitrin series and from older Kigluaik series in character of metamorphism. Can hardly be considered a strat. unit, as lithological constitution of its beds is rather heterogeneous. Most typically developed to S. of Kigluaik Mtns and Bendeleben Mtns.

Nomlaki tuff member (of Tehama and Tuscan formations).

Pliocene: Northern California (Tehama County).

R. D. Russell and V. L. Vander Hoof, 1931 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 20, No. 2, pp. 12–15). *Nomlaki tuff memb.*—A massive coarse-grained pumice tuff memb. that occurs near base of Tehama fm. and also near base of Tuscan fm. Is of dacitic composition and consists of white pumice fragments embedded in a medium- to light-gray matrix of glass and crystal shards. Most of pumice fragments are less than 3 in. max. diam., but they occasionally exceed 1 ft. Upper 6 ft. of the tuff has a salmon-pink color, in marked contrast to the predominant gray below. Thickness variable; in Tehama Co. the max. is 50 ft. A separate designation for this tuff memb. seems advisable because of its highly distinctive appearance, dacitic composition in contrast to the andesitic Tuscan, much wider distribution, and value as a horizon marker. The Tehama fm. with exception of this tuff memb. contains only a very subordinate amount of volcanic debris. The tuff memb. is therefore named for its good exposures on old Nomlaki Indian Reservation, in Tehama Co.

Nonesuch shale. (In Oronto group.)

Pre-Cambrian (late Keweenawan): Northern Michigan and northeastern Wisconsin.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 221–224, pls. 17 and 18). The *Nonesuch sh. belt* consists of black sh. and gray ss. It overlies Outer cgl. and underlies a red ss. [Freda ss.]. At Nonesuch mine, SE¼ sec. 1, T. 51, R. 43 W., the sh. is seen with a thickness of over 200 ft., trending N. 45°–50° E., and dipping SE. 28°. Near base of the sh. is the ss. seam, 4 ft. thick, worked at Nonesuch mine for its copper, and known as Nonesuch lode.

According to C. R. Van Hise and C. K. Leith (U. S. G. S. Bull. 360, p. 346, 1909) the Nonesuch sh. has been traced 125 mi. and varies in thickness from 125 to 500 ft.

Named for occurrence at Nonesuch mine, Gogebic Co., Mich.

Noodle Creek lime.

A subsurface unit, of Penn. age, in Noodle Creek field, Jones Co., north-central Tex., lying at 2,500 ft. depth.

Noonday greensand.

A name locally applied to Tyler greensand of Wendlandt and Knebel in Smith Co., Tex.

Nora limestone.

Upper Devonian: Central northern Iowa.

A. O. Thomas, 1913 (Sci., n. s., vol. 37, p. 459). A new substage, for which *Nora ls.* is proposed, is added as lowest memb. of Lime Creek stage. Uncon. overlies Cedar Valley stage in Floyd Co.

According to C. L. Fenton (Am. Jour. Sci., 4th, vol. 48, 1919) this ls. possibly belongs to Cedar Valley ls. In 1924 (Univ. Mich. Pub. Contr. Mus. Geol., vol. 1, frontispiece) C. L. and M. A. Fenton divided the Cedar Valley into (descending) *Nora*, Shell Rock, and Lower Cedar Valley.

C. H. Belanski, 1927 (Am. Mid. Nat., vol. 10, No. 10), redefined *Nora substage of Shell Rock stage* to include at base the uppermost part (first *Actinostroma* zone) of Mason City ls. of previous repts. He divided his Nora substage into (descending) Second *Actinostroma* zone, *Platyrachella* zone, and First *Actinostroma* zone, and described it as consisting of 0–20 ft. of hard white stromatoporoidal ls., mag. sh., shaly ls., and (in northern phases) dol.

Named for exposures in an abandoned quarry near Nora Junction, Floyd Co.

See also under *Shell Rock ls.* (Upper Dev.).

Nordenskiöld dacite.

Jurassic or Cretaceous: Yukon Territory, Canada.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 29).

Nordheimer formation.

Carboniferous (?): Northwestern California (Klamath Mountains).

O. H. Hershey, 1906 (Am. Jour. Sci., 4th, vol. 21, pp. 58–66). *Nordheimer fm.*—Black slaty sh. with max. estimated thickness of 3,000 ft. At base a slight development of coarse ss. apparently made up of debris from underlying quartz-bearing rhyolite. This ss. is nowhere more than 50 ft. thick, but can be traced for several miles. No evidence of noncon. btw. the ss. and the rhyolite. No other sss. and no cgl. or ls., but contains a few thin layers of chert. Is badly shattered by intrusive rocks. No fossils. May be late Dev. but is more likely Carbf. Some characters suggest Baird fm. It might also be a western representative of Triassic Pit shales, but is not likely to be any younger. The valley of Nordheimer Creek is cut in the fm.

Nordstrom oil zone.

Subsurface Plio. beds encountered in wells of Santa Fe Springs oil field, Los Angeles Co., Calif., that lie lower than Meyer oil zone and higher than Buckbee oil zone.

†Norfolk formation.

Pleistocene and Pliocene (?): Southeastern Virginia.

W. B. Clark and B. L. Miller, 1906 (Va. Geol. Surv. Bull. 2, pt. 1, p. 20). *Norfolk fm.*—Clays and sands; in places sandy clays, as in canal cuts below Portsmouth; contain great quantities of shell remains, making the beds distinctly calc. Thickness probably not 50 ft. Buried beneath heavy mantle of later Pleist. sediments so that areal extent and thickness cannot be readily determined. Probably forms northward extension of Plio. beds of N. C. Fossils chiefly marine Mollusca of characteristic Plio. types. Underlies Lafayette fm. Named for Norfolk Co., Va., where the deposits have been recognized in deep cutting in Dismal Swamp Canal.

T. L. Watson, 1909 (Va. Geol. Surv. Bull. 1A, p. 9). *Norfolk* included in Plio. Underlies Lafayette.

Later revision of fossil lists by T. W. Vaughan and W. C. Mansfield has led to opinion that these beds are Pleist. and Plio. (?).

†Norfolk Basin series.

Carboniferous: Southeastern Massachusetts.

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull. vol. 49, Geol. ser., vol. 8, No. 4, pp. 91–271). *Norfolk Basin series.*—Narrow belt of sediments which bear many resemblances to members of Roxbury cgl. series. Consists of arkose, coarse and fine cgls., sss., and slates much like Roxbury series. Pebbles are composed of same substances as Roxbury series. Both Roxbury series and Norfolk Basin series contain casts of same tree trunks. The Narragansett Basin sediments are redder than Norfolk Basin sediments, and latter are redder than Roxbury series. Connected through a narrow pass at Sheldonville with the cgls. and other sediments of Narragansett Basin.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the belt of sediments described above as Wamsutta fm. and Pondville cgl.

†Norian.

A name applied in some early repts to the anorthic rocks of the pre-Camb. Laurentian series. Named for prevalence of rocks of this age at Esmark, Norway, where the norites were first described. For particulars see U. S. G. S. Bull. 360, 1909.

†Norman division.

Permian: Central Oklahoma.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 43). *Norman div.*—All rocks of Red-beds from base of that series to lowermost gyp. ledges on E. slope of Gypsum Hills. Chiefly brick-red clay shales with some interbedded ledges of red and whitish ss. To E. sss. predominate, but along base of Gypsum Hills the beds are almost wholly clay. Underlies Ferguson gyp. memb. of Blaine div., where that gyp. is present; elsewhere extends up to base of Medicine Lodge gyp.

Later work showed that Norman, Cleveland Co., is not on unit named.

Norman sandstone.

Permian (?): Central Oklahoma.

C. T. Kirk, 1904 (Okla. Dept. Geol. and Nat. Hist. 3d Bien. Rept., p. 10). *Norman ss.*—Ss. carrying a mass of peculiar concretions commonly called petrified roses. Well exposed on hilltops 6 mi. SE. of Norman [Cleveland Co.] and on bluffs at Purcell, Ind. T. Separated from overlying Wreford ls., or its equivalent Payne ss., by 15 to 40 ft. of reddish-gray sh. or clay. Gould's prior use of "Norman" has been dropped.

Normandy limestone.

Middle and Upper Ordovician: Central Tennessee.

M. R. Campbell, 1899 (U. S. G. S. Standingstone folio, No. 53, p. 2). *Normandy ls.*—Blue calc. sh. and thin-bedded ls., with, locally, at top, a bed of dark heavy-bedded brown siliceous ls. 20 ft. thick. Thickness of fm. 200 or more ft. Constitutes upper part of Safford's Nashville series. In McMinnville folio (No. 22) the southward extension of presumably these same beds has been termed Chickamauga ls. Neither of these terms is definite enough for detailed mapping of central basin, therefore *Normandy ls.* has been suggested by Dr. Safford as an appropriate term for the two uppermost members of his Nashville series. These two divisions are presumably inseparable in field, but are clearly distinguished from the *Orthis* bed, which lies immediately below. Underlies Chattanooga sh.

Includes beds of Trenton, Eden, Maysville, and later (?) age.

Named for Normandy, Bedford Co.

Normanskill shale.

Lower and Middle (?) Ordovician: Eastern New York, southwestern Vermont, and northwestern Massachusetts.

R. Ruedemann, 1901 (N. Y. State Mus. Bull. 42, pp. 489–568). *Normans Kill sh. (Lower Dicellograptus zone).*—It is proposed to employ *Normans Kill shales* for the clastic facies of part of lower Trenton, which is characterized by the graptolite fauna at the Normans Kill [a tributary entering Hudson River just S. of Albany, at Kenwood]. Includes [in upper part] the lower Trenton ls. cgl. of Rysedorph Hill [named *Rysedorph Hill cgl.* in Bull. 49, 1901]. Underlies sh. containing middle Trenton fauna and overlies lower Trenton ls. The Normanskill shales differ strongly faunistically and lithologically from lower Trenton ls. and certainly deserve to be designated by separate name. Heretofore included in "Hudson River shales," abandoned because too inclusive.

In 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 371–372, 512, and pl. 27) E. O. Ulrich stated that Normanskill fauna (which comprises little besides graptolites) occurs in great development in Athens sh. of Tenn., and assigned both fms. to upper Chazy.

In 1912 (N. Y. State Mus. Hdb. 19, p. 35) C. A. Hartnagel stated that *Rysedorph cgl.* is intercalated in or overlies Normanskill sh., and in accompanying chart stated that Normanskill sh. includes at top Rysedorph cgl. and possibly the Burden cgl.

In 1914 (N. Y. State Mus. Bull. 169, pp. 66-99, 140) R. Ruedemann classified *Upper Normanskill sh.* as of Black River age, and included in it the *Rysedorph Hill cgl.*, "which is intercalated at a number of localities." He stated: "Fossils of Rysedorph Hill cgl. indicate it is younger than typical Normanskill sh. and that it intervenes in age btw. typical Normanskill sh. and Snake Hill sh. (of lower and perhaps middle Trenton age). The *Normanskill sh. s. str.*, 1,000± ft. thick, is of upper Chazy age, based on evidence obtained by Ulrich in Athens trough of Tenn., and consists of blue to gray, mostly argill., often more or less sandy shales with thin bands of black, highly carbonaceous graptoliferous and pyritiferous shales, with some included grit beds; it uncon. overlies Bald Mtn ls., of Beekmantown age." [The map accompanying Bull. 169 maps Rysedorph Hill cgl. as overlying Normanskill sh.] In 1921 (N. Y. State Mus. Bull. 227 and 228, p. 130) Ruedemann classified Normanskill sh. as of Black River and upper Chazy age. In letter to compiler dated May 3, 1927, Dr. Ruedemann stated: "It appears that the Athens sh. in Va. has afforded fossils which demonstrate the upper Chazy age of the Normanskill sh. At the same time here [N. Y.] an upper zone of the Normanskill sh. (that with *Corynoides gracilis*) appears to be younger and has therefore been correlated by me with the Lowville and Leray lss. No positive evidence for this correlation has as yet been obtained."

R. Ruedemann, 1929 and 1930. [See these entries under *Rysedorph cgl.*]

L. M. Prindle, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 257-302, fig. 2) mapped *Normanskill sh.* in N. Y., Vt., and Mass. parts of Taconic quad. As mapped in Vt. it occurs in SW. part of Bennington Co. "The Normanskill fauna of Capital dist., N. Y., ranges in age from Chazy to possibly Black River."

Norrie ferruginous chert member (of Ironwood formation).

Pre-Cambrian (upper Huronian): Northwestern Michigan (Gogebic district) and northwestern Wisconsin.

W. O. Hotchkiss, 1919 (Eng. and Min. Jour., vol. 108, pp. 501, 504). *Norrie ferruginous chert memb.*—Almost wholly wavy-bedded granular and fine-grained ferruginous cherts with hematite in beds and grains. Thickness 30 to 230 ft. Is a memb. of Ironwood fm. Uncon. underlies Pence ferruginous sl. memb. and conformably overlies Yale memb. Named for Norrie mine, E. of Ironwood, Mich.

Norris limestone. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 889, 897, pls. opp. pp. 889, 900, 912, 921). *Norris ls.*—Buff ls., usually less than 2 ft. thick, 25± ft. below Shawnee or Buff ls. in Hocking Valley. In southern Ohio, if correctly identified, it becomes an important ore horizon.

Later repts state it is same as Snow Fork and Lower Freeport lss.

Named for proximity to Norris coal.

Norristown sandstone. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Montgomery County).

E. V. d'Invilliers, 1883 (2d Pa. Geol. Surv. Rept. D_3, vol. 2). *Mesozoic fm.* (*"Trias," "New Red," "Norristown ss.," etc.*)—Unaltered red sss. and shales, trap dikes, and altered beds, and cgl. beds.

Probably same as Stockton fm.

†Norristown shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Bucks and Montgomery Counties).

B. S. Lyman, 1893 (Pa. Geol. Surv. geol. and topog. map of Bucks and Montgomery Counties) and 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, pp. 2589–2638). *Norristown shales*.—Red shales, brown and gray ss., and pebble rock, 6,100 ft. thick. Underlies Gwynedd shales. Is basal fm. of Mesozoic.

Same as Stockton fm.

Named for exposures at Norristown.

†Norristown stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, pp. 51–52). *Norristown stage*.—Ss. 100 ft. thick in Okla., where it overlies Booneville stage and underlies Tomlinson stage. In Ark. usually consists of two sss. (upper one 0 to 200 ft. thick and lower one 100 to 200 ft. thick), underlies Spadra stage (absent in Ind. T.), and overlies Booneville stage. In Ind. T. underlies Tomlinson sh., the intervening Hartwell ss., Belva sh., and Ozark ss. of Ark being absent.

Same as Hartshorne ss., later but better-established name.

Probably named for Norristown, Pope Co., Ark., just across river from Dardanelles.

North amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs to Central Mine group. Is older than National ss. and younger than Calico amygdaloid. The mineralized part is the North lode. Derivation of name not known.

North flow.

Includes North amygdaloid and underlying trap.

North Ada limestone.

Miners' local name for an ore-bearing ls., 3 ft. thick, in lower part of Oquirrh fm. (Penn.), Stockton dist., central northern Utah. Lies 140 ft. below their St. Patrick ls. and 18 ft. above their South Ada ls. Exposed in Ada claim. (See U. S. G. S. P. P. 173, 1932.)

†North Amherst granite.

Late Carboniferous or post-Carboniferous: Central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 323). *North Amherst granite*.—A peculiar rock appearing in hills SE. and W. of North Amherst Station and at foot of W. slope of Pelham Ridge E. of D. Hawley's, beside a brook.

B. K. Emerson, 1914 (personal communication). The North Amherst granite is same as Williamsburg granodiorite.

Northbrae rhyolite.

Pliocene: Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Northbrae rhyolite*.—Numerous isolated patches of white rhyolite lava, apparently the remnants of a flow the greater part of which has been removed by erosion. Thickness probably nowhere exceeds 100 ft. Occurs on W. slope of Berkeley Hills N. of Berkeley. Rests on worn surface of Franciscan and Cret. fms. Overlain by Campus and Orinda fms. Named for occurrence in Northbrae dist., near Berkeley.

Northbridge granite gneiss.

Pre-Cambrian: Central southern Massachusetts and northwestern Rhode Island.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18), showed *Northbridge gneiss* of Worcester Co., Mass., as older than Sutton gneiss. (All of definition.)

B. K. Emerson and J. H. Perry, 1903 (Geol. of Worcester, with map). *Northbridge gneiss.*—Light gray, tinted flesh red by feldspar. Oldest fm. in area. Overlain by Westboro qtzite.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 155–156 and map). *Northbridge granite gneiss.*—Occupies a broad area, with a core of coarse, slightly gneissoid porphyritic microcline-biotite granite and a broad border of completely mashed, stretched, and penciled, highly muscovitic gneiss. Named for occurrence at Northbridge, Worcester Co., Mass. Assigned to Archean (?).

North Butler amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Older than Mass amygdaloid and younger than Butler amygdaloid. The mineralized part is North Butler lode. Probably named for its occurrence N. of Butler amygdaloid.

North Butler flow.

Includes North Butler amygdaloid and underlying trap.

North Carolina grit.

Commercial term for quartz cgl. at Parkwood, Moore Co., N. C., that is used for an abrasive material.

†North Denison sand.

Lower Cretaceous (Comanche series): Northeastern Texas and southeastern Oklahoma.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 13, pp. 302, 303, 328–330, 334). *North Denison sands.*—Fossiliferous beds characterized by alternations of excessively ferruginous laminated sands and clay, which by infiltration and induration are sometimes converted into fossiliferous hematite. Thickness 100 to 130 ft. Overlie Marietta clays and are inseparable from overlying Pawpaw clays; all included in Denison beds. Include, at top, Quarry ls.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 384–385), applied *North Denison terrane* to beds beneath Pawpaw terrane and above Denton terrane, or to Weno clay memb. of current nomenclature.

Named for exposures in northern half of Denison, Grayson Co., Tex.

Northeast shale.

Upper Devonian: Western New York (Chautauqua County) and northwestern Pennsylvania (Erie County).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Northeast sh.* is applied to beds overlying Shumla ss. and uncon. underlying Volusia sh. in Chautauqua Co., the uncon. representing Cuba ss.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 152). Shumla ss. initiates over 400 ft. of beds in no wise different from the Gowanda and Westfield as they enter the State. These, the "Portage flags" of I. C. White, are here renamed *Northeast sh.*, from twp in Erie Co., Pa. Fully exposed (about 415 ft.) in Chautauqua Creek gulf and on the Canadaway (Arkwright Falls) above Shumla. Here nearly barren, but eastward they assume an easily recognized fauna, best exhibited in Pierce quarry W. of Machias. [See explanation about this fauna under *Machias fauna.*] Northeast sh. is part of Wellsburg ss. to E. Included in Chautauquan [Chemung] of N. Y. Survey.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), placed Northeast sh. below Cuba ss. and above Shumla ss., and included them all in Chemung.

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). Restudy of Upper Dev. correlation problems in SW. N. Y. indicates a discrepancy in thicknesses along Genesee River and at Lake Erie of beds formerly supposed to be identical, which may require some further examination in field before publication of map. Former revisions may not have gone far enough in their departure from old ideas. The beds involved are only those above Dunkirk black sh., whose continuity with Canaseraga sss. above the Wiscoy sh. has been amply corroborated. It now seems likely, however, that the Cuba ss., 835 ft. above the Dunkirk along Genesee River, goes below, instead of above, Northeast shales at Lake Erie, whose base there is

526 ft. above the Dunkirk, and their top, 1,001 ft. With the known westward thinning of all these Upper Dev. strata, generally to about 98.52 percent a mi. NW., which would bring the Cuba top down to 484 ft. above the Dunkirk, the Cuba seems likely to connect with Shumla ss., and the Northeast to embrace all beds above it, perhaps including the Cattaraugus. Consequently it becomes desirable to introduce local names for two of these members on the Genesee-Olean meridian, namely, *Cadiz beds* for the supposed "*Volusia*" btw. the Cuba and the Hinsdale sss., and *Haymaker beds* for those formerly taken for the Chadakoin, btw. *Hinsdale* ("*quarry*") *ss.* and Wolf Creek cgl. The succession thus becomes Cuba, Cadiz, Hinsdale, Haymaker. In any event, it grows increasingly clearer that there are no Miss. strata in N. Y.

†Northern Lignitic.

A descriptive term applied to Claiborne group, also to Wilcox group and Midway fm., in early geologic repts on Gulf Coastal Plain.

A. C. Veatch, 1906 (La. Geol. Surv. Bull. 4, p. 28). The name Chickasaw fm. or stage was suggested by Hilgard as an appropriate equiv. for his Northern Lignitic (Geol. Miss., 1860, pp. 110–123; Am. Jour. Sci., 3d, vol. 2, 1871, pp. 304–396), for the very sufficient reason that the entire Northern Lignitic is within Chickasaw Purchase, and its most characteristic and conspicuous outcrops are on the four Chickasaw Bluffs, of which the Memphis Bluff is the last. Dall, however, assumed that Hilgard's Northern Lignitic was exact equiv. of the Lignitic defined by paleozoologic criteria in Ala. section, and so used it. As a matter of fact the Northern Lignitic is a lignitiferous complex, containing representatives of all beds btw. the Midway and the Jackson, and therefore represents the swamp and estuarine deposits of the Sabine, Claiborne, and Jackson epochs. The strata exposed in Chickasaw Bluff, the type loc., are stratigraphically either Jackson or underlying Cockfield, which is uppermost Claiborne. In the whole of Chickasaw Purchase (about 20,000 sq. mi.) no locality of the Sabine (Lignitic) containing typical marine fossils has been found, and it is necessary to go 100 mi. from its border for such a locality. It therefore appears necessary either to use the name Chickasaw fm. in sense in which Hilgard defined it or to abandon it.

†Northfield slate.

Lower Ordovician (Beekmantown): Northeastern Vermont (Washington County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., p. 95). [See 1906 entry under †*Montpelier sl.* Northfield is in Barre quad., in Washington Co.]

Northfield conglomerate.

Lower Ordovician: Northeastern Vermont (Northfield Township, Washington County).

C. H. Richardson, 1919 (11th Rept. Vt. State Geol.). [Suggests *Northfield cgl.* as name for geologic equiv. of Irasburg cgl. in Northfield and Roxbury Twps. See 1919 entry under *Irasburg cgl.*]

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 107–110). *Northfield phase of Irasburg cgl.* is characterized by pebbles of devitrified rhyolite embedded in a paste of clay sl. from which Ruedemann identified Deepkill (Beekmantown) fossils.

C. H. Richardson and J. E. Maynard, 1933 (18th Rept. Vt. State Geol., p. 346). The *Irasburg, Albany, and Northfield cgls.* form base of Ord. in eastern Vt.

North Fork shale. (In lower part of Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 239). *North Fork sh.*—Black sh. with lenses 1 to 2 in. thick of iron ore. Marine fossils. Thickness 5 to 10 ft. Lies 10 to 15 ft. below Keystone coal and overlies Simmons coal. Exposed flush with N. & W. Railway grade at North Fork, McDowell Co.

North Haven greenstone.

Cambrian (?): Central southern Maine (Penobscot Bay quadrangle).

G. O. Smith, 1896 (Geology of Fox Islands, Maine, pp. 12, 13–19). *North Haven greenstone complex.*—Greenstone schists, in the main aphanitic and of light-yellow to grayish-green color. Includes diabases, also large masses of amygdaloidal greenstone and smaller amounts of a rather tuffaceous rock, at one point breccialike. Locally the greenstone is quite plainly crystalline. The greenstone complex resolves itself into a series of diabase flows with accompanying pyroclastics. The age of these diabasic lavas is determined as pre-Niagara, from their relations to the cgl. at base of Niagara sediments.

G. O. Smith, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 6). *North Haven greenstone.*—Name applied to rocks earlier described and mapped as North Haven greenstone complex. Is much older than the Sil. sediments and about contemp. with Islesboro and Castine fms. Assigned to Camb. (?). Named for development on North Haven Island, Penobscot Bay.

On 1933 geol. map of Maine, by A. Keith, this fm. is included in block labeled "Mainly Sil., but some of Dev. age."

North Higgins moraine.

Pleistocene (Wisconsin stage): Northern central Michigan (Roscommon County).

W. A. Ver Wiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 161). Lies on N. and NE. side of Higgins Lake.

North Hill member.

Mississippian (Kinderhook): Southeastern Iowa.

L. R. Laudon, 1931 (Iowa Geol. Surv., vol. 35, pp. 344, 347, 366–371). *North Hill* is proposed for oldest memb. of Hampton fm. in SE. Iowa. Thickness 8 ft.; at Burlington 20 ft. Conformably underlies Wassonville memb. of Hampton fm. and rests uncon. on English River fm. and possibly in a few places on underlying Maple Mill fm. Consists of (descending): (1) oolitic ls. (*Schellwienella* zone), 3 ft.; (2) yellow ss. (*Palaeoneilo* zone), 6 ft.; (3) semilithographic ls. (*Parypho-rhynchus* zone); (4) oolitic ls. (*Chonetes* zone), 9 inches. Named for exposure on North Hill, in city of Burlington, where both upper and lower contacts are exposed. Is correlated with Chapin memb. of Hampton fm. of north-central province and with some part of the Chouteau of Mo.

L. R. Laudon, 1933 (Univ. Iowa Studies, n. s., No. 256, vol. 15, No. 2, p. 9), gave a "Composite Mississippian section of Iowa," in which he applied *North Hill memb.* to beds underlying Maynes Creek memb. and overlying English River fm., and did not mention Chapin memb., which as defined occupies this interval and has priority over *North Hill.*

L. R. Laudon (1935) stated these beds should be removed from Hampton fm. (See 1935 entry under *Hampton fm.*)

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc. pp. 241, 245). I am inclined to accept Laudon's conclusions that entire North Hill memb. should be classed as Chouteau, but not the higher parts of so-called Hampton fm.

North Lake zone. (In Negaunee formation.)

Pre-Cambrian (middle Huronian): Northern Michigan (Marquette County).

J. L. Adler, 1935 (Jour. Geol., vol. 43, No. 2, pp. 113–132). *North Lake zone of Negaunee fm.*—Chiefly straight, medium- to thin-bedded or massive red, yellow, brown, and gray dense ferruginous cherts with interbedded hematite and limonite at many horizons in form of concretions (characteristic feature) and branching growths. Some wavy-bedded portions in upper part. Thickness 650 to 670 ft. Grades into overlying Corning Creek zone and into underlying Makasin Hill zone. [Type loc. not stated, but the map shows it around North Lake Location.]

North Leon limestone member (of Graham formation).

Pennsylvanian: Central northern Texas.

F. Reeves, 1923 (U. S. G. S. Bull. 736E, p. 117). *North Leon ls. memb.*—Blue fine-textured siliceous ls., stained pink in spots, which weathers in thin yellow plates and shelly fragments. Thickness 4 ft. Lies 71 ft. below Bunger ls. memb. and 50 ft. above Gonzales ls. memb. in Ranger oil field, Eastland Co. Exposed on North Fork of Leon River, in Eastland Co., but North Fork and Leon are both preoccupied, so that North Leon is used.

North Mound conglomerate and quartzite.

Pre-Cambrian (upper Huronian): Central northern Wisconsin (Wood County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 371). *North Mound cgl. and qtzite.*—The rock forming North Mound [about 5 mi. NW. of Babcock, Wood Co.] is mainly a qtzite grading into a fine cgl. Rests on laminated and schistose rhyolite. Thickness 200 to 500± ft. Resembles Baraboo qtzite. Is either upper or middle Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this fm. to upper Huronian.

North Mountain basalt.

Triassic: New Brunswick and Nova Scotia.

S. Powers, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 93).

North Nahanna River dolomite.

Silurian: Mackenzie, Canada.

E. M. Kindle, 1936 (Sci., n. s., vol. 83, No. 2140, pp. 14–15). *Lone Mtn dol.* (preoccupied) replaced by *North Nahanna River dol.* North Nahanna River enters Mackenzie River adjacent to Lone Mtn.

North Park formation.

Tertiary (Miocene?): North Park, Colorado, and Hanna Basin, Wyoming.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, map 1). [*North Park (Pliocene?)* of northern Colo. is shown as younger than *Niobrara (Pliocene)*, White River (Miocene), and Vermillion Creek (Eocene), and as overlain by Quaternary.]

A. Hague, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, p. 128). The Tert. deposits of North Park, Colo., a few hundred ft. thick, are probably of late Plio. age. They are given local name *North Park Tert.* They uncon. overlie sss. that may prove to belong to Fox Hill. [On pp. 130–141 he stated that North Park Tert. of Park Range uncon. overlies Laramie group.]

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 431–434, 458, 544). *North Park group.*—Lake deposits of loose friable drab sss., soft whitish and grayish-white and buff marls which cannot be distinguished from Niobrara Plio. of Horse Creek. Occupy entire valley of North Park, except where Cret. and volcanic rocks rise above its surface. Uncon. overlies Cret. and in places rests on Archean. Believed to be Plio. and may prove to be same as Niobrara Plio. to E. Thickness not over 300 ft.

A. C. Veatch, 1907 (U. S. G. S. Bull. 316, p. 246, columnar section of Cret. and Tert. rocks of central Carbon Co., Wyo.). *North Park fm.*—White volcanic-ash beds, cherty bands; base conglomeratic. Thickness 4,500 ft. Uncon. overlies Fort Union fm., which consists of 1,200± ft. of dark-colored shales and shaly sss., resting on "Upper Laramie."

A. L. Beekly, 1915 (U. S. G. S. Bull. 596, pp. 20, 49, 66, 71). The uppermost stratified rocks of North Park constitute *North Park fm.*, which outcrops in a long, comparatively narrow area in south-central part of field. The geologists of King Surv. (U. S. Geol. Expl. 40th Par., vol. 1, pp. 431–434, 1878) applied *North Park group* to all strata overlying the marine Cret. in North Park field, but they particularly described the appearance and character of the uppermost white calc. and ashy beds. In 1907 Veatch (U. S. G. S. Bull. 316, pp. 244–260) used *North Park* to designate a similar white calc. and ashy fm. in east-central Carbon Co., Wyo., which, though considerably thicker, is apparently the strat. equiv. of upper white beds of North Park group of King. He used the name in a much more restricted [?] sense in Wyo. than it was originally applied in North Park, for he made a distinction btw. the white ashy beds and the underlying fm., which now appears to be=Coalmont fm. or lower part of North Park group as defined by King. The name *North Park* is therefore restricted [?] in this rept to topmost fm. in North Park, which is characterized by white calc. ss. and ash beds. Relation of North Park fm. to underlying rocks, though very much obscured, is believed to be one of uncon., and Tert. age is unquestioned. Thickness 500± to 1,000 or more ft. Overlies Coalmont fm. (of Cret. or Tert. age, and consisting of 4,000 to 5,000 ft. of fresh-water beds, of dark color and coal-bearing). Contact with Coalmont fm. not sufficiently well exposed to prove relationship, but evidence observed outside the park leaves little doubt it is one of uncon. [See also under *Coalmont fm.*]

North Point member.

Middle Devonian: Southeastern Wisconsin (Milwaukee County).

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 262, 263, 266). *North Point memb.* (*novum*).—Upper memb. of Milwaukee fm. Does not outcrop. Known in borings, tunnel excavations, and material in glacial drift. Consists of gray shales and shaly lss. with quantities of silica in nature of chalky-textured chert. Many fossils [listed]. Thickness in wells 50 ft. Overlies Lindwurm memb. of Milwaukee fm. and underlies Kenwood fm. (Miss.). Type loc., North Point, Intake Tunnel.

Northport clays.

Term applied by A. Hollick, in heading in N. Y. Bot. Garden Bull., vol. 3, No. 11, 1905, to the Cret. clays exposed in vicinity of Northport, Long Island.

Northport limestone.

Paleozoic(?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 75, map). *Northport ls.*—In reality is interbedded with Mission argillites, but as a strat. unit is so distinct it has been mapped as separate fm. Varies greatly in character. Is prevailingly massive fine-grained white ls., in places dolomitic. South of Northport it forms large areas and is typically massive, pure white, passing to light gray, usually finely crystalline, but occasionally becomes rather coarse and shows stratification planes. From Marble to Blossburg it has tendency to become banded and is interstratified with bands of quartz-mica schist and argillite. Thickness 3,000± ft.

North Ridge agglomerate.

Upper Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81). [See under *Combe ss.*]

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 5, pp. 896, 901). *North Ridge fm.*—A crudely stratified pyroclastic aggl. of medium grain and basic composition; dark gray, speckled white. Thickness 200 ft. Few fossils. Occurs on Hinchman Ridge and Ravine, north ridge of Mount Jura (type loc.), and elsewhere. Age early Upper Jurassic. Underlies Forman argillite and overlies Hinchman arkose.

North River blue stone.

Commercial term for a quarried bed in Sherburne flagstone memb. of Portage fm. (See C. S. Prosser, 1899, N. Y. State Geol. 17th Ann. Rept., pp. 312–315.)

North Star conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 80 and chart). *North Star cgl.* is cgl. No. 12 of Houghton Co.

According to B. S. Butler (U. S. G. S. P. P. 144, 1929) the North Star cgl. of Marvine is probably same as Allouez cgl., which is No. 15. It belongs to Central Mine group.

Named for occurrence in old North Star mine, Houghton Co.

Northumberland formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 100).

†North Valley Hill sandstone.

Lower Cambrian: Southeastern Pennsylvania (Chester and Montgomery Counties).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, pp. 79, 165, 166). *North Valley Hill ss.* of Chester Co. Same as Chiques ss. *North Valley Hill rock* is popular name for the fm. in its long outcrop through Chester and Montgomery Counties. Exposed for miles along North Valley Hill, Chester Co., where it rests uncon. on azoic gneiss of Welsh Mountain country.

Included Chickies qtzite and possibly some of overlying Harpers albite schist.

North Vernon limestone.

Middle Devonian: Southeastern Indiana (Jennings County).

W. W. Borden, 1876 (Ind. Geol. Surv. 7th Ann. Rept., p. 148). *North Vernon ls.*—Dark-blue compact stratified ls. with an occasional upper ledge of gray ls. Thickness 11 ft. 3½ in. Overlain by New Albany sh. and underlain by Corniferous ls. [E. T. Cox, 1879 (Ind. Geol. Surv. 8th, 9th, and 10th Ann. Repts, p. 88) gives exposed thickness as 25 to 33 ft.]

Same as Sellersburg ls.

Named for North Vernon, Jennings Co.

Northview shale. (In Kinderhook group.)

Mississippian: Southwestern Missouri.

S. Weller, 1901 (Jour. Geol., vol. 9, p. 140). *Northview ss. and sh.*—Fossiliferous yellowish ss. grading imperceptibly downward into bluish sh., latter most persistent and very fossiliferous in places but usually barren of fossils. Thickness 10 to 90 ft. Known as Vermicular ss. and sh. in early repts. Overlain by Pierson ls. and underlain by so-called (not typical) Louisiana ls. [Compton ls. of R. C. Moore, 1928]. Not equiv. to typical Hannibal sh. of central Mo. Included in Kinderhook group. Faunas of upper yellow ss. at Burlington and Northview ss. are analogous.

Named for exposures at Northview, Webster Co.

†Northville moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Replaced by *Defiance moraine* (*outer ridge*).

North Warren shale member.

Upper Devonian or Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 203). *North Warren sh. memb.* (of Cattaraugus fm.), new name, is in midst of the Salamanca. It underlies Millers ss. memb. and overlies Watson ss. memb. (Venango 2d "A"). Is Dev.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 87). *North Warren sh. memb.*—Middle memb. of Salamanca formational suite (Dev.). Underlies Pope Hollow cgl. and overlies Bimber Run cgl. memb. Resembles the older Amity sh., but has increased number of yellowish sandy cgl. lenses and contains a rather characteristic Salamanca fauna. Thickness, 20 ft. at Warren and 35 to 40 ft. along the Allegheny. In other places it is indistinguishable and the overlying and underlying cgls. come together. Named for occurrence btw. Asylum quarries at North Warren and Tanner's Hill quarries (now Warren reservoir) on Tanner's Hill, Warren, Pa. Best place for study is in ravines along Allegheny River on E. side, S. and N. of junction of Bimber Run and the river.

The U. S. Geol. Survey classifies Cattaraugus fm. as Upper Dev. or Miss.

Northwestern formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799, 836–843, with maps). *Northwestern fm.*—Essentially green, finely foliated garnet-mica schists interstratified with thin micaceous qtzites. Overlain by Garfield fm. and underlain by West Ledge fm. Thickness 2,200 ft. Believed to be of Keewatin age.

Named for exposures in cuts of Chicago & Northwestern R. R. btw. Lead and Blacktail, Lawrence Co.

See under *Lead system*.

Norton formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky and southwestern Virginia.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 34). *Norton fm.*—Shales, sss., clays, and coals, 1,280 to 1,310 ft. thick, underlying Gladeville ss. and overlying Lee cgl. in Bigstone Gap coal field of Va. and Ky.

Belongs in middle of Pottsville group.

Named for Norton, Wise Co., Va., but according to J. B. Eby and M. R. Campbell (Va. Geol. Surv. Bull. 24, 1923) it is now known that Norton is not on Norton fm. but on the younger Wise fm. The full thickness of Norton fm., however, can be seen at Coeburn and Virginia City, Va.

†Norton zone. (In Niobrara formation.)

Upper Cretaceous: Northwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies vol. 6, p. 51). *Norton zone.*—Yellow to white, red, etc., more chalky zone of Smoky Hill chalk than underlying Trego zone. Named for Norton and Norton Co.

Is middle part of Smoky Hill chalk memb. (See W. W. Rubey and N. W. Bass, 1925, Kans. Geol. Surv. Bull. 10, p. 28.)

Norwalk sandstone member (of Jordan sandstone).

Upper Cambrian: Western Wisconsin.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, No. 7, p. 547). Trempealeau fm. is divided by E. O. Ulrich [unpublished at this time] into four members, of which Norwalk fine-grained dolomitic ss. is topmost one. It is overlain by Jordan ss. [as restricted by Ulrich] and underlain by Lodi memb. of Trempealeau fm.

E. O. Ulrich, 1924 (Wis. Acad. Sci., Arts, and Lett. Trans., vol. 21, pp. 83, 86). The thickest and therefore perhaps the most important of the members of Trempealeau fm. is the one at the top, for which the term *Norwalk sandstone member* is proposed. As a rule it consists of fine-grained ss., sometimes nearly white and often with a yellowish or brownish tinge, commonly rather massive in upper two-thirds and more or less thin bedded and in even plates 1 to 6 inches thick in its lower third. Thickness 0 to over 40 ft.; is about 35 ft. thick at Norwalk, Monroe Co. Has not been observed E. of Cross Plains, in which region Trempealeau fm. is terminated above by Lodi shale memb., which underlies Norwalk ss. memb. in the complete section. The Norwalk contains a large and varied fauna.

C. R. Stauffer, 1925 (Jour. Geol., vol. 33, pp. 699–713). Norwalk ss. memb. of Ulrich should not be excluded from Jordan ss., as it composes all of the beds present at Jordan.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 60). We believe, with Stauffer, that Norwalk ss. is=Jordan ss. at Jordan, Minn., and that these beds and their equivalents can not properly be called *Norwalk* and be classified as a fm. older than the Jordan. Otherwise there would be Norwalk but no Jordan present at Jordan type loc.

A. C. Trowbridge, W. H. Twenhofel, G. O. Raasch, and others (?), 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 142, etc.) abandoned Norwalk ss. and restored the beds to Jordan ss.

E. O. Ulrich, 1936 (Geol. Soc. Am. Proc. 1935, p. 113). There are 3 sss. in Wis. that previously have been regarded as constituting an indivisible strat. unit. The Norwalk ss. is top memb. of Trempealeau fm., the Jordan is a separate final deposit of the Camb. of upper Miss. Valley, and the Madison is first deposit of Ozarkian of the region.

Norway limestone.

Huronian: Northern Peninsula of Michigan (Menominee iron region).

C. L. Rominger, 1881. [See under *Lake Hanbury sl. group.*]

J. Fulton, 1888. [See under *Lake Hanbury sl. group.*]

Norway Point formation.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526). *Norway Point fm.*—Brown and gray lss., grading up into argill. lss.

and calc. clay. Several beds carry *Spirifer* cf. *granulosus* and *Cryphaeus boothi*. Greatest measured thickness, 46 ft. Underlies Potter Farm fm., and rests on Alpena ls., sometimes with slight hiatus. Type loc., Norway Point dam (also known as Boom Co. or Sevenmile dam), Thunder Bay River, Alpena Co.

Norwich conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and pp. 17–18). *Norwich cgl.*—The first of the intrusive rocks with which we meet is a belt of cgl. and sss. of undet. but not great width. Its southern portion is hidden by deep deposits of drift, but its northern bdy is exposed in deep adit at Norwich mine, where its disturbed and broken structure gives decided evidence of uplifting forces which elevated the trap and associated sedimentary belts through the superincumbent strata of Potsdam ss. [Lies considerably below cgl. No. 8.]

Norwich trap.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and p. 18). A series of trappean belts 1,253 ft. wide, generally characterized by great hardness, peculiar fracture, and presence of an unusual amount of epidote, and in its southern portion by a segregated or banded structure not common elsewhere. For convenience of reference termed *Norwich traps*. [Shown as younger than Norwich cgl., from which it is separated by 80 ft. of trap and 20 ft. of ss.]

Named for occurrence in Norwich mine, Ontonagon Co.

Nosoni formation.

Permian: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Nosoni fm.*—Largely andesite or basalt tuffs and tuffaceous cgl. and a few flows of lava, locally interstratified with shales and sss., in part calc. and often rich in fossils. Thickness 500 to 1,200 ft. Top fm. of Penn. Conformably overlies McCloud ls. and underlies Dekkas andesite. Includes "McCloud shales" of Smith and Fairbanks, as well as the pyroclastic rocks with which these shales are so intimately associated. Named for exposures on Nosoni Creek.

N. E. A. Hinds, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 274, and Calif. Univ., Dept. Geol. Sci. Bull. 20, p. 404), assigned Nosoni to Perm., as did H. E. Wheeler, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 218).

The U. S. Geol. Survey now classifies this fm. as Perm.

Notch Peak limestone.

Upper Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll. vol. 53, No. 1804, p. 9). *Notch Peak fm.*—Gray aren. ls. in more or less massive layers. Thickness 1,890 ft. Overlies Orr fm. Type loc. is upper part of main mass of Notch Peak.

Nottely quartzite.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 5). *Nottely qtzite.*—Entirely fine white qtzite. Thickness more than 150 ft. Overlies (through gradation) Andrews schist. Highest Camb. fm. in area.

Named for excellent exposures along Nottely River, in Cherokee Co., N. C.

Nounan limestone.

Middle Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll. vol. 53, No. 1804, p. 6). *Nounan fm.*—Light-gray to dark lead-colored aren. lss., 1,041 ft. thick in Blacksmith Fork Canyon, Cache Co., Utah, and 814 ft. W. of Liberty, Bear Lake Co., Idaho. Overlies Bloomington fm. and underlies St. Charles fm. Type loc. is E. slope of Soda Peak, W. of Nounan, Bear Lake Co., Idaho. Nounan Creek Canyon cuts through the fm.

Nouvelle dacites.

Age (?): Quebec.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 73).

Novillo beds.

Cretaceous (?): Mexico.

A. Heim, 1926 (Eclogae geol. Helvetiae, vol. 20, p. 84)

Nowadaga.

Upper Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Nowadaga* introduced for lower Utica or zone of *Climacograptus typicalis* in Mohawk Valley.

Nowata shale.

Pennsylvanian: Northeastern Oklahoma and southern Kansas.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 23). *Nowata sh.*—Bluish or greenish shales with a few sss. and at least one bed of coal. Thickness 50 to 600 ft. Top fm. of Tulsa group. Overlies Altamont ls. memb. of Oologah ls. and underlies Lenapah ls. Named for Nowata, Nowata Co., Okla.

In Okla. is treated by U. S. Geol. Survey as a distinct fm., and in Kans. as a memb. of Parsons fm. But R. C. Moore has recently (Kans. Geol. Surv. Bull. 22, 1936) discarded Parsons fm. and treats Nowata sh. as a fm. in his Marmaton group. These changes have not been considered by U. S. Geol. Survey for its publications.

Nowhere Island granite gneiss.

Age (?): Ontario (Rainy Lake district).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 97).

Noxlini shales.

See under *Nazlini shales.*

Ntlakapamux formation.

Jurassic: British Columbia.

C. H. Crickmay, 1930 (Calif. Univ., Dept. Geol. Sci. Bull., vol. 19, No. 2, p. 33). "The name is that of Thompson River Indian people."

Nugget sandstone.

Jurassic (Middle?): Southwestern Wyoming, southeastern Idaho, and northeastern Utah.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56, p. 56, chart opp. p. 50, map, etc.). *Nugget fm.*—The group of yellow, pink, and red sss. bounded below by the gray fossiliferous lss. of Thaynes fm. and above by the dark-colored fossiliferous shales and lss. of Twin Creek fm. Named for Nugget Station, on Oregon Short Line, SW. Wyo., at and near which the beds are well exposed. Along Twin Creek in vicinity of Nugget the fm. is 1,900± ft. thick and shows two distinct members, a lower brightly colored red-bed memb. 600 ft. thick and an upper light-colored ss. memb. The upper memb. is a thin-bedded ss. the layers of which are perforated with holes at right angles to the bedding planes, but are otherwise without a suggestion of organic life. This ss. is light yellow on fresh exposures and weathers dark brown. In Absaroka Ridge, Wyo., these two divisions are not distinct. [The Nugget fm. of Veatch corresponds essentially to Ankareh sh. as originally defined by Boutwell in Park City dist., Utah, according to studies of G. R. Mansfield (U. S. G. S. Bulls. 713, 716, and P. P. 152).]

H. S. Gale and R. W. Richards, 1910 (U. S. G. S. Bull. 430), in attempting to reconcile the definitions of Boutwell in NE. Utah and of Veatch in SW. Wyo., subdivided the rocks of SE. Idaho and adjacent parts of Utah and Wyo. into following fms. (descending):

Twin Creek ls. 3,500 [ft.].

Nugget ss. 1,900. (Massive red and white ss. and red sandy sh.; greater part dark red or brown, although in places an upper zone is distinct as a clear white ss.; includes intervals of sandy sh.)

Ankareh sh. 670. (Red sh., mottled red and greenish clay and sh., some ss. and ls.)

Thaynes ls. 2,000 or less. (Main body dark-blue ls., in many places fossiliferous; weathers brown muddy color; includes sandy and calc. sh.)

J. M. Boutwell, 1912 (U. S. G. S. P. P. 77, p. 59). *Nugget ss.*—About 500 ft. of white sss. with some intercalated reddish shales complete the section in Park City dist., Utah. These were originally grouped with Ankareh sh., but subsequent work in adjoining areas, in which overlying beds are well represented, makes it apparent they represent lower part of upper portion of Nugget ss. of Veatch (U. S. G. S. P. P. 56, 1907), and further described and mapped by Gale and Richards in U. S. G. S. Bull. 430, 1910. Veatch's Nugget included at base 600± ft. of reddish strata which properly belong to Ankareh sh., and in all later repts Nugget has been restricted to upper heavy white sss., which also include some sh. beds. The beds in Park City dist. that are correlated with Nugget ss. outcrop in ridges E. and W. of Iron Hollow, in extreme NW. corner of dist. They overlie Ankareh sh. [as here restricted]. [Boutwell in above rept. reduced thickness of Ankareh sh. from 1,500+ ft., as given in his original definition, to 1,150+ ft.]

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 31–42), divided rocks of Fort Hall Ind. Res., SE. Idaho, as follows (descending):

Twin Creek ls.

Nugget ss.

Main ss. memb. 1,500 [ft.] (red and light-colored sss.).

Wood sh. memb. 250 (red).

Deadman ls. memb. 150±

Higham grit memb. 500±

Ankareh ss. 800

Thaynes group 3,650 (chiefly lss., some sss. and sh.).

Woodside sh. 900.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713), restricted *Nugget ss.* to the upper or "main ss. memb." of his earlier repts, elevated Wood, Deadman, and Higham to rank of fms., and replaced *Ankareh ss.* of that area with *Timothy ss.* According to his 1927 rept (U. S. G. S. P. P. 152) the Nugget ss. as now recognized in SE. Idaho is=upper part of Veatch's typical Nugget of SW. Wyo., and of Gale and Richards' Nugget of SE. Idaho, but includes more than Boutwell's Nugget of NE. Utah; and *Ankareh* appears not to be applicable to any specific unit in SE. Idaho.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, p. 3). It is believed that typical Nugget ss. of SW. Wyo. and Wasatch Mtns is direct equiv. of Navajo ss. [For further details see pp. listed in index to vol. cited.]

Nulato formation.

Upper Cretaceous: Southwestern Alaska (Nulato-Norton Bay district, lower Yukon River region).

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 247, 276, 331, pl. 3). *Nulato sss.*—Brownish marine sss., 60 to 200 ft. thick, best exposed just above Nulato, a village on Yukon River. Belong to Mio. Conformably overlie Kenai group (probably Eo.).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 395, 400). *Nulato fm.*—Marine ss. and sh., 3,000± ft. thick. Overlies Melozi fm., with apparent conformity, and underlies Kaltag fm., apparently conformably. Marine invertebrates and few plants. Is Upper Cret. Includes Nulato sss. of Dall. Is typically exposed in NW. bank of the Yukon for 2 to 10 mi. above Nulato.

See under *Shaktolik group*, of which these beds form a part. Also see U. S. G. S. P. P. 159, 1930.

Nummulitic.

A term employed by some European geologists to include Oligocene and Eocene of American geologists.

†Nummulitic limestone.

Paleontologic term applied in early repts to Ocala ls. (upper Eocene) of Fla., also to Vicksburg group (Olig.) of Ala.

Nunatami formation.

Ordovician: Greenland.

Chr. Poulsen, 1927 (Meddelelser om Grønland, Bd. 70, pp. 246, 342).

†Nunda group.

Upper Devonian: New York and Pennsylvania.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, p. 172). *Portage or Nunda group.*—Is=Sherburne flags of Hall. Includes Cashaqua sh., Gardeau and Portage groups, and Sherburne flagstone and sh. of repts. Relative position perfectly seen on Cayuga Lake. Underlies Ithaca group and overlies Genesee sl.

The use of *Nunda* for *Portage group* was generally abandoned many years ago, *Portage* having both priority and usage in its favor. The N. Y. State Survey and U. S. Geol. Survey both use *Portage group* and apply *Nunda* to the ss. formerly sometimes called †Portage ss. G. H. Chadwick, however, has recently adopted *Nunda* for the group and *Portage* for the ss. (See his papers in Pan-Am. Geol., vol. 60, 1933, and Geol. Soc. Am. Bull., vol. 46, No. 2, 1935.) He includes in his Nunda group all beds from base of Ithaca to top of Wellsburg.

"Named for superior development along banks of Genesee River in dist. formerly included in town of Nunda, now Portage." (James Hall, 1843.)

Nunda sandstone.

Upper Devonian: New York.

J. M. Clarke and D. D. Luther, 1908 (N. Y. State Mus. Bull. 118, p. 61). *Nunda ss.* is introduced to replace "Portage sss.," the upper terminal memb. of Portage group as defined by Hall. In Portage and Nunda quads. the fm. consists of 215 ft. of light blue-gray ss. in layers 3 to 10 ft. thick, some of which are calc. Is only part of Portage group that can be said to be fairly well exposed in town of Nunda, and only to these sss. can name *Nunda* with any propriety be applied. Is overlain by Wiscoy shales and sands, which paleontologically belong to Portage group. Underlain by Gardeau flags and sh.

The name *Nunda ss.* was also applied to †Portage ss. by Luther in 1911 (N. Y. State Mus. Bull. 152, p. 22), Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), Luther 1914 (N. Y. State Mus. Bull. 172, p. 27), and Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157), 1920 (idem, vol. 31, p. 118) and 1922 (idem, vol. 34, pp. 68–69). The use of *Nunda* for *Portage group* was generally abandoned many years ago. In 1933 (Pan-Am. Geol.) and 1935 (Geol. Soc. Am. Bull.), however, G. H. Chadwick adopted *Nunda* for the group and *Portage* for the ss. (See under *Portage group*.) W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 369, 402, etc.), used *Nunda* for the *ss.* and *Portage* for the *group*.

The U. S. Geol. Survey now treats Nunda ss. as a fm., underlying Wiscoy sh. and overlying West Hill fm. (=Gardeau sh. to E.). This is also the present usage of N. Y. State Survey.

Nunnally coal group.

Pennsylvanian: Central Alabama.

A group of six coal beds in Pottsville fm. of Cahaba coal field, the group lying 650 ft. above Chestnut ss. memb., and occurring within a vertical section of 300+ ft. Includes D or Figh coal, C or Cubical coal, B or Lemley coal, and A coal, also coals called Upper, Middle, and Lower Nunnally.

Nushagak formation.

Tertiary (Miocene or Pliocene): Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 173–174, 184). *Nushagak beds.*—Sands, gravels, arkoses, and clays, practically unconsolidated, slightly folded. Form E. shore of Nushagak Bay, and around Cape Etolin to Bristol Bay. Mio. fossils. Uncon. underlie Bristol Bay silts and gravels (Pleist.).

Nussbaum formation.

Tertiary (Pliocene?): Eastern Colorado (Pueblo and adjacent regions).

G. K. Gilbert, 1897 (U. S. G. S. Pueblo folio, No. 36). *Nussbaum fm.*—Chiefly sand, with gravel and silt. Rests uncon. on Pierre sh. Underlies Pleist. alluvium.

Named for Nussbaum Spring, E. of Pueblo.

Nutrian series.

A term employed by C. [R.] Keyes to include Todilto ls. and underlying Wingate ss. (See Pan-Am. Geol., vol. 66, No. 3, 1936, p. 225.)

Nuttall sandstone member (of Sewell formation).

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1902 (U. S. G. S. Raleigh folio, No. 77). *Nuttall ss. lentil of Sewell fm.*—Massive cgl., 150 to 200 ft. thick, forming top bed of Sewell fm. along New River from Caperton to Deepwater. Forms the cliffs from Gauley Bridge to Nuttallburg, for which it is named.

Nuttall (Lower) sandstone. (In middle of Pottsville group.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western parts of Mercer and Summers Counties, pp. 112, 139, 210, 330, 355). *Lower Nuttall ss.*—Current-bedded grayish-white coarse-grained, frequently conglomeratic ss., 50 to 100 ft. thick, lying 20 to 60 ft. below Nuttall ss. Is probably a split off Nuttall ss. [Sections show it 0 to 85½ ft. below Douglas coal and overlying Lower Douglas coal.]

†Nutzotin series.

Jurassic, Carboniferous, and older: Southeastern Alaska.

A. H. Brooks, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 359). *Nutzotin series.*—Provisional name. Includes great thickness of slates, graywackes, lss., flags, and sss., with heavy cgl. at base. Assigned to upper Paleozoic. Rests, probably uncon., on Kotlo series.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, pp. 231–232). The rocks composing Nutzotin Mtns were grouped together by writer in 1900 rept under name *Nutzotin series*, a strat. subdivision since abandoned. Schrader, who mapped this country in more detail in 1902, found enough fossils to make it evident most of rocks of Nutzotin Mtns are Mesozoic, but was unable to subdivide them.

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 240–245). "Nutzotin series" of Brooks included Jurassic, Carbf., and other pre-Jurassic rocks.

Nuuanu volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Nuuanu volcanics.*—Chiefly basalt of 3 petrographic types and of different ages, mapped together. Included in lower part of Honolulu volcanic series [q. v.]. Exposed in Nuuanu Valley, 1 mi. from Pali Gap.

Nye shale.

Oligocene (upper): Northwestern Oregon (Lincoln County).

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, p. 269). *Nye sh.*—Shales of upper Olig. age. Type loc. in Lincoln Co. Regarded as older than *Aturia* bed and younger than Eugene fm.

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 450, 456, 459). *Nye sh.*—Dark concretionary shales; on fresh exposures black, massive, jointed, and might more properly be termed a mudstone. [No thickness given.] Replaces "Acila shales" (paleontologic term) of Harrison and Eaton. Underlies, probably uncon., the Mio. deposits of the area and rests, with apparent uncon., on Yaquina fm. Assigned to upper Olig. Type loc. at town of Newport and at Nye Beach, in NW¼ sec. 5, T. 11 S., R. 11 W., Lincoln Co.

H. G. Schenck, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 1, table opp. p. 4). *Nye sh.* of Smith, 1926, was adopted from ms. rept. of H. G. Schenck.

Oak Creek beds.

Lower Cretaceous: Northeastern Wyoming and western South Dakota (Black Hills).

W. P. Jenney, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, p. 593, fig. 122, and map). *Oak Creek beds.*—Lower Cret. clays and ss.; upper beds mostly soft clays, clay shales, sandy shales, and soft sss., 60 to 120 ft. thick; basal 35 to 40 ft. consists of massive yellow ss., often cross-bedded. Uncon. underlie Dakota ss. and uncon. overlie Barrett shales in Black Hills. Formerly included in Dakota ss. (Upper Cret.). [Map shows these beds along Oak Creek, Crook Co., Wyo.]

According to W. W. Rubey (personal communication Jan. 1937) the rocks described are Fuson fm. and upper part of Lakota ss. as mapped in U. S. G. S. Aladdin folio, No. 128, 1905.

Oak Creek formation.

Pliocene (early) or upper Miocene: Central southern South Dakota (Mellette County).

E. L. Troxell, 1916 (Am. Jour. Sci., 4th, vol. 42, pp. 345–348). *Oak Creek fm.*—Very fine-grained ss., built up by a stream, probably a channel deposit resting upon and within the upper Mio. or earliest Plio. Fauna (including a new sp. of horse) indicates early Plio. Occurs in E. part of Rosebud Indian Res., near town of Mission, S. Dak.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, p. 23). *Oak Creek fm.*, near Mission, S. Dak., is upper Mio. or lower Plio.

Named for Oak Creek, E. part of Mellette Co.

Oakdale quartzite.

Carboniferous: Central Massachusetts, central southern New Hampshire, and northeastern Connecticut.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 59, 60–62, 76–78). *Oakdale qtzite.*—Fine, even-grained flaggy qtzite, in many places greatly jointed, reddish brown from development of secondary biotite in minute scales or greenish from development of actinolite in small lenses or subordinate beds that were originally calc. Presumably = Merrimack qtzite, but because of some uncertainty regarding the correlation, and because of its wide separation, it seems best for present to give the qtzite of Worcester trough the name Oakdale, from village in town of Sterling [Twp], Mass., where it is conspicuously displayed. In my opinion the Oakdale qtzite grades into Paxton quartz schist to W. It is overlain by Worcester phyllite.

Oakes moraine.

Pleistocene (Wisconsin stage): Southeastern North Dakota.

H. A. Hard, 1929 (U. S. G. S. Bull. 801, pp. 31–32). Of late Wisconsin age. Younger than Antelope morainic system. Lies E. of village of Oakes, in Lamoure quad.

Oakes sand.

Name applied to a subsurface sand in Homer field of northern La., which is correlated with Buckrange sand lentil of Ozan fm. (Upper Cret.) of southern Ark. Named for Oakes farm. Also known as *Blossom sand* in Cotton Valley and *Haynesville sand* in Haynesville field.

Oak Grove sand. (In Alum Bluff group.)

Miocene (middle): Northwestern Florida and probably southwestern Georgia and southeastern Alabama.

W. H. Dall and J. Stanley Brown, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 166 and 170). *Oak Grove sand.*—Further W., at Oak Grove, on Yellow River [in Okaloosa Co.], Fla., what appears to be this same [Chipola] fauna occurs in a fine incoherent gray sand, with a number of species not found in Chipola marl, including the *Turritella* (n. sp.) referred to as occurring at Rock Bluff. It would seem, therefore, that this same zone is represented at that point, though the matrix is different.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 104, 105). *Oak Grove sand memb. of Alum Bluff fm.*—Fine-grained light-gray to greenish sands—a sandy shell marl, which often has a considerable admixture of calc. material. Thickness a few ft. Contains many excellently preserved shells. Fauna closely related to that of Chipola memb. Is a middle memb. of Alum Bluff fm.

The Alum Bluff was in 1926 (U. S. G. S. P. P. 142, p. 2) elevated by Julia Gardner to rank of a group, and the Oak Grove to rank of a fm., overlain by Shoal River fm. and lying higher than Chipola fm.

Oak Grove member.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to 20± ft. of undescribed beds of alternating lss. and sh. in lower part of Carbondale fm. (Penn.) of central western Ill. Said to underlie his Purington sh. and overlie his Francis Creek sh., which rests on coal No. 2. Derivation of name not stated.

Oak Hill clay. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

W. Stout, 1916 (Ohio Geol. Surv., 4th ser., Bull. 20, pp. 19, 27, 252). *Oak Hill clay*, 2 to 3 ft. thick, locally lies directly on Lower Kittanning coal, but in places lies 20 ft. above that coal. Burned for brick in vicinity of Oak Hill, Jackson Co. Noted in Jackson, Scioto, and Muskingum Counties. [In table on p. 19 Oak Hill clay underlies Lost Seam coal; in tables on pp. 27 and 252 Oak Hill clay is placed immediately above Hamden ore and several ft. above Lost Seam coal.]

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21, p. 177). *Oak Hill clay.*—Flint and plastic clay, 0 to 12 ft. thick. Overlies Hamden ls. in Jackson and Muskingum Countjes.

W. Stout and R. E. Lamborn, 1924 (Ohio Geol. Surv., 4th ser., Bull. 28, p. 141). *Oak Hill clay.*—Impure, part flint, 0 to 12 ft. thick. Found locally from Lawrence Co. to Columbiana Co. and to Beaver Valley, Pa. Very unsteady in position. May form roof of Lower Kittanning coal or may merge with Middle Kittanning clay. In Columbiana Co. it lies 15± ft. below Middle Kittanning memb. and 0 to 19 ft. above Hamden memb.

Oak Hill slate.

Cambrian (Upper): Southern Quebec.

T. H. Clark, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 1, pp. 225–226). Uppermost Camb. bed is *Oak Hill sl.*, which may or may not have been forerunner of a third cycle whose other representatives have been lost by faulting and erosion.

†Oak Hill-Pine Barren group.

A name applied by E. A. Smith (Rept. on Coastal Plain of Ala., 1894, p. 188) to beds now known as *Midway fm.*

Oakland limestone.

Oligocene: Southwestern Oregon (Roseburg quadrangle).

J. S. Diller, 1898 (U. S. G. S. Roseburg folio, No. 49). *Oakland ls.* on map, *Oakland ls. lentils* in text.—Shaly and nodular argill. ls. generally known in vicinity of Oakland as "cement rock." Only 3 small areas, rather widely separated, were observed, one a mi. NE. of Oakland, another at head of Green Valley, and the third on Starr's ranch, about 4 mi. NE. of Umpqua Ferry. None of areas is more than acre in extent. There are probably other localities. Fossils show it is much younger than Umpqua fm., and must rest on it uncon. According to Dall, fossils are probably Olig., most likely upper Olig.

Oakland conglomerate member (of Chico formation).

Upper Cretaceous: Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, table on p. 416). *Oakland*, 500 ft. (cgl.). [Shown as underlying Chico and as younger than Knoxville.]

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, table on pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Oakland cgl. memb. of Chico fm.*—Cgl., 100 to 1,000 ft. thick, forming basal memb. of Chico fm. in Berkeley Hills. At many places the cgl. shows distinct stratification, but exhibits none of subordinate plication observed in underlying sh. of Knoxville fm., upon which it rests conformably. Named for type exposure at city of Oakland.

Oakland City sand.

A subsurface productive oil sand, 0 to 50 ft. thick, in Tri-County oil field of SW. Ind. Top lies 40 to 60 ft. below top of Big lime and 20 to 60 ft. above Brown oil sand. Lies in Mooretown ss. of Cumings.

Oakridge sandstone.

Jurassic (?): Western California (Alameda County).

C. F. Tolman, Jr., 1915 (Nature and science on Pacific coast, San Francisco, Elder & Co., p. 45). *Oakridge ss.*—Upper memb. of Franciscan series at Corral Hollow [near Livermore, Alameda Co.]; slightly metamorphosed. Younger than Corral Hollow shales.

Oak Ridges moraine.

Pleistocene (Wisconsin stage): Eastern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17.

Oaks shale.

Pennsylvanian: Kansas and Nebraska.

R. C. Moore and G. E. Condra (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.). [*Oaks sh.* is shown as top memb. of Admire sh. and as overlying Houchen Creek ls. and underlying true Americus ls. Whether these beds were included in Hughes Creek sh. as originally defined or are a newly discovered unit was not stated, but it appears that this sh. and overlying true Americus ls. were included in Hughes Creek sh. of previous repts. Derivation of name not stated.]

G. E. Condra, 1935. (See under *Hamlin sh.*)

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated October 16). Type loc. of Oaks sh. is Oaks farm, SW. of Salem, NE¼ sec. 9, T. 1 N., R. 15 E., Richardson Co., Nebr.

Oakville sandstone.

Miocene (middle and lower?): Southwestern Texas.

E. T. Dumble, 1894 (Jour. Geol., vol. 2, pp. 556–559). *Oakville*.—Grits and coarse sand, cross-bedded, with some beds of clay, but oftener with balls, nodules, or lenses of clay embedded in the grit. Assigned to Mio. Overlies Eocene Frio clays and underlies Lapara div. (Plio.).

A. Deussen, 1924 (U. S. G. S. P. P. 126). *Oakville ss.* is 180 to 603 ft. thick. Contains Mio. fossils. Uncon. overlies Catahoula ss. and underlies (probably uncon.) Lapara sand.

Named for Oakville, Live Oak Co.

O-atka beds.

Silurian: Western New York.

G. H. Chadwick, 1917 (see 1917 entry under *Bertie ls. memb.*).

Derivation of name not stated.

Oatka Creek shale (in Marcellus shale).

Middle Devonian: Central and western New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 130–131+). *Oatka Creek sh.*—Upper memb. of Marcellus sh. from Cayuga Lake westward to Seneca Lake, being overlain by Mottville memb. of Skaneateles sh. and underlain by Cherry Valley ls. memb. of the Marcellus. To W. of Seneca Lake the Oatka Creek memb. comprises all of Marcellus and includes time equivalents of (descending) Cardiff memb., Chittenango memb., Cherry Valley ls. memb., and Union Springs memb. In area to W. of Cayuga Lake the Oatka Creek memb. is overlain by Stafford ls., the equiv. of Mottville memb. The Oatka Creek consists of black sh., markedly calc. and fossiliferous, in which characters it differs from black Chittenango sh., which overlies Cherry Valley ls. in E. part of State. Type section is below Main St. bridge over Oatka Creek at LeRoy, where whole section (30 ft.) is exposed. It thickens to E. and to W. to 50± ft. Other exposures are in bed of Conesus Creek at Ashantee, Genesee Valley, and in Flint Creek 1½ mi. NE. of Orleans. At all these localities it is overlain by a thin Stafford ls.

Oatman andesite.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). Volcanic flows, but connected in places with intrusive bodies of same rock. Thickness estimated at 2,700 ft. In places intrudes Alcyone trachyte. In places rests on Esperanza trachyte and in places is separated from the Esperanza by 50± ft. of light-colored tuffaceous ss. Exposed N. of Oatman.

Oatman Creek granite.

Pre-Cambrian: Central Texas (Llano uplift).

H. B. Stenzel, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 144). [See under *Six-mile granite*.]

Obispo limestone.

Age (?): Panama.

E. Howe, 1907 (Isthmian Canal Comm. Ann. Rept. 1907, pp. 108–138).

Obispo breccia.

Age (?): Panama.

E. Howe, 1908 (Am. Jour. Sci., 4th, vol. 26, p. 213).

Observatory Hill quartz porphyry.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Marquette County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 519). *Observatory Hill quartz porphyry* occurs 6 mi. N. of outcrop of Marcellon quartz porphyry, in SE¼ sec. 7, town of Buffalo, Marquette Co.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). "May be supposed to be pre-Huronian."

Ocala limestone.

Eocene (upper): Northern and northwestern Florida, southern and western Georgia, and southern Alabama.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 103, 157, 331). *Ocala ls.*—Yellowish friable rock containing many Foraminifera, conspicuous among which are two species of *Nummulites* (*N. willcoxii* and *N. floridana* Hp.), which appears in central Fla. directly and conformably to overlie *Orbitoides* ls. (Vicksburg). It is best displayed at Ocala, Fla., where it forms the country rock and has been quarried to a depth of 20 ft. without coming to bottom of the beds. [Other places where it is exposed are mentioned.] Assigned to "Eocene or 'Oligocene'."

Later studies by C. W. Cooke (see Ala. Geol. Surv. Spec. Rept. No. 14, 1926) have proved this ls. to be of Jackson (upper Eocene) age and to underlie Vicksburg group of lss.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). As now understood Ocala ls. comprises all rock of Eo. age exposed in Fla. This includes "Orbitoidal," "Nummulitic," and "Miliolitic" lss. of Dall as well as "Peninsular" ls. as interpreted by Matson. The Ocala ls. is of Jackson (upper Eocene) age.

†Ocala group.

Eocene: Florida and Georgia.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, p. 331). *Ocala group.*—Typical locality at Ocala, Fla. W. H. Dall, 1892; this essay, p. 331. Includes the various foraminiferal lss. in which the Floridian and Georgian Eocene culminates, above the typical Orbitoides ls. [Vicksburg]. [All of definition.]

Occoquan granite.

Pre-Cambrian: Northeastern Virginia.

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). *Occoquan granite.*—Coarse-grained and sheeted, mainly horizontally; of greenish-gray color. Exposed on Occoquan Run, from Occoquan village to forks of Bull Run, and at other places. Is capped by crystalline schist.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.), mapped the granite along Occoquan Run as pre-Camb. and as intrusive into Glenarm series, and mapped the overlying schist as Wissahickon fm.

Oceana limestone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 164). *Oceana ls.*—Dark gray, lenticular, calc.; 0 to 2 ft. thick. Lies 35 ft. above Glenalum Tunnel coal and is separated from overlying Upper Gilbert ss. by a thin bed of black sh. May possibly belong at horizon of marine Dorothy sh., but no marine fossils found in it. Present at Oceana, Wyoming Co. Not observed in McDowell Co.

Oceanic series.

Oligocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 69–85).

†Ocheesee beds.

Miocene (lower): Western Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 105, 112, 157, 158, 331). *Ocheesee beds.*—Typically developed at Ocheesee, Jackson Co., where there is visible 5 ft. of creamy-white granular ls. with obscure fossil corals, surmounted by 10 ft. of greenish-yellow unfossiliferous argill. ls. At Rock Bluff 30 ft. of ls., in strata of varying purity, are exposed. These lss. are slightly phosphatic and by disintegration afford a rich black loam characterized by growth of *Torregia taxifolia*. The beds as a whole are more siliceous and argill. than those of *Orbitoides* ls., and were estimated by Langdon to have total thickness of 250 ft. He referred them to newest memb. of Eo. or oldest of Mio., under name of "Chattahoochee group." [In table on p. 157 *Ocheesee beds* are shown to include (ascending) "water-bearing sands, Chattahoochee ls., and (?) Cerithium rock (Tampa)," and they are included in his Chattahoochee group.]

Replaced by *Tampa ls.*

†Ochelata member.

Pennsylvanian: Northeastern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 38, chart, and map). *Ochelata memb.*—Chiefly sh., 20 to 85 ft. thick, with persistent ss., 5 to 12 ft. thick, near middle. Underlies Avant ls. memb. and overlies Dewey ls. memb. All included in Ramona fm.

The broader definition of Ochelata of Ohern 1925 (for beds above Dewey ls. and below Nelagoney fm.) is considered more useful unit.

Named for Ochelata, Washington Co.

Ochelata formation.

Pennsylvanian: Northeastern, central northern, and central Oklahoma.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 75). *Ochelata fm.*—Named by D. W. Ohern, in unpublished ms. Chiefly shales, with several ss. and ls. members. Thickness 400 ft. (in Washington and Osage Counties) to 480 ft. or more to S. Underlies Nelagoney fm. and overlies Dewey ls. Includes Avant ls. memb. about 200 ft. above base. Named for Ochelata, Washington Co.

Ochoco erosion surface.

Name applied by J. P. Buwalda, 1930 (Carnegie Inst. Wash. Pub. 404, p. 3), to an erosion surface that "bevels Columbia [River] lava, Mascall fm., and Rattlesnake fm. in parts of Ochoco Range and John Day country, Oreg. May=*Condon erosion surface* of area N. of John Day country."

Ochre Mountain limestone.

Mississippian (upper): Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Ochre Mtn ls.*—Almost entirely massively bedded lss., usually brownish gray on fresh fracture but weather to light bluish gray. Chiefly fine-grained, but locally there are coarser beds. Beds are 1 to 10 ft. thick. Basal hundred ft. includes beds that contain large amounts of chert, some of them being more than half chert. Thickness 4,500± ft. About 1,700 ft. above base of western facies of fm. is a thin, poorly exposed horizon of black sh. interbedded with ss., which is here named *Herat sh. memb.* Fossils are upper Miss. Overlies Woodman fm. and underlies, uncon. (?), Manning Canyon fm. Named for exposures on Ochre Mtn, Gold Hill region.

See also U. S. G. S. P. P. 177, 1934, by T. B. Nolan.

†Ocoee group.

Lower Cambrian: Eastern Tennessee, western North Carolina, and northwestern Georgia.

J. M. Safford, 1856 (Geol. reconn. Tenn., 1st Rept., pp. 149, 151–152). *Ocoee cgls. and slates.*—Grandly exposed along narrows of the Ocoee [Polk Co., Tenn.], hence the name. Is a very heavy fm., many thousand ft. thick; constitutes most of mtn parts of Polk, Monroe, Blount, Sevier, and Cocke [Counties in Tenn.]. The rocks are coarse gray cgls. and talcose, chlorite, and clay slates, all repeatedly interstratified and generally dipping at high angles to SE. The cgl. abounds in quartz and feldspar pebbles; occasionally it is ss. The slates are generally greenish, though dark-purplish clay slates are present; talcose and chlorite varieties mostly prevail. Assigned to Azoic. Overlie Mica Slate group and underlie Chilhowee sss. and shales.

As mapped and more fully described by Safford in his 1869 rept on Geol. of Tenn., his Ocoee group included the fms. later named by A. Keith Clingman cgl., Hazel sl., Thunderhead cgl., Cades cgl., Pigeon sl., Citico cgl., Wilhite sl., Cochran cgl., Hiwassee sl., Nottely qtzite, Andrews schist, Murphy marble, Valleytown fm., Brasstown schist, Tusquitee qtzite, Nantahala sl., Great Smoky cgl., Snowbird fm., and Unicoi fm.

Oconee Creek zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908 in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 8, 12). *Oconee Creek zone* (*Archean*) comprises a belt bounded on NW. by Poor Mtn zone; on SW. by Tugaloo River; on NE. by N. C. line from point intermediate to Horsepasture River and Toxaway Creek to point about 2 mi. E. of Sassafras Gap; on SE. by line from latter point extending to Tugaloo River, near confluence of Chauga River. This zone consists chiefly of granite and granite gneiss derived from porphyry. Its most characteristic form consists of repeated thin wavy bands of quartz, biotite, and muscovite with fine crystalline texture, separated by eyes of pink feldspar (microcline). It probably pertains to Keith's Henderson granite, of which characteristic exposures may be seen at "The Tunnel," in Tunnel Hill zone, and on Oconee Creek immediately below dam at Lays mill. A granite similar in its petrographic relations may be observed in Vaucluse zone at a small quarry 0.1 mi. N. of jail at Edgefield. The Oconee Creek series is regarded as junior to Carolina gneiss series.

Named for exposures on Oconee Creek, Oconee (?) Co.

O'Connell oil zone.

Drillers' name for Plio. beds encountered in wells in Santa Fe oil field, Los Angeles Co., Calif., that lie lower than Buckbee oil zone and higher than Clark oil zone.

†Ocoya Creek beds.

Miocene (middle): Southern California (Kern County).

H. W. Turner, 1894 (Am. Geol., vol. 13, p. 239; and U. S. G. S. 14th Ann. Rept., pt. 2, p. 461). *Ocoya Creek beds* [heading].—Prof. W. P. Blake (Pacific R. R. Repts, vol. 5, pp. 164–173, 1856) reported extensive deposits of Mio. age on Ocoya or Posé Creek and farther S. [Turner mentioned 3 fossil sp. from these beds that had been identified by Gabb.]

In Pacific Railway Repts, vol. 5, pp. 164–173, 1856, W. P. Blake described the Mio. beds along Ocoya Creek, but did not name them. His heading (p. 164) is: *Ocoya Creek-Miocene.* His opening sentence, beneath the heading, is: "The most extensive Mio. deposits examined during course of the survey were at base of Sierra Nevada, around Depot Camp, at Ocoya or Posé Creek." On pl. 1 he gave a graphic "section at Ocoya or Posé Creek." On p. 167 he gave a lithologic description of "section of the strata at Ocoya Creek." On subsequent pages of his description of "Ocoya Creek-Miocene" he nowhere used *Ocoya Creek* in a formational sense. On p. 169 he mentioned beds elsewhere "similar to those seen in the *Ocoya Creek strata.*" On subsequent pages, under descriptions of other geographic areas, in 3 places (pp. 184, 188, 207) he referred to "the Mio. strata of Ocoya Creek" and "the Mio. fm. at Ocoya Creek." On p. 189 in 2 places he mentioned, in correlation, "*Ocoya Creek series.*" It seems evident from a perusal of Blake's rept that he intended to use *Ocoya Creek* in a purely geographic sense. At bottom of p. 45 he refers to "the Mio. fm. along Ocoya Creek." At top of p. 46 he refers to beds that "more nearly resemble the Ocoya Creek beds," and a few lines beneath he refers to soft strata that are "very probably of the same age as the Ocoya Creek fm."

J. P. Smith, 1910 (Jour. Geol., vol. 18, No. 3) and F. M. Anderson, 1911 (Calif. Acad. Sci. Proc., 4th ser., vol. 3) mentioned *Ocoya Creek beds.*

These beds were for a time included in Vaqueros ss., but according to J. P. Smith (Jour. Geol., vol. 18, No. 3, 1910) they carry the *Turritella ocoyana* fauna, and are therefore younger than Vaqueros ss., which is now restricted to beds characterized by *Turritella inezana* fauna. The name *Temblor fm.* is now generally applied to beds carrying *Turritella ocoyana* fauna in this region.

Octh Louie sand.

Drillers' name for a ss., 25± ft. thick, forming basal bed of Mowry sh. in Basin oil field, Bighorn Co., Wyo. Lies 45 ft. below Kimball sand. (See U. S. G. S. Bull. 621, Jan. 21, 1916, pp. 167, 169, etc.)

†Octoraro schist.

Pre-Cambrian: Southeastern Pennsylvania.

See under *Wissahickon fm.*

Named for exposures in banks of Octoraro Creek btw. Lancaster and Chester Counties.

Odanah series.

Upper Cretaceous: Manitoba.

J. B. Tyrrell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 83E–85E, 199E, 212E–215E).

M. Y. Williams, 1932 (Jour. Geol., vol. 40, No. 6, p. 561), correlated *Odanah* of Manitoba with Bearpaw of Mont., Wyo., and Alberta.

Oddie rhyolite.

Tertiary (upper Miocene?): Central Nevada (Tonopah district).

J. E. Spurr, 1905 (U. S. G. S. P. P. 42, pp. 49+, map, etc.). *Oddie rhyolite.*—White siliceous intrusive rhyolite. Makes up Mount Oddie and Rushton Hill, Tonopah dist. Intrudes later andesite, Fraction dacite breccia, Tonopah glassy rhyolite-dacite breccia, and Siebert tuffs. Is apparently of about same age as Brougher dacite and of same nature and origin.

J. A. Burgess, 1909 (Econ. Geol., vol. 4, pp. 681–712), assigned this fm. to Plio., but A. Knopf, 1921 (U. S. G. S. Bull. 715), said it is probably upper Mio.

Odell shale. (In Sumner group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv., Bull. 6, 2d ser., p. 59). *Odell sh.*—Basal memb. of Enterprise fm., limited by Krider ls. above and by either Cresswell ls. or transitional top of Luta ls. below [see under *Cresswell ls.*], and generally consisting of 3 zones, as follows (descending): (1) Olive-drab to buff sh., with top 1 ft. becoming quite calc., somewhat fossiliferous, and transitional to Krider ls., 3½ ft.; (2) chocolate-maroon shales, distinctive because of banded appearance due to presence of thin persistent seams of bright olive and light-greenish argill. sh., 18 ft.; (3) olive-drab to gray argill. massive shales with some calc. content, geodal, and some chalcedony concretions, 8 ft. or more. Thickness of Odell sh., 30± ft. in Nebr. and 37 or 38 ft. in vicinity of Arkansas City, southern Kans. Type loc. ravines and highway cuts ¼ mile S. and 2¼ mi. E. of Odell, Gage Co., Nebr.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), treated *Odell sh.* as distinct fm.

Odenville limestone.

Lower Ordovician (Beekmantown): Northern central Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 99, etc.). *Odenville ls.*—Impure argill. and siliceous dark fine-grained cherty ls., 50± ft. thick. Overlies Newala ls. and uncon. underlies Mosheim ls. Only known exposure is in a cut or borrow pit on N. side of Seaboard Air Line Ry about ⅛ mi. E. of Odenville, St. Clair Co. Contains Beekmantown fossils.

Offley Island formation.

Silurian: Greenland.

C. Poulsen, 1934 (Meddelelser om Grönland, Band 72, 2d Afd., No. 1).

Ogalalla.

See *Ogallala*, the correct spelling.

Ogallala formation.

Miocene (upper) and Pliocene: Western Nebraska, northeastern Colorado, southeastern Wyoming, southern South Dakota (?), western and central Kansas, western Oklahoma, northwestern Texas, and eastern New Mexico.

N. H. Darton, 1898 (U. S. G. S. 19th Ann. Rept., pt. 4, pp. 732–742). *Ogallala fm.*—Calc. grit or soft ls., sandy clay, and sand, with basal cgl. at many places. Of late Tert. (Plio.?) age. Thickness 150 to 300 ft. Uncon. underlies *Equus* beds and uncon. overlies Arikaree fm. Extends from Kans. and Colo. far into Nebr. Is a part, if not the whole, of the deposit which in Kans. and southward has been called "Mortar beds," "Tertiary grit," and other names. Is upper part of Loup Fork beds, the lower part of Loup Fork being Arikaree fm.

N. H. Darton, 1920 (U. S. G. S. Syracuse-Lakin folio, No. 212). *Ogalalla fm.*—Thick sheet of sand and gravel (chiefly sand) of late Tert. age, which constitutes surface of Great Plains in western Kans. region and occupies most of highlands of Syracuse and Lakin quads. Extends across Haskell, Grant, and Stanton Counties. Surface considerably eroded, but base is not cut through except by Bear Creek, W. of Johnson. Thickness 180 to 300 or more ft. Is believed to be a strat. unit and to be continuous from type loc. near Ogalalla Station in western Nebr. Hay supposed the deposits comprised 2 fms., "Plains marl" at top and "mortar beds" below, but later studies by Haworth, Adams, and others have shown that these apparent divisions are local features and that generally fine-grained sediments alternate with the coarser "mortar beds" at different horizons. It is possible the 300 ft. or more of beds that constitute Ogalalla fm. comprise deposits elsewhere separable, even including locally in their upper part a representative of McPherson fm. ("*Equus* beds"). Apparently no separation is practicable in this region. Originally the entire fm. was known as "Loup Fork beds," but this term also included Arikaree fm., which is older than the Ogalalla and apparently does not extend into Kans. No fossils in or near these quads., but many bones have been found in the Ogalalla area elsewhere in Nebr. and northern Kans. They range in age from very late Mio. to early Pleist., indicating a longer range in time than would appear to have been required for the continuous deposition of the Ogalalla. Most of material appears to have been laid down rapidly by streams, although the fine-grained strata required considerable time for their accumulation. It is believed the bones of Pleist. age found in some places are in local deposits of later age that overlie true Ogalalla, which appears more likely to have been laid down in Plio. and late Mio. time. In the valleys and in places on the uplands the Ogalalla grades up into fine sands and silts, which appear to have been carried and deposited by the wind at various times from Tert. to very recent. In part these are *Plains marl* of Hay, and fossils found in them are Recent.

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7, Kans. Geol. Surv. Bull. 18, pp. 131–180). *Ogallala fm.* is here restricted to beds beneath "Plains marl." In Wallace Co., Kans., the Ogallala rests uncon. on Pierre sh. and is uncon. overlain by Pleist. loess here named *Sanborn fm.* It is usually buff-colored to pinkish and chiefly unsorted sand and gravel, usually mixed in various proportions with fine dust (loesslike fine sand or silt), which makes the rocks of the fm. rough to the touch. In some areas fine unctuous clays of light-green and reddish-brown colors constitute important beds in lower part of fm., and in middle and, especially uppermost parts, lenses of white and pinkish ls. occur. Beds of gravel and light-gray or greenish sorted sand, some cross-bedded, occur in places. The name Sanborn fm. is proposed for the Pleist. loess, with some gravel and sand at base, that is widely distributed on the divides in western Kansas, and is intended as a substitute for the old terms "Tertiary marl" or "*Plains marl*" of Hay. "As far as present experience indicates *Biorbia rugosa* fruits are the most valuable index fossil of the Ogallala in the restricted sense." Fossils found in middle part of typical "mortar beds" of Wallace Co. are Lower Plio. No identified bones were collected near base or near top of Ogallala in Wallace Co., but unbroken continuity of the fm., which is composed largely of coarse material and is only about 200 ft. thick, suggests possible completion of its sedimentation within Lower Plio. One mi. W., and also SW., of Guy Woodhouse ranch bentonitic clays of bright mottled colors are exposed, which writer named *Woodhouse clays*. These clays are a local lateral change in lithology of lower half of Ogallala fm. The prel. examination by H. T. Martin of vertebrate remains from the Woodhouse clays showed decisively they may belong to either Mio. or Lower Plio., or to the age of Ogallala fm. of Wallace Co. [See also under *Woodhouse clay* and under *Rhinoceros Hill beds*. Elias has visited Ogallala, Nebr., and presents his interpretation of where base of Ogallala fm. should be drawn.]

C. J. Hesse, 1935 (Univ. Kans. Sci. Bull., vol. 22, No. 5, pp. 79–117), described and figured vertebrate fauna from Feldt ranch, Nebr., which he stated is type loc. of Ogallala fm. He assigned the fossils collected to Mio., Plio., and Pleist., but stated the latter are not regarded as belonging to the Ogallala. "So far as I am able to determine there is no satisfactory indication that the Ogallala should be subdivided."

H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5, pp. 43 (footnote), 44), assigned Ogallala fm. to Plio. and upper Mio.

See also under *Arikaree fm.*

Named for exposures around Ogallala (correct spelling), Keith Co., Nebr.

Ogan clay. (In Allegheny formation.)

Name applied to the plastic clay, 2 ft. 8 in. thick, underlying Ogan coal and lying 16 ft. 4 in. above Putnam Hill ls. in Vinton Co., Ohio. (See W. Stout, Ohio Geol. Surv., 4th ser., Bull. 31, 1927.)

†Ogden quartzite.

Middle and Lower Cambrian: Northeastern Utah (Ogden Canyon).

C. King, 1876 (Am. Jour. Sci., 3d, vol. 11, pp. 477–479). *Ogden qtzite.*—Usually white or pale green, very fine-grained and slightly schistose toward top, and contains zones of cgl. consisting of remarkably smooth quartz pebbles in a fine siliceous matrix. Thickness 1,000 to 1,600 ft. Named for development in Ogden Canyon, Utah. Overlain by Wasatch ls. (Carbf. and Dev., 7,000 ft. thick) and underlain by Ute ls., of Quebec [Ord.] age. The Ogden is provisionally assigned to Dev. In western Nev. it is 700 or 800 ft. thick and is also seen to lie btw. upper and lower Helderberg [Dev.] horizons.

S. F. Emmons, 1907 (Geol. Soc. Am. Bull., vol. 18, p. 297), assigned Ogden qtzite to Ord.(?), and F. B. Weeks (p. 432 of same publication) assigned it definitely to Ord., as did H. S. Gale, 1910 (U. S. G. S. Bull. 415, p. 46).

E. Blackwelder, 1910 (Sci., n. s., vol. 32, p. 188), stated that Ogden qtzite appears to be neither Dev., as first reported, nor Ord., as stated in more recent years, but a repetition of the Lower Camb. qtzite due to overthrusting. In U. S. G. S. Bull. 430, p. 539, 1910, Blackwelder reported 500 to 2,000 ft. of Ord. ls. "with local sh. and qtzite" in Ogden region, but not in Ogden Canyon. Later (Geol. Soc. Am. Bull., vol. 21, pp. 519, 526–527, Sept. 1910) he proposed *Geneva* for the Ord. qtzite from which F. B. Weeks (unpublished ms.) reported Ord. fossils. He also adopted Brigham for the Camb. qtzite, and proposed the abandonment of Ogden qtzite. (See under †*Geneva qtzite.*)

G. B. Richardson, 1913 (Am. Jour. Sci., 5th, vol. 36, pp. 407, 409), proposed *Swan Peak* for the Ord. qtzite (Geneva being preoccupied) and adopted *Brigham* for the Camb. qtzite. These are the present approved names for these qtzites. It seems apparent that King mistook the Ord. qtzite (which is not present in Ogden Canyon) for the upper qtzite in Ogden Canyon, which is now generally conceded to be an overthrust of the Brigham qtzite (Middle and Lower (?) Camb.). There is no Dev. qtzite in Utah. The name †Ogden qtzite has been abandoned, owing to the confusion resulting from its misapplication.

Ogden flint.

Permian: Central Kansas.

C. S. Prosser, 1894 (Geol. Soc. Am. Bull., vol. 6, p. 48). If for any reason the local name *Wreford ls.* should not prove desirable, on account of prominence of this ledge near Ogden, it might appropriately be called *Ogden flint.*

Ogdensburg formation.

Lower Ordovician: Northern New York (Saint Lawrence Valley).

G. H. Chadwick, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 289, 291). In St. Lawrence Valley the *Upper Beekmantown* (*Ogdensburg*) *dol.* lies uncon. on *Bucks Bridge* (*approx.=Tribes Hill*) *mixed beds or fm.*

H. P. Cushing, 1916 (N. Y. State Mus. Bull. 191). *Ogdensburg fm.*—Alternating beds of massive blue-gray granular dol. and thin-bedded iron-gray fine-grained dol. with occasional bed of gray calc. ss. Thickness more than 120 ft. Is upper fm. of Beekmantown in Ogdensburg region, and according to letter from Ulrich dated Jan. 13, 1915, it corresponds, at least essentially, to div. D of Beekmantown. Uncon. overlies Tribes Hill fm., lower fm. of Beekmantown.

G. H. Chadwick, 1920 (N. Y. State Mus. Bull. 217, 218). *Ogdensburg dol. or upper Beekmantown ls.* in Canton quad. underlies a possible outlier of Trenton ls. and rests discon. on Bucks Bridge mixed beds (roughly=Tribes Hill). Thickness perhaps 50 ft., basal part only being present. Typical sections near Ogdensburg.

Ogima amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs to Central Mine group. Is younger than Evergreen amygdaloid and older than South Butler amygdaloid. The mineralized part is the Ogima lode. Named for occurrence in Ogima mine, Ontonagon Co.

Ogima flow.

Includes Ogima amygdaloid and underlying trap.

Ogishke conglomerate member (of Knife Lake slate).

Pre-Cambrian (Knife Lake series): Northeastern Minnesota (Vermilion district).

A. Winchell, 1887 (Minn. Geol. Nat. Hist. Surv. 15th Ann. Rept., pp. 149, 179). *Ogishke cgl.*—Solid and indestructible cgl. of several varieties of granitic and quartzose boulders embedded in a finely granular, mostly greenish groundmass. Also includes boulders of flint, jasper, granulite, porphyry, and "greenstone." Exposed on SW. shore of Ogishke-Muncie Lake, and attains enormous development in region of that lake.

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept., btw. pp. 330 and 367), gave thickness of *Ogishke cgl.* as 4,500 ft., but later repts place thickness at 1,000 to 2,000 ft. He also used *Ogishke group* in what he seems to have regarded as a broader sense than *Ogishke cgl.*, but his Ogishke group was described as consisting of cgl., "10,000 ft., but local. (Perhaps half this.)"

C. R. Van Hise and J. M. Clements, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 401–409, map). *Ogishke cgl.*—Slates and cgls. underlying the Lower Huronian iron-bearing fm. [Agawa fm.] and uncon. overlying the Archean. Been known by this name for years.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 130–131). *Ogishke cgl.*—Consists of 4 varieties: (1) Greenstone cgl. where it rests on Ely greenstone; (2) granite cgl. along W. border of Lake Saganaga; (3) porphyry cgl., called "Stuntz" cgl. and "Stuntz Island aggl.;" and (4) chert and jasper cgl. where it lies on Soudan fm.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), included Agawa iron fm. memb. and *Ogishke cgl. memb.* in Knife Lake sl., which they tentatively removed from Huronian series and assigned to *Knife Lake series* (pre-Huronian and post-Laurentian).

†Ogishke dolomite.

A name applied by A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept.), to a 10-foot bed of dol. in Ogishke cgl.

Ogishke "group."

See 1888 item under *Ogishke cgl.*

Ogontz member (of Stonington beds).

Upper Ordovician: Northern Michigan (Delta County).

R. C. Hussey, 1926 (Univ. Mich. Mus. Geol. Contr., vol. 2, pp. 113–150). *Ogontz memb.*—Top memb. of Stonington beds. Mostly cherty ls., but varies from soft and argill. ls. to hard and cherty; is massive and irregularly bedded; ranges from light gray through yellowish brown to dark brown, the softer material usually in irregular bands and lenses; a well-defined layer of intraformational cgl. 1 ft. 3 in. thick near top. Thickness of memb. 3 ft. to 20 ft. 2 in. Outcrops 6 mi.

NW. of Ogontz, on farm of Andrew Barbeau N. of Ensign, and at other places along E. shore of Little Bay de Noc for 6½ mi. N. of Lighthouse Point. Overlies Bay de Noc memb. and underlies Big Hill beds.

Ohara limestone member.

Mississippian: Western Kentucky and southern Illinois.

E. O. Ulrich and W. S. T. Smith, 1905 (U. S. G. S. P. P. 36, pp. 24, 41). *Ohara ls.*—Thin-bedded fine-grained earthy lss. and shaly lss., interbedded with soft greenish calc. and clayey shales and so-called marls; 30 to 107 ft. thick. Topmost memb. of Ste. Genevieve ls. in western Ky. Overlies Rosiclare ss. memb. of Ste. Genevieve and underlies Cypress ss. [not true Cypress but Bethel ss.]. [See S. Weller's views of this memb. under *Shetlerville fm.*; E. O. Ulrich and C. Butts contend that all of Ohara ls. memb. is present at Ste. Genevieve and that all of it belongs to Ste. Genevieve ls.]

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430, 439). *Ohara* as originally defined should not be considered a strat. unit, because it transgresses an important uncon. and is capable of easy subdivision. The part that has been termed "Upper Ohara" is strictly equiv. to the Renault of Ill. [Some geologists do not accept this correlation.] The "Lower Ohara" is a well-defined memb. of the Ste. Genevieve and is worthy of a distinctive name. Were it not for persistent use of *Ohara* by Butts and Ulrich for beds of Renault age in western Ky. and probably elsewhere, this name might be redefined and restricted to lower part of original memb. Under the circumstances, however much the writers regret doing so, it seems advisable to reject *Ohara* as a name made useless by nearly 30 years of misinterpretation, and the name *Levias*, with type loc. just E. of town of that name in Crittenden Co., Ky., is now proposed for uppermost memb. of the Ste. Genevieve btw. Rosiclare ss. below and Renault fm. above in western Ky. and adjacent part of southern Ill. [The Renault fm. of Weller includes Renault fm., Bethel ss., and upper part of Ohara ls. memb. of Ste. Genevieve ls. of Ulrich and Butts.]

See also under *Ste. Genevieve ls.*

Named for Ohara, Caldwell Co., Ky. The P. O. was for many years known as Cedar Hill or Cedar Bluff.

In May 1937 the U. S. Geol. Survey decided (1) to adopt Weller's interpretation that the "Upper Ohara" of repts is a part of Renault fm.; (2) to adopt Levias ls. (="Lower Ohara" of repts) as top memb. of Ste. Genevieve ls.; and (3) to include Ste. Genevieve ls. in Meramec group.

Ohio shale.

Upper Devonian: Ohio and north-central Kentucky (north of 37°15′).

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, p. 62). *Ohio black sl.*—Black bituminous sl., 320 ft. thick, overlying Corniferous ls. [Delaware ls.] near Columbus, Ohio. Overlies Cliff ls. in Adams County, Ohio, and underlies Waverly ss. group.

As thus defined Ohio sh. included at base the blue Olentangy sh., but Olentangy sh. has for many years been excluded from the Ohio. There is some question about relation of Cleveland sh. of northern Ohio to Ohio sh. Latter name is applied by U. S. Geol. Survey in Ohio and as far S. in Ky. as 37°15′; S. of that line Chattanooga sh. is recognized fm. (See also under *Chattanooga sh.* and †*Black sh.*)

Named for Ohio River hills.

†Ohio conglomerate.

A name applied in some early Ohio repts to Sharon cgl. memb. of Pottsville fm.

Ohio Creek conglomerate.

Eocene: Western Colorado (Gunnison County).

W. Cross, 1892 (Am. Jour. Sci., 3d, vol. 44, pp. 21–23). *Ohio Creek beds.*—Two small isolated patches of loose friable sss., grits, and fine cgls., resting on coal measures of

Laramie fm. and seemingly in small basins of erosion. The chert pebbles contain crinoid stems and other apparently Carbf. fossils of identical character with those frequently found in basal cgl. of Ruby beds near Irwin. These facts suggest the chert pebbles of Ruby cgl. may be the residuum from destruction of Ohio Creek beds formerly existing to N. of Anthracite Range. No fossils except carbonized plants. Lithologic and strat. evidence suggests it may possibly represent Arapahoe fm. and that Ruby beds may represent Denver fm. Rests uncon. on Laramie fm.

W. T. Lee, 1912 (U. S. G. S. Bull. 510, pp. 18, 48–49). *Ohio Creek cgl.*—In Grand Mesa and West Elk Mtn coal fields consists of 100 to 200 ft. of white friable conglomeratic ss. containing pebbles of quartz, jasper, and igneous rock. Uncon. overlies Mesaverde fm. and uncon. underlies Wasatch ("Ruby") fm. May be of Fort Union age.

Ohio River formation.

Post-Carboniferous (late Tertiary ?): Southern Indiana.

G. H. Ashley, 1903 (Ind. Dept. Geol. and Nat. Res. 27th Ann. Rept., p. 68). *Ohio River fm.*—Remnants, 20 to 30 ft. thick, of once extensive deposit of sand and gravel overlying Coal Measures and underlying Quat. along divide btw. streams flowing E. into the Ohio or Silver Creek and streams flowing W. or S.

Ohio Trap Rock traps.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and p. 19). *Ohio Trap Rock traps.*—We next pass alternating belts of sed. and trappean rocks as follows: Cgl. 75 ft. wide, trap 400, cgl. 80, traps for 270 ft., ss. 30 ft., followed by traps for 390 ft., succeeded by a belt of cgl. 86 ft. wide. Little of a definite character is known of these alternating belts. They are exposed on or near the old Ohio Trap Rock or Colling Locations, and have not, I believe, been positively identified E. of these points. Their position, however, is deducible from analogy and comparison. From data collected, it is probable that last-mentioned belt of cgl. is identical with the belt exposed 500 ft. N. of old Forest mine, and termed Forest cgl. [From description they seem to lie 1,396 ft. higher than Norwich traps.]

†Oil City lime.

A name applied to a subsurface Penn. ls., 0 to 45 ft. thick, in central northern Okla. that is believed to correspond to Avant ls. memb. of Ochelata fm.

Oil Creek formation.

Lower Ordovician (Chazy): Central southern Oklahoma (Arbuckle Mountains).

E. O. Ulrich, 1928 and 1930. [See under *West Spring Creek fm.*]

C. E. Decker, Dec. 1930 (A. A. P. G. Bull., vol. 14, No. 12, pp. 1498–1505). *Oil Creek fm.*—Consists chiefly of dolomites and lss., with some sh. and ss. beds, and at base a ss. from 8 to 200 ft. thick. Underlies McLish fm. and overlies Joins fm. Thickness of fm. 1,600 to 2,300± ft. Of Chazy age.

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 11+). The *Simpson* is here raised to a *group*, divided into 5 fms. (ascending) Joins, *Oil Creek*, McLish, Tulip Creek, and Bromide. Oil Creek is of lower Chazyan age.

See also 1933 entries under *Simpson fm.*

Named for exposures on Oil Creek, W. Johnston Co. and SE. Murray Co.

Oil Creek third sand.

Generally known as "Third sand" in Allegany Co., N. Y. Lies 1,000 ft. above Allegany sand in wells.

Oil Creek Lake group.

Mississippian and Upper Devonian: Northwestern Pennsylvania.

J. P. Lesley, 1895 (2d Pa. Geol. Surv. Final Rept., vol. 3, pt. 1, p. 1767). *Oil Creek Lake group*, 130 ft. thick at Oil Creek Lake, 14 mi. NW. of Titusville, may be considered lowest part of Pocono ss. (No. X) of eastern and middle Pa. and corresponds to Berea group of Ohio. [This name is not used in Ohio.] Includes Corry ss. (=Berea grit), Cussewago ls., Cussewago shales, and Cussewago ss. Overlies Riceville sh.

Oilfields shale.

See under *Lillis sh., J. H. Ruckman, 1931.*

Oil Lake group.

Mississippian and Devonian (?): Northwestern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 91–98). *Oil Lake group.*—At Oil Creek Lake, Crawford Co., is 130 ft. thick. Divided into (descending): Corry ss., 20 ft.; Cussewago Upper shales, 5 ft.; Cussewago ls., 2 ft.; Cussewago Middle shales and flags, 30 ft.; and Cussewago ss., 25 ft. Underlies Orangeville sh. and overlies Riceville shales.

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, p. 464), seems to discard "Oil Lake group," as he quotes the name and shows it as including Corry ss. (at top), Bedford sh., big hiatus, Hayfield sh., and Cussewago ss. (at base).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 39–53, 102, table opp. p. 61), advocated use of *Oil Lake series*, as he called the unit extending from top of Berea ss. down to top of Riceville sh., or "the oldest major division of the Mississippian," including *Berea stage* and *Cussewago stage*, as he called them. In Ohio he included Berea, Bedford, Hayfield, and Cussewago ss., and stated there is discon. at top of Berea.

Other workers have ignored the name.

K. E. Caster, 1935 (A. A. P. G. Bull., vol. 19, No. 6, p. 913). *Oil Lake series*, suggested (1933) by writer for Miss. part of the Bradfordian, includes, in upper part, Corry ss. The Oil Lake series is to writer clearly Miss.

G. H. Chadwick, 1935 (A. A. P. G. Bull., vol. 19, No. 6, p. 915), dissents from Caster's claim of Miss. age of *Oil Lake beds*. He considers them Upper Dev.

Oil Springs.

See 1st entry under †*Popo Agie beds.*

Ojibway.

Name applied to a glacial lake, of Pleist. age, in Canada, north of Great Lakes.

Ojinaga formation.

Cretaceous: Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 326).

Ojo Alamo sandstone.

Upper Cretaceous: Northwestern New Mexico (San Juan County).

B. Brown, 1910 (Am. Mus. Nat. Hist. Bull., vol. 28, pp. 267–274). Less than a mi. S. of the store at Ojo Alamo the Puerco fm. rests uncon. on a cgl. composed of red, gray, yellow, and white pebbles. Below the cgl. is a series of shales and sss. evenly stratified and usually horizontal. The shales below the cgl. that contain numerous dinosaur and turtle remains I shall designate as *Ojo Alamo beds*. They were estimated to be about 200 ft. thick, but owing to lack of time I was unable to determine their relation to underlying fms.

W. J. Sinclair and W. Granger, 1914 (Am. Mus. Nat. Hist. Bull., vol. 33, pp. 300–304). Puerco fm. [of Ojo Alamo and Barrel Spring Arroyos] rests with marked erosional uncon. on a coarse cross-bedded conglomeratic yellow-brown ss. 28 to 66 ft. thick, which rests discon. on rusty-yellow, bluish, greenish, and wine-red banded clays with lenses of yellow channel ss. having max. measured thickness of 58 ft. and containing abundant but badly crushed dinosaur bones, ceratopsian, trachodont, and carnivorous, also turtles, crocodiles, and garpikes. This lies conformably on a lower cgl., 6 to 8 ft. thick, which varies from a pebbly ss. to a coarse cgl., with waterworn, chatter-marked qtzite, jasper, andesite, and porphyrite pebbles, the source of which has not been traced. This lower cgl. lies discon. on a series of bluish shales, or rather clay, containing dinosaur remains. [All these beds were included in *Ojo Alamo beds of Brown* according to table at end of paper.]

C. M. Bauer, 1916 (U. S. G. S. P. P. 98K). Overlying Kirtland sh. with apparent conformity is a thin fm. of conglomeratic ss. and sh. These beds were first described by Barnum Brown, who named them *Ojo Alamo*, from locality in which they were examined, but assigned no base and indicated no relation btw. them and underlying beds. On Ojo Alamo Arroyo Brown found dinosaur-bearing sh. below a cgl., which is overlain uncon. by Puerco fm. Later Sinclair and Granger examined Ojo Alamo locality and found that the dinosaur-bearing sh. on Ojo Alamo and Barrel Spring Arroyos is split by a thin cgl., referred to by them as "lower cgl." The discrepancies in these descriptions and failure of these investigators to assign a strat. or paleontologic lower limit to Ojo Alamo beds call for a more accurate definition. Writer made careful study of the beds in type loc. On Ojo Alamo and Barrel Spring Arroyos the succession of sh. and cgl. described by Sinclair and Granger was noted. Section measured by writer on Ojo Alamo Arroyo shows (descending): (1) "upper cgl.," 25 ft.; (2) wine-red and bluish-gray banded shales interbedded with lenses of gray-white, easily eroded ss., 34 ft.; (3) poorly consolidated cgl., 9 ft. Has irregular base, the irregularities amounting to 2 or 3 ft. in a horizontal distance of 50 ft.; (4) bluish-gray to greenish-gray sh., banded here and there with purplish beds and gray-white ss. lenses. Both shales mentioned above contain dinosaur and turtle remains. However, the lower cgl. has been traced laterally to points where the sh. btw. it and the upper cgl. is absent and only a single lithologic unit is present. The lower sh. is lithologically like and conformable with underlying beds and is clearly a part of Kirtland sh. Brown placed upper limit of his Ojo Alamo beds at base of "upper cgl.," and Sinclair and Granger placed it at top of "upper cgl.," and neither of them assigned a lower limit to fm. As writer found the fm. to be essentially a ss. including lenses of sh. and cgl., it seems desirable to call it *Ojo Alamo ss.* and to define it as consisting, on Ojo Alamo Arroyo, of 2 conglomeratic beds and the sh. lenses which they include. Its thickness where overlain by Puerco fm. ranges from 63 to 110 ft. The Ojo Alamo ss. is highly cross-bedded, and pebbles of ss., andesite, felsite, porphyrite, gneiss, and schist are fairly common at different horizons or are scattered through it irregularly. In some places lower 20 or 30 ft. is almost lacking in pebbles.

J. B. Reeside, Jr., 1921 (U. S. G. S. Bull. 716G, p. 173). Field work done by writer in 1920 has shown that a thinning wedge of Animas fm. extends as far S. as San Juan River. The Ojo Alamo ss. extends N. upon the Animas wedge as far as T. 31 N., R. 13 W., where Puerco or Torrejon beds rest on Animas beds. The base of Animas wedge in N. Mex. is apparently conformable, but in Colo. it is clearly uncon. on Kirtland sh. To SE. of Escavada Wash the Ojo Alamo ss. is also clearly uncon. on Kirtland sh., and it is likely both Animas and Ojo Alamo belong with the later rather than with the earlier beds. Full discussion of these new data is in preparation.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134), separated uppermost part of Kirtland sh. of Bauer as a distinct fm., to which he applied the name *McDermott fm.*, and stated that *Ojo Alamo ss.* as now defined rests uncon. upon the McDermott near Ojo Alamo, N. Mex. Also that Ojo Alamo ss. and at least lower part of Animas fm. as restricted in this rept are of nearly same age and overlie the most widespread strat. break in whole series of beds described. Also that Animas fm. as now restricted wedges out a few mi. SW. of Durango, Colo.

C. H. Dane, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 14, p. 407) and 1937 (U. S. G. S. Bull. 860C), transferred Ojo Alamo ss. from Tert. (?) to Upper Cret. and J. B. Reeside, Jr., concurred in transfer.

Ojo Bonito porphyry.

Cretaceous (?): Western Texas (Chinati Mountains).

C. L. Baker, 1929 (Univ. Tex. Bull. 2901, pp. 73–74, 79–82). One of intrusives outcrops in valley of Cibolo Creek, at E. foot of main mass of Chinati Mtns, and will be called *Ojo Bonito porphyry*. It is a coarse-grained porphyry. Is covered on SW. and S. sides by the volcanic series, and it probably underlies that series in SE. part of Chinati Mtns proper. Is post-Trinity Cret.

Okanogan.

Pleistocene: Washington.

C. [R.] Keyes, 1927 (Pan-Am. Geol., vol. 47, p. 353). Some such title as *Okanogan*, possibly, will have to be used for what is commonly known as the Spokane till, since the latter term is preoccupied by Walcott, for a Proterozoic sh. terrane in Mont.

Okaw formation. (Of Chester group.)

Mississippian: Southwestern Illinois.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 127). *Okaw fm.*—Series of alternating dark-blue to gray and nearly white lss. and soft shales, 150 to 200 ft. thick, with four, and perhaps five, important ls. members, the uppermost of which is the quarry ledge at the Penitentiary, which is overlain by 10 to 12 ft. of calc. shales, with thin lss. interbedded, forming top part of Okaw fm. Underlies Menard fm. and overlies Ruma fm.

E. O. Ulrich, 1917 (Ky. Geol. Surv., Miss. fms. of western Ky., pt. 2, pp. 55-61, 112-113). Typical *Okaw ls.* underlies, with probable hiatus, a ss. that apparently corresponds to Hardinsburg ss., and overlies, with probable break, Ruma fm. It is believed to be essentially contemp. with Cypress ss.

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41). *Okaw fm.* of Randolph Co., Ill., is = Glen Dean ls., Hardinsburg ss., and Golconda fm., and is overlain by Menard ls. [restricted].

S. Weller, 1920 (Jour. Geol., vol. 28, pp. 285, 298-303). *Middle Chester or Okaw group.*—Includes (descending) Glen Dean ls., Hardinsburg ss., Golconda ls., and Cypress ss. Underlies Tar Springs ss., basal fm. of Upper Chester group.

A. H. Sutton, 1934 (Jour. Geol., vol. 42, No. 6, pp. 622+). Purpose of this article is to show that the Okaw consists of 2 well-defined portions separated by a discon. Weller (ms. Rept. on geol. of parts of St. Clair, Monroe, and Randolph Counties, Ill.) noted this erosion surface but did not recognize a late Chester age for the Okaw beds above it. During summers of 1932 and 1933 writer examined the Okaw and identified in it 5 and possibly 6 fms. of standard Chester section. These fms. have been grouped into 2 well-defined mappable units, one of middle Chester and one of late Chester age, and each correlated with a definite portion of the Chester farther E., in Eastern Interior Basin. Although *Okaw* has been used with different meanings, it is retained, and the 2 divisions designated *Lower* and *Upper Okaw*. Writer believes this is justified because name is well known and because these strat. units occur in only a limited area. Following is writer's section for SW. Ill.:

Menard.
Okaw:

Upper Okaw [mapped]: Waltersburg memb. Vienna memb. Tar Springs memb.	Upper Chester (in part).
Lower Okaw [mapped]: Glen Dean memb. Hardinsburg memb.* Golconda memb.	Middle Chester.

Conformity.
Cypress (Ruma).

* Believed to be represented by 1 to 3 ft. of chert and cherty ss. that occurs in area S. of Marigold, which is only place Glen Dean and Golconda can be separated with any degree of certainty.

The U. S. Geol. Survey in 1914 adopted *Okaw fm.* as defined by Weller in 1913.

Named for Okaw or Kaskaskia River, SW. Ill., whose valley is entirely excavated in these rocks. The several members of fm. are well exposed in Mississippi River bluffs above and below mouth of the Okaw.

Okay limestone lentil (of Pawhuska formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

K. C. Heald, 1918 (U. S. G. S. Bull. 686E, pp. 28-32). *Okay ls. lentil of Pawhuska ls.*—Lowest ls. in Pawhuska fm. in T. 25 N., R. 9 E. Lies 10± ft. above Elgin ss. and 50 to 100 ft. below Deer Creek ls. memb. of Pawhuska fm. Color ranges from gray to buff, but buff predominates. In most places is of flinty hardness and contains abundant small *Fusulina*, but either or both of these features may locally be absent. Thickness 0-1 ft. Does not crop out N. of Clear Creek in this twp. and although it extends to S. line of T. 24 N. it has not been noted by geologists working the territory to S. Named for good exposures on and in neighborhood of O. K. ranch, in sec. 31.

†Okefenokee formation. (In Columbia group.)
Pleistocene: Georgia Coastal Plain.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, pp. 60, 424–434). *Okefenokee fm.*—In part coastal-terrace deposits and in part river-terrace or fluviatile deposits. During this period there was probably a depression of the land, the coast line perhaps being 40 to 75 mi. W. of its present position. Coastal sands and probably other sediments were laid down, forming a terrace, and contemp. fluviatile deposits were formed on terraces skirting the larger rivers as far as the Fall Line. The coastal terrace formed during this period is a flat plain 20 to 40 mi. wide, which varies in elev. from 60 to about 125 ft. above sea level. It is covered with gray and white quartz sand. The river terraces lie 50 to 100 ft. above zero water level and form prominent topographic features along Savannah, Ocmulgee, and Chattahoochee Rivers. The terrace deposits consist of sands and gravels of fluviatile or fluvio-estuarine origin. The Okefenokee is older and higher than Satilla fm. Is not in contact with any fm. older than Plio. and Mio. Thickness 5 to 40 ft. Included in Columbia group.

The Pleist. terrace deposits of Atlantic Coastal Plain from Del. to Fla. are now divided into the 7 fms. enumerated under *Columbia group*, and Satilla and Okefenokee fms. have been abandoned.

Named for Okefenokee Swamp, a great swampy tract in southern Ga. covering part of Charlton, Ware, and Clinch Counties. The swamp occupies a portion of the plain on which these deposits were laid down.

Okesa sandstone member (of Ochelata formation).
Pennsylvanian: Central northern Oklahoma (Osage County).

O. B. Hopkins, 1918 (U. S. G. S. Bull. 686H, pp. 76–77, pl. 12). *Okesa ss.*—Named by F. R. Clark, in rept on T. 26 N., R. 11 E. (U. S. G. S. Bull. 686–I, 1918). In N. part of T. 25 N., Rs. 11 and 12 E., it consists of 3 prominent ss. beds separated by thin beds of sh., and aggregates 30± ft. in thickness. Is separated from overlying Bigheart ss. by 50 to 100 ft. of red clay sh.; in places a thin ls. occurs 7 ft. above it. Increases in thickness to S., so that on line btw. Twps. 25 and 24 N., R. 11 E., it replaces most of underlying sh. (25 ft. thick in places), and locally rests on Torpedo ss. Named for exposures near Okesa.

F. R. Clark, 1918 (U. S. G. S. Bull. 686–I, p. 95). *Okesa ss.* so named because it crops out near railroad station and town of Okesa, forming first prominent bench ½ mi. to SE. Lies 65 to 115 ft. below Buck Point ss. Thickness 20 to 30 ft. In vicinity of Okesa it consists of one bed, which contains numerous pelecypods and a few brachiopods, but in most places within this area two benches are developed, separated by sh. The lower bench is generally massive and forms a ledge, and its upper surface contains fossils. A thin nodular ls. crops out at many places about 5 ft. above lower bench. The upper bench, which lies 10 to 13 ft. above the lower, is thinner and not so well exposed, but wherever seen it contains many pelecypods. The Okesa is separated from underlying Torpedo ss. by 25 to 75 ft. of sh.

Oketo shale. (In Chase group.)
Permian: Central Kansas.

R. C. Moore, Sept. 4–7, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, pp. 12, 69). *Oketo sh.* underlies Fort Riley ls. [restricted] and overlies Florence ls. [Florence flint of the literature, not Florence ls. of Prosser]. [There is no description of this unit, but graphic section on p. 12 shows it as consisting of shaly ls. 5 ft. thick. Derivation of name not stated. This shaly ls. appears to be included in Fort Riley ls. of previous repts.]

Okikeska series.
Pre-Cambrian (Keewatin): Quebec, Canada (upper Harricana River basin).

G. W. Bain, 1925 (Jour. Geol., vol. 33, pp. 728–743). A pre-Keewatin series of sed. rocks, consisting of carbonaceous sl., continental ss., ls., qtzite, and greywacke gneiss, in which original bedding can still be recognized by variation in color and character of clastic material. Uncon. overlain by Keewatin volcanic rocks and intruded by granite, which also intrudes the Keewatin. Okikeska is old name of lake around which these sediments are best developed.

The U. S. Geol. Survey applies *Keewatin series* to all pre-Laurentian rocks, the Laurentian consisting of intrusives.

Oklahoma series.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed that *Permian system*, as he called it, be divided into two series, and that lower one be designated *Oklahoma series*.

Oklahoman series.

Permian: Oklahoma.

C. R. Keyes, 1896 (Am. Geol., vol. 18, pp. 22–28). *Oklahoman series* intended to apply to all rocks of Carbf. age which occur N. of Canadian River in Okla. and which lie btw. top of Missourian series, or top of Cottonwood ls., and base of Cret. Essentially covers same succession of strata that has long been vaguely known under title of "Permian." [This name was later restricted by Keyes (Am. Geol., vol. 28, pp. 299–305, 1901) to beds extending from top of Wellington sh. above to top of Cottonwood ls. below, the overlying Perm. rocks being included in his Cimarron series.]

Named for Oklahoma.

†Oklune series.

Tertiary, Mesozoic, and late Carboniferous (?): Southern Alaska (Kuskokwim region).

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 163–169, 181). *Oklune series*.—Shales, impure lss., and cherts, with beds of arkose and characterized by volcanic material. Folded. Cut by intrusives of probable Neocene age. Exposed where Kanektok River emerges from Oklune Mtns and along the Kanektok on W. side of the mtns. Contains Lower Cret. fossils.

Embraced a wide variety of units of different ages and has been discarded.

Okmulgee group.

Pennsylvanian: Kansas and Oklahoma.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Des Moines series* is divided into 2 uncon. groups—*Okmulgee group* (above) and *Wilburton group* (below). Okmulgee group includes Pleasanton sh. (at top) down to base of Savanna ss. of Okla. [Derivation of name not stated. Not used in 1932 or later classifications of R. C. Moore up to and including Kans. Geol. Surv. Bull. 22, Aug. 31, 1936.]

†Oktibbeha tongue (of Selma chalk).

Upper Cretaceous: Northeastern Mississippi.

L. W. Stephenson, 1917 (Wash. Acad. Sci. Jour., vol. 7, pp. 243–250). *Oktibbeha tongue*.—A long thin tongue of chalk, projecting from extreme top of Selma chalk in Noxubee, Oktibbeha, Clay, and Chickasaw Counties. Probably 50 ft. thick and 50 to 60 mi. long. Underlain conformably by nonchalky sands and clays of the Ripley fm., and uncon. overlain by strata of Midway (Eocene) age.

Named for Oktibbeha Co. Especially well developed at Starkville.

This name was discarded by U. S. Geol. Survey in April 1937, as explained under *Prairie Bluff chalk*.

Olathe limestone member.

Pennsylvanian: Central eastern and northeastern Kansas.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pt. 1, pp. 76–79). *Olathe ls. memb. of Stanton ls.*—Thin-bedded, wavy ls., bluish gray, usually fine-grained, the beds separated by thin limy partings; weathers dark buff. Thickness 15± ft. along Captain Creek; 11 ft. in SW. corner of Johnson Co. Named for Olathe, Johnson Co. Overlies Eudora sh. memb. and underlies Victory Junction sh. memb., all in Stanton ls.

See also Newell, 1936 (Jour. Geol., vol. 44, No. 1, pp. 23–31).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 134). Type loc. of *Olathe ls. memb.* (of Stanton ls.) is quarries at W. edge of Olathe, secs. 34 and 35, T. 13 S., R. 23 E., Johnson Co., Kans. The Stoner ls. of Condra is possibly same as Olathe ls., but it is not possible to trace the beds of Platte Valley southward to NE. Kans. outcrops, and there has been so much confusion in correlation of beds btw. the 2 areas that it seems inadvisable to use *Stoner* in Kans. The Stoner ls. of Platte Valley section in Nebr. includes †Louisville ls. (abandoned), †Kiewitz sh. (abandoned), and "Du Bois" ls.

Olcese sand.

Miocene: Southern California (Kern County).

A. Diepenbrock, 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, p. 14, pl. 2). *Middle Temblor (Olcese sand of Round Mtn area)*.—Mainly unconsolidated medium-grained to coarse gray sand, containing numerous seashell fragments and occasional pebble and siltstone beds; lower part commonly of finer texture, with some clay and silty materials and strongly sulphurous. Thickness 242 ft. Underlies Round Mtn silt (Upper Temblor), in Mount Poso oil field, NE. of Bakersfield, Kern Co. [Derivation of name not stated.]

Old Colony sandstone.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 304, 375, 421, 445, fig. 37). *Old Colony ss.* lies 980 ft. below Wolverine ss.

Belongs in Central Mine group.

Named for occurrence in Old Colony mine, Houghton Co.

Old Colony amygdaloid.

Keweenawan: Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Is younger than Old Colony ss. and older than Wolverine ss. The mineralized part is the Old Colony lode. Named for occurrence in Old Colony mine, Houghton Co.

Old Colony flow.

Includes Old Colony amygdaloid and underlying trap.

Old Crow gypsum.

Permian: Northwestern Oklahoma (Blaine or Dewey County).

F. W. Cragin, 1897 (Am. Geol., vol. 19, p. 363). *Old Crow gyp.*, 1 to 2 ft. thick, is exposed in brow of bluffs on S. side of Canadian River in D Co., Okla., 90 or 200 [100?] ft. below One Horse gyp. Included in Taloga fm.

Named for Old Crow crossing of Canadian River, Blaine or Dewey Co.

Old Dominion limestone.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 66, map). *Old Dominion ls.*—Varies greatly in physical character and color. Exposures along NW. side of North Fork of Mill Creek are very low-grade lss., in places only calc. argillites. They have a banded or shaly appearance and vary from pure white to black, but are prevailingly light to dark gray with occasionally a bluish tint. At S. end of Old Dominion Mtn the ls. is nearly pure white, of uniform texture, and highly crystalline. Varies greatly in mag. content; some varieties become true dolomites. Thickness 1,500± ft. Underlies, apparently conformably, Colville qtzite and overlies Chewelah argillite. Extends as far N. as Old Dominion Mtn.

Olden sand.

A subsurface sand, of Penn. age, in Hightower field, Eastland Co., north-central Tex., lying at 1,200 ft. depth.

Oldham limestone.

Silurian (Niagaran): East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 47). *Oldham ls.*—Fossiliferous ls., 10 to 14 ft. thick, forming upper memb. of Indian Fields fm. Underlies Alger fm. and overlies Plum Creek clay (memb. of Indian Fields fm.). All of Niagaran age.

In 1931 (Ky. Geol. Surv. ser. 6, vol. 36, pp. 172, 173) Foerste assigned this ls. to Clinton time. In 1935 (Denison Univ. Bull., Sci. Lab. Jour., vol. 30, pp. 130–133) he amplified his description of this ls. and stated it is probably older than Dayton ls.

Named for Oldham Branch, btw. Panola and Brassfield, Madison Co.

Old Mayflower amygdaloid.

Same as Mayflower amygdaloid.

Old Pewabic amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 86 and chart).

Belongs to Ashbed group. Is older than Pewabic amygdaloid and younger than Albany and Boston cgl. The mineralized part is the Old Pewabic lode. (See B. S. Butler, U. S. G. S. P. P. 144, 1929.)

Named for occurrence in an old mine on Pewabic property, in Keweenaw Co.

Old Pewabic flow.

Includes Old Pewabic amygdaloid and underlying trap.

Old Rag granite.

Pre-Cambrian: Northern central Virginia (Madison County).

A. S. Furcron, 1934 (Jour. Geol., vol. 42, No. 4, pp. 400–410). *Old Rag granite.*—Coarse-grained blue-quartz granite of untwinned light-gray feldspar and blue or smoky quartz. Where it occurs in large masses, as in Old Rag Mtn. E. of Oldrag P. O., it may be as coarse or coarser than the hypersthene granodiorite, which it intrudes. Also intrudes Catoctin schist. Is believed to be older than Air Point granite.

†Old Red sandstone.

A name applied in early geological repts to Devonian system of present terminology; also to Catskill fm., of N. Y.; and to rocks btw. top of Catskill fm. and base of Genesee sl.

Olds sand.

A subsurface sand, of Ord. age, in NE. Okla. See under *Kinter sand.*

Olean conglomerate member (of Pottsville formation).

Pennsylvanian: Western New York and northwestern Pennsylvania.

J. P. Lesley, 1875 (2d Pa. Geol. Surv. Rept. I, pp. 89, 96), referred on p. 89, to *Ellicottville, Olean, Chautauqua cgl.* of western N. Y.; and on p. 96 stated this cgl. is also known as "Second Mountain sand" of Venango Co.; "Garland cgl."; "Great Bend cgl." of Warren Co., Pa.; "Rock City cgl." W. of Olean, at Ellicottville, and elsewhere in Cattaraugus Co., N. Y.; and "Rock City cgl." of Chautauqua Co. W. of Lake Chautauqua, N. Y. In same rept J. F. Carll mentioned (p. 38) *Olean cgl. (Garland)*, and on pp. 45 to 46 he described Garland cgl.

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. G_4, pp. 73–78). *Olean cgl.* is basal bed of Pottsville cgl. Thickness 50+ ft. [L. C. Glenn, 1903, gave thickness in Olean and Salamanca quads., N. Y., as 60 to 90 ft., and described it as a round-pebble cgl.]

See *Little Genesee cgl.*

Typical outcrop is at Olean Rock City, 6 mi. S. of Olean, Cattaraugus Co., N. Y.

†Olean shale.

Pennsylvanian: Western New York.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, p. 525). Overlying Olean cgl. in Olean quad. are "calcareous shales which have been termed the Olean sh." [These shales occupy position of Sharon sh. memb. of Pottsville fm., by which name they are now known.]

Olentangy shale.

Upper Devonian: Central Ohio.

N. H. Winchell, 1874 (Ohio Geol. Surv., vol. 2, pp. 243, 287). *Olentangy sh.*—Bluish, sometimes greenish sh., 30 ft. thick, more sectile and containing less bituminous matter than overlying Huron sh. [restricted], and interstratified with black sl.-like beds like those in Huron sh. Overlies blue Upper Corniferous ls. [Delaware ls.] and underlies black Huron sh., of which it is really a subdivision. No fossils found. [Included in Hamilton group on p. 328 and in Genesee on p. 302.]

This sh. was included in original definition of Ohio sh. and in Huron sh. of some early repts, but for many years it has been treated as a distinct fm. It contains few fossils, but has generally been considered to be of Hamilton age. However, A. W. Grabau in 1915 (Geol. Soc. Am. Bull., vol. 26, p. 112) stated that it is of Upper Dev. age and=in part to Huron sh.; and he proposed *Prout series* "for the northern Ohio shales and lss. of Lower Hamilton age" (the Upper Hamilton being absent). In 1917 (Jour. Geol., vol. 25, pp. 337–343) Grabau applied *Plum Creek shales* to the shales beneath Prout ls. of northern Ohio, repeating his opinion that Olentangy sh. of central Ohio is Upper Dev.

C. R. Stauffer, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 95–96) and 1916 (Jour. Geol., vol. 24, pp. 476–487) classified Olentangy fossils as of Hamilton age.

A. W. Grabau (1915 and 1917) assigned Olentangy sh. to Upper Dev.

E. R. Pohl, 1930 (Tenn. Acad. Sci. Jour., vol. 5, No. 2, p. 61). True Olentangy sh. of central Ohio has been repeatedly shown to be Upper Dev. In 2 articles I have incidentally suggested that the name be restricted to its original use for beds in central Ohio.

Named for exposures on Olentangy River, Delaware Co.

Olequa formation.

Eocene: Southwestern Washington.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 566, 568). *Olequa fm.*—Aren. bedded tuffs, of Tejon Eocene age. Younger than Chehalis fm. as redefined in this rept. Olequa and Chehalis fms. are zone of *Venericardia horni* Gabb. [Type loc. not stated.]

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 225–242). Fauna of Olequa and Chehalis fms. is quite similar, but flora is markedly different. Writers are of opinion Olequa may represent a Tejon age, while Chehalis of Arnold and Hannibal, 1913, may possibly represent a higher horizon corresponding to Jackson of east coast. It would seem that an arbitrary line should be drawn through the fresh-water beds which occur btw. Olequa and Chehalis fms. thus separating them if they are to be recognized as separate fms.

Oley Valley slates.

Pre-Cambrian: Southeastern Pennsylvania (Berks County).

E. V. d'Invilliers, 1883 (2d Pa. Geol. Surv. Rept. D_3, vol. 2, pp. 47, 158, 180). *Oley Valley slates.*—Generally considered to belong to Potsdam epoch, but portions of them may belong to Hudson River slates.

According to A. I. Jonas (personal statement Jan. 1937) the Oley Valley slates of D'Invilliers are Martinsburg sh.

Oligocene epoch (or series).

Next to oldest of the 4 epochs of Tertiary period and the rocks formed during the epoch. For definition see U. S. G. S. Bull. 769, pp. 53–54.

Olinger gray shale member (of Chattanooga shale).

Devonian or Carboniferous: Southern Tennessee and southwestern Virginia.

J. H. Swartz, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 485–499). *Olinger gray sh. memb.*—Middle gray sh. memb. of Chattanooga sh. at Chattanooga, Tenn., and in SW. Va. Best exposed at Olinger, Va. Varies in thickness from 0 to 54 ft. 5 in. at Olinger, Va. Uncon. underlies Big Stone Gap sh. memb. (the upper black sh. memb. of Chattanooga sh.) and overlies Cumberland Gap sh. memb. (the lower black sh. memb. of Chattanooga sh.). The Olinger memb. is of same age as [upper part of] Cumberland Gap memb., with which it intertongues to S., representing merely a different environmental condition.

J. H. Swartz, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 431–448), assigned these beds to Miss.

Olive Hill fire clay. (In Pottsville formation.)

Pennsylvanian: Northeastern Kentucky.

A. F. Crider, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 2, btw. pp. 594 and 616). *Olive Hill fire clay* is of same age and origin as Sciotoville fire clay of Ohio. It is associated with the Miss. ls. [The true Sciotoville clay is now known to be younger, and to lie higher than Sharon coal.]

Named for Olive Hill, Carter Co.

Olive Hill formation.

Lower Devonian (Helderbergian): Western Tennessee.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 738). *Olive Hill fm.*—Uncon. underlies Birdsong sh. and uncon. overlies Rockhouse sh., all included in Helderbergian or Linden group. Divided into (descending) Flat Gap memb., Bear Branch memb., and Ross ls. memb. Outcrops in Hardin Co., Tenn., and adjacent portions of Miss. and Ala. Named for exposure in bluff on Indian Creek at Olive Hill, Hardin Co., Tenn., where it is over 150 ft. thick and consists of the 3 members mentioned above. Fauna early New Scotland or late Coeymans.

Oliver granite.

Jurassic (?): British Columbia.

W. E. Cockfield, 1935 (Canada Dept. Mines, Geol. Surv. Bur. Econ. Geol. Mem. 179, Pub. 2392, pp. 2, 14).

Oliverian magma series.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke, Mount Cube, and Rumney quadrangles).

M. Billings, 1934 (Sci., n. s., Jan. 19, vol. 79, pp. 55–56). [See under *Highland Croft magma series*.]

M. Billings, 1935 (personal communication April 26). *Oliverian* was chosen from stream of that name (Oliverian Brook) in SW. corner of Moosilauke quad.

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., Moosilauke map and p. 26). *Oliverian magma series* (late Dev. or late Carbf.) is proposed for a series of intrusive igneous rocks which are definitely younger than lower Dev. and older than the great period of folding. In Moosilauke quad. it is represented only by Owls Head granite, but other rock types of this series are present in Mount Cube and Rumney quads.

†Oljeto sandstone member.

Upper (?) Triassic, Lower Triassic, and upper Permian: Southeastern Utah (San Juan River region).

E. G. Woodruff, 1912 (U. S. G. S. Bull. 471, pp. 80, 87, etc.). *Oljato ss. memb.*—Massive, ferruginous, gritty, cross-bedded tan ss. containing clay pellets, fossil wood, and charcoal. Thickness 20 to 382 ft. Is upper memb. of Moencopie fm. Overlies 1,260 ft. of red sandy sh. and massive tan ss. beds forming lower part of Moencopie fm. Underlies Dolores sh., probably uncon. At Oljato [*Oljeto* now, in San Juan Co.] it forms the cliffs in Moonlight Valley.

Later detailed studies by H. E. Gregory, H. D. Miser, J. B. Reeside, Jr., and other geologists showed that as mapped the †Oljato ss. memb. included Shinarump cgl. (Upper? Triassic) and tan-colored sss. of Lower Triassic and upper Perm. age. The rocks having been subdivided, the name †Oljeto ss. memb. has been discontinued.

Olmos formation. (In Navarro group.)

Upper Cretaceous (Gulf series): Southwestern Texas (Maverick County).

L. W. Stephenson, 1927 (A. A. P. G. Bull., vol. 11, pp. 10, 14). *Olmos fm.*—Greenish-gray shaly clay and fine sandy clay, irregularly interbedded with fine to coarse greenish-gray thin-bedded to massive, more or less cross-bedded soft to hard ss., some layers of which are ripple-marked, and with seams of coal and lignite. Ranges in thickness from zero to 400 or 450 ft. Uncon. underlies Escondido fm. and uncon. overlies San Miguel fm. In previous repts called "Coal Series." Named for flag station of Olmos, Maverick Co., which is located on outcrop of the fm., and also for Olmos Creek (now generally called by its English equiv. Elm Creek), which follows the strike of the fm. near center of belt of its outcrop from a point 7 or 8 mi. N. of Eagle Pass to junction of the creek with Rio Grande.

Olmos sand.

Eocene (Jackson): Southeastern Texas (Atascosa and Live Oak Counties).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1316, etc.). *Olmos sand.*—Top zone of Whitsett fm. in Live Oak and Atascosa Counties. Grayish-brown medium-textured sand or ss. that weathers brown. Thickness 15 ft. Disappears in E. part of Atascosa Co. Exposed on Olmos Creek where Fant City-Whitsett highway crosses the creek about 1 mi. S. of Whitsett. Overlies Fashing clays.

Olmsted shale member (of Cleveland shale).

Upper Devonian or Mississippian: Northeastern Ohio.

H. P. Cushing, 1912 (Am. Jour. Sci., 4th, vol. 33, p. 583). *Olmsted sh.*—Soft blackish sh., with thin bands of blue sh.; 15 to 60 ft. thick, underlying Cleveland sh. and overlying Chagrin sh. Seems to pinch out to E. [Not present at type loc. of Cleveland sh. but has heretofore been included in Cleveland.]

Adopted as basal memb. of Cleveland sh.

Named for exposures at Olmsted Falls, Cuyahoga Co.

Olney limestone.

Silurian: Central New York (Onondaga County).

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 26, 27+). *Olney ls.*—Very largely fine interlaminated blue and drab layers, especially in lower 10 or 15 ft. Upper part often more coarsely bedded than lower part and frequently contains many stromatoporoids of dark color. It is often convenient to regard a zone of 1 to 3 ft. as transitional into overlying water lime (Elmwood A). Base of Olney provisionally placed at sharp contact with a sun-cracked water lime which forms quarry floor at type loc. This subjacent water lime is thought to be below, or at least near lower limit of, *Spirifer vanuxemi;* in central Onondaga Co. Thickness of Olney 33± ft. Is basal fm. of Manlius group in Onondaga Co. Named for Olney Station, on Auburn & Syracuse Elec. R. R. Type section 1¾ mi. E. of station, at old quarry at Split Rock, formerly worked by Solvay Process Co. The Olney ls. may safely be regarded as included in Vanuxem's Manlius. It is also unquestionably represented in the 77 ft. of strata which Hartnagel (1903, p. 1165) allows for the Manlius at type loc., but this latter thickness carries the Manlius of Hartnagel far below base of the Olney.

B. Smith, 1935 (N. Y. State Mus. Bull. 300, p. 18). [See 1935 entry under *Manlius ls.;* also, for further details, see pp. 14–22 of book cited.]

Olpe shale.

Pennsylvanian: Eastern Kansas (Lyon County).

G. I. Adams, 1903 (U. S. G. S. Bull. 211, pp. 51–52). *Olpe shales* is here proposed for the fossiliferous shales, 50 to 60 ft. thick, overlying Barclay ls. (=Burlingame ls., preoccupied), and underlying Emporia ls.

A. J. Smith, 1905 (Kans. Acad. Sci. Trans., vol. 19, pp. 150–154), mapped following fms. in Greenwood, Lyon, and Osage Counties, Kans. (descending): * * *; Admire sh.; Emporia ls. system (of 5 lss.); *Olpe sh.*, 60 ft.; Reading blue ls., 3 ft. (formerly called Emporia blue ls.); Humphrey sh., 40–45 ft. (including 2 thin lss.); Barclay (Burlingame) ls., 12 ft.; * * *.

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2). Admire sh. memb. of Kans. is 300± ft. thick and includes, 70 ft. above base, the 5 thin lss. called by Smith "Emporia system." It rests on true Emporia ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 221). †Olpe sh. of Adams included beds from top of †Barclay (Burlingame and Wakarusa) to base of Emporia. [On p. 224:] †Olpe sh. of Adams included beds btw. top of †Barclay (Wakarusa) ls. and "Emporia ls.," latter indicating beds more than 60 ft. above Reading ls. (=lower Emporia of more recent common usage). [On p. 228:] †Olpe sh. of Adams was defined to include beds btw. †Barclay (Burlingame and ?Wakarusa) and "Emporia" ls., the latter being "Emporia system" of A. J. Smith, 1905, which included Maple Hill to Grandhaven of present classification. The "Emporia" of Adams and Smith thus belong 60 ft. or more above Emporia as generally defined.

Named for exposures at Olpe, Lyon Co.

Olson.

Name applied by C. [R.] Keyes to 200 ft. of lss. in Kootenai fm. of Mont. Derivation of name unknown.

Olympia sand.

A subsurface sand, of Sil. age, in Ky.

Olympus granite.

An abbreviation of *Mount Olympus granite* that has been used by some geologists.

Omega limestone. (In McLeansboro formation.)

Pennsylvanian: Southeastern Illinois.

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, p. 135). *Omega ls.* is less than 1 ft. to 17 ft. thick. Lies higher than La Salle ls. From data at hand it is thought to be a pure ls. [Derivation of name not stated. Probably refers to Omega, in E. part of Marion Co.]

Omen member. (In Mount Selman formation.)

Eocene (middle): Northeastern Texas (Smith, Harrison, Gregg, Rusk, and Cherokee Counties).

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, No. 10, pp. 1355–1356). *Omen memb.*—A local greensand memb. of Queen City memb. of Mount Selman fm. Lies approx. 140 ft. above the main glauconite of the Reklaw and btw. 240 and 280 ft. below top of the Weches. Well exposed near Omen and Arp, in eastern Smith Co., and is here termed *Omen* from the community where it was first recognized. This greensand extends from Harrison, through Gregg, NW. Rusk, and E. Smith Counties, into Cherokee Co. It consists of 10 to 15 ft. of partly cross-bedded mealy, sandy glauconite, which weathers rapidly and is difficult to recognize. The best ores are found in Omen memb.

C. L. Moody, 1931 (A. A. P. G. vol. 15, No. 5, pp. 538, 542). Reklaw as defined by Wendlandt and Knebel the writer considers as basal Claiborne of Tex. and that it properly includes the Omen memb., which they assigned to Queen City sand.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 630). *Omen greensand memb.* was named by MacNaughton (private rept. written for Humble Oil & Refining Co., Feb. 10, 1929). The name was published by Wendlandt and Knebel, 1929. It is middle memb. of Queen City fm.

Onaga limestone.

Pennsylvanian: Northeastern Kansas.

F. F. Crevecoeur, 1903 (Kans. Acad. Sci. Trans., vol. 18, pp. 124, 125). *Onaga ls.*—Series of lss. of economic importance in vicinity of Onaga [Pottawatomie Co.]. Consists of 5 in. of brown ls. at top, underlain by 8 in. of hard brown ls., underlain by 6 in. of bluish-gray ls., with 8 in. of light-blue ls. at base. Separated from overlying Neva ls. by 11½ ft. of dark-blue sh., overlain by two layers of ls., each 9 in. thick, and by 45 ft. 8 in. of yellowish ferruginous shales.

Records show no other use of this name, and R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), does not mention it. It appears to be a part of Elmdale fm.

Onalaska clay.

Miocene: Eastern Texas.

E. T. Dumble, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 466). *Onalaska clays.*—Transitional zone in the Corrigan, in which the sands of the Corrigan are interbedded with calc. clays similar to those of overlying Fleming. On this account the limit is not as well defined as farther E., and upper line is drawn where the sands with porcelaneous cement cease and the clays weather entirely dark brown or black, instead of showing the characteristic yellow weathering of Corrigan clays. These upper beds maintain their character and thickness as far W. as Navasota River. While they appear later than Catahoula proper, they are definitely connected with it by character of the sands and clays of which they are composed. Assigned to upper Olig.

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869, pp. 29, 189–218). *Onalaska beds*, at top of Corrigan fm., are assigned to upper Olig. and possibly Mio. in upper part.

The Catahoula ss. is now considered to be probably Mio., so that this overlying clay cannot be Olig.

Onaping tuff.

Pre-Cambrian (upper Huronian): Ontario.

A. P. Coleman, 1905 (Ont. Bur. Mines Rept. 1905, vol. 14, pt. 3, p. 94).

Once Lomas sandstone member (of Carrizo sandstone).

Eocene (middle): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1369–1370, 1371, 1385). *"Once Lomas" ss. memb.*—Massive white and red banded micaceous ss., 135 ft. thick, lying 562 ft. above base of Carrizo ss. Well exhibited at the "Once Lomas," a series of dip-slope hills making a scarp around S. end of Aldamas anticline. Can be traced from Rio Grande to Rio San Juan, Tamaulipas.

Oneco amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Oneco Copper Mining Co., 1925 (The Mines Hdb., by W. H. Weed, p. 1061). An amygdaloid that "has been variously identified as the Isle Royale, Grand Portage, and Kearsarge amygdaloids, but is now termed the *Oneco amygdaloid.*"

According to B. S. Butler (personal communication) this amygdaloid is probably near horizon of Isle Royale amygdaloid. Belongs in Central Mine group. The mineralized part is the Oneco lode. Named for occurrence in Oneco mine, Houghton Co.

Oneco flow.

Includes Oneco amygdaloid and underlying trap.

One Horse gypsum.

Permian: Northwestern Oklahoma (Blaine or Dewey County).

F. W. Cragin, 1897 (Am. Geol., vol. 19, p. 363). *One Horse gyp.*, 3 or 4 ft. thick, is exposed in brow of bluffs on S. side of Canadian River in D Co., Okla., about 250 ft. above river and 90 or 200 [100?] ft. above Old Crow gyp. Included in Taloga fm.

Named for One Horse Ford of Canadian River, Blaine or Dewey Co.

Oneida conglomerate.

Silurian: New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 374). *Oneida cgl.*—The "millstone grit" of Prof. Eaton. There is no other rock of the kind in Oneida Co., if we except the thin irregular layers of small-sized pebbles which make a part of the succeeding group, and which may be seen at Blackstone's quarry, S. of Utica. Overlies Medina ss. and underlies Protean group [Clinton fm.].

L. Vanuxem, 1842 (Geol. N. Y., pt. 3). *Oneida or Shawangunk cgl.*—Composed of quartz pebbles rarely exceeding ¾ in. diam., and white or yellowish quartz sand; in some localities there is some interposed greenish sh. Named for Oneida Co., where its position is well defined. In Herkimer rests on Frankfort sl.; in E. and W. parts of Oneida Co. it rests on Pulaski shales. Forms part of Clinton group, the next mass in order of superposition. It was separated as being a convenient point for division, and from importance which was once attached to this rock, having been confounded with the cgl. of the Coal era. [The Shawangunk cgl. is now considered to be of Tuscarora and Clinton age (see C. K. and F. M. Swartz, Geol. Soc. Am. Bull., vol. 42, pp. 621–662, 1931).]

J. Hall, 1843 (Geol. N. Y., div. 4, 4th dist., pp. 18, 31). *Oneida cgl.* overlies Hudson River group in E. part of State, and occupies same strat. position as Grey ss. of Oswego, which rests on Hudson River group and is overlain by Medina ss. Forms Shawangunk Mtn. and in Oneida Co. [N. Y.] and Pa. attains a much greater thickness. Not seen in place W. of Oneida.

For many years the position of Oneida cgl. was given by most geologists as btw. Medina ss. and the Ord. †Hudson River group, or Lorraine sh., and it was believed to be same as "Grey ss. of Oswego." Some repts, however, included it in the Medina, and some geologists regarded it as younger than "Grey ss. of Oswego." Its thickness in Oneida Co. was given as ranging from 25 to 100 ft.

C. A. Hartnagel, 1905 (N. Y. State Mus. Bull. 80). *Oneida cgl.* in its W. extension gradually grades into ss. known as *Oswego ss.*, and both Oneida cgl. and Oswego ss. are transitional into Medina ss. above.

A. W. Grabau, 1906 (N. Y. State Mus. Bull. 92). In central N. Y. Oswego ss. merges into the Oneida, a pure-white quartz-pebble cgl.

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114). *Oneida cgl.* is here considered a local facies of upper Medina. [In Bull. 107, 1907, Hartnagel says Oneida cgl. contains *Arthrophycus alleghaniensis*, which is practically confined to upper Medina, and that for strat. and paleontologic reasons the Oneida cgl. is to be considered part of upper Medina. "Its position is never far below the base of the Clinton."]

J. M. Clarke, 1907 (N. Y. State Mus. 59th Ann. Rept., vol. 1, p. 17). The nonfossiliferous Oswego ss. is older than Oneida cgl.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 46). In Oswego Co. the Oneida cgl. actually lies within upper part of Medina fm. and westward disappears in Wayne Co.

E. O. Ulrich, 1913 (12th Int. Geol. Cong., Canada). *Oneida cgl.* belongs at top of the Medina, if, indeed, it is not, as Vanuxem long ago contended, the basal deposit of the Clinton. [Ulrich continued to thus classify Oneida in 1923 Silurian vol. of Md. Geol. Surv.]

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 431, 460). Thorold ss., top bed of the Medina, is westward extension of Oneida cgl.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, p. 340). Evidence in hand favors conclusion of Vanuxem and Hartnagel that the Oneida is "never far below the base of the Clinton" and is closely connected with its basal sh. [In correlation charts on pp. 359 and 364 Chadwick placed Oneida opposite Thorold ss. (which he excluded from Medina) and the overlying Maplewood sh.]

The Oswego ss. is now considered to be much older than Oneida cgl., and of Upper Ord. (Maysville) age.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 191, 317, 318, 324), included *Oneida cgl.* in the Clinton of central N. Y., and stated that it was named for its excellent exposures in vicinity of Verona, Oneida Co. She placed it beneath Maplewood sh., and stated that it is = Thorold ss. of western N. Y.

C. Schuchert and C. R. Longwell, 1932 (Am. Jour. Sci., 5th, vol. 23, pp. 305–311), excluded Oneida cgl. from Clinton.

J. T. Sanford, 1936 (Jour. Geol., vol. 44, p. 811), excluded Oneida cgl. from Clinton.

The U. S. Geol. Survey does not include Oneida cgl. in the Clinton.

See also under *Oswego ss.*

†Oneida conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map. Phila., 1863; p. 21 and map). Next [above the Toltec trap] follows a narrow belt of cgl., which from the circumstance of being first opened upon the Oneida Location is known as *Oneida cgl.* Overlying it is a large and promising vein, carrying, where opened, sheet and stamp copper. [Shown as younger than National ss. and older than West Minesota cgl.]

According to B. S. Butler (U. S. G. S. P. P. 144, 1929) is probably same as Allouez cgl.

Oneida glass sand.

A commercial term for a sand of Pleist. age occurring at E. end of Oneida Lake, N. Y.

Oneonta sandstone.

Upper Devonian: Eastern and east-central New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 381). *Montrose ss. or ss. of Oneonta.*—Younger than Chemung group. [See quotation under †Montrose ss.]

T. A. Conrad, 1841 (N. Y. Geol. Surv. 5th Rept., p. 31). [*Oneonta group* appears in table as overlying Cazenovia group, which is shown resting on Tully ls.]

J. Hall, 1886 (N. Y. State Geol. 5th Rept., p. 11) and 1893 (N. Y. State Geol. 12th Ann. Rept., pp. 9, 34). Results of recent investigations clearly show that Oneonta ss. rests upon well-marked Hamilton strata and is succeeded by strata carrying fossils of Chemung group. It is not=Catskill, as has been reported. [In 1894 (N. Y. State Geol. 13th Ann. Rept. pl. opp. p. 16) Hall correlated Oneonta with Portage.]

C. S. Prosser, 1893 (N. Y. State Mus. 46th Ann. Rept.). The Oneonta ss. of Vanuxem (Vanuxem's Oneonta or Montrose group) forms upper part of hill at Oneonta [Otsego Co.]. Consists of barren red and gray sss. and shales and is above Oneonta group of Conrad, which Vanuxem quite correctly regarded as belonging to Ithaca group. The Oneonta group of Conrad consists of red and gray shales and sss., and is well exposed in Susquehanna River Valley near Oneonta.

J. M. Clarke, 1894 (N. Y. State Mus. 47th Ann. Rept., p. 750), showed Oneonta ss. as younger than Ithaca and=Upper Portage or Portage sss. In 1897 (N. Y. State Geol. 15th Ann. Rept., p. 62), however, Clarke considered the Oneonta=upper part of Ithaca beds. In 1903 (N. Y. State Mus. Hdb. 19, p. 24) Clarke stated that Oneonta beds are "looked on as nonmarine, contemporaneous with later Portage time."

H. S. Williams, 1913 (U. S. G. S. P. P. 79), showed the fresh-water Oneonta ss. the time equiv. of upper part of marine Ithaca sh., and of middle Portage age.

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7) and 1933 (Sci., n. s., vol. 77, pp. 86–87). True Oneonta ss. is of Ithaca age. It is present in Catskill Mtns, type loc. of Catskill fm., but it is not basal ss. of Catskill fm., as erroneously correlated for many years. The basal ss. of the Catskill is of Hamilton age, according to writer's studies, which are verified by studies of G. A. Cooper, and is here renamed *Kiskatom red beds.*

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 858). To E. the Cincinnatus flags become almost at once the continental *Oneonta red beds.* The type Oneonta probably absorbs also the underlying Otselic.

Oneota dolomite. (In Prairie du Chien group.)

Lower Ordovician (Beekmantown): Iowa, southern Minnesota and Wisconsin, and northwestern Illinois.

W J McGee, 1891 (U. S. G. S. 11th Ann. Rept., pt. 1, pp. 331, 332). *Oneota ls.*—Aren. dol., with intercalations of ss. in upper part; dol. usually coarsely saccharoidal, frequently vesicular and cavernous, and generally of buff, yellow, or light-brown color. Thickness 200 to 300 ft. Corresponds to "Main body" of Lower Mag. ls. of Minn. and Wis., which underlies New Richmond ss. and overlies Jordan ss.

For many years the Iowa Geol. Survey used *Oneota ls.* to include the Shakopee at top. In 1906, however, S. Calvin recognized in Iowa the 3 subdivisions then recognized in Minn. and Wis., i. e., Shakopee ls., New Richmond ss., and Oneota ls., and since that time these names have been generally employed in Iowa also. Ulrich assigns the Oneota to his Ozarkian system, in view of which the U. S. Geol. Survey formerly classified it as "Camb. or Ord." It is lower fm. of Prairie du Chien group, all of which Trowbridge and Atwater would include in Lower Ord. (See under *Prairie du Chien group.*) The U. S. Geol. Survey at present classifies Oneota dol. as *Lower Ord.* (*Beekmantown*).

See also under *Shakopee dol.* and *New Richmond ss.*

In 1925 (Jour. Geol., vol. 33, pp. 706–713) C. R. Stauffer published a section of Oneota dol. and Jordan ss. in Minn. River Bluff and at adjacent quarries at Kasota, Minn., in which he transferred to Oneota dol. 6½ ft. of fossiliferous ss. which he stated had "always been included in Jordan ss., but which was probably reworked after deposition and should be included in the Oneota, where its fauna seemed to belong. L. H. Powell, 1935 (St. Paul Inst., Sci. Mus., Sci. Bull. 1), introduced *Kasota ss.* for this 6½-ft. bed, and named the overlying 6 in. to 3 ft. of "siltstone," as he called it, *Blue Earth siltstone*. Powell excluded both of these thin beds from the Oneota and treated them as distinct fms., stating that they occur only in region from Ottawa, Minn., to Mankato. The Rept. 9th Field Conf. Kans. Geol. Soc., 1935, fig. 1, shows "*Blue Earth and Kasota, local formations in Minn.*" as=basal part of Oneota dol., which is shown as underlain by Madison ss.

Named for exposures on Oneota River, Allamakee Co., Iowa.

Onion Creek marl.

Pleistocene: Central Texas.

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 252–254, 277). *Onion Creek marl.*—Faint yellow or salmon-yellow calc. marl, sometimes accompanied by fine-pebble cgl., all derived from Cret. ls. Thickness about 50 ft. Usually deposited in furrows eroded in Pliocene Uvalde fm. May ultimately be correlated with Leona fm.

Named for Onion Creek, Hays Co.

†Onondaga limestone series.

Devonian: New York.

T. A. Conrad, 1837 (N. Y. Geol. Surv. 1st Rept., pp. 178–181). *Onondaga ls. series.*—Numerous strata of blue and gray ls., hydraulic ls., shales and gyp. beds, which are linked together by paleontological affinities. Comprises the "calcareous slate," or "liasold rocks," "geodiferous" and "corniferous limerocks" of Eaton, stretching across the State from Helderberg Mtns to lake Erie, and appearing as a narrow belt, bordering Erie Canal on S. In descending the slope from village of Onondaga to Syracuse, we find, in succession, most of the rocks of this series, in the following order: (1) Gray sparry crinoidal ls. quarried near Auburn and on Onondaga Hill, near Syracuse; (2) alternating strata of blue and hydraulic ls.; (3) shales, with gyp. beds.

A much larger aggregate than Onondaga ls. of modern terminology.

Onondaga limestone.

Middle Devonian: New York, Pennsylvania, western Maryland and Virginia, and northern West Virginia.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 293–309). The "*gray crinoidal or Onondaga ls.*" underlies Seneca ls. and succeeds Oriskany ss. Consists of gray or grayish blue compact crystalline ls.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 378). *Onondaga ls.*—Is the ls. or marble so well known and extensively wrought from Auburn to Cherry Valley. In bottom layer pebbles of black ss. are often seen, having been derived from breaking up of Oriskany ss. [In this rept the following succession is given (descending) Marcellus shales, Seneca ls., Corniferous limerock, *Onondaga ls.*, Schoharie layers, Fucoides Cauda-Galli, and Oriskany ss. In his 1842 rept Vanuxem used same classification, and gave thickness of †Corniferous ls. as 60 to 80 ft. and of Onondaga ls. as 10 to 14 ft. He also stated that Onondaga ls. is †Gray Sparry ls. of earlier repts.]

J. Hall, 1843 (Geol. N. Y., div. 4, 4th Rept., p. 18, also W. W. Mather, 1843). *Onondaga ls.* overlies Schoharie grit and underlies Corniferous ls. Thickness 0 to 40 ft.

E. Emmons, 1846 (Agric. N. Y., vol. 1). *Onondaga ls.*—Dark-colored ls. which has been described in ann. repts. under names *Selenurus ls.*, *Seneca ls.*, and *Corniferous ls.* Underlies Marcellus sl. or shales and overlies Schoharie grit. [This is present commonly accepted definition of Onondaga ls. Hall, however, for many years followed his 1843 definition.]

J. M. Clarke and D. D. Luther, 1905 (N. Y. State Mus. Bull. 82). *Onondaga ls.*—Underlies Marcellus sh. and overlies Oriskany qtzite. Thickness 65 to 70 ft. Formerly the term was applied to the lower and purer layers and *Corniferous ls.* was attached to the chert-bearing upper deposits, but this distinction, while an important one locally, has given way to application of *Onondaga* to entire fm.

This fm. has also been called †*Upper Helderberg ls.* In western Md., Va., and W. Va. the beds of Onondaga age are now called *Onondaga sh. memb. of Romney sh.*

Named for exposures in Onondaga Co., N. Y.

†Onondaga group.

Name applied in some early N. Y. repts to the "Middle Silurian group," including all rocks btw. "Lower Helderberg group" [Helderberg group] and Niagara group.

†Onondaga saliferous group.

Silurian and Lower Devonian: New York.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 290–293, 304). *Onondaga saliferous group.*—The rocks btw. Lockport ls. below and *top* of "waterlime series" or base of "shell grit" of Eaton, which underlies Oriskany ss. [As thus defined the term includes Salina fm. at base and Helderberg group at top, and is of Sil. and Dev. age.]

†Onondaga salt group.

Silurian (Cayugan): New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 375–376, 378). *Onondaga salt group.*—Embraces all the salines of Onondaga and Cayuga, as well as all the gypsum beds of the State. Thickness in Onondaga about 700 ft. Divided into four parts or masses (descending): (1) Those rocks which abound in groups of needle form cavities originally occupied by sulphate of magnesia; (2) the gyp. deposit; (3) the lower gypsiferous shales; (4) red sh. Underlies Manlius water lime group and overlies Protean group, of which Lockport ls. is top div.

Essentially same as Salina fm. of present terminology.

Onslow syenite.

Pre-Cambrian: Quebec.

M. E. Wilson, 1924 (Canada Geol. Surv. Mem. 136, p. 40).

†Ontarian.

Name proposed by J. D. Dana in 1890 (Geol. Soc. Am. Bull., vol. 1, pp. 40–41) for the rocks now called *Silurian system.* For definition see U. S. G. S. Bull. 769, p. 81.

†Ontarian.

Name proposed by A. C. Lawson in 1890 (Geol. Soc. Am. Bull., vol. 1, pp. 176–177) for the *pre-Laurentian rocks* of NW. Ontario. In 1914 (Ont. Bur. Mines Rept., vol. 22, pt. 2, p. 127) W. G. Miller and C. W. Knight

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

proposed to replace this name with *Loganian*, because of conflict with "Ontaric system" of N. Y. Geol. Survey, proposed by E. Emmons in 1842.

†Ontario group.

Name proposed by E. Emmons in 1842 (Geol. of N. Y. pt. 2, div. 4, geol. 2d dist., pp. 100–101, 429). For definition see U. S. G. S. Bull. 769, p. 81. Essentially synonymous with Silurian system, as it included Manlius "waterlime" at top and Medina ss. at base.

†Ontario division.

A variant of †Ontario group used in some early N. Y. repts. As used by L. Vanuxem in 1842 rept it included all beds btw. top of Niagara group and top of †Hudson River group. James Hall (1843 rept) included in it his Niagara group, Clinton group, and Medina ss.

†Ontario quartzite.

A local name that has been applied to Weber qtzite (Penn.) in Park City dist., Utah. See W. P. Jenney, 1906 (Min. and Sci. Press, vol. 92, p. 108), J. M. Boutwell, 1904 (U. S. G. S. Bull. 225, pp. 142–143), 1907 (Jour. Geol., vol. 15, pp. 434–458). Named for Ontario mine.

Ontario series.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed *Ontario series* to "include Niagara, Clinton, and Medina" of N. Y.

Onteora red beds.

Upper Devonian: Southeastern New York (Greene County).

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 16, pp. 480, 483, 484). *Onteora red beds*.—Lower part (Tully to Oneonta in age) of Catskill fm. as I proposed (16th Int. Geol. Cong. Guidebook 9A, p. 4, 1933) to restrict that name, but proposed restriction now seems questionable. I therefore now propose *Katsberg red beds* for the upper (Enfield) part and *Onteora red beds* for the lower part, which overlies Kiskatom red beds. Onteora ("hills of the sky") is aboriginal Indian name for Catskill Mtns. Type section of Onteora fm. will be in vicinity of Haines Falls, Greene Co., N. Y., up the sides of the Kaaterskill "High Peak" and "Round Top" Mtns. Up the opposite slope is Onteora Park.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 4, p. 286). This expanded red mass, from Tully to Ithaca, embraces a good deal more than the Oneonta, under which name it has been passing, wherefore I have lately rechristened it *Onteora fm., or memb., of Catskill group* in its wider sense. On E. front of the Catskills the Onteora is bulk of what was recently being called (restricted) Catskill, in contradistinction to supposed "Oneonta" (now the Kiskatom beds, of Hamilton age).

Onwatin slate.

Pre-Cambrian (Huronian): Ontario.

A. P. Coleman, 1905 (Ont. Bur. Mines Rept., vol. 14, pt. 3).

Oolithic.

Oolitic.

Terms applied by European geologists to Middle and Upper Jurassic combined.

Oologah limestone.

Pennsylvanian: Northeastern Oklahoma.

N. F. Drake, 1897 (Am. Phil. Soc. Proc., vol. 36, p. 377). *Oologah ls.*—Massive hard gray, rather unevenly textured ls., in places containing chert nodules. Forms east-facing escarpment, 50 to 100 ft. high, along W. side of Verdigris River Valley E. of Oologah.

In northern part of Rogers Co. the Bandera sh. thins out and Altamont and Pawnee lss. unite and continue southward under the name *Oologah ls.* The Oologah overlies Labette sh. and underlies Nowata sh.

Named for Oologah, Rogers Co.

[library stamp]

†Oostanaula shales.

†Oostanaula series.

Cambrian: Northwestern Georgia.

J. W. Spencer, 1893 (Ga. Geol. Surv., Paleozoic group, pp. 34, 37, 77, 87, 99, 108, 112, 115, 119, 123, 130). *Coosa Valley phase of Oostanaula shales.*—Reddish, yellowish, brownish, and greenish shales and thin-bedded lss. with shaly partings, thickness 3,000 to 6,000 ft. *Connasauga Valley phase of Oostanaula shales.*—Red, green, and variegated calcareous shales, thin beds of ss., sometimes qtzitic in lower members, and dark bedded lss. in higher strata; thickness 4,000 to 6,000 ft. Overlies Chilhowee series and underlies Knox dol.

Probably included Conasauga (†Coosa) sh., Rome fm. and Apison sh. of present classification of rocks of NW. Ga. Has also been called "Oostanaula series."

Named for exposures on Oostanaula River.

Opeche formation.

Permian? (may be Triassic): Western South Dakota, Wyoming, northwestern Nebraska.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 513). *Opeche fm.*—Red soft slabby sss. and sandy sh.; at top, for first few ft. below Minnekahta ls., there are shales of invariably deep-purple color; basal beds are usually red sss. varying in thickness from 4 to 15 in.; a few local gyp. beds. Thickness 90 to 130 ft. in Black Hills. Underlies Minnekahta ls. and overlies Minnelusa fm. Typically developed on Battle Creek, the Indian name of which is *Opeche*.

Opemiska series.

Pre-Cambrian: Quebec (Opemiska district).

C. Tolman, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, p. 232, and Pan-Am. Geol., vol. 55, pp. 316–317). *Opemiska series.*—A thick series of pre-Camb. sediments in Opemiska dist., about 300 mi. N. of Montreal. Their great interest is centered in their apparent conformity within the basal volcanics which in this part of Quebec have been termed Abitibi volcanics. Because of their position at base of pre-Camb. section they are generally assumed to be Keewatin. Appear to be at least 10,000 ft. thick. Are predominantly arkose, tending to be gritty and conglomeratic at a number of horizons; very little argill. material and only one narrow bed of ls.; near base some interbedded andesitic flows; schistosity generally developed throughout series. The underlying volcanics and Opemiska series have been closely folded. No structural discordance btw. underlying and overlying volcanics.

C. Tolman, 1932 (Jour. Geol., vol. 40, No. 4, pp. 356+). *Opemiska series.*—Metamorphosed arkose, cgls., and minor amounts of graywacke, sl., and ls. Overlain and underlain by volcanics that are generally referred to Keewatin.

Opemiska granite.

Pre-Cambrian: Northern Quebec (Opemiska district).

C. Tolman, 1932 (Jour. Geol., vol. 40, No. 4, p. 356). *Opemiska granite* (intrusive). Much later than Opemiska series.

Open Bay group.

Cretaceous or Jurassic: British Columbia.

J. A. Bancroft, 1913 (Canada Geol. Surv. Mem. 23, pp. 68, 145). [Assigned to upper Paleozoic, but Cairnes in 1914 assigned it to Cret. or Jurassic.]

Opex dolomite.

Cambrian (Upper?): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Opex dol.*—Variable beds, poorly exposed. Only continuous exposed section is along saddle W. of Eureka Peak, where fm. consists of (descending): (1) Dark shaly ls., mottled or thinly banded, with thin beds of true sh., 85 ft., resembles Herkimer ls. and parts of Opohonga ls.; (2) dark-gray granular dol., somewhat cross-bedded, 92 ft.; (3) light-gray granular dol. similar to Emerald memb. of Ajax ls., alternating with and grading upward into greenish and reddish sh., 26 ft.; (4) dark shaly ls., 13 to 18 ft.; (5) dark-gray dol., some beds mottled, some with short white spangles, some granular and finely cross-bedded, some spotted either with small dark included fragments or with carbonaceous spots left by destroyed fossils, 172 ft. Total 388 to 393 ft. Uncon. underlies Ajax ls. and overlies, with arbitrary bdy, Cole Canyon dol. Named for Opex mine.

Ophian.

Pre-Cambrian: General.

See under *Pelodian*.

Ophir formation.

Middle and Lower Cambrian: Central northern Utah (Tintic district and Oquirrh Mountains region).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107, pp. 25-27). *Ophir fm.*—Name proposed by B. S. Butler, for the shales (locally slates), with a little ss. and intercalated ls. beds, overlying Tintic qtzite as here restricted and underlying Teutonic ls. in the ranges of central Utah. Thickness 159 to 475± ft. Well exposed at Ophir, eastern Toole Co. Lower part of these beds (100 to 190 ft.) was included in Tintic qtzite as originally defined, but Tintic is herein restricted to the massive qtzites.

In U. S. G. S. 19th Ann. Rept., pt. 3, 1899, p. 620, footnote, G. W. Tower, Jr., and G. O. Smith stated that in Tintic folio the Camb. †Robinson qtzite would be named *Ophir fm.*, to avoid duplication of names. In Tintic folio, however, the Camb. †Robinson qtzite was renamed *Tintic qtzite*, and Ophir fm. was not used.

Opohonga limestone.

Lower Ordovician: Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Opohonga ls.*—Mottled shaly ls.; bands or short lenses of medium- to light-gray ls. alternating with bands of yellow to red argill. material. These colors are due to weathering. In the underground workings the rock is uniformly light gray ("White lime"). A noticeable feature of the fm. is the great number of thin beds of cgl. it contains, most of them intraformational. Thickness 700 to 1,000 ft. Conformably underlies Bluebell dol. but with sharp contact. Grades into underlying Ajax ls. Named for Opohonga mine.

Oppello breccia.

Cretaceous (probably middle): Central northern Arkansas (Conway County).

C. Croneis and M. Billings, 1929 (Jour. Geol., vol. 37, pp. 543, 551), and 1930 (Ark. Geol. Surv. Bull. 3, pp. 155-158). The rock here described as *Oppello breccia* crops out about 1 mi. W. of Oppello, in N½SE¼ sec. 2, T. 5 N., R. 17 W., on farm of W. J. Sadler. Matrix is physically very strong but is nonresistant chemically. The igneous mass therefore does not crop out naturally, and its size can be inferred only from the distribution of the inclusions which remain behind after the groundmass has been completely weathered. Indications are that the igneous plug has a diam. of 300 to 500 ft. Macroscopically it is composed of both angular and rounded fragments of black sh., gray to reddish-brown ss., and ouachitite and of lesser amount of fragments of alkaline syenite and aegerite granite, set in a dense gray groundmass containing conspicuous crystals of biotite and, less commonly, black glassy grains of pyroxene. Fragments range from microscopic grains to pieces 4 in. in diam. The groundmass composes 25 percent of the rock. Probably middle Cret.

The town is spelled Oppelo on all maps consulted by compiler.

Oquirrh quartzite.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 37). *Oquirrh qtzites.*—Qtzites, 500 ft. thick, underlying Butterfield lss., and composing basal fm. of Weberian series, Mid Carbonic, in Utah. [Derivation of name not stated.]

Oquirrh formation.

Pennsylvanian (and Permian in some areas): Central northern Utah (Oquirrh Mountains region).

J. Gilluly, 1932 (U. S. G. S. P. P. 173). *Oquirrh fm.*—Interbedded lenticular qtzite and ls., becoming more qtzitic toward top, with very subordinate thin beds of sh. and dol. Thickness in Stockton and Fairfield quads. 16,000 to 18,000 ft. Top not exposed in this area. Contains fossils of Pottsville and later Penn. age. Grades into underlying Manning Canyon sh.; where lss. greatly predominate over sh. the beds are assigned to Oquirrh fm. Uncon. underlies Tert. cgl. and grit. Is most important strat. unit in Oquirrh Range, hence name. [This fm. was first defined by T. B. Nolan (Wash. Acad. Sci. Jour., vol. 20, No. 17, pp. 423, 431, 1930), in a paper on the Paleozoics of Gold Hill quad., Utah, he having correlated the rocks in Gold Hill quad. with those in Fairfield and Stockton quads. to which Gilluly was applying the name *Oquirrh fm.* in an unfinished rept.]

See also T. B. Nolan, 1934 (U. S. G. S. P. P. 177).

Orabai sandstone.

Upper Cretaceous: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 337). *Orabai sss.*—Sss., 250 ft. thick, constituting basal memb. of Montanan series as developed in NE. Ariz. Overlie Mancos shales and underlie Mesa Verde shales. Well exposed at Orabai Mesa, N. of Winslow, Apache Co.

Oran sandstone lentil. (In Graford formation.)

Pennsylvanian: Central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 96, 97, 99, 100). *Oran ss. lentil (of Brownwood sh. memb. of Graford fm.)*.—A fairly continuous ss. locally present in lower part of Brownwood sh. in Palo Pinto Co. [The town of Oran is in Palo Pinto Co.] Consists of (descending): (1) Light-brown massive thick-bedded ss., 3 ft. thick, weathering to dark rusty-brown massive irregular blocks, in most places loosely cemented; (2) massive brown ss., 50 ft. thick, loosely cemented in some portions, other portions very friable; slightly closer-grained than overlying bed. Rests on ss. very similar to No. 2 of Oran lentil, but containing much more iron. Top of Oran ss. lies 227 ft. below top of Brownwood memb. in escarpment due W. of Strawn oil field.

†Orange sand.

†Orange sand group.

Descriptive terms applied in early repts on Gulf Coastal Plain States to late Tert. and early Quat. deposits characterized by their bright color. Introduced by J. M. Safford, Geol. reconn. of State of Tenn., 1st Rept., p. 162, 1856. The *Orange sand* of Safford's 1856 rept included the Upper Cret. and Tert. deposits of western Tenn. In later Tenn. repts the name was applied to the Plio. and Eo. deposits of western Tenn. In still later Tenn. repts the name was applied to †Lagrange fm. (=Wilcox group and Jackson fm.), the overlying Plio. beds being the †Bluff lignite. The term was also widely used as a synonym of †Lafayette fm. The Plio. deposits to which the name was applied in the Gulf States are the Citronelle fm. of modern terminology. (See †*Lafayette fm.* and *Citronelle fm.*)

Orange phyllite.

Pre-Triassic: Western and western central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 86, 101–102, and map). *Orange phyllite.*—Sl. or phyllite, highly fissile, sericitic, and usually dotted with minute garnets. Toward W. is much more micaceous, in places approaching mica schist, and is also frequently feldspathic. Is minutely folded, contorted, and jointed. Beds of impure ls. or marble are interstratified at a number of places. The fm. is believed to have been originally a sh., more or less calc. In Orange and Woodbridge the fm. is 6 mi. wide. It lies btw. Prospect granite gneiss (Ord.) and Triassic ss. and sh.

†Orange group.

Lower Cretaceous to Pennsylvanian: Yukon-Alaska boundary, between Porcupine and Yukon Rivers.

D. D. Cairnes, 1912 (Canada Geol. Surv. Summ. Rept. 1911, pp. 27–32). *Orange group.*—Chiefly slates, phyllites, qtzites, sss., shales, and occasional dol. and magnesite beds. Overlies Raquet group (whether conformably or uncon. not ascertained) and underlies surficial deposits. Thickness at least 6,000 ft. Mesozoic, probably chiefly Cret. Named for Orange Fork of Black River, Yukon, to S. of which it outcrops and continues 40 mi.

Later work led to discovery that †Orange group included Mesozoic and Penn. rocks, and the term was abandoned by D. D. Cairnes in 1914 (Canada Geol. Surv. Mem. 67, p. 103).

Orange granite.

Devonian: Northeastern Vermont (Orange County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Named for Orange Twp, Orange Co.

†Orangeburg formation.

Eocene (middle): Western and central South Carolina and southern Georgia.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 344, and chart opp. p. 334; also published in 1897 as House Doc. 5, 55th Cong., 2d sess.). *Tallahatta or Orangeburg fm.* [See quotation under *Tallahatta fm.*]

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). The deposits referred to are McBean fm., but latter name is better defined and is established. Dall designated as typical a locality in the old Orangeburg dist. (Lang Syne plantation, near Fort Motte, now in Calhoun Co.). *Orangeburg* has since been applied by U. S. Bureau of Soils to a series of soil types that is widely distributed and not restricted to any one geologic fm.

Orange-Martin limestone.

Mississippian: Indiana (Orange and Martin Counties).

D. D. and R. Owen, 1862 (Rept. of geol. reconn. of Ind., pp. 126–7). The upper sub-carboniferous ls., which might be also termed the *Orange-Martin ls.*, from its prevalence in those counties, is often characterized, in its [lower] submemb. "B," by abundant Bryozoa, of genus *Retepora*, *Fenestella*, *Ceriopora*, etc., and it is occasionally oolitic. The [upper] submemb. "A" is more frequently compact, with few fossils and a very clear ring when struck by hammer, sometimes more closely crystalline and containing *Archimedipora*, *Archimedes*, or spines and fragments of *Echinites*. [Section on p. 127 shows submemb. "B" to be 5 to 30 ft. thick, the submemb. "A" to be 3 to 20 ft. thick, and the two to be separated by 0 to 30 ft. of grindstone grit and sh. The upper ls. is overlain by Ferruginous ss. 50 to 100 ft. thick, and the lower memb. rests on 50 to 100 ft. of aluminous and calc. shale.]

Orangeville shale. (In Cuyahoga group, in Ohio.)

Orangeville shale member (of Cuyahoga formation in northwestern Pennsylvania).

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3, p. 63). *Orangeville shales.*—A group of shales, prevailingly blue, but often rusty or reddish brown on exposed surfaces, always more or less argill., seldom exhibiting sandy layers more than 6 in. thick, and containing considerable quantities of scattered iron-ore balls. Is lowest surface fm. in Mercer Co., Pa. About 75 ft. thick at Orangeville, near State line, where most of it is exposed. Underlies Sharpsville ss.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 83-90). *Orangeville sh.*—Usually 100 ft. thick in Crawford Co., Pa. Underlies Sharpsville ss. and overlies Corry [Berea] ss.

In NE. Ohio the Cuyahoga is treated as a *group* and Orangeville sh. as a *fm.* It rests on Berea ss.

†Orbitoides limestone.

†Orbitoidal limestone.

†Orbitoitic.

†Orbitolite limestone.

Names, of paleontologic derivation, used in early repts for all and for part of Ocala ls., of upper Eocene (Jackson) age, of Fla., and for Vicksburg group (Olig.) of Ala.

†Orbitolina limestone.

Paleontologic name for a part of Glen Rose ls. (Lower Cret.) of Tex.

Orca group.

Paleozoic and Mesozoic(?): Central southern Alaska (Prince William Sound region).

F. C. Schrader, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 404, 413). *Orca series.*—Thick-bedded brown and gray sss., black lss., and arkoses, interlarded with usually thin layers of dark sh. and sl. and occasionally some cgl.; arkoses form by far larger part of series, which is probably several mi. thick. Jointed, folded, faulted, and somewhat altered. Form N. shore of Prince William Sound and adjacent islands, beginning below Orca and extending N. to vicinity of Fidalgo Bay, and NW. Fragmentary plants indicate slight probability of Upper Cret. or Lower Tert. age.

See 1911, 1924, and 1926 entries under *Valdez group.*

Orcas group.

Mississippian and Upper and Middle(?) Devonian: Northwestern Washington (San Juan Islands).

R. D. McLellan, 1924 (Am. Jour. Sci., 5th, vol. 8, pp. 217-222). *Orcas group.*—Highly metamorphosed and contorted marine sediments with some interbedded volcanic rocks (altered basalts and basic andesites). Chiefly light bluish-gray chert, badly fractured, and cherty qtzite, with intercalated beds of ls. and argillite. Thickness estimated at not less than 10,000 ft. Is oldest group exposed on Orcas and San Juan Islands, the underlying strata being covered by the waters of the straits. Is overlain by Leech River group. Forms basal div. of San Juan series. Is of Miss. and Middle or Upper Dev. age.

Named for exposures on Orcas Island.

Orchard gneiss.

Pre-Cambrian: Northeastern New York (Essex County).

J. F. Kemp, 1898 (Am. Inst. Min. Engrs. Trans., vol. 27, p. 178, map, and cross sections). *Orchard gneiss*, a light-colored granitoid gneiss occurring near Port Henry [Essex Co.]. Overlain by Barton gneiss and underlain by gabbro gneiss. [Apparently named for Orchard Pit, which is shown on map.]

Orchard Creek shale.

Silurian (early): Southwestern Illinois and southeastern Missouri.

T. E. Savage, 1909 (Am. Jour. Sci., 4th, vol. 28, p. 515). *Orchard Creek sh.*—Bands of bluish-gray sh. 4 to 6 in. thick, alternating with 2- to 4-in. layers of impure crystalline ls. Thickness 17 to 22 ft. Uncon. underlies Girardeau ls. and uncon. overlies Thebes ss. Included in Richmond stage and in Ord. system.

T. E. Savage, 1910 (Ill. Geol. Surv. Bull. 16). *Orchard Creek sh.*—On account of faunal differences these lower shaly beds are described as separate fm. from Girardeau ls. Should further study show sedimentation was continuous from Orchard Creek sh. into Girardeau ls., no especial confusion will have been caused by this discussion of the lower argill. horizon separate from that of overlying ls. memb. Fauna belongs to Maquoketa phase of Richmond. Included in Ord. [These beds were included in Ord. by Savage and all other geologists up to 1915. They apparently were excluded from Cape Girardeau ls. of Swallow in 1855, 1858, and other geologists, and included in "Hudson River sh." (See under *Girardeau ls.*)]

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 4). [Orchard Creek sh. shown as post-Richmond and correlated with basal Albion.]

T. E. Savage, 1917 (Ill. Acad. Sci. Trans., vol. 10, pp. 261–265), removed Orchard Creek sh. from Richmond and designated it the "oldest fossiliferous marine fm. of Silurian age in U. S." "More recent study of fauna of Girardeau ls. and Orchard Creek sh. has convinced writer that affinities of Orchard Creek fauna are much closer with Girardeau ls. fauna than with that of any Richmond." Is known in Ill. at only a few places in Alexander Co. in a distance 4 or 5 mi. N. and S. of Thebes. Is younger than Thebes ss. [Savage now includes this sh. in his Alexandrian series.]

The age of this sh. seems now to be generally accepted as early Sil.

Named for Orchard Creek, 2 mi. S. of Thebes, Alexander Co., Ill.

Orcutt formation.

Pleistocene: Southern California (Santa Maria district).

H. W. Hoots and S. C. Herold, 1935 (Geol. of nat. gas, A. A. P. G., p. 156). *Orcutt fm.*—Gravels and fresh-water clays, 300± ft. thick. Uncon. overlies Schumann fm. (Plio.). [Derivation of name not stated.]

Ordovician period (or **system**).

The time (and the rocks) of the next to oldest period of the Paleozoic era, succeeding the Cambrian and preceding the Silurian.

In early repts was called "Lower Silurian," but for many decades Silurian has been restricted to the rocks originally called "Upper Silurian." The U. S. Geol. Survey and geologists generally include in the Ordovician the Beekmantown rocks at base and the Richmond rocks at top. Some geologists, however, exclude both the Richmond and the Beekmantown. For definition see U. S. G. S. Bull. 769, pp. 83–89.

Ordovicic.

A variant of *Ordovician* employed by some geologists.

Oread limestone. (In Douglas group, in Kansas.)

Oread limestone member (of Douglas formation, in Missouri).

Pennsylvanian: Eastern Kansas, southeastern Nebraska, central northern Oklahoma, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1894 (Kans. Univ. Quart., vol. 2, pp. 123, 124). *Oread ls.*—Very fossiliferous ls., light-blue, weathering buff; 10 ft. thick; capping all hills in vicinity of Lawrence, Kans. Overlies Lawrence shales and underlies 8 ft. of sh. [Kanwaka sh. memb.].

Was for many years treated as top memb. of Douglas fm. in Mo. In Kans. the Douglas is now treated as a group and the Oread as a fm. In Okla. the Oread ls. is treated as a memb. of Nelagoney fm. In Okla. thicknesses as high as 107 ft. have been assigned to it.

Since 1931 the Kans. Geol. Surv. has included this ls. in Shawnee group, q. v. This change of definition has not been considered by U. S. Geol. Surv. for its publications.

Named for fact it caps Mount Oread, at Lawrence, Douglas Co., Kans.

Oreana shale.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 80). *Oreana shales* are early Jurassic sediments, highly inclined, occupying W. flank of Humboldt Range, Nev., from Oreana Station southward. Consist of 1,000 ft. of shales overlying Muttleberry lss. and composing upper fm. of Lovelockian series.

Oreapolis limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 6, 10, 19, 34). *Oreapolis ls.*—Unweathered stone is light bluish gray and partly crystalline. Basal part weathers light gray. Upper 2 to 3 ft. is thin-bedded and slightly yellowish. Thickness 6 to 12 ft. Included in Andrew (Lawrence) sh. Lies 7 to 18 ft. below Weeping Water ls. Named for Oreapolis, Cass Co., Nebr.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). *Oreapolis ls.* abandoned, as another name has priority over it. [Does not state what name replaces it.]

†Oregon beds.

Miocene and Oligocene (?): Central northern Oregon.

E. D. Cope, 1879 (Am. Nat., vol. 13, p. 333), described fossils "from beds of *Truckee* epoch of White River fm." and said: "This name, introduced by King, has priority of publication over the term *Oregon beds* introduced by me [probably 1880 publication in press], hence the latter name must be abandoned."

E. D. Cope, 1880 (U. S. Geol. and Geog. Surv. Terr. Bull. 5, pp. 51, 52). *Oregon beds.*—The Oregon White River beds differ from those found E. of Rocky Mtns, although they contain a majority of same genera and many of same species. [Fossils listed. On p. 53 he assigned White River to Olig.]

E. D. Cope, 1884 (U. S. Geol. and Geog. Surv. Terr. Mon. 3, pp. 3, 13–20). *Oregon fm.* of Cope is same as Truckee beds (Mio.) of King, and Oregon fm. is abandoned.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 332). *Oregon beds*, named for State of Oreg., is=John Day group.

Oregon limestone.

Middle Ordovician (Lowville): Central Kentucky.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, p. 13). *Oregon substage.*—Even-bedded mag. ls., 25 ft. thick, in two beds. Middle part of Highbridge stage. Overlain by Tyrone beds and underlain by Camp Nelson beds. Is "Kentucky marble" of Linney.

Named for Oregon, Mercer Co.

Oregonia division. (In Arnheim formation.)

Upper Ordovician: Southwestern Ohio and north-central Kentucky.

A. F. Foerste, 1910 (Denison Univ. Sci. Lab. Bull. 16, p. 18). *Oregonia div.*—Upper div. of Arnheim bed, characterized by introduction, at base, of characteristic Richmond fossils *Leptæna richmondensis-precursor*, *Rhynchotrema dentata-arnheimensis*, and *Dinorthis carleyi*. Included in Richmond. Overlies Sunset div. of Arnheim bed. Thickness 26 ft.

The U. S. Geol. Survey treats Fort Ancient div. of Foerste as top memb. of Arnheim fm. in Ohio and Ind.

Named for Oregonia, Warren Co., Ohio.

Ore Hill limestone member (of Gatesburg formation).

Cambrian (Upper): Central Pennsylvania (Blair County).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 527, 534, 537). *Ore Hill ls. memb.*—Thin-bedded blue ls. in middle of Gatesburg fm. Fauna related to Hoyt ls. of N. Y. Named for exposures in quarry 1 mi. SW. of Ore Hill, Blair Co.

C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227, in press). *Ore Hill ls. memb.*—Thin-bedded bluish to dark-gray, mostly fine-grained ls., but has a few layers of coarse-grained rock. Thickness 100±ft. "Occupies about the middle of the upper two-thirds of Gatesburg fm."

Orejon andesite.

Tertiary (?): Southern New Mexico (Dona Ana County).

K. C. Dunham, 1935 (N. Mex. School Mines Bull. 11, pp. 53, 54). *Orejon andesite*, thin flows, 600 ft. thick, in Organ Mtns. Named for Orejon mine, in which it occurs as the hanging wall of the main fault. Older than Cueva rhyolite. In absence of evidence assigned to Tert.

†Oreodon beds.

A paleontologic name that has been applied to lower and major part (*Oreodon* zone) of Brule clay (Olig.) western Nebr. and S. Dak.

Organ Rock tongue (of Cutler formation). (Also **Organ Rock member.**)

Permian: Southeastern Utah (San Juan County).

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1420, 1422, 1423, 1441, 1443, 1446). *Organ Rock tongue of Cutler fm.*—Red sandy sh. and sss., 380 to 550 ft. thick, underlying true DeChelly ss. memb. of Cutler and overlying Cedar Mesa ss. memb. Named for fact the beds compose the natural monument known as Organ Rock, San Juan Co., lying S. of San Juan River, btw. Moonlight and Copper Creeks. In earlier repts included in Moenkopi fm. (Lower Triassic).

In areas where the Organ Rock rocks can be separated from main mass of Cutler fm. they are called *Organ Rock memb.*

Oriana gypsum member (of Peacock formation).

Permian: Central northern Texas (Stonewall County).

L. T. Patton, 1930 (Univ. Tex. Bull. 3027, pp. 47+). About 100 ft. above Swenson gyp. memb. of Peacock fm. there occurs another rather prominent bed of gyp. which may be known as *Oriana gyp.*, as it is exposed near station of Oriana, on Stamford & Northwestern R. R. In places it consists of two ledges separated by 5± ft. of sh. The lower beds vary in thickness from 2 to 16 ft., and the upper from 3 to 5 ft. Well exposed in valleys of Double Mtn Fork and Salt Fork Rivers. Does not develop as prominent an escarpment as Swenson gyp., but is more resistant to weathering and erosion than the soft shales and sss. of Peacock fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). Relation of *Oriana gyp.* to Croton gyp. has not been determined. They may be the same.

Orient gneiss.

Pre-Cambrian (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 85; map). *Orient gneiss.*—Chiefly gneissoid and sheared granite and diorite; in places inter-laminated with coarsely crystalline light- to medium-colored lss. and highly foliated schists. Associated with these are masses of slightly altered granites and diorites, apparently intrusive. The typically gneissoid rocks were originally granites and diorites which were intrusive into a sed. series, and later both the intrusives and sedimentaries were subjected to intense dynamic metamorphism. Is older than Stevens metamorphic series and may be pre-Camb. Good exposures in railway cuts at town of Orient.

Orienta sandstone. (In Bayfield group.)

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Bayfield and Douglas Counties).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, p. 41). *Orienta ss.*—Basal fm. of Bayfield ss. group. Conformably overlies Amnicon fm. (of Oronto group) and underlies Devils Island ss. Consists of (descending): (1) Mainly white and red ss. with few ripple marks, 300 to 400 ft.; (2) upper brownstone (of Port Wing), 500 to 700 ft.; (3) Copper Creek beds, 75 to 100 ft.; (4) main beds (brown, red, and white sss., becoming progressively more feldspathic toward bottom, with thin beds of red sh., 1,800 to 2,000 ft. Named for exposures in quarries near Orienta, Bayfield Co.

Orinda formation.

Pliocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, p. 371 and map). *Orindan fm.*—Fresh-water cgls., sss., shales, clays, lss., and tuffs, with pebble cgl. at base. Thickness 800 to more than 2,400 ft. Basal fm. of Berkeleyan series. Rests on Monterey series and is overlain by rhyolite tuff that forms basal div. of Upper Berkeleyan.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Orinda fm.*—Fresh-water cgls., ss., clay shales, lss., some thin seams of lignite, and at a few horizons thin layers of brown decomposed volcanic tuff. Farther E., in Mount Diablo quad., it includes, in lower part, a few beds of pumiceous tuff similar to Pinole tuff. Thickness 2,000 to 2,500 ft. in San Pablo Ridge, but 6,000 ft. to SE., near S. border of Concord quad. Lies conformably on Pinole tuff, or, where that is absent, rests on San Pablo or older fms. Excluded from Berkeley group. Is overlain by Moraga fm., which is now treated as basal div. of Berkeley group. Named for exposures at Orinda, Contra Costa Co.

B. L. Clark (1921) and R. R. Morse and T. L. Bailey (Geol. Soc. Am. Bull., vol. 46, No. 10, 1935, pp. 1437–1455) assigned Orinda fm. to *lower* Plio. The latter authors correlate it with Petaluma fm.

†Orindan formation.

See *Orinda fm.*

Oriskanian.

A time term covering interval during which the rocks of Oriskany group were deposited. (See explanation under *Oriskany group.*)

Oriskany formation.

Oriskany group.

Oriskany sandstone.

Lower Devonian: New York, Pennsylvania, western Maryland and Virginia, and eastern West Virginia.

L. Vanuxem, 1839 (N. Y. Geol. Surv. 3d Rept., p. 273). White ss. occurring on hill at the falls of Oriskany, which for the present may be called *Oriskany ss.* Is well known to extend over several States. Is 30 ft. thick at Oriskany Falls; at quarries near Auburn it is a few inches to 2½ ft. thick; is 700 ft. thick in Pa. Rests on water-lime group of Manlius and is overlain by 8 to 12 ft. of gray sparry crinoidal ls.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 308–309). The *Oriskany ss.* is well characterized in 3d geol. dist., and described by Mr. Vanuxem. It appears but at one point in this [Ontario] county and not at all in Seneca, being either entirely wanting or deeply covered with superficial materials. Is overlain by "gray crinoidal" or Onondaga ls.

W. W. Mather, 1841 (N. Y. Geol. Surv. 5th Rept.). Downward succession of fms.: Onondaga ls.; Schoharie layers; grit rock characterized by fucoides caudagalli [Esopus grit]; Oriskany ss. (0 to 2 ft. of highly siliceous ls. sometimes approaching hornstone and chert and in places hard siliceous grit); Scutella ls. [Becraft ls.].

J. Hall, 1843 (Geol. N. Y., div. 4, 4th dist., p. 147). In Pa. and Va. the Oriskany ss. is an important fm. Is 700 ft. thick in former State. In N. Y. greatest thickness is not more than 30 ft. and usually much less.

For many years the name *Oriskany ss.* was commonly applied to the rocks below Esopus grit. The 1863, 1864, 1868, 1869, 1875, and 1895 editions of Dana's Textbook of geology used the time term *Oriskany period* to cover the Oriskany ss. only, excluding Esopus grit and pre-Oriskany ss. rocks. In 1898 F. J. H. Merrill (N. Y. State Mus. Bull., vol. 4, No. 19, p. 158) employed *Oriskany group* to include †Cauda Galli grit [Esopus grit] and underlying Oriskany ss., stating that only fossil of the grit is *Spirophyton cauda galli*, which also occurs in Oriskany ss. A. W. Grabau, 1898 (Buffalo Soc. Nat. Hist., vol. 6, p. xviii), included Schoharie grit and Esopus sh. in what he called *Schoharie stage*, and used *Oriskany stage* to cover Oriskany ss. only. In 1899 J. M. Clarke and C. Schuchert (Sci., n. s., vol. 10, pp. 874–878) introduced *Oriskanian period or group* to cover the Oriskany beds, which they defined as underlying Esopus grit and overlying Kingston beds [Port Ewen ls.]. In 1900 Schuchert, also J. M. Clarke, employed *Oriskanian* in latter sense, but Schuchert divided the *Oriskany* into Upper Oriskany and Lower Oriskany. In 1901 (N. Y. State Mus. Bull. 52) and 1902 E. O. Ulrich and C. Schuchert, also A. W. Grabau, applied *Oriskanian* to the pre-Esopus and post-Kingston beds, but also stated that the Esopus "is only a phase of the Oriskany." The same year F. J. H. Merrill (geol. map of N. Y.) included the Esopus in the *Oriskany*, while A. W. Grabau excluded both Esopus and Kingston from the *Oriskanian*. In 1903 (Am. Geol.) Schuchert included in *Oriskanian* the following (descending): Decewville, Esopus, Oriskany, Kingston. The same year (N. Y. State Mus. Bull. 69) G. Van Ingen and P. E. Clark, also J. M. Clarke, applied *Oriskanian* to Oriskany ss. (pre-Esopus and post-Port Ewen). In 1906 Grabau included in *Oriskanian group* the Esopus grit and Oriskany ss. In 1908 G. H. Chadwick (Science) divided the *Oriskanian* of N. Y. into Esopus, Glenerie ls., Connelly cgl., and Port Ewen (†Kingston), with statement that the Glenerie and Connelly are=the *Oriskany*, and that Oriskany fossils occur in the Esopus (Decewville), 40 ft. above its base, "so that at least lower part [of that fm. also] is Oriskany." In 1909 J. M. Clarke included the Port Ewen in the Oriskany. In 1911 (Geol. Soc. Am. Bull., vol. 22) E. O. Ulrich divided the *Oriskany* into Esopus, Glenerie, Connelly, and Port Ewen, and assigned the Decewville to the overlying group. In 1912 (N. Y. State Mus. Hdb. 19) C. A. Hartnagel divided *Oriskanian group* of eastern N. Y. into Esopus, Glenerie, Connelly, and Port Ewen, and also used *Oriskany ss.* for the pre-Esopus and post-Becraft beds of east-central to western N. Y.

The U. S. Geol. Survey at present uses *Oriskany group* in broad sense, to include the Esopus at top and the Port Ewen at base, and where the undiff. deposits of Oriskany age are chiefly or wholly ss. it applies to them the term *Oriskany ss.* In central Pa., western Md., northern W. Va., and parts of Va. the Oriskany group is divided into Ridgeley ss. (above) and Shriver chert (below). The present N. Y. State Survey uses *Oriskanian* to include Esopus grit (above) and *Oriskany ss.* (below), and has transferred Port Ewen ls. to underlying Helderberg group. (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931, p. 370.)

Orito limestone.

Cretaceous: Mexico.

G. E. Anderson, 1926 (Am. Inst. Min. and Met. Engrs. Trans. [preprint], No. 1551, p. 3).

Orizaba limestone.

Cretaceous: Mexico.

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, p. 124).

Orlando limestone. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1916 (W. Va. Geol. Surv. Rept. Lewis and Gilmer Counties, p. 147). *Orlando ls.*—Gray, somewhat shaly ls., 3 ft. thick, containing fossils probably of brackish- or fresh-water origin. Lies 10 to 30 ft. below Morgantown ss. and overlies Elk Lick coal. Exposed at Orlando, Lewis Co.

Orleans phyllite.

Ordovician: Northeastern Vermont (Orleans County).

E. C. Jacobs, 1923 (Vt. State Geol. Rept. 1921–22, pp. 93–108). *Orleans phyllite.*—Gray highly schistose rocks, formed from fine sediments, more or less completely recrystallized. Extends N. and S. across E. part of Orleans Co., according to writer's observations, and Richardson mentions belts of it in W. part of Co. Constitutes a distinct fm. and is entitled to a name. Richardson's rather inclusive term *Bradford schists* [Ord.] perhaps embraces it, although it is not a typical schist but a phyllite. No fossils.

C. H. Richardson, 1924 (Vt. State Geol. Rept. 1923–24, pp. 77–103). *Orleans phyllite* of Jacobs underlies Waits River ls. and is therefore older than Randolph phyllite, which is interbedded and interstratified with Waits River ls.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this phyllite to Ord.

Orofino series.

Pre-Cambrian (Belt series): Northern Idaho (Orofino region).

A. L. Anderson, 1930 (Idaho Bur. Mines and Geol. Pam. 34). *Orofino series.*—Assigned provisionally to Belt series is a series of highly metamorphosed igneous and sed. rocks with beds of exceptionally pure crystalline ls. or marble in lower Clearwater drainage near Orofino. These cannot be correlated with any of Belt members farther N. They must either be older or belong in lower part of the Prichard, whose counterpart in other places has not been exposed by erosion or is not present. The term *Orofino series* has been given to these rocks. This series as defined above is assigned to lower part of the Belt (Prichard fm.). It apparently lies beneath the known Prichard and conforms with it in strike and dip, although precise plane separating one from the other is unknown. The series is best exposed in Clearwater Canyon, near Orofino, the lower 11 mi. of Orofino Creek in lower canyon walls, and along lower course of N. Fork btw. Elk Creek and Ahsahka. It is composed of a great thickness of banded micaceous and hornblendic rocks including micaceous qtzites, mica schists, hornblendic gneisses, and intercalated beds of crystalline ls. or marble. Many of the gneisses and schists are undoubtedly of igneous origin, but much also has fairly distinct bedding planes. Probably much of the metamorphism was induced by the batholithic invasions, as the younger granitic bodies are numerous in vicinity of the series, and some is intercalated as injection gneiss, but part of the metamorphism was probably much earlier. Most of the schist and gneiss has scattered crystals of reddish garnets, more numerous than is ordinarily observed in the altered Prichard. The bedding is most distinct in the massive micaceous qtzites, and these are most prominent near the ls. members. The number of lss. is not known, but several beds are present, ranging in thickness from 10 ft. to over 800 ft.; they are more or less lenticular. Most of the lss. are near Orofino, beginning near mouth of Jim Fords Creek and lying parallel to the river to Ahsahka. The beds are thicker and purer farther S. above Orofino. No part of Wallace fm. has ls. members as pure, as thick, or as metamorphosed as these.

Oro Grande series.

Lower Cambrian: Southern California (San Bernardino County).

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 273–290). Nearly pure ls. underlain by pure qtzite. The alteration of *Oro Grande series* has destroyed all fossils, and its age can only be conjectured. Except for higher degree of metamorphism it is identical in character with Lower Camb. series described by Walcott from Inyo Co., and I believe the propriety of classing it as Lower Camb. will hardly be questioned.

†Orohippus beds.

A paleontologic name that has been applied to lower part (*Orohippus* zone) of Bridger fm. (middle Eo.).

Oronto group.

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Bayfield, Douglas, and Iron Counties).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, p. 48). *Oronto group.*—Largely or wholly nonmarine arkosic sss., cgls., and red shales. Thickness 21,500± ft. No fossils. Top fixed at top of highest thick beds of red shales and well-marked arkosic sss. Divided into (descending) Amnicon fm., Eileen ss., Freda ss., Nonesuch fm., and Outer cgl. Conformably underlies Bayfield ss. group and overlies middle and lower Keweenawan traps. Named for exposures on Oronto Bay, Iron Co.

Oroville beds.

Jurassic (Upper?): Northern California (Oroville region).

W. M. Fontaine, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, p. 342). The plants described in this paper were collected in Sept. 1895, by Mr. Lester F. Ward, assisted by Mr. James Storrs. They were obtained near Oroville, Calif., from a fm. which for convenience of reference I will call the *Oroville beds*. They were collected from following 4 localities, all near together, and on same horizon: (1) Old dump at Banner mine, near Feather River, 5 mi. E. of Oroville; (2) the new dump, 300 yds farther N. than old dump; (3) bank of Feather River ½ mi. S. of Banner mine; (4) in bed of a ravine that leads from Banner mine to Feather River, from ¼ to ½ mi. S. of the mine. Mr. Ward says, in a note, that these Oroville beds closely resemble the Jurassic Mariposa slates, but identity is not made out. The beds contain no fossils besides the plants, and are not connected stratigraphically with any known fm. Their age must be determined from the plants. Judging from specimens collected by Messrs Ward and Storrs, most of the rock of Oroville beds that carries plants consists of alternations of sandy-looking beds with layers of sl.

C. H. Crickmay, 1931 (Am. Phil. Soc. Proc., vol. 70, p. 60), assigned Oroville flora to "undoubted Upper Jurassic," and R. W. Brown, of U. S. Geol. Survey, concurs in Jurassic age of the flora.

See also *Monte de Oro fm.*

The omission of this name from U. S. G. S. Bull. 191 (and consequently from U. S. G. S. Bull. 826) was discovered and reported by Mr. Lesh Forrest, of Stanford Univ., in Feb. 1937.

Orr formation.

Upper Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 10). *Orr fm.*—Gray, slightly aren. lss. and shales, 1,825 ft. thick, underlying Notch Peak fm. and overlying Weeks fm. Type loc., Orr Ridge, a spur extending E. from main mass of Notch Peak, on S. side of Weeks Canyon.

†Orthaulax bed.

Paleontologic term that has been applied, in early repts. to so-called "silex bed" of Tampa ls. of Fla.

†Orthis bed.

Paleontologic name used by J. M. Safford for beds in Tenn. later named *Hermitage fm.*

Orting gravel.

Pleistocene (pre-Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Orting gravels.*—Coarse gravel deposits, interbedded with orange-colored sands. Color frequently orange brown. In heterogeneous composition and varying structure resemble Vashon drift. Underlie Puyallup sands throughout Puyallup Valley. Well exposed on E. bank of Carbon River at Orting.

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54), gave thickness of *Orting gravels* as 40 to 140 ft.

Ortonville granite.

Trade name of a dark-red pre-Camb. granite that occurs at and in vicinity of Ortonville, western Minn., and has been quarried near that town. (See E. F. Burchard, U. S. G. S. Bull. 430, 1910, p. 281; and O. Bowles, U. S. G. S. Bull. 663, 1918, p. 68.)

Osage group.

Mississippian: Mississippi Valley region.

H. S. Williams, 1891 (U. S. G. S. Bull. 80, p. 169). *Osage group* proposed to include Keokuk and Burlington lss., whose faunas are closely allied and differ from those of underlying and overlying rocks.

The Fern Glen ls. is now generally included in Osage group, instead of in underlying Kinderhook group. The Ill. Geol. Survey includes the Warsaw in Osage group; the U. S. Geol. Survey includes it in overlying Meramec group.

Named for Osage River, Mo., along which both Keokuk and Burlington are exposed in vicinity of Osceola, St. Clair Co.

†Osage limestone.

Lower Ordovician (Beekmantown): Central Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 366, 375). *Osage ls.*—Mag. lss. and chert, 270 ft. thick, underlying Moreau [Roubidoux] ss. and overlying Cole Camp ss.

Corresponds to all of Gasconade dol. restricted of present usage and all of Van Buren fm. above Gunter ss. memb.

Named for Osage Bluff, Cole Co.

†Osage limestone. (In Shawnee formation.)

Pennsylvanian: Eastern Kansas.

J. G. Hall, 1898 (Kans. Univ. Geol. Surv. vol. 3, p. 71), applied *Osage shales* to beds underlying Osage coal, and *Osage ls.* to ls. overlying Osage coal and occurring at a considerably lower level than Burlingame ls. On p. 73 of vol. cited E. Haworth stated that *Osage ls. of Hall* thins out and becomes unimportant, so that it cannot be used as a div. btw. the shales; Osage shales, therefore, may be considered to extend upward to Burlingame ls. (This definition includes Scranton sh. in *Osage shales.*)

Replaced by Howard ls. memb. of Shawnee fm.

Named for exposures at Osage City, Osage Co.

†Osage shale.

Pennsylvanian: Eastern Kansas.

See under †*Osage City sh.*

†Osage City shale. (In Shawnee formation.)

Pennsylvanian: Eastern Kansas.

E. Haworth, 1895 (Kans. Univ. Quart., vol. 3, p. 278 and pl. 20; Am. Jour. Sci., 3d, vol. 50, pp. 461–462). *Osage City sh.* proposed by G. I. Adams for shales with much ss., 100 ft. thick, overlying Topeka coal and including Osage coal at top. Separated from overlying Burlingame [Scranton] shales by a thin but persistent ls. [Howard ls.]. [As thus originally defined is practically same as Severy sh. memb.]

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, p. 73). *Osage ls. of Hall* thins out and becomes unimportant, so that it cannot be used as a division line btw. the shales. Osage shales, therefore, may be considered to extend upward to Burlingame ls. [As thus defined includes Scranton sh., Howard ls., and Severy sh.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 209–214). Osage sh. of Haworth (1898) included White Cloud sh., Happy Hollow ls., Cedarvale sh., Rulo ls., and Silver Lake sh., and is discarded. [See Kans.-Nebr. correlation chart by M. G. Wilmarth.]

Named for exposures at Osage City, Osage Co.

†Osage City limestone.

Pennsylvanian: Eastern Kansas.

J. G. Hall, 1896 (Kans. Univ. Geol. Surv., vol. 1, p. 104). *Osage City ls.* (No. 4) outcrops 6 mi. SE. of Burlingame, but can be traced only short distance. It is 60 ft. above No. 3 and of grayish-white color, very soft. Overlies Osage City sh. and underlies Burlingame sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 204). Osage City ls. of Hall is Howard ls. and is abandoned.

Osagian.

A time term employed by some geologists to cover the epoch during which the Osage group was deposited.

†Osborne limestone.

Upper Cretaceous: Central northern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 51). *Osborne ls.*—Ls., in rather thick courses, overlying Victoria sh. [also called *Victoria fm.* and *Victoria clays*] and constituting lower fm. of Niobrara. Overlain by Smoky Hill chalk, upper fm. of Niobrara. Named for exposures at Osborne and in Osborne Co.

Same as Fort Hays ls. memb. of Niobrara fm., the better established name.

Oscar sandstone.

Pennsylvanian: Central southern Oklahoma (Jefferson County).

J. R. Bunn, 1930 (Okla. Geol. Surv. Bull. 40PP, pp. 11+). *Oscar ss.* (also *Oscar sand series*).—Largely sss. with intervening beds of brown and gray shales. Individual beds vary in thickness from 1 to 50+ ft. and are very lenticular. Certain beds contain cgl. phases of varied coarseness. The sss. are massive to thin-bedded, light gray to brown on fresh exposure, weathering darker gray, brown, and black. Large brown to black concretions common in upper members. In general the beds are hard and resistant. The lowest bed stratigraphically of Oscar series is exposed on Ketchum's Bluff along Red River, in sec. 24, T. 7 S., R. 6 W., and adjoining section to E. It is composed largely of cgl., the pebbles mostly chert fragments from small grains to 2 in. diam.; is ripple-marked and cross-bedded, and attains max. thickness of 50 or more ft. [On cross-section sheet this bed is called *Ketchum Bluff cgl. bed.*] The cgl. phases of the Oscar fade out to N. and NW. and become coarser to SE. Thickness 300 ft. Lies 100 to 125 ft. lower than *top* of Ryan ss., the interval being occupied largely by brown sh. with occasional thin sandy streaks. Is separated from underlying Pontotoc cgl. by a zone of brown and blue sh. and sandy shales with interbedded ss. (fine- to coarse-grained and locally with gravel streaks). Exposed at and near town of Oscar, Jefferson Co.

Osceola amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1894 (Lake Superior Min. Inst. Proc. 2d Ann. Meeting, pp. 79–96).

Belongs to Central Mine group. The mineralized part is the Osceola lode. Named for occurrence in Osceola mine, Houghton Co.

Osceola flow.

Includes Osceola amygdaloid and underlying trap.

Osceola glacial drift.

Pleistocene (Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Osceola till.*—Till deposited by a lobe of Cascade glacier (which opposed Vashon glacier in E. part of Tacoma quad.) on the plain on which is situated the hamlet of Osceola. Consists of fine silt with numerous angular stones of volcanic rocks.

Osceola clay.

Pleistocene (Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Osceola clays.*—Blue-gray clays of aspect and compact character of Osceola till, but unlike it in being evenly stratified. Lie 650 to 700 ft. above sea in bluffs which form N. bank of Carbon River, 2 to 3 mi. below Carbonado. Deposited in quiet water when Vashon and Cascade ice sheets enclosed a water body btw. their fronts and the hills to S. and SE.

Oscuro limestone.

Name applied by C. R. Keyes (Iowa Acad. Sci. Proc., vol. 16, pp. 159–163, 1909) to Penn. lss. uncon. overlying his Mosca ls. in Rio Grande region, N. Mex. Derivation of name not stated.

Osgood formation (in Kentucky and Tennessee).

Osgood shale (in Indiana).

Silurian (Niagaran): Southern Indiana and west-central Kentucky and Tennessee.

A. F. Foerste, 1896 (Cincinnati Soc. Nat. Hist. Jour., vol. 18, pp. 191–192). *Osgood phase of Laurel fm.*—Richly fossiliferous basal part of Laurel ls.

A. F. Foerste, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., pp. 217–218, 227–229). *Osgood beds.*—Underlie Laurel ls. and overlie [so-called] Clinton ls. [*Brassfield ls.*]. Thickness 15 to 25 ft. In places divisible into an upper clay, 3 to 5 ft. thick (called *Upper Osgood* clay); a middle ls. memb., 3 ft. thick (called *Osgood ls.*); and a lower clay, 6 to 16 ft. thick (called *Lower Osgood clay*).

Adopted by U. S. Geol. Survey as distinct fm. in southern Ind. and north-central Ky., underlain uncon. by Brassfield ls. and overlain by Laurel ls. In west-central Tenn. the rocks become *Osgood earthy ls. memb. of Wayne fm.*, and are overlain by Laurel ls. memb. of the Wayne and underlain by Brassfield ls. Contains Niagara fossils.

Named for Osgood, Ripley Co., Ind.

A. F. Foerste, 1935 (Denison Univ. Bull., Sci. Lab. Jour., vol. 30, pp. 150–152). In Adams and Highland Counties, Ohio, the clay sh. overlying Dayton ls. is here called *Osgood of Ohio*, since it appears to be an eastern continuation of clay sh. at top of Osgood fm. at Laurel, Ind., but there is no fossil evidence in favor of this correlation. Thickness S. of Yellow Springs, Ohio, on Bryan Farm State Park, is 35 or 40 ft. [Lists fossils of Dayton ls. and *Osgood of Ohio*, and discussed it under heading *Osgood clay*.] The typical Osgood fauna cannot be traced farther N. than Ripley Co., Ind. [Further details given on these and later pages.]

Osgood earthy shale member (of Wayne formation).

Silurian (Niagaran): West-central Tennessee.

See under *Osgood sh.*

Oshawanan series.

A term introduced by C. [R.] Keyes to designate a part of early Carbf. time. Named for "the old name Oshawano Mtns, which was once applied to the easternmost folds of the Ozark uplift in southern Ill. on the flanks of which the complete section reclines." (See Pan-Am. Geol., vol. 55, pp. 45, 50, 222, 1931.)

Oskaloosa shale. (In Deer Creek limestone.)

Pennsylvanian: Eastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12). *Oskaloosa sh.*—Gray sh., largely argill., 4 to 7 ft. thick. Underlies Rock Bluff ls. and overlies Ozawkie ls., all included in Deer Creek ls. [Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 182–184). The sh. memb. of Deer Creek ls. that lies next below Rock Bluff ls. and above Ozawkie ls. is here named *Oskaloosa sh.* It is bluish-gray or yellowish blocky clay with one or two calc., somewhat ferruginous siltstones in outcrops in northern Kans., but S. of Coffey Co. parts of the memb. are distinctly sandy and micaceous, a prominent red zone appears, and there are one or two thin beds of nodular light bluish-gray impure ls. Thickness 5 to 10 ft. in northern Kans., but to S. it increases to 25 ft. Has been miscalled Larsh sh., but is older than true Larsh sh. of Nebr. Type loc., vicinity of Oskaloosa, Jefferson Co. The Oskaloosa and Ozawkie members are absent in Nebr., where Rock Bluff ls. is basal memb. of Deer Creek ls.

Osler series.

Pre-Cambrian: Canada (Rainy River district and Thunder Bay region).

T. L. Tanton, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 114, abstract). [See under *Kaministikwia group.*]

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned *Osler basic flows* of Thunder Bay region, Ontario, to Keweenawan.

Osos basalt.

Jurassic (?): Western California (San Luis Obispo region).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *Osos basalt.*—Dark, fine-grained, generally amygdaloidal basalt, which occurs in several areas, and from its relation to San Luis fm. [Franciscan] does not appear to be intrusive but to have cooled as surface flows. Other basalts occur in the area. Named for outcrops in Los Osos Valley, San Luis Obispo Co.

Osoyoos granodiorite.

Jurassic (?): Southern British Columbia and central northern Washington (Okanogan batholith).

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376).

Ost limestone. (In Tecumseh shale.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 47, 52). *Ost ls.* is proposed for the ls. next above Kenosha sh. and below Rakes Creek sh., the type loc. being on Ost farm, on South Fork Weepingwater Creek about 3½ mi. E. of Avoca, Cass Co., Nebr.

†Ostrea shales.

Upper Cretaceous: Northern and central Kansas.

A paleontologic name applied in early repts to the beds now known as *Fairport chalky sh. memb. of Carlile sh.*

Ostrea sellaeformis beds. (In Claiborne group.)

A paleontologic name applied in early repts to a bed in lower part of Yegua fm. of Tex., La., and Miss., and in Gosport sand of Ala., which is characterized by profusion of *Ostrea sellaeformis*, and is now called "*Ostrea sellaeformis* zone" by U. S. Geol. Survey.

Oswald lime. } Subsurface.
Oswald limestone. }

Pennsylvanian: Southwestern Kansas (Ness and Hodgeman Counties).

R. G. Moss, 1932 (Kans. Geol. Surv. Bull. 19, pp. 36–37). The beds locally known as "Oswald lime" consist of cream to gray-colored ls. containing some beds of gray sh.; one or two thin red shales occur in most places 300± ft. below top; the lss. contain cherty and oolitic beds, which in general are porous; these porous beds carry oil at Fairport, Gorham, and elsewhere, but in Ness and Hodgeman Counties only water and a small amount of gas. No identifiable fossils in upper 100 ft. of "Oswald lime" in these counties, but *Triticites* has been found in upper 30 to 50 ft. in Russell and Rush Counties. As that genus has not been reported below Missouri series, the upper part of "Oswald lime" is correlated with lower part of Missouri series and lower part with upper part of Des Moines series, and belongs to Marmaton and possibly Cherokee groups.

E. A. Koester, 1935 (A. A. P. G. Bull., vol. 19, No. 10, p. 1412). *Oswald ls.* refers to the fm. commonly known as "Oswald lime." Name derived from the farm name of the discovery oil well of western Kans. Top of the ls. probably represents a horizon in Lansing group, but, due to erosion, it is not same horizon at all places. Max. thickness on flanks of central Kans. uplift is 275± ft., where it is underlain by beds probably of Marmaton age. Is thinner on local "highs" where it overlies pre-Penn. rocks. In Gorham field 238 ft. of Oswald ls. overlies granite in one well. It is composed of alternating ls. and sh., latter of minor amount. Many of its members are oolitic. It is time equiv. of Lansing, Kansas City, and Bronson groups of E. Kans. surface section. Below Oswald ls., or below Marmaton beds, and extending to base of Penn. section, is Sooy cgl. of Edson.

Oswaldo formation. (Of Magdalena group.)

Pennsylvanian: Southwestern New Mexico (Santa Rita district).

A. C. Spencer and S. Paige, 1935 (U. S. G. S. Bull. 859). *Oswaldo fm.*—In descending order: (1) Banded ls., 80 ft.; (2) upper blue ls., 210 ft.; (3) marker sill of ss., 50 ft.; (4) middle blue ls., 85 ft.; (5) parting sh., 30 ft. Lower fm. of Magdalena group. Underlies Syrena fm. and overlies, probably uncon., Lake Valley ls. Named for Oswaldo patented mining claim, 1± mi. S. of Hanover P. O.

Oswayo formation.

Devonian or Carboniferous: Southwestern New York and northern Pennsylvania (?).

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, pp. 978–989, map). *Oswayo beds.*—Olive-green to rusty-colored sandy shales, with here and there thin ss. layers with limonitic seams or incrustations. Marine invertebrates. Thickness 160 to 250 ft. Underlie Knapp beds and overlie, probably uncon., Cattaraugus beds. Assigned to Carbonic. [Mapped near Oswayo Creek, in Olean quad.]

In Warren Co., Pa., the lithology of Oswayo and Cattaraugus deposits changes, so that they cannot be separated, as in N. Y., and C. Butts in 1910 named the combined unit *Conewango fm.*

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 88). *Oswayo beds* carry marine fauna, with *Camarotoechia allegania* as index species. Near base contain thin beds of ls. composed largely of fossil remains. In N. Y. recognized only in Allegany and Cattaraugus Counties. Named for exposures in vicinity of Oswayo Creek, Cattaraugus Co., N. Y. [In Olean quad.]

G. H. Chadwick, 1924 and 1933. See entries under *Conewango fm.*

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Oswayo sh. memb. (facies), (lower "Riceville," upper Chagrin)*, represents Riceville fm. [restricted], top fm. of Venango group, and includes Wild Cat coquinite. Is Upper Dev.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 23), proposed *Tioga magnafacies* to replace *Oswayo fm.* in Tioga and Elkland region of northern Pa., which he stated is not same fm. as typical Oswayo fm. of Olean region, N. Y., but older and of Chautauquan age. In chart opp. p. 61 he divided his *Riceville stage (Riceville monothem), Upper Dev.*, into *Oswayo sh. memb.* [restriction] and Roystone ("Wild Cat" discarded) coquinite, excluded it from his Venango group, and treated it as a distinct "stage."

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 861). Only the lower Cattaraugus extends as far as eastern Potter Co., Pa., being there included in top of Oswayo of Fuller (not Glenn), a continental mass of "Pocono" facies. The *Oswayo of Glenn* (not Fuller), which is marine and fossiliferous, goes no farther E. than western Potter Co., since Pottsville cgl. bevels down across these higher beds of Upper Dev. from Olean, N. Y., eastward.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 581). Writer doubts that there is any true Oswayo (or Elk Mtn) in NE. Potter or northern Tioga Co., Pa., and believes that what has been considered to be Oswayo there is green Coudersport memb. of Cattaraugus fm.

The U. S. Geol. Survey recognizes Oswayo fm. as originally defined, and at present classifies it as Dev. of Carbf.

†Oswegan period or group.

Silurian (early) and late Ordovician: New York.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Oswegan period or group.*—Basal div. of "Ontaric or Siluric" system. Includes Medina ss. (="Oswego ss." of Vanuxem) and underlying Oneida cgl. or Shawangunk grit. Underlies Niagaran and overlies Cincinnatian [in which Richmond was included at top]. This name is appropriate on account of widespread occurrence of Oneida and Medina fms. in Oswego Co., N. Y. Vanuxem employed "Oswego ss." for the fm. subsequently and by common consent called Medina ss. In reviving the name, though with a broader meaning than in its original use, it derives its title from its early date.

Subsequent studies developed fact that Oswego ss. and "Red Medina" of early repts (Queenston sh. of modern nomenclature) are of Ord. age, the Oswego ss. being of Maysville age and Queenston sh. of Richmond (latest Ord.) age. The term "Oswegan" has therefore fallen into disuse.

†Oswegatchie series.

Pre-Cambrian: Northern New York (St. Lawrence and Jefferson Counties).

C. H. Smyth, Jr., 1894 (N. Y. State Mus. 47th Ann. Rept., pp. 687–692). *Oswegatchie series.*—White to gray crystalline ls., weathering nearly black, and interbedded gneiss of sed. origin but extremely metamorphosed. Uncon. underlies Potsdam ss. Base is a matter of doubt, because of uncertainty whether all gneiss of region belongs with the ls. and is a part of Oswegatchie series, or whether part of gneiss is older and uncon. beneath the Oswegatchie. Similarity of rocks suggests equivalency to Grenville series of Canada, as suggested by Van Hise, but local name seems desirable. Oswegatchie River flows through these rocks for many miles.

H. P. Cushing, 1899 (N. Y. State Geol. 16th Ann. Rept., pp. 5–26). *Grenville (Oswegatchie) series.*—The rocks of Smyth's Oswegatchie series are, in writer's opinion, so similar to those of typical Grenville series of Logan, and are separated by such a slight geographic distance, that Grenville might with perfect propriety be applied to them. Some gneisses of region are older than Grenville.

D. H. Newland, 1908 (N. Y. State Mus. Bull. 119, pp. 8–22). The *Grenville series* includes, so far as known, the oldest rocks of Adirondack region.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 621). Following the conclusions of the international committee in 1906, there is little doubt that this series may safely be correlated with Grenville series of the original Laurentian and Hastings districts. This being the case, the term Grenville has priority and "Oswegatchie" is unnecessary.

W. J. Miller, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 400–462). *Grenville series* comprises oldest rocks of Adirondack region.

H. L. Alling, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 47–68). The *Grenville series* of ancient sediments is oldest fm. of Adirondacks so far as known.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, pp. 120–126, 140). The *Grenville* is most ancient memb. of pre-Camb. of the Adirondacks. It consists of completely metamorphosed lss., shales, and sss., comprising paraschists, para-gneisses, qtzites, arkosites, and meta-lss. Is post-Keewatin.

See also under *†Dannemora fm.*

Oswego sandstone.

Upper Ordovician (Maysville): New York, Ontario, central Pennsylvania, and western Virginia.

In Geol. N. Y., pt. 2, div. 4, geol. 2d dist., 1842, E. Emmons included in top of "Champlain group" the *Grey ss.*, 100 ft. thick, underlying Medina ss. (included in overlying "Ontario group") and overlying Lorraine sh. In Geol. N. Y., pt. 3, geol. 3d dist., 1842, L. Vanuxem treated "Gray ss. of falls of Salmon River and Oswego," 0 to 107 ft. thick, as basal fm. of "Ontario div.," and as underlying Medina red ss. and overlying Pulaski shales of Hudson River group. In 1846 (N. Y. Nat. Hist. Agric., vol. 1) Emmons used "gray ss. of Oswego," and repeated his 1842 definition. In succeeding years "Grey ss. of Oswego" became confused with Oneida cgl., which led to recognition by J. D. Dana, in early editions of his Textbook of geology, of an "*Oneida epoch*" in Upper Sil., btw. Medina epoch and Hudson River epoch of Lower Sil.

C. S. Prosser, 1888 (Am. Inst. Min. Engrs. Trans., vol. 16), referred to this fm. as "Gray Medina or gray ss. of Oswego" on p. 942, and as "Medina or Oswego gray ss." on p. 947, and located it btw. Medina red ss. above and Hudson River below. In 1890 (Am. Geol., vol. 6, pp. 205–206) Prosser called the fm. "Oswego ss.," gave its thickness as 210 ft., and located it btw. Red Medina above and "Transition from Oswego ss. to Hudson shales" below, which was described as consisting of 170 ft. of gray ss. and blue shales. In 1893 (Geol. Soc. Am. Bull., vol. 4, pp. 91–117) Prosser gave thickness of *Oswego ss.* as varying from 83 ft. in western N. Y. to 210 ft. in west-central N. Y., and located it btw. Medina above and Lorraine sh. (of Hudson group) below.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878), abandoned Oswego ss. (which they stated was=Medina ss.), and used "Oswego period or group" for basal div. of their Ontaric or Siluric system, including in it only Medina ss. and the supposedly underlying Oneida cgl. In 1899 (N. Y. State Geol. 16th Ann. Rept., pp. 199–226) D. D. Luther used "Oneida cgl. or Oswego sss." for beds beneath Medina ss. and above Hudson River sl. In 1900 (N. Y. State Mus. Mem. No. 3, vol. 3) J. M. Clarke continued to use his 1899 classification. In 1901 (N. Y. State Mus. Bull. 45, pp. 20–21) and 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 4) A. W. Grabau placed "Oswego ss., Oneida cgl., or Shawangunk grit" beneath Medina ss., gave its thickness as 75± ft., and treated it as basal bed of "Siluric" and as younger than the Richmond. In 1902 (N. Y. State Mus. Bull. 52, table opp. p. 658) E. O. Ulrich and C. Schuchert used *Oneida* for the beds beneath Medina, and dropped Oswego ss., as did Schuchert in 1903 (Am. Geol., vol. 31), J. M. Clarke in 1903 (N. Y. State Mus. Hdb. 19), and C. A. Hartnagel in 1903 (N. Y. State Mus. Bull. 69). In 1905 (N. Y. State Mus. Bull. 80, p. 358) Hartnagel revived *Oswego ss.* for the beds beneath Medina in western N. Y., but correlated it with Oneida cgl. of Herkimer Co., as did Grabau in 1906 (N. Y. State Mus. Bull. 92), Grabau stating that in central N. Y. the Oswego ss. merges into Oneida cgl. In 1907 (N. Y. State Mus. Bull. 107) Hartnagel stated that Oneida cgl. is unquestionably of *upper* Medina age, and that although Oswego ss. is practically unfossiliferous he is inclined to correlate it with the Richmond, but that because of marked paleontologic break at close of the Lorraine he treated Oswego ss. as basal fm. of Ontaric [Sil.] system. The same year (N. Y. State Mus. Bull. 114) Hartnagel again included Oswego ss. in Sil., but stated "there is evidence which may show that the Oswego, and probably part of the Medina, could with propriety be included in Lower Siluric" [Ord.]. In N. Y. State Mus. Bull. 111, p. 404, he gave thickness of Oswego as 200 ft. In N. Y. State Mus. 59th Ann. Rept., vol. 1, p. 17, 1907, J. M. Clarke concurred in Hartnagel's recent opinions.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348), stated that *Oswego ss.* constitutes merely closing episode of Lorraine div., and that it is older than Lewiston [Queenston] sh. In 1909 (Sci., n. s., vol. 29, pp. 351–356) A. W. Grabau included Oswego and Queenston in the Ord. and in Lorraine, and the same year (Jour. Geol., vol. 17, pp. 234–252) he repeated his statement that Oswego ss. of western N. Y. is of Lorraine age, and correlated the Oneida cgl. with "Upper Medina."

In 1910 (N. Y. State Mus. Bull. 135) W. J. Miller described Oswego ss. of Port Leyden quad., Lewis Co., N. Y., as consisting of 100+ ft. of gray fine-grained thin-bedded ss.,=Gray ss. of Vanuxem, and named for Oswego Co., N. Y.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), placed Oswego ss. stratigraphically beneath Queenston sh. and correlated it with upper (McMillan) part of Maysville group of SW. Ohio, which underlies Richmond group.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), included Oswego ss. in "Ontaric or Siluric," but excluded it from Medina, and stated that it is found in Oswego, Oneida, Lewis, and Jefferson Counties and to W. extends beyond limits of State as a concealed fm. under Lake Ontario. He included the overlying Queenston sh. and Oneida cgl. in the Medina.

In 1913 (Canada Geol. Surv. Guidebook 4) F. B. Taylor and W. A. Parks put Oswego ss. in Ord., and E. O. Ulrich (12th Int. Geol. Cong., Canada) excluded it from *Medinan*, included it in underlying Maysville group, and stated that "it has so far proved practically unfossiliferous in both N. Y. and central Pa.;" that it "is possibly a land deposit or perhaps river silts laid down in a shallow bay;" and that "chiefly on account of its strat. position it is correlated with McMillan fm., but is not regarded as strictly conterminous with the McMillan."

In 1914 (Denison Univ. Sci. Lab. Bull., vol. 17, pp. 249–252) A. F. Foerste correlated Oswego ss. with upper part of Maysville of Ohio, as did R. S. Bassler in 1919 (Md. Geol. Surv. Camb. and Ord. vol., pp. 170–172). Bassler stated that the unfossiliferous gray Oswego ss. "actually occurs under the Red Medina," and is a "valid formation," overlying Pulaski sh., which contains lower Maysville fossils. In 1921 (Textbook of geol.) A. W. Grabau placed Oswego ss. btw. Queenston sh. above and Lorraine (Pulaski) shales and sss. below.

A. F. Foerste, 1924 (Canada Dept. Mines Geol. Surv. Mem. 138), stated that no identifiable fossils are known from Oswego ss.; that it is 150 ft. thick along W. slope of Tuscarora Mtn, Pa.; more than 107 ft. thick at Salmon River Falls, N. Y.; 75 ft. thick at Niagara, N. Y., westward of which it soon disappears. On Tuscarora Mtn, Pa., it rests on beds carrying a characteristic Fairview [lower Maysville] fossil, and is overlain by soft red unfossiliferous ss. and red sh. regarded as of Richmond age, and "it therefore corresponds to the upper or McMillan div. of the Maysville."

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258), correlated Oswego ss. with Maysville fm. of Ohio and showed it as resting on Pulaski sh., of Lorraine group. This is position assigned to it by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 268).

The U. S. Geol. Survey excludes *Oswego ss.* from Medina group, classifies it as Upper Ord., and uses the following names in central Pa. (descending): Clinton fm; Tuscarora qtzite (=Albion ss.); Juniata fm. restricted (=Queenston sh.); Oswego ss. (=†Bald Eagle cgl.); Reedsville sh. (=Lorraine group and Utica sh.). In 1933 (Int. Geol. Cong. Guidebooks of western Va.) C. Butts reported 250 to 400 ft. of *Oswego ss.* in Little North Mtn, Va., and as far N. as Harrisonburg, Va., but reported it as absent throughout most of Valley of Va. In Va. it underlies Juniata fm. and overlies Martinsburg sh.

†Oswego limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 105–107, 116). *Oswego ls.*—Compact light-buff fossiliferous ls., 28 to 55 ft. thick, separated into two parts by 8 to 10 ft. of sh. Overlies Cherokee shales and underlies Laneville shales.

Same as Fort Scott ls., older name.

Named for Oswego, Labette Co.

Oswego lime.

Drillers' name for Fort Scott ls.

Oswego moraine.

Pleistocene (Wisconsin stage): East-central New York. Named for Oswego. See Jour. Geol., vol. 32, pp. 644, 655, 1924.

Otero formation.

Tertiary (?): Southeastern New Mexico.

C. L. Herrick, 1904 (Am. Geol., vol. 34, pp. 179, 186). *Otero fm.*—Marls, great saline beds, gyp., etc., 200+ ft. thick. Of Tert. (?) age. Sharply separated from overlying Tularosa fm. Overlies Cret. ss. and sh. [Derivation of name not stated, but rept in which it is described is on Lake Otero, an ancient salt-lake basin in SE. N. Mex., btw. Sacramento and San Andres Mtns.]

Otero limestone.

A name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 65, No. 1, Feb. 1936, pp. 39, 42, 46) to "upper black ls." of Shumard and Girty (later called "Frijole ls." by some geologists), which forms top memb. of Delaware Mtn fm. (Perm.) in Guadalupe Mtns, western Tex. Derivation of name not stated.

Otis limestone.

Middle Devonian: Central eastern Iowa.

W. H. Norton, 1894 (Iowa Acad. Sci. Proc., vol. 1, pt. 4, pp. 22-24). *Otis beds.*—Nearly pure nonmag. ls., some macrocrystalline and some noncrystalline and compacted or impalpable calc. silt, with some thin-bedded mag. ls. at base. Separated from overlying Kenwood beds by 5 ft. of bluish or greenish sh. believed to represent Independence sh. Thickness 30 ft. Overlie Coggon beds (Sil.).

In all later repts these beds are included in lower part of Wapsipinicon ls.

W. H. Norton, 1921 (Iowa Geol. Surv. vol. 27, p. 373). *Otis lss.*, a zone of transition (btw. Independence sh. above and Sil. Bertram beds) demarked because of its distinctive fauna. About 80 ft. thick at Cedar Rapids. Comprises lowest beds that can be assigned to Dev. with certainty. Divided into Cedar Rapids phase, Vinton phase, Coggon phase, and Westfield phase. Named for railway junction of Otis, E. of Cedar Rapids, where typically displayed in both its mag. and nonmag. phases, and in immediate contact with the Independence.

Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, shows Independence sh. as lying btw. Cedar Valley and Wapsipinicon lss., and divides latter fm. into following members (descending): Davenport, Spring Grove (new name), Kenwood, *Otis*, and Coggon. On p. 251 M. A. Stainbrook includes Bertram beds of Norton in Otis, which he places above the Coggon. The Bertram was originally assigned to Sil. and placed below the Coggon.

†Otis limestone.

A name applied by B. K. Emerson (U. S. G. S. Bull. 159, pp. 54, 57, 1899) to Coles Brook ls. as exposed at Otis and vicinity, in eastern Berkshire Co., Mass.

Otisco member.

Middle Devonian: Central New York (Skaneateles quadrangle).

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 11, 45). *Otisco memb.*—Basal memb. of Ludlowville fm. At some localities it is a mass of relatively homogeneous and comparatively fine gray sh., softer and more thinly bedded than underlying and overlying members. In places one and sometimes two coral beds or zones occur about 50 and 90 ft. respectively above base of the memb. Lower coral bed is underlain by a hard platform. Otisco memb. rests on Centerfield memb. of Skaneateles fm. with sharp contact. Underlies Ivy Point memb. with definite contact. Marine fauna. Lower 10 or 15 ft. highly fossiliferous. Thickness 150± ft. Type section in Millers Place ravine, on W. side of Otisco Lake, 1 mi. NW. of the causeway.

Otisville moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. See U. S. G. S. Mon. 53. Named for Otisville, Genesee Co.

Otisville shale member (of Shawangunk formation).

Silurian: Southeastern New York (Orange County).

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 651, 652, 656, 660). *Otisville sh. memb.*—Upper memb. of Shawangunk fm. at Otisville, Orange Co., N. Y. Interbedded greenish-gray arkosic ss. and aren. sh.; some of ss. is conglomeratic. Thickness 484 ft. Overlies the massive conglomeratic beds of the Shawangunk. Both faunal and strat. evidence combine to show that the Shawangunk is the united Clinton and Tuscarora at Delaware River. What the relationship of Otisville sh. memb. is to the deposits observed elsewhere is unknown. A similar sh. occurs above the cgls. of the Shawangunk at Delaware Water Gap. [On p. 660 they correlated the part of Shawangunk below Otisville sh. memb. with Rose Hill fm. (lower Clinton) and Tuscarora, and correlated their Otisville sh. memb. with Rochester sh. (post-Rose Hill).]

†Otozoum beds.

See under †*Connecticut ss. group.*

Otsego member (of Marcellus shale).

Middle Devonian: Eastern New York (Berne quadrangle).

G. A. Cooper, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 544, 548). In Unadilla and Chenango Valleys *Bridgewater memb.* is used to define the soft aren. shales btw. Chittenango and Solsville members of Marcellus fm., but on each side of Otsego Lake N. of Cooperstown the rocks btw. the Solsville and Chittenango are divisible into 2 parts, a lower portion characterized by a definite fauna and an upper part that is transitional to the Solsville. *Otsego memb.* is proposed for this lower part with characteristic fossils. In places the upper part of the Otsego is a heavy ss. or gray cross-bedded ss. containing *Cornellites flabellus* and other fossils. Type section is in the "Dugway" on E. side of Otsego Lake. Thickness at Otsego Lake 256 ft., in Schoharie Valley 385 ft., and in Berne quad. 505 ft. Overlies Berne memb. and underlies Panther Mtn sh. and ss. [Diagram on p. 544 shows Otsego is=Bridgeport.]

Otselic shale and sandstone.

Upper Devonian: Central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 24 and chart). [See first entry under *Cincinnatus ss.*]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 81–82 and chart). *Otselic sands and sh. (1897 Clarke).* [The compiler does not find that Clarke used this term in 1897, although he described the rocks of Otselic region.] Along Otselic River in Chenango and Cortland Counties the members of the Ithaca are excellently exposed. The lower or *Otselic memb.*, above the Sherburne ss., contains earliest manifestations of Ithaca fauna with Hamilton types strongly emphasized. The upper memb. is Cincinnatus flags.

G. H. Chadwick, 1932 (Eastern States Oil and Gas Weekly, vol. 1, No. 17, p. 7). *Lower Ithaca or Otselic* underlies Oneonta, turns red in crossing Schoharie Valley, and becomes the supposed "Oneonta" of Catskill front. Overlies Kiskatom red beds.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 3, p. 191). Otselic=lower part of Ithaca, underlies Oneonta red beds, and overlies "Sherburne."

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 858). Oneonta red beds is=Cincinnatus flags and probably also underlying Otselic.

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 804, 828). Btw. Tioughnioga and Chenango Valleys the Ithaca sediments above Sherburne fm. have been divided into *Otselic memb.* (below) and Cincinnatus flags (above). The Otselic (585 ft. thick in Otselic Valley and 500 ft. in Chenango Valley) is characterized by large number of Hamilton sp. and absence of *"Spirifer" mesistrialis*, and Cincinnatus contains *"Spirifer" mesistrialis.* Three mi. S. of Sherburne the Otselic is 87 ft. thick and rests on Sherburne.

Otsquago sandstone.

Silurian: East-central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Otsquago ss.*—Heavily cross-bedded red laminated ss. typically seen in and near Otsquago Creek (spelled also Otsquak and Squak) below Vanhornsville [Herkimer Co.], whence it extends westward, with gradual loss of color, to near New Hartford, where it seems to merge into supposed Martville [ss.]. It may be a distinct memb. [of lower part of Clinton fm.] wedging in above the "Martville," or=the Bear Creek; probably latter is correct.

Ottauquechee formation.

Lower Cambrian: Southeastern Vermont (Windsor County).

E. L. Perry, 1927 (15th Rept. Vt. State Geol., p. 161). *Ottauquechee fm.*—A black phyllite with shaly parting, interbedded with massive gray qtzite streaked with white quartz veinlets. Lies stratigraphically below Bethel schist and above Pinney Hollow schist. Assigned to Camb.(?). Type exposures on Ottauquechee River in Bridgewater [Windsor Co.].

E. L. Perry, 1929 (16th Rept. Vt. State Geol., pp. 1–61). Most typical exposure of *Ottauquechee phyllite and qtzite* is in Ottauquechee River Valley about halfway btw. West Bridgewater and Bridgewater Corners. Is probably late Camb. Grades into overlying Bethel schist.

E. J. Foyles and C. H. Richardson, 1929 (p. 288 of rept. cited above), assigned this fm. to Lower Camb.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 406), tentatively assigned *Ottauquechee phyllite* to Lower Camb.

Ottawa gneiss.

Pre-Cambrian: Ontario and Quebec.

A. R. C. Selwyn, 1879 (Canada Geol. Surv. Rept. 1877–78, p. 10A).

See also U. S. G. S. Bull. 360, 1909, by C. R. Van Hise and C. K. Leith.

Ottawa beds.

Ordovician: Ontario.

H. M. Ami, 1880–1883 (Ottawa Field Nat. Club Trans. 1879–83, vol. 1, pp. 63–65). Included in Utica. [Only recorded use.]

Ottawa limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth, 1894 (Kans. Univ. Quart., vol. 2, pp. 121–122, 124). *Ottawa ls.*—Ls., 10 ft. thick, quarried at Ottawa. Overlain by Lawrence shales and separated from underlying Garnett ls. by 40 ft. of sh. with some ss.

According to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 131, 154), †Ottawa ls. is same as Stanton ls. "Ottawa is preoccupied and abandoned."

Otter shale member (of Quadrant formation).

Mississippian (upper): Central northern Montana (Great Falls-Fort Benton region).

W. H. Weed, 1892 (Geol. Soc. Am. Bull., vol. 3, p. 307), published a detailed section on Belt Creek, Mont., in which he gave following succession in lower part: (1) Cgl. and ss. containing Jurassic fossils, 215 ft.; (2) white ls., red earthy patches, Paleozoic facies, 90 ft.; (3) *Otter Creek shales* (alternating gray, purple, green, and black shales and earthy lss. yielding Carbf. fossils), 212 ft.; (4) black chert belt, 8 ft.; (5) lss. and shales, 80 ft.; (6) gyp., 3 ft.

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). In this quad. lowest beds of Quadrant fm. are the gypsiferous Kibbey ss., which is overlain by *Otter shales*, the upper memb. of the Quadrant, consisting of 303 ft. of dark-gray or purplish shales near base, becoming a bright coppery-green color higher up, and interbedded with lss., the latter seldom more than 1 or 2 ft. thick, frequently oolitic, and carrying lower Carbf. fossils. Assigned to Carbf. The Otter sh. is overlain by Ellis fm. [Quadrant fm. is mapped over large area along Little Otter Creek, down to near where it flows into Otter Creek, in Fort Benton quad.]

The U. S. Geol. Survey adopted *Otter sh. memb. of Quadrant fm.* in 1907.

See under *Big Snowy group*, of which H. W. Scott (1935) treats this as middle fm.

Otter granite.

Miocene: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 110) and 1913 (Canada Geol. Surv. Mem. 26, p. 99).

Otter sand.

A subsurface sand in New Providence fm. of eastern Ky.

†Otter Creek shale.

See 1st entry (1892) under *Otter sh. memb.*

Otter Creek granite.

Pre-Cambrian: South-central Wisconsin (Baraboo district).

J. T. Stark, 1932 (Jour. Geol., vol. 40, No. 2, pp. 120, 121, 133). *Otter Creek granite*, pre-middle Huronian. Dark reddish gray to light pink, medium- to fine-grained. Ledges outcrop on both sides of Otter Creek, Sumpter Twp, SE¼ sec. 32 and SW¼ sec. 33, T. 10 N., R. 6 E., a short distance N. of old Myers mill.

Otterdale sandstones. (In Newark group.)

Upper Triassic: Eastern Virginia (Richmond Basin).

N. S. Shaler and J. B. Woodworth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, pp. 435–436). *Otterdale sss. (Araucarioxylon beds).*—Coarse sss., often feldspathic, with silicified trunks of *Araucarioxylon*. Thickness 500+ ft. Top div. of Chesterfield group, of Newark system. Overlies Vinita beds. Well developed N., S., and W. of Otterdale, Chesterfield Co.

Otter Lake moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for lake in Lapeer Co.

Ottertail white quartzite.

Huronian: Canada.

A. Winchell, 1888 (4th Int. Geol. Cong. Am. Comm. Repts., p. A14).

Ottertail formation.

Cambrian: British Columbia.

C. D. Walcott, 1912 (Smithsonian Misc. Coll., vol. 57, No. 7, p. 230).

Ottertail limestone.

Cambrian: British Columbia.

J. A. Allan (also R. A. Daly), 1913 (12th Int. Geol. Cong. Guidebook 8, pp. 179, 120). [Several geologists have assigned this fm. to Upper Camb., others have assigned it simply to Camb.]

†Ottertailian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). *Ottertailian series.*—Lss. 1,700 ft. thick, composing uppermost subdivision of Late Cambric in Alberta. [Apparently same as Ottertail ls.]

Otterville limestone member. (Of Dornick Hills formation.)

Pennsylvanian: Central southern Oklahoma (Carter County).

W. L. Goldston, Jr., 1922 (A. A. P. G. Bull., vol. 6, p. 8). *Otterville ls., memb. of Glenn fm.*—Solid brown ls., of oolitic texture, which grades locally into several beds of brown ls. separated by blue shales. Thickness 70 ft. Forms low ridge running SE. from Otterville. Underlies Cup Coral memb. and overlies Springer memb.

G. H. Girty and P. V. Roundy, 1923 (A. A. P. G. Bull., vol. 7, No. 4, pp. 331–347). *Otterville ls.* of Goldston does not belong to Glenn fm. It is older than Glenn. The Otterville correlates with beds which in some places have been included in Wapanucka and in other places in upper part of Caney sh., but would probably better be excluded from both of those fms. It was not included in typical Wapanucka ls. as delimited in Atoka folio.

H. D. Miser, 1925 (Okla. Geol. Surv. Bull. 35, p. 26, footnote). [See entry under *Hoxbar memb.*]

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 29–30). *Otterville memb. of Dornick Hills fm.*—Goldston applied *Otterville ls.* to different ls. ledges as much as 2,400 ft. apart stratigraphically, though he described it as a single ls. only 70 ft. thick. It is desirable to confine term to the ls. from which Girty and Roundy made their "Otterville" collections. This is probably, though not quite certainly, identical with the Otterville of Goldston's type loc., in sec. 3, T. 3 S., R. 1 W., near site of abandoned hamlet of Otterville. It attains an observed thickness of 25 ft., and may locally, including shaly layers, reach Goldston's figure of 70 ft. Most characteristic facies is a slightly ferruginous, platy granular ls. composed chiefly of tiny shell fragments; but oolite is common, and in Love Co. it locally carries ls. cgl. Lies 750 ft. below Bostwick memb. and 300 to 1,000 ft. above Jolliff memb. Correlates faunally with lower part of Wapanucka ls., with part of Morrow group, and with part of Marble Falls ls. of Tex.

Ottosee shale (also **Ottosee limestone**). (In Blount group.)

Lower Ordovician (late Chazy): Eastern Tennessee and southwestern Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 453, 538, 539, 551, 555, 556, 557, pl. 27). *Ottosee sh.*—Mainly shales and thin lss.; in one area includes an 80-foot bed of massive pink marble. Thickness 35 to 1,200 ft. Has hitherto been referred to Sevier sh. Uncon. overlies Holston marble in part of Knoxville trough and overlies Tellico ss. in Athens trough and part of Knoxville trough. Underlies Lowville. Top fm. of Blount group.

At Sevier type loc. this sh. is basal calc. memb. of Sevier sh. In Va. it is now treated as a distinct fm., called *Ottosee ls.*, because it is there a ls., underlying the Lowville and overlying Athens sh. Is of late Chazy age. Named for exposures at Ottosee Lake, in park at Knoxville, Tenn.

Ottumwan epoch (and series).

Term proposed by G. F. Kay (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 449–452, 1931) to include Yarmouth (interglacial) and Kansan (glacial) stages of Pleistocene epoch (and series), which Kay would elevate to *Pleistocene period* (and *system*). Named for Ottumwa, Iowa, where both Kansan and Yarmouth stages are well developed.

†Ouachita shale.

Lower and Middle Ordovician: Southwestern Arkansas.

A. H. Purdue, 1909 (Slates of Arkansas, Ark. Geol. Surv., pp. 30, 33). *Ouachita sh.*—Chiefly dark-colored clay sh., but not uncommonly the dark layers alternate with green ones. In many places slaty cleavage is developed, when the alternating dark and green layers produce ribboned sl. Thin layers of ls. are interbedded in lower part. Quartz veins and thin layers of hard flinty material are common. Thickness probably not less than 900 ft. Grades into underlying Crystal Mountain ss. [which at this time included Blakely ss., according to H. D. Miser, 1917]. Uncon. overlain by 75 to 150 ft. of sh. called Stringtown sh. [only a part of typical Stringtown sh.], which separates it from overlying Bigfork chert.

H. D. Miser (1917) interpreted †Ouachita sh. as=Mazarn sh., Blakely ss., and lower part of Womble sh. of present terminology. (See 1917 entry under *Blakely ss.*)

Named for Ouachita Mountains, Ark., the pronunciation of which is *Washita*.

Ouachita stone.

Commercial term for a bed of novaculite in lower part of Arkansas novaculite of SW. Ark. and SE. Okla.

Ouray limestone.

Upper Devonian: Southwestern Colorado.

W. Cross and A. C. Spencer, 1899 (U. S. G. S. La Plata folio, No. 60, p. 8). [See 1st entry under *Hermosa fm.*]

A. C. Spencer, 1900 (Am. Jour. Sci., 4th, vol. 9, pp. 125–129). *Ouray ls.* is name proposed for only memb. of pre-Carbf. section of San Juan region, SW. Colo., which is definitely shown by its fossils to be of Dev. age. Named for prominent occurrence in vicinity of Ouray at junction of Canon Creek with Uncompahgre River. The fm. consists of 100 to 300 ft. of massive ls. In places it is one massive layer; in other places it consists of 2 or 3 heavy bands separated by greenish crumbling marls. The ls. is usually white, but sometimes is stained red or pink. Certain strata are somewhat coarsely crystalline, but as a rule the ls. is fine-grained. The Dev. fossils (identified by G. H. Girty) were found a short distance below top. Neither extreme upper nor lower layers have yielded fossils. Rests on 0 to 100 ft. of Dev. sh., and, in places, on Algonkian; and underlies, apparently conformably, rocks containing, a few ft. above Ouray ls., Upper Carbf. fossils. The Lower Carbf. appears to be absent, but possibly a few ft. of unfossiliferous ls. above the true Dev. and not differentiated from it may be of Lower Carbf. age.

A. C. Spencer, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 37–78). *Ouray ls.* (Dev.) is overlain by Hermosa fm. (Penn.). The sh. on which Ouray ls. rests may be pre-Dev.

W. Cross, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 245–252). *Ouray ls.* of San Juan region is a lithologic unit, and contains Miss. fossils in upper part and Dev. fossils in lower part. It overlies Elbert fm. (Dev. sh.).

W. Cross and E. Howe, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 470–496). *Ouray ls.* of SW. Colo. is uncon. overlain by Molas fm. (Penn.).

W. Cross, A. C. Spencer, and F. L. Ransome, 1905 (U. S. G. S. Rico folio, No. 130). *Ouray ls.*, 100 to 300 ft. thick, is of Miss. and Dev. age. When defined by Spencer it was supposed to be all Dev. Is a lithologic unit and the Miss. and Dev. can not be separated. The Miss. fauna is found also in Leadville ls.

W. S. Burbank, 1930 (Colo. Sci. Soc. Proc., vol. 12, No. 6). The *Ouray ls.* is chiefly of Miss. age, the Dev. part being 65 to 70 ft. thick, and the Miss. part 180 to 235 ft. thick. Fossils 15 to 20 ft. above base are pronounced by Kirk to be Upper Dev. No other fossils found in Dev. part of the ls. The Dev. part is chiefly gray, buff, or white lss. of medium grain; the Miss. part is largely gray or brownish-gray crystalline ls. alternating with beds of ls. breccia containing red shaly seams. The top of Dev. part in Ouray dist. is drawn at base of a blue-gray thin-bedded ls. that commonly contains nodules of black chert. An inconspicuous ls. breccia occurs at places in overlying beds. At Box Canyon the dark-colored chert-bearing beds and the breccia are both absent, but base of Miss. ls. seems to be marked by ss. layers containing calc. cement.

E. Kirk, 1931 (Am. Jour. Sci., 5th, vol. 22, p. 224). *Ouray ls.* here restricted to Dev. part of Ouray ls. as previously used, the Miss. part to hereafter be called *Leadville ls.* It is understood that *Ouray* will not be applied outside of SW. Colo. [See under *Chaffee fm.*]

Oursan sandstone. (In Monterey group.)

Miocene (middle): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Oursan ss.*—Rather fine-grained ss., 600 ft. thick. A fm. of Monterey group. Underlies Tice sh. and overlies Claremont sh. Named for exposures on Oursan Ridge, Concord quad., Contra Costa Co.

Outer conglomerate. (In Copper Harbor group.)

Keweenawan (late): Northern Michigan and Wisconsin.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 186, etc., pls. 17 and 18). *Outer cgl.* consists of red ss. and cgl. underlying Nonesuch sl. belt and overlying Lake Shore trap. Thickness about 1,000 ft.

According to C. R. Van Hise and C. K. Leith (U. S. G. S. Bull. 360, p. 346, 1909) the Outer cgl. has been traced a distance of btw. 175 and 200 mi., and its estimated thickness varies from 350 to nearly 5,000 ft.

Is top fm. of Copper Harbor group.

Named for fact that at Keweenaw Point, Mich., it is the outer cgl., the supposedly thicker Great cgl. being the inner cgl.

Well established in literature of Michigan geology.

†Outer Copper Harbor conglomerate.

A name that has been applied to Outer cgl., of Copper Harbor group.

Outlet Tunnel quartz latite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). Is a chaotic aggregate of lava flows and breccia beds. Found in only two small bodies in canyon of East Willow Creek a short distance N. of Ridge mine and has not been recognized in reconn. of adjoining region. Is basal fm. of Alboroto group of Potosi volcanic series. Uncon. underlies at least a part of Willow Creek rhyolite. Thickness 250 to 350+ ft. Named for development at Outlet tunnel.

†Overbrook granite gneiss.

Pre-Cambrian: Southeastern Pennsylvania (Philadelphia region) and Maryland.

F. Bascom, 1904 (Am. Jour. Sci., 4th, vol. 17, p. 143). *Overbrook porphyritic granite gneiss* is included in Hall's Philadelphia gneisses.

In U. S. G. S. Phila. folio, No. 162, 1909, the rocks at and around Overbrook are mapped as granite gneiss (unnamed). According to E. B. Knopf (letter dated June 21, 1922) this granite gneiss is same as Port Deposit gneiss, the older name.

Overbrook sandstone member (of Springer formation).

Pennsylvanian: Central southern Oklahoma (Carter and Love Counties).

R. Roth, Feb. 1928 (Econ. Geol., vol. 23, pp. 45, 53). Three oil-bearing sss. of Springer fm. were expected at a depth of 1,000 to 3,500 ft. in N. C. Jolliff well No. 1, in sec. 24, T. 5 S., R. 1 E. They are as follows: *Primrose ss. series*, which was not expected to produce oil, at a depth of 100 ft.; *Lake Ardmore ss.* at 750 ft.; *Overbrook or City Lake ss.* at 1,250 ft.; and *Castle Rock ss.* at about 2,250 ft.

C. W. Tomlinson, Sept. 1928 (Okla. Geol. Surv. Bull. 40Z, p. 13). About 1,000 ft. above Rod Club memb. (basal memb. of Springer fm.) is the white massive *Overbrook ss.*, ranging in thickness from 45 to 100 ft., which is thoroughly saturated with asphalt along several miles of its outcrop in T. 3 S., R. 1 W., where it possesses its max. thickness and was formerly quarried for asphalt. From 300 to 500 ft. higher in section is Lake Ardmore memb. of Springer fm.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 17). *Overbrook ss. memb.* is named for outcrop across middle of N½ sec. 6, T. 6 S., R. 2 E., ¼ mi. E. of village of Overbrook, at N. edge of Love Co.

Overton fanglomerate.

Cretaceous and Tertiary (?): Southeastern Nevada.

C. R. Longwell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 52) and 1928 (U. S. G. S. Bull. 798). *Overton fangl.*—Coarse, heavy alluvial-fan deposit that includes fragments of all older local rocks. In large part is coarse ls. fragments cemented by calcium carbonate—a lime fangl. Fragments are not rounded, and many hardly show signs of wear by transportation. In all its features it is a series of fossil alluvial fans. Thickness 0 to 3,500 ft. Exposures indicate the deposit once covered practically every part of Muddy Mtns area, but subsequent deformation and erosion have reduced its extent. No fossils. Assigned to *Tert.* (*Mio?*). Grades into overlying Horse Spring fm. and rests uncon. on Jurassic(?) cross-bedded bright-red ss.

The finding, later, of a Cret. flora in lower part of Overton fangl. led to reclassification (in March 1936) of the Overton as *Cret. and Tert.* (*?*). (See American Cret. ferns of genus *Tempskya*, by C. B. Read and R. W. Brown, U. S. G. S. P. P. 186F, 1937.)

Owasco member.

Middle Devonian: Central New York (Skaneateles quadrangle).

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 11, 50). *Owasco memb.*—Cross-bedded calc. and finely aren. rock, 7 in. to 2 ft. 9 in. or 2 ft. 10 in. thick. Is the important *Spirifer tullius* zone, which overlies Spafford memb. of Ludlowville fm. and underlies Portland Point or basal memb. of Moscow fm. Is top memb. of the Ludlowville. On W. side of Owasco Lake Valley it outcrops in Edgewater Ravine at a level about 200 ft. above Owasco Lake and just below the new cement road, also in Willow Point Ravine just below a bridge near junction of old and new roads, and at other places.

Owen substage or beds.

Upper Devonian: Central northern Iowa.

W. H. Norton, 1897 (Iowa Geol. Surv. vol. 6, p. 148). [Only definition is use of *Owen substage* in a table, in which it is applied to upper part of Lime Creek sh., or to beds overlying Hackberry substage of Lime Creek sh.]

S. Calvin, 1897 (Iowa Geol. Surv. vol. 7, pp. 144, 163–164). *Owen substage* (*of Lime Creek sh. or stage*).—In type section consists of 20 ft. of light-gray calc.

beds carrying *Acervularia*, underlain by 30 ft. of mag. shales and argill. dolomites carrying *Naticopsis gigantea*, and, at base, 4 ft. of ls. carrying *Idiostroma*. Overlies Hackberry substage [restricted, apparently] of Lime Creek sh.

According to C. L. Fenton (Am. Jour. Sci., 4th, vol. 48, 1919) these beds were included in Hackberry group of Webster, 1889. The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, treats *Owen memb.* as top div. of Lime Creek sh.

Named for exposures on Owen Creek, Cerro Gordo Co.

Owenyo limestone.

Permian: Eastern California (Inyo Range).

E. Kirk, 1918 (U. S. G. S. P. P. 110). *Owenyo ls.*—Mainly massive grayish crystalline to compact lss. Basal 2 ft. blue-gray compact ls. carrying irregular lenses and stringers of ss. whose grains were apparently derived from underlying Reward cgl. Here and there, particularly in upper third, are layers carrying rounded chert pebbles. Thickness 125 ft. The lss. carry a Perm. (*Spiriferina pulchra*) fauna throughout, and according to G. H. Girty are probably to be correlated in part with Park City, Phosphoria, and Embar fms. of Utah, Idaho, and Wyo. Only two exposures of Owenyo ls. are known, both of which lie btw. Reward mine and Union Wash. One shows the base and the other the top of the fm. It is uncon. overlain by Lower Triassic shales and uncon. underlain by Reward cgl. Named for exposures about 3½ mi. N. of Owenyo Station on Southern Pacific, btw. Union Wash (the first large canyon to N.) and Reward mine.

Owl Creek formation.

Upper Cretaceous: Northeastern Mississippi and southwestern Tennessee.

E. W. Hilgard, 1860 (Rept. geol. and agric. Miss., pp. 79, 84–91, 102). *Owl Creek marl.*—Dark-bluish micaceous fossiliferous marl, more or less clayey in different portions. Thickness at Owl Creek Bluff 20 ft. Overlain by [Eocene] concretionary ls. Included in Ripley group.

B. Wade, 1917 (Johns Hopkins Univ. Circ., n. s., No. 3, p. 74). *Owl Creek horizon.*—A fossiliferous horizon that can be traced from southern Tenn. southward into Miss. to Owl Creek, Tippah Co. Overlain by Eocene and underlain by McNairy sand memb. [restricted].

In 1926 and subsequent years the marine beds designated *Owl Creek marl* by Hilgard were treated by U. S. Geol. Survey as a tongue of typical Ripley deposits, overlying the near-shore deposit called *McNairy sand memb. of Ripley fm.* (See B. Wade, 1926, U. S. G. S. P. P. 137.) In 1937 the name was changed to *Owl Creek fm.*, and Ripley fm. was restricted to underlying deposits, the overlying chalk (heretofore designated "Oktibbeha tongue of Selma chalk") to hereafter be treated as a part of Prairie Bluff chalk (expanded), and *Oktibbeha* to be discarded. (See L. W. Stephenson and W. H. Monroe, A. A. P. G. Bull., 1937.)

Named for exposures on Owl Creek, 3 mi. NE. of Ripley, Miss.

Owls Head granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., pp. 26, 34, and Moosilauke map). *Owls Head granite.*—Pink medium-grained rock, somewhat foliated near its margins, but more massive in interior. Intrudes Ammonoosuc volcanics. Occurs on and around Owls Head Cliff, SW. corner Moosilauke quad. Is late Dev. or late Carbf. Only representative of Oliverian magma series in this region.

Owosso moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Owosso, Shiawassee Co.

Owyhee basalt.

Miocene: Southeastern Oregon (Malheur County).

K. Bryan, 1929 (U. S. G. S. W. S. P. 597A) and B. C. Renick, 1930 (Jour. Geol., vol. 38, p. 494; named by Renick). *Owyhee basalt.*—Normal (augite-hypersthene-labradorite) basalt, of black, greenish-black, to reddish colors, including scoriaceous and cindery types; contains a few beds of volcanic tuff. Thickness 1,200 to 1,500 ft. Underlies Payette fm. and overlies Tert. (Mio.?) rhyolite porphyry and sediments.

Named for occurrence in bluffs along lower part of Owyhee River, in Malheur Co.

Owyhee rhyolite.

Tertiary (upper Miocene or lower Pliocene?): Southwestern Idaho.

V. R. D. Kirkham, 1931 (Jour. Geol., vol. 39, No. 6, p. 579). *Owyhee rhyolite (extrusive).*—A widespread sheet of acidic lavas which extends over southern Idaho and parts of adjacent States. Probably at same time occurred intrusion of one or more small batholiths in Payette fm. and Columbia River basalt. Contains some aggl. and tuffaceous phases with massive flows. Thickness 1,850 ft.

†Oxford type.

†Oxford gneiss.

Pre-Cambrian: Northern New Jersey.

F. L. Nason, 1889 (N. J. Geol. Surv. Ann. Rept. 1889, pp. 30+). *Oxford type.*—Is in part probably the syenite gneiss of Prof. Smock and the hornblende gneiss, in part, of Dr. Britton. Occurs typically in Van Nest Gap tunnel of Delaware, Lackawanna & Western R. R. at Oxford Furnace. [In text he calls it *Oxford gneiss.*]

Is a facies of Byram gneiss, for which a geographic name is considered unnecessary.

Oxford schist.

Carboniferous: Eastern Massachusetts (south of Worcester city).

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 60–68 and map). *Oxford schist.*—Lead-gray mica schist full of large black crystals of garnet and staurolite and containing tourmaline derived from the granite. Eastward from Worcester trough it grades into Worcester phyllite. In places it is silvery white, from absence of graphite and biotite. Named for town of Oxford.

Oxford gravel.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). *Oxford gravel.*—Scattered gravels and boulders left by meandering streams on graded terraces during post-Durango and pre-Wisconsin interglacial stage. Covers the lowland surrounding village of Oxford, La Plata Co.

†Oxmoor sandstone and shales.

Mississippian: Northern Alabama.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, pp. 155–157, section opp. p. 162, map). [For definition see under *Bangor ls.* As defined it included equivalents of all Mississippian fms. of Ala. above Fort Payne (†Lauderdale) chert, but Fort Payne chert as defined in this same book included the rocks later named *Tuscumbia ls.* (see under *Fort Payne chert*); and Smith also applied "Oxmoor" to the 100 ft. of ss. in the midst of the Bangor, which is the Hartselle ss. of present classification. The Oxmoor ss. of C. W. Hayes (Geol. Soc. Am. Bull., vol. 2, pp. 141–152, Feb. 9, 1891) in NE. Ala. is Hartselle ss.]

Named for Oxmoor, Jefferson Co.

Oyster Ridge sandstone member (of Frontier formation).

Upper Cretaceous: Southwestern Wyoming (Uinta County).

A. C. Veatch, 1906 (U. S. G. S. Bull. 285, pl. 12). *Oyster Ridge ss.*, in Colorado fm. [Text states that 400 ft. below top of Colorado fm. in southern Uinta Co. is a pronounced bed of coarse ss., occasionally conglomeratic, containing numerous large oysters and known as "Oyster Ridge ss."]

A. C. Veatch, 1907 (U. S. G. S. P. P. 56). *Oyster Ridge ss. memb. of Frontier fm.*—Pronounced bed of coarse ss., occasionally conglomeratic and containing numerous large oysters; in upper part of Frontier fm. Forms pronounced ridge named Oyster Ridge by Hayden in 1872. Thickness usually 200± ft. [Mapped and fossils listed.]

Ozan formation.

Upper Cretaceous (Gulf series): Southwestern Arkansas (Sevier, Howard, and Hempstead Counties) and southeastern Oklahoma.

C. H. Dane, 1926 (U. S. G. S. Press Bull. 8823, Sept. 10, 1926). *Ozan fm.*—Sandy micaceous marl, with, at base, a bed of sandy marl or marly sand, 3 to 8 ft. thick, containing as much as 50 percent of coarse glauconite grains, and 50 ft. higher in section another bed of glauconitic sand marl. Toward top some beds of poorly bedded and cross-bedded marly sand; also a few beds of hard ls. Thickness 150 to 250 ft. in Hempstead Co., but gradually thins eastward. Heretofore included in Brownstown marl, but is uncon. separated from underlying beds, to which name *Brownstown marl* is now restricted. Is conformably overlain by Annona chalk. Named for exposures along middle fork of Ozan Creek and for town of Ozan, Hempstead Co., which is located on its outcrop. [See also C. H. Dane, 1929, Ark. Geol. Surv. Bull. 1.]

According to L. W. Stephenson, 1937 (U. S. G. S. P. P. 186G, p. 135), Ozan fm. is = lower part of Annona chalk of Red River Co., NE. Tex., which lower part of Annona is = lower part of Taylor marl.

†Ozark marble.

Upper Cambrian: Southeastern Missouri.

G. C. Broadhead, 1889 (Am. Geol., vol. 3, pp. 7-8). *Ozark marble.*—Marble, 20 ft. thick, underlying Fourth Mag. ls. and overlying 90 ft. of ss. and cgl. resting on Archean granites and porphyries. Is basal part of Potsdam in Madison Co.

J. Bridge, 1930 (personal communication), stated that this marble consists of lenses in lower part of Bonneterre ls.

Named for Ozark uplift.

†Ozark series.

Lower Ordovician and Upper Cambrian: Southeastern Missouri.

G. C. Broadhead, 1891 (Am. Geol., vol. 8, p. 33). *Ozark series.*—Includes (descending): First Mag. ls.; First or Saccharoidal ss. (St. Peter's ss.); Second Mag. ls.; Second ss.; Third Mag. ls.; Third ss.; Fourth Mag. ls.; Ozark marble; and basal ss. and cgl. (90 ft. thick). Rests on Archean granites and porphyries. [This definition of *Ozark series* appeared in many Mo. repts up to 1898. The Ozarkian system of Ulrich as defined in 1911 included Cotter dol. at top and Potosi dol. at base. Ulrich's 1929 definition of his Ozarkian system extends from top of Gasconade dol. down to base of Potosi dol. There have been many other definitions of †Ozark. (See Mo. chart.)]

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106-1108), proposed that *Ozark series* be used to cover rocks occupying time interval btw. base of Beekmantown and base of Little Falls dol. of N. Y.

Named for development of the rocks in Ozark Mtns of southern Mo.

†Ozark sands.

Pleistocene: Southern Alabama.

E. A. Smith, 1892 (Sketch of geology of Ala., Birmingham, Ala., Roberts & Son. pam. of 36 pp.). *Ozark sands.*—Gray sands with pebbles at base. Thickness 4 to 5 ft. or more. Occur especially in S. part of State, overspreading the country btw. the watercourses up to altitudes as high as 150 to 200 ft. above sea level. Correspond to interfluvial phase of Columbia fm. of McGee. Usually lie uncon. on red loam of Lafayette fm. In two instances I think I have seen the gray Ozark sands overlying the second-bottom loams, but in neither case could I be perfectly certain of the identifications.

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala., explanatory chart). *Ozark or Geneva sands.*—In southern counties the Ozark or Geneva sands form terraces along small streams and are also spread over the divides up to altitudes of 100 ft.

or more. Pebbles in lower part of these sands. Formation not separately shown on map. Ozark sands cover 2,000 sq. mi. in Henry, Dale, Geneva, Covington, Escambia, Mobile, and Baldwin. [See also E. A. Smith, Am. Jour. Sci., 3d, vol. 47, pp. 285–296, 1894.]

E. A. Smith, L. C. Johnson, and D. W. Langdon, Jr., 1894 (Ala. Geol. Surv. Rept. Coastal Plain, pp. 27, 56–57). [*Ozark or Conecuh sands; also Ozark or Geneva sands.*]

Name is preoccupied and undesirable because of other conflicting uses of Ozark.

Derivation of name not stated. May have been suggested by presence of the sands at Ozark, Dale Co.

Ozark sandstone.

Pennsylvanian: Western Arkansas coal field.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Ozark ss.*—Ss., 0 to 500 ft. thick, composing basal memb. of Sebastian stage. Underlies Belva sh. and overlies Spadra stage. [Is a part of Fort Smith fm.]

Probably named for Ozark, Franklin Co.

†Ozark group.

Mississippian: Mississippi Valley region.

H. S. Williams, 1922 (Pan-Am. Geol., vol. 37, No. 1, pp. 36–40; posthumous paper; written for publication in Bull. 3 of Mo. Geol. Surv., published in 1890, but withdrawn from page proof and suppressed). *Ozark group.*—A group proposed to include the fms. heretofore described as Encrinital ls., Burlington ls., Keokuk group, and their equivalents in Mo., Ill., and Iowa, and part if not all of Siliceous group of Tenn., all the faunas of which indicate close paleontologic relationship. It is possible that some of the fms. heretofore referred to as Warsaw group may more properly belong to this group.

Replaced by Osage group.

Named "for prominent development of the fms. constituting the group on the southern and western margins of Ozark uplift."

Ozark stone.

Name formerly applied locally in SW. Ark. and SE. Okla. to a Dev. rock known commercially as *Ouachita stone*.

†Ozarkian.

Pliocene and Quaternary: Time term.

O. H. Hershey, 1896 (Sci., n. s., vol. 3, pp. 620–622). A marked period of elevation and subaerial erosion instituted by the great post-Tert. epeirogenic uplift of North America, and terminated by Kansan epoch of widely extended glaciation. Preceded by Lafayette epoch of deposition. Assigned to Pleist.

See *Sierran*.

Ozarkian system.

Name proposed by E. O. Ulrich in 1911 (Geol. Soc. Am. Bull., vol. 22) to include rocks now classified as late Upper Camb. and early Lower Ord. (Beekmantown). For definition see U. S. G. S. Bull. 769, pp. 89–92.

See also under †*Ozark series*.

†Ozarkian series.

A term proposed by C. [R.] Keyes in 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 147–151) to include Shakopee dol., New Richmond ss., and Oneota dol.

†Ozarkian stage.

A term employed in some Iowa repts to cover "bog and other deposits" underlying Nebraskan drift and overlying Cret., and assigned to Plio. (See Iowa Geol. Surv. vol. 27, 1916.)

†Ozarkic.

A variant of *Ozarkian system* of E. O. Ulrich.

Ozaukee formation.

Middle Devonian: Southeastern Wisconsin.

See under *Thiensville fm.*, 1929 and later entries.

Ozaukee member.

Devonian: Southeastern Wisconsin (Ozaukee County).

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 260, 262, 263). *Ozaukee memb.* (*novum*).—Upper and major part of Lake Church fm. Is firm, fairly thick-bedded brown to dark-gray pyritiferous dol. with strong basal cgl. Fauna differs somewhat from that of underlying Belgium memb. of Lake Church fm. (0 to 8 ft. thick), but is closely related to Belgium fauna. Thickness 27 ft. Overlain by basal cgl. of Thiensville fm. Rests on Niagara dol. Is cut out S. of Milwaukee-Ozaukee Co. line, where Thiensville fm. overlaps onto Niagaran. Named for Ozaukee Co.

Ozawkie limestone. (In Deer Creek limestone.)

Pennsylvanian: Eastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12). *Ozawkie ls.*—Basal memb. of Deer Creek ls. fm. Dark-gray to bluish-gray dense ls. 5± ft. thick. Underlies Oskaloosa sh. and overlies Tecumseh sh. fm. [Derivation of name not stated.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 182–184). The ls. here termed *Ozawkie ls. memb. of Deer Creek ls.* is "lower Deer Creek" of Kans. geologists. It is brown massive or thick-bedded ls., somewhat sandy and impure. Av. thickness, 5 ft., but near Lyndon it is 15± ft. Has been called *Rock Bluff ls.*, under misapprehension it was same as Rock Bluff ls. of Nebr.; but it is an older ls. than the Rock Bluff, from which it is separated by 5 to 25 ft. of sh., here named *Oskaloosa sh. memb. of Deer Creek ls.* The Ozawkie and Oskaloosa members are absent in Nebr., where Rock Bluff ls. is basal memb. of Deer Creek ls. Type loc., Ozawkie, in road cut in NE¼ sec. 31, T. 9 S., R. 18 E., Jefferson Co.

Ozuluama series.

Tertiary: Mexico.

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, p. 146). [Assigned to Tert. In 1924 W. A. VerWiebe assigned it to Olig.]

Pabos formation.

Upper Ordovician: Quebec (Gaspe Peninsula).

C. H. Kindle, 1935 (Geol. Soc. Am. Proc. 1934, p. 354).

C. H. Kindle, 1936 (Eastern Geol., No. 1, April 1936, p. 1). *Pabos fm.*—Shales and impure lss., very sparingly fossiliferous, but the fossils found on W. bank near head of Little Pabos Bay and elsewhere are Upper Ord.

Pabst member (of Tyler slate).

Pre-Cambrian (upper Huronian): Northwestern Michigan and northwestern Wisconsin (Gogebic district).

W. O. Hotchkiss, 1919 (Eng. and Min. Jour., vol. 108, pp. 501, 506). *Pabst memb.*—Cherty and fragmental and ferruginous sl. beds, containing a "flatwise" cgl. that is believed to represent an uncon. Thickness 67 ft. Is a memb. of Tyler graywacke sl. Can hardly be defined with accuracy because of scarcity of information concerning it. Is known in few places except in diamond-drill holes, and whether it should include the whole of the heavily ferruginous basal portion of Tyler fm., or be limited to the dominantly cherty portions, it is difficult to determine. As drawn in the sections it includes only the dominantly cherty parts of lower portion of Tyler fm. Named for Pabst mine, E. of Ironwood.

†Pacific sandstone.

Lower Ordovician: Central eastern Missouri.

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser., p. 79). *Pacific ss.*—Thin beds of ss., chert, and cherty ss., 0 to 50 ft. thick, called First

Saccharoidal ss. by Swallow. Uncon. overlies Jefferson City fm. and uncon. underlies Chouteau ls. in Miller Co.

Discarded in 1907 as a synonym of St. Peter ss.

Named for Pacific, Franklin Co.

Pacific quartz latite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). Alternating thin tuffs and thick flows, 0 to 700 ft. thick. Older than Mineral Creek andesite and younger than Cooney quartz latite. Contemp. with upper part of Cranktown ss.

Named for outcrops near Pacific mine, in W. part of Mogollon dist.

Packard rhyolite.

Tertiary (post-Eocene): Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, map). [Exposed on Packard Peak.]

Packard shale.

Upper Cretaceous: Mexico (Sonora).

See under *Cabullona group.*

†Packer clay.

Pleistocene (late Illinoian): Southeastern Pennsylvania.

E. H. Williams, Jr., 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 281–288). *Packer clay.*—Varies from perfectly clean clay to clayey sand. Is generally a reddish-brown unstratified sandy deposit, with a burden of glaciated angular and river-rolled material scattered irregularly through it. Thickness 3 to 39 ft. Is a local deposit existing btw. Easton and the Topton divide and below level of 500 ft. with exception of the part of Saucon Valley W. and S. of Hellertown. A lake formed by damming of the Lehigh by the glacier was noted on the map within contour line of 500 ft. It is proposed to call this lake Packer, in honor of late Asa Packer, of Mauch Chunk. The clays are the work of the ice in slack water. No signs of life found in them so far. Deposited immediately after retreat of the ice. The oldest are at W. part of lake.

F. Leverett regards this clay as a surface deposit of Illinoian drift and not a ponded deposit.

Packsaddle schist.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvii, lviii, 276–281). *Packsaddle series.*—Metamorphosed shaly beds and marble forming top div. of Texan system. Uncon. underlies Cambrian Hickory series and overlies Llano series [restricted sense].

S. Paige, 1911 (U. S. G. S. Bull. 450, pp. 14–23). *Packsaddle schist.*—Dominantly basic rocks, generally of dark color, including biotite, amphibolite, and graphitic schists and crystalline ls., also lighter-colored, more feldspathic bands resembling qtzite. Intruded by granite, which is not easily separated [but which is not a part of fm.]. Upper fm. of Llano series in Llano and Burnet Counties. Grades into underlying acidic Valley Spring gneiss by a transition zone. Uncon. overlain by Hickory ss. [Adopted definition.]

Named for Packsaddle Mtn, Llano Co.

Packsaddle Mountain granodiorite.

Probably Cretaceous or Jurassic: Northern Idaho (Pend Oreille district).

J. L. Gillson, 1927 (Jour. Geol., vol. 35, No. 1). *Packsaddle Mtn granodiorite.*—Markedly porphyritic granodiorite, of darker color than Bayview granodiorite. Named for fact it composes Packsaddle Mtn, Bonner Co.

†Packsand beds.

A term applied in a titular sense in some early Tex. repts to upper part of Trinity group, or to the beds later named *Paluxy sand.*

Paddock shale. (In Sumner group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 61). *Paddock sh.*—Top memb. of Enterprise fm., overlying Krider ls. and underlying Herington ls. Typically olive-drab to bluish-gray massive argill. sh., usually containing some platy argill.-calc. stringers which locally become quite prominent. Weathers buff to yellowish. Thickness 9 or 10 ft. in southern Kans.; 14± ft. in northern Kans. and Nebr. Named for Paddock Twp, southern Gage Co., Nebr. Type loc., road cut ¼ mi. S. of Krider, Gage Co.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), discarded Enterprise and treated *Paddock sh.* as middle memb. of his Nolans fm. (new).

Paducah formation.

Pleistocene: Western Kentucky.

F. J. Fohs, 1907 (Ky. Geol. Surv. Bull. 9, p. 67). *Paducah fm.*—Brown gravels, firesand, and ss., 5 to 30 ft. thick, composing upper part of Lafayette fm. Overlies Tennessee River gravels (lower part of Lafayette fm.) and underlies Port Hudson clays.

Probably named for Paducah, McCracken Co.

Paget formation.

Age (?): Bermudas.

A. E. Verrill, 1907 (Conn. Acad. Arts and Sci. Trans., vol. 12, pp. 189, 195).

Paget limestone.

Upper Cambrian: British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 3). *Paget fm.*—Bluish-gray oolitic lss., usually thin-bedded. Thickness at Mount Bosworth 360 ft. Type loc. on SE. slope of Paget Peak, beneath Sherbrooke fm., which forms the high cliffs of Paget Peak and Mount Daly. Overlies Bosworth fm. Contains Upper Camb. fauna.

Pageton sandstone.

Mississippian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 243). *Pageton ss.*—Massive, medium-grained, brownish gray, micaceous, 40 ft. thick. Lies 10 to 25 ft. below top of Mauch Chunk series and about 250 ft. below Pocahontas No. 3 coal. Quarried at Pageton, McDowell Co. Included in Mauch Chunk series.

Pagoda oolite.

Upper or Middle Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 37 and passim). *Pagoda oolite.*—Most striking character is oolitic texture. Consists of (descending): (1) Cream-colored to chocolate-gray thick-bedded, massive oolitic ls., entirely free from clay, 56 ft.; (2) thin- to medium-bedded fine-grained chocolate-colored ls. in beds 1 to 3 inches thick, all carrying small amounts of buff-colored clay disseminated in flakes, 30 ft.; (3) thin-bedded cream-gray platy oolitic ls. that weathers white gray, 75 ft. Thickest (400 ft.) in Dearborn section; thinnest (87 ft.) in Wall Creek section; at type loc. 168 ft. Type loc. is on E. side of peak lying N. 20° E. of top of Pagoda Mtn, in SW¼ sec. 3, T. 22 N., R. 13 W. Named for Pagoda Mtn, but is not present on the peak that forms very top of that mtn. Underlies Pentagon sh. and overlies Steamboat ls.

Pagoose.

See under *Union Valley ss.*

Pagwa River formation.

Silurian: Ontario.

W. S. Dyer, 1930 (Ont. Dept. Mines 38th Ann. Rept., pt. 4, p. 51).

Pahala basalt.

Pleistocene (?): Mauna Loa and Kilauea, Hawaiian Islands.

W. O. Clark, L. F. Noble, and H. S. Washington, 1923 (Am. Jour. Sci., 5th, vol. 6, p. 119). *Pahala series.*—Characterized chiefly by thick beds of stratified yellow ash which are interbedded with the lava flows. Ash bed [30 to 55 ft. thick] at top. In general the rocks are medium to rather light bluish gray, lighter in color than most of the historic and recent flows, but much darker than most of the pre-Pahala lavas [Ninole basalt], and lacking the pinkish tints of many of the pre-Pahala rocks. Separated from pre-Pahala rocks by a profound angular and erosional uncon. Thickness probably over 300 [600] ft.

According to H. T. Stearns, 1930 (U. S. G. S. W. S. P. 616), the *Pahala basalt* comprises all lava beds that are uncon. on Ninole basalt and that were laid down before end of deposition of ash-bed memb. at its top, and is overlain by Kamehame basalt.

Named for occurrence around Pahala, Mauna Loa, Hawaiian Islands, which is built at edge of extensive fields of yellow ash that form top memb. of Pahala basalt.

Pahasapa limestone.

Mississippian (lower): Western South Dakota and northeastern Wyoming (Black Hills).

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 509). *Pahasapa ls.*—Massive gray ls., 250 to 500 ft. thick, heretofore called Gray ls. Underlies Minnelusa fm. and overlies Englewood ls. Name (which is Dakota [Sioux] Indian name for Black Hills) was suggested by T. A. Jaggar.

Pahranagat limestone.

A name introduced by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 80), "to cover the Ordovicic part (500 ft.) of Hague's Lone Mountain ls." "Named for Pahranagat Mtns, N. of Las Vegas," SE. Nev.

Paicines formation.

Pliocene: Southern California (San Benito County).

P. F. Kerr and H. G. Schenck, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 470 and 476 and map). Continental Plio. is herein given local formational name *"Paicines,"* pending more exact correlation. Consists of yellow, loosely consolidated ss. interbedded with sh.; soft gray ss. colored by fragments of Franciscan metamorphics; occasional peat seams. Fresh-water fossils. The age of the Paicines is in all probability Plio. It lies uncon. on Etchegoin fm., and is overlain, probably uncon., by San Benito gravels. [Apparently named for extensive development W. of Paicines, Benito Co.]

Paine shale member (of Madison limestone).

Mississippian (lower): Central northern Montana (Fort Benton quadrangle) and central southern Montana (Little Belt Mountains quadrangle).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). At base of Madison ls. the strata are thin-bedded and darker in color than upper part of fm., owing to presence of much argill. material forming the *Paine sh.* Outcrops are frequently stained pale orange or red by iron oxide. In great cliffs along both Belt Creek and Dry Fork the section shows a ribboned structure, due to differences of weathering, the harder and more massive beds of Woodhurst ls. projecting in relief. [Derivation of name not stated, but Madison ls. is mapped over broad area at and around Paine Gulch, in SW. corner of this quad.]

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Lower third of Madison ls. consists of thin-bedded shaly lss. named *Paine sh.* They are commonly of gray color, and are overlain by Woodhurst ls. memb. of the Madison.

Painesville moraine.

Pleistocene (late Wisconsin): Northern Ohio and northwestern Pennsylvania. Included in Lake Escarpment morainic system. Named for Painesville, Ohio. See U. S. G. S. Mon. 41.

Paint slate.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Iron County).

R. C. Allen, 1910 (Mich. Geol. and Biol. Surv. Pub. 3, geol. ser. 2, pp. 100–101). *Paint slates*.—Mainly graywacke and arkose. Vary in texture from conglomeratic to fine-grained and in structure from massive thick-bedded rocks to micaceous schists. Occur in Iron River dist., N. and W. of Iron River and Crystal Falls dists. Same as Michigamme sl.

R. C. Allen and L. P. Barrett, 1915 (Mich. Geol. and Biol. Surv. Pub. 18, geol. ser. 15, pp. 131–139). *Paint sl. fm.*—Unknown but undoubtedly great thickness of graywacke, graywacke-sl., and gray sl., associated with basic intrusive and extrusive igneous rocks occupying a large but ill-defined area N. and W. of Iron River and Crystal Falls dists. and S. of W. end of Marquette iron range. Uniformly gray or grayish green in weathered exposures. "Is a large part of what has been described as Michigamme sl. series." Named for Paint River, Iron Co.

Paint limestone.

A name employed by C. [R.] Keyes instead of Paint Creek fm. of other geologists. (See Pan-Am. Geol., vol. 39, No. 4, 1923, p. 320.)

Paint Creek formation. (Of Chester group.)

Mississippian: Southern Illinois and western Kentucky.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 125). *Paint Creek fm.*—Upper part largely ls. with sh. partings; lower half or more almost wholly sh., with bed of deep-red compact clay about 20 or 25 ft. above base. Thickness 60 to 80 ft. Overlies Yankeetown chert and underlies Ruma fm.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 281–290, and No. 5, pp. 395–416; also Ill. Geol. Surv. Bull. 41), redefined this fm., by including in its top the lower part of †Ruma fm., the upper part of the †Ruma being Cypress ss., which now limits Paint Creek fm. at top.

Named for Paint Creek, Monroe Co., Ill. Typically developed in a tributary of Paint Creek about 5½ mi. NE. of Prairie du Rocher.

†Painted Desert formation.

Jurassic and older (?): Northern Arizona, southwestern Utah, and northwestern New Mexico.

L. F. Ward, 1901 (Am. Jour. Sci., 4th, vol. 12, pp. 401–413). *Painted Desert beds*.—Consist of (descending): White sss., 100 ft.; brown sss., 200 ft.; variegated sss., regularly stratified and brilliantly colored, 800 ft. (the well-known Painted Cliffs); and red-orange sss., 100 ft. Overlie Le Roux beds. Occur in Little Colorado Valley.

Now divided into (descending) Morrison fm. (Upper Jurassic), Navajo ss., Kayenta fm., and Wingate ss., the latter 3 of Jurassic (?) age. The Leroux beds of Ward comprise upper part of Chinle fm. of present nomenclature. The Painted Desert fm. of E. Huntington and J. W. Goldthwait (Jour. Geol., vol. 11, 1903, pp. 46–63), of Toquerville dist., SW. Utah, is Chinle fm., according to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr. (U. S. G. S. P. P 183, 1936), who also show Painted Desert fm. of N. H. Darton, 1910 (in NW. N. Mex. and northern Ariz.), included (descending) Morrison, Summerville, Curtis, Entrada, Carmel, Navajo, Kayenta, and Wingate fms.

Named for Painted Desert, Coconino Co., Ariz.

†Painterhood limestone.

Pennsylvanian: Southeastern Kansas.

F. C. Schrader and E. Haworth, 1905 (U. S. G. S. Bull. 260, p. 447). *Painterhood ls.*—Fine-grained fossiliferous ls., 12 ft. thick, underlying 10 ft. of ss. regarded as probably Elgin ss., and overlying Buxton fm. in Independence quad. Probably same as Oread ls.

Same as Oread ls., older name, and discarded many years ago.

Named for Painterhood Creek, Elk Co.

Paint Lick limestone. (In Eden group.)

Upper Ordovician: East-central Kentucky and southwestern Ohio.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 19, 212, 215). *Paint Lick bed or Upper Eden.*—Lss., 40 to 60 ft. thick, containing large percentage of siliceous material, with often less than 1 percent of carbonate of lime but with 6 to 10 percent of alumina. Overlies Million bed (Middle and Lower Eden) and underlies Mount Hope (basal bed of Maysville fm.). Equiv. to lower part of Garrard ss. of Richmond folio.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, pp. 289–324). *McMicken or Paint Lick beds* consist of 66 ft. of massive argill., more or less siliceous fine-grained lss., overlying Southgate memb. and forming top div. of Eden group. Underlie Mount Hope beds.

Probably named for Paint Lick Creek, Madison and Garrard Counties, Ky., as later repts state beds are traceable from Bath Co. to Boyle Co., Ky.

Paint Rock bed. (In Wichita group.)

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 428). *Paint Rock bed.*—Largely dark-colored shaly, slightly carbonaceous ls. interstratified with thin layers of carbonaceous argill. lime sh. Fossiliferous. Thickness 150 ft. Top memb. of Albany [Wichita] div.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, pp. 8, 9, 30–41, map). *Paintrock fm. (redefined).*—As here considered begins with No. 128 of general section and extends to top of No. 141. This leaves a thickness of 81 ft. for the fm.; Drake's thickness was 150 ft. He began Paintrock beds much lower than base here used, judging from his map, showing lower limit along Pony Creek. [These lower rocks must have been transferred to underlying Talpa ls.] The rocks of this fm. are more evenly bedded and somewhat more resistant than those of the two underlying fms. [Talpa and Grape Creek]. The fauna is more sparse and less varied. Upper limit is rather hard to determine before fauna of whole section is worked out, since lithologic changes are not sharp at any point. Underlies Lueders fm., which contains a larger proportion of sh. and nearly impure lss. All included in Wichita stage.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 197–198). [As Clyde fm. was defined in this rept it did not include Paint Rock bed of Drake, but the Paint Rock appears to be included in Wichita group, for authors state (p. 198, footnote) "the Talpa [top memb. of their Clyde fm.] and Paint Rock beds are two fms. sufficiently closely related to go in one and the same group."]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 169). *Paint Rock beds of Drake* are basal part of Lueders fm. as defined in this rept. Named for Paint Rock, Concho Co.

Paisley limestone.

Miners' local name for an ore-bearing ls. in lower part of Oquirrh fm. (Penn.) of Stockton dist., central northern Utah. Lies 2,000± ft. below their Larsen ls. and 550± ft. above their Galena King ls. Outcrops in Paisley claim. (See U. S. G. S. P. P. 173, 1932.)

Pakan formation.

Upper Cretaceous: Alberta.

J. A. Allan, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 12). Included in Belly River series.

Pakowki formation.

A series of Upper Cret. marine shales and sss., 100 to 300 ft. thick, underlying Foremost fm. and overlying Milk River fm. in southern Alberta, Canada. Named by D. B. Dowling (Canada Geol. Surv. Summ. Rept. 1915, and Canada Geol. Surv. Mem. 93, 1917), from exposure in Pakowki Coulee. Correlated with Claggett fm. of Mont.

Pala conglomerate.

Pleistocene: Southern California (San Diego County).

A. J. Ellis, 1919 (U. S. G. S. W. S. P. 446). *Pala cgl.*—Coarse valley-fill cgl. of type not common in this area. It is a conglomeratic mass of boulders and residuum, having thickness of about 200 ft. above and extending to undet. depth below present level of river. Is older than the valley fill which underlies present valley floors, and it may be as old or even older than San Pedro fm. Occurs in valley of San Luis Rey, in vicinity of Pala, San Diego Co.

Palaeozoic. See *Paleozoic*, the modern spelling.

Palafox sandstone member (of Mount Selman formation).

Eocene (middle): Southern Texas (Webb County) and northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1370, 1371, 1377, 1381, 1385). The upper Mount Selman (which overlies Bigford memb.) has the massive *Palafox ss.* as its basal memb. This prominent ridge-forming ss. can best be seen on the American side, where it forms a high cliff down E. bank of Rio Grande from mouth of Espada Creek to bluffs E. of Palafox [Webb Co., Tex.]. Can be traced from Rio Grande to Rio San Juan, Tamaulipas. Thickness 150 to 184 ft.

Pale beds.

A term applied by D. B. Dowling (Canada Geol. Surv. Summ. Rept. 1915, and Canada Geol. Surv. Mem. 93, 1917) to the alternating gray and greenish-gray sss., shales, and sandy shales, of continental origin and Judith River (Upper Cret.) age, conformably underlying the marine Bearpaw sh. and overlying Foremost fm. in southern Alberta, Canada. Thickness 740± ft.

†Paleocene.

A European name applied to basal part of Eocene series as used by U. S. Geol. Survey and most other American geologists, but some American geologists separate these basal rocks from the Eocene and treat them as a distinct series. For definition see U. S. G. S. Bull. 769, pp. 54–56.

Paleogene.

A term employed by many European geologists to include pre-Mio. Tertiary time and deposits, which they divide into Paleocene (=lower part of Eocene of most American geologists), Eocene (restricted to upper part of Eocene of most American geologists), and Olig. (See also *Neogene*.)

Paleozoic era.

A major time term, meaning old or ancient life, that covers (descending order) Carboniferous, Devonian, Silurian, Ordovician, and Cambrian periods. For definition see U. S. G. S. Bull. 769, 1925, pp. 10–14.

Palestine sandstone. (Of Chester group.)

Mississippian: Southwestern Illinois and western Kentucky.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 128). *Palestine fm.*—Aren. fm., 75 ft. thick, consisting in part of heavy beds of ss. suitable for building purposes and in part of thinly bedded ripple-marked sss. or aren. shales, with, locally, argill. shales. Uncon. overlies Menard ls. and conformably underlies Clore ls.

Named for Palestine Twp, Randolph Co., Ill., where fm. is well developed along some tributaries of Tindall Creek.

Pali volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Pali volcanics.*—Basalt and breccia, mapped separately. Included in lower part of Honolulu volcanic series [q. v.]. Crops out along the road down the famous Nuuanu Pali, for which the fm. is named.

†Palisade porphyry.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 262–268). *Palisade porphyry.*—The porphyry of Beaver Bay group (of Keweenaw series), which forms the Great Palisades of Minn. coast of Lake Superior. Thickness 300 ft.

Palisade diabase.

Upper Triassic: Eastern New York and northern New Jersey.

N. H. Darton, 1889 (Am. Jour. Sci., 3d, vol. 38, pp. 134–139). *Palisade trap.*—Best exposed instance of intrusion on large scale in N. J. In greater part an essentially conformable sheet throughout. Exposed for many mi. along Hudson River in contact with underlying strata. [In U. S. G. S. Bull. 67, 1890, Darton gave thickness 30 to 850 ft.]

W J McGee, 1894 (Geol. map of N. Y., prepared under direction of James Hall). *Palisade diabase, Juratrias.*

N. H. Darton, 1902 (U. S. G. S. New York City folio, No. 83). The *Palisade diabase*, a great sheet of igneous rock intruded among the lower sss. and shales of Newark group, forms the Palisades of the Hudson.

The U. S. Geol. Survey treats this intrusive fm. as distinct from Newark group. That group, however, includes some interbedded basalt flows.

†Palisade andesite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado.

Field name (preoccupied) used by E. S. Larsen for rocks he formally named *Conejos fm.* This field name crept into print in Colo. Geol. Surv. Bull. 13, 1917, simultaneously with the adopted name.

Palisades conglomerate.

Pliocene(?): Southwestern Alaska (Yukon gold district).

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3). *Palisades cgls.*—Pure-white clean sand and well-washed pebbles, strongly cross-bedded and containing much woody matter—sticks, logs, etc.—in condition btw. wood and lignite. Occur on left bank of Yukon, about 35 mi. below mouth of Tanana, at base of cliffs, 150 ft. high, that have been named *the Palisades.* Overlain by Pleist. silts (Yukon silts). Are Plio. or possibly upper Mio.

Palma Real.

Oligocene: Mexico.

J. A. Villatoro, 1932 (Bol. Petrolo, vol. 34, Nos. 1–3, p. 8, and Nos. 4–6, p. 204).

†Palm Beach limestone.

Pleistocene: Southern Florida.

S. Sanford, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 209–211). *Palm Beach ls.*—Nonoolitic marine lss., of white to yellowish color, containing variable proportion of fine to medium quartz sand. The lime cement is not coarsely crystalline, nor does rock contain, like other lss. of southern Fla., many patches and streaks of coarsely crystalline calcite, replacing amorphous material or filling cavities left by solutions of shell fragments. Its hardness varies greatly; in some places it is compact, dense, and rings under the hammer; in others, the proportion of sand is so great that the rock becomes a friable calc. ss. Thickness probably 5 to 50 ft. Scattered outcrops are found throughout a considerable extent of country in E. part of Palm Beach Co., but the ls. is not exposed near city of Palm Beach. Typical exposure is in T. 45, R. 41, 12 mi. W. of Lantana. It probably extends northward into St. Lucie Co. Is overlain by the sands of the pineland and the sands and peat of the Everglades, and is underlain, so far as can be told from well records, by marl and sand.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). "Palm Beach ls." is local facies of Anastasia fm. that marks transition into Miami oolite, and name is unnecessary.

Palmer gneiss.

Pre-Cambrian (Laurentian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., p. 514). *Palmer gneiss.*—Light-gray, dark-gray, and pinkish schists, fine-grained; sometimes homogeneous like a chert; at other times show little eyes of quartz in a hydromicaceous matrix, like a devitrified and schistose quartz porphyry. All varieties highly foliated. Typical exposures W. of Palmer Lake. Is Archean.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360), 1911 (U. S. G. S. Mon. 52), and subsequent repts assigned Palmer gneiss to Laurentian, as did C. K. Leith, 1934 (Geol. Soc. Am. Proc., p. 176). Mon. 52 showed that some rocks included in Palmer gneiss are middle Huronian sediments.

C. A. Lamey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 7, p. 1155). It has been shown [after a special study] that original Palmer gneiss belt contains both Middle and Lower Huronian rocks (Ajibik qtzite, Kona dol., and Mesnard qtzite). Since much of Palmer gneiss has been shown to be Huronian sediments, and since the Republic granite, in addition to being a younger intrusion than the diorite, has batholithic proportions, there appears to be good reason to conclude that a large part of the gneiss within the original belt represents Lower Huronian fms. much metamorphosed by Republic granite. [On pp. 1160-61:] It has been shown *Palmer gneiss* is in reality a variety of Huronian sediments—cgls., qtzites, dol., graywacke, and sl.—intruded by granite which writer believes is post-Upper Huronian, instead of Laurentian, as formerly believed.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned *Palmer gneiss* to Laurentian.

Palmer volcanics.

Tertiary (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 103, map). *Palmer volcanics.*—Tuffs, lavas, breccias, and intercalated bands of gravels the pebbles of which attain nearly 12 in. diam. Tuffs and breccias predominate. May be in part = Phalen Lake volcanics. Rest uncon. on Colville qtzite and covered by glacial drift. Form residual patch observed at only one place, W. of town of Palmer. Assigned to Tert.

Palmetto formation.

Lower Ordovician: Southwestern Nevada.

H. W. Turner, 1902 (Am. Geol., vol. 29, pp. 261-272). *Palmetto fm.*—Rocks of Ord. age, consisting of dark thin-bedded cherts with layers of gray graptolite slates, smaller amounts of reddish slates, and an occasional ls. layer. Conformably overlies Emigrant fm. Contains graptolites of Normanskill and Quebec [Beekmantown] age. Thickness not stated. Exposed in Palmetto Mtns, Esmeralda Co.

Palms quartzite.

Pre-Cambrian (middle Huronian): Northwestern Michigan and northwestern Wisconsin (Penokee-Gogebic district).

C. R. Van Hise, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, p. 338). *Palms fm.*—Quartz sl. Underlies Ironwood fm. and uncon. overlies Bad [River] ls. (Lower Huronian). Is basal fm. of Upper Huronian. Named for exposures just S. of Palms mine, on Palms property, near Bessemer, Mich.

Later repts give thickness 400 to 800 ft. Some repts have used *Palms quartz sl.*

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360) and 1911 (U. S. G. S. Mon. 52) assigned this fm. to upper Huronian.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), changed name to *Palms qtzite* and assigned the fm. to middle Huronian.

Palm Spring formation.

Miocene (middle or upper): Southeastern California (Imperial County).

W. P. Woodring, 1931 (Carnegie Inst. Wash. Pub. 418, p. 10). *Palm Spring fm.*—Unconsolidated or poorly consolidated nonmarine sands and light chocolate-brown and faint brick-red silts 1,000± ft. thick. Of middle or upper Mio. age. Conformably overlies marine Imperial fm. in Carrizo Mtn and vicinity, Imperial Co. Named for spring on lower part of Vallecito Creek, a southeastward-flowing tributary entering Carrizo Creek about 1 mi. above the old stage station.

Palm Spring member.

Miocene (?): Mexico (Baja California).

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 208).

†Palo Duro beds.

Pliocene: Panhandle of Texas.

W. B. Scott, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 594–595). *Palo Duro beds.*—Latest of three horizons of Loup Fork, characterized by first appearance of genera *Equus* and *Hippidium*, while *Protohippus* and *Aphelops* continue up from Nebraska or Loup Fork proper. Underlie Blanco beds and overlie Nebraska or Loup Fork proper.

Same as Goodnight fm. of W. F. Cummins (older name), which, according to J. W. Gidley, 1903 (Am. Mus. Nat. Hist. Bull. 19, p. 632), is same as his Clarendon beds.

Named for Palo Duro Canyon, W. part of Panhandle of Tex.; but later repts state the beds do not occur within 10 mi. of Palo Duro Canyon, which is in Randall and Armstrong Counties.

Is part or all of Ogallala fm. (all of Plio. age in Tex.).

Palomas gravel.

Pleistocene: Southwestern New Mexico.

C. H. Gordon, 1907 (Sci., n. s., vol. 25, pp. 824–825; and Jour. Geol., vol. 15, pp. 91–92). *Palomas fm.*—Stratified deposits of gravels and sands, 1,500 to 2,000 ft. thick in Sierra and Grant Counties, N. Mex. In western Sierra Co. they are cemented into cgl. comparable to Gila cgl. of Ariz.

Named for exposures on Palomas River, Sierra Co.

Palomasan series.

A term introduced by C. [R.] Keyes to cover 200 ft. of Quat. till in N. Mex. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 10.) Probably same as *Palomas gravel* of other geologists.

Palo Pinto limestone. (In Canyon group.)

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Palo Pinto fm.*—Everywhere easily recognized in well logs and in field, because it forms lowermost series of thick lss. in section above Strawn sands. The lower memb. is a massive ls. that forms a prominent scarp dividing the Strawn area from the Canyon. Overlies Strawn div. and underlies Graford fm. Is basal fm. of Canyon div. [group].

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 34). *Palo Pinto ls.*—Crystalline rock, dark gray, made up of beds 2 to 6 inches thick. Is basal fm. of Canyon group. Thickness 50 to 100 ft. Underlies Graford fm. and overlies Mineral Wells fm.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 44). *Palo Pinto fm.* was named by Plummer and Moore, and made to include only the massive ls. ledges conformably overlying Strawn group and conformably underlying the thick marl bed in base of Graford fm. at its type loc. along Highway No. 1 W. of Palo Pinto. The fm. includes a thin ls. above, 10 to 15 ft. of marl, and a massive ls. below.

Named for Palo Pinto, Palo Pinto Co.

Palos Verdes sand.

Pleistocene (upper): Southern California (Los Angeles County).

A. J. Tieje, 1926 (A. A. P. G. Bull., vol. 10, No. 5, pp. 502–512). *Palos Verdes fm.*—Name suggested by W. S. W. Kew for "Upper San Pedro" fm. of Arnold, the name *San Pedro fm.* being restricted to the [uncon. underlying] "Lower San Pedro" fm. of Arnold. The Palos Verdes consists of massive gray-green, very coarse to gravelly quartzose and loosely cemented marine sands, of several varieties, containing pebbles up to ½ in. diam. Thickness 50 ft. Sand dollars (*Echinarachnius excentricus* Esch.?) amazingly abundant, and the pelecypods and gastropods are typically Palos Verdes, with some 70 species thus far identified.

Rests on 104 ft. of unfossiliferous sands of beach type, and is overlain by 150 ft. of unfossiliferous sands assumed to be of fresh-water origin. Assigned to Pleist. Younger than San Pedro sands.

J. E. Eaton, 1928 (A. A. P. G. Bull., vol. 12, No. 2, p. 124), introduced *Hall Canyon fm.* for beds uncon. overlying San Pedro fm., restricted and uncon. underlying *Palos Verdes fm.* in Ventura Basin.

According to W. P. Woodring (16th Int. Geol. Cong. Guidebook 15, pl. 2, 1932) the *Palos Verdes sand* of San Pedro Hills is separated from San Pedro sand by "older terrace deposits," which rest uncon. on the San Pedro.

†Palouse formation.

Palouse soil.

Pleistocene: Southeastern Washington (Palouse Hills).

R. C. Treasher, 1925 (Sci., n. s., vol. 61, p. 469). Throughout east-central Wash., especially that region known as the "Palouse wheat country," is a large area underlain by basalt, which is a part of Columbia lava plateau. Above this basalt is a covering of very fine sand, 250 ft. or more thick, which has the characteristics of loess. For these sed. beds writer proposes *Palouse fm.* The fertile soil of Palouse region is largely a residual modification of Palouse fm. and has locally been redeposited by wind and surface wash.

R. C. Treasher, 1926 (Pan-Am. Geol., vol. 46, pp. 306–314). Of all the evidences with reference to Palouse loess [mapped], by far the greater part indicates (1) water deposition, rather than eolian; (2) that the laminated phase is older than the massive phase. The laminated loess may have been deposited either in a lake, or on a flood plain, or a combination of both. While glacial origin of the loess seems now most reasonable to writer, much further investigation is needed to establish its verity. Since no mention is made of a widespread laminated phase of the loess in Palouse region, and this phase seems to be the originally deposited material, writer proposes for it the name *Palouse fm.* Most reasonable explanation of its origin at present time is that it was laid down on retreat of the continental ice sheet, pre-Spokane in age, probably Illinoian or Iowan age, as suggested by Bretz. The Palouse Hills are composed of the two phases of the loess.

K. Bryan, 1927 (U. S. G. S. Bull 790B). Treasher has proposed "Palouse fm.," but the common origin of the material is doubtful, and it seems best therefore to use the popular and local term "Palouse soil" without any implication that a fm. name is being established.

Paluxy sand. (In Trinity group.)

Lower Cretaceous (Comanche series): Eastern Texas.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 504). *Paluxy sands.*—Fine white, gray, to yellowish packsand, stratified and occasionally cross-bedded, oxidizing red at surface. Resembles Trinity sands and hitherto confused with them, but differs by absence of fine pebbles and by being rather calc. and argill. in places, while Trinity sands are more ferruginous. Thickness 15 to 100 ft. Tentatively included in Fredericksburg div., but may prove to be inseparable from Trinity. Overlies Glen Rose or alternating beds and underlies *Gryphaea* Rock and Walnut clays.

This fm. was transferred to Trinity group by J. A. Taff in 1892 and by Hill in 1894, as explained under *Fredericksburg group*, and under *Trinity group*. The subdivisions of Trinity group at present generally recognized are (descending) Paluxy sand, Glen Rose ls., and Travis Peak sand.

Named for town and creek in Somervell Co.

Pamelia limestone.

Lower Ordovician: Northern New York (Jefferson County).

H. P. Cushing, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 155+). *Pamelia ls.*—Chiefly blue and dove ls. with intercalated mag. lss., and in upper half much whitish impure ls. and some yellow waterlime; at base 10 to 20 ft. of thin ss. overlain by greenish sh. Thickness 40 to 150 ft. Probably of Stones River age. Overlain by Lowville ls. and uncon. underlain by Theresa fm. (Camb.). The

Depauville waterlime of Emmons is in lower part, but he thought the beds were later than Birdseye, and abandoned name when he discovered his error. It seems better to introduce *Pamelia* than to rehabilitate *Depauville*, since latter represented only small part of Pamelia. The Pamelia occupies strat. position btw. Valcour ls. and Crown Point ls. of the Chazy of Champlain Valley.

H. P. Cushing, 1910 (N. Y. State Mus. Bull. 145). *Pamelia (Stones River) ls.*—Both the rocks and contained fossils differ from the Chazy, and the fm. is known as *Stones River*. Notwithstanding difference of name the two fms. represent substantially same time interval. Is of upper Stones River age. Stones River is of Chazy age but laid down in separate basin. In Thousand Islands region rests uncon. on Tribes Hill fm. and is uncon. overlain by Lowville ls.

H. P. Cushing, 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 135–144). *Pamelia ls.*, of supposed Chazy age, has length of outcrop of some 70 mi. in N. Y. and probably even greater in Canada. Cannot be successfully correlated with any of Champlain Chazy, either lithologically or faunally, and seems to represent a deposit in a wholly separate basin. According to Ulrich's correlations, the Pamelia is in age intermediate btw. middle and upper Chazy of Champlain Valley, [and occurs btw. Valcour and Crown Point lss.]. Rests on Tribes Hill, Theresa, Potsdam, and pre-Camb.

P. E. Raymond, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 353), 1913 (12th Int. Geol. Cong. Guidebook 3, p. 141) and 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 348), assigned Pamelia to Black River (instead of Chazy).

G. M. Kay, 1929 (A. A. P. G. Bull., vol. 13, No. 9, p. 1214), placed *Pamelia ls.* in Chazyan and showed it as considerably older than and uncon. with Lowville ls. He continued to include it in Chazyan in 1931 (Jour. Geol., vol. 39, No. 4, p. 362).

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 278). *Pamelia ls.* is of age intermediate btw. middle and upper Chazy.

A. E. Wilson, 1932 (Am. Jour. Sci., 5th, vol 24, pp. 135–146), assigned Pamelia to Black River.

G. M. Kay, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 227). *Pamelia fm.*, commonly classified as Chazyan, may belong in [Middle Ord.] Black River group below the Lowville, according to Alice E. Wilson. [In his tables he included it in Black River.]

The U. S. Geol. Survey classifies *Pamelia ls.* as Lower Ord.

Named for exposures at Pamelia, Jefferson Co.

Pamlico formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

W. B. Clark, 1910 (Geol. Soc. Am. Bull., vol. 20, p. 651). Name proposed by L. W. Stephenson in unpublished ms. In N. C. the Talbot terrace divides into two terraces, constituting Chowan and Pamlico fms.

L. W. Stephenson, 1912 (N. C. Geol. Surv. vol. 3, pp. 286–290). *Pamlico fm.*—Fine sandy loams, sands, and clays, and to a limited extent gravels. In the swamp lands the soils consist in large part of accumulations of peaty matter, which are of later origin than main body of deposits. Thickness 15 or 20 ft. The Pamlico terrace has been traced N. through Va. into Md. The upper surface of Pamlico beds forms a low, nearly level plain whose elevation above sea level nowhere exceeds 25 ft. Younger than Chowan fm., whose surface lies at elevations varying from 25 to 70 ft. above sea level. Top fm. of Columbia group in N. C. Named for Pamlico Sound, in eastern N. C., "away from whose shores the terrace plain forming the surface extends as broad, nearly level stretches of lowland."

C. K. Wentworth, 1930 (Va. Geol. Surv. Bull. 32, pp. 67–83), divided Pamlico fm. of Stephenson into *Princess Anne fm. and terrace* (at 25 ft. elev.), of marine origin, and *Dismal Swamp fm. and terrace* (at 12 ft. elev.), largely of marine origin, as explained under *Princess Anne fm.* and *Dismal Swamp fm.*

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, Dec. 1931), proposed following reclassification of younger Pleist. terrace fms. of Md., Va., and N. C.:

Pamlico fm., 25-foot level.

Talbot fm. *restricted*, 40-foot level. (Same as *typical* "Chowan," abandoned but not same as "Chowan" *as defined*.)

Penholoway terrace (deposits not yet named), 70-foot level. [These deposits have heretofore been included in Wicomico to N. and in Chowan to S.]

Wicomico fm. *restricted*, 100-foot level.

As "Dismal Swamp" terrace has identically same shore line (25 ft.) as the Pamlico, the name Pamlico, which has many years priority, should be retained. The

"Princess Anne" terrace was separated from the "Dismal Swamp" because of presence of a low scarp above 12 ft. in neighborhood of Norfolk and elsewhere in Va.

See also 16th Int. Geol. Cong. Guidebook 5, pp. 34–35, 1932, and Guidebook 12, 1932, where Cooke states †Dismal Swamp terrace is same as Pamlico terrace and recognizes Princess Anne terrace (and fm.) at 12-ft. level. The terrace fms. (including the Pamlico) shown on pp. 2 and 5 of Guidebook 12 (and herein enumerated under *Columbia group*) are now recognized by Cooke from Del. to southern Ga. and probably into Fla. He includes *Princess Anne* in *Pamlico*.

Pamunkey group.

Eocene: Eastern Virginia and Maryland.

N. H. Darton, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 431–450, map). *Pamunkey fm.*—A representative of the Eo. restricted to Md. and Va. Named for extensive exposures on Pamunkey River, Va. Consists of a homogeneous sheet of fine-grained materials, mainly glauconitic sands, usually profusely fossiliferous. Includes locally a few beds of clay, secondary lss., and at base some gravels. Thickness 150 ft. Uncon. underlies Chesapeake fm. [group] and uncon. overlies Severn fm. (Cret.).

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Pamunkey group.*—Divided into Nanjemoy fm. above and Aquia fm. below. Uncon. underlies Chesapeake group and uncon. overlies Cret.

Considered to be of Wilcox (lower Eo.) and Claiborne (middle Eo.) age.

Panaca formation.

Tertiary (Pliocene?): Eastern Nevada (Pioche region).

C. Stock, 1921 (Geol. Soc. Am. Bull., vol. 32, pp. 146–147; Am. Jour. Sci., 5th, vol. 2, pp. 252–257). Near village of Panaca, Lincoln Co., Nev., the deposits in which mammalian remains occur consist of red-brown and green sands and clays. Cross-bedded sands and gravels as well as tuffaceous materials are also present. The beds are slightly folded. Several series of terraces are developed in them. Fauna [listed] suggests Plio. age. The mammal-bearing sediments of Meadow Valley may be known as *Panaca beds*.

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. Met. Engrs. Trans., No. 1647, p. 8) and 1932 (U. S. G. S. P. P. 171). *Panaca fm.*, named by Stock, includes a series of water-laid tuffs of Tert. (probably late Plio.) age, well shown in badlands E. and W. of Panaca, and lying today in essentially same position as when they were deposited. The beds range in color from snow-white through cream color and brown to terra cotta, the most common color being light brown, and in grain from almost impalpable powder to sand. In a few places distinctly bedded and cross-bedded. Concretions (dark-gray or brownish-gray flinty bodies) occur in middle and upper parts of Panaca tuffs in buttes in N. part of village of Panaca. Exposed only in Meadow Valley and its tributary Patterson Wash. Thickness at least several hundred ft.

Panama conglomerate.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_3, pp. 58, 60, 70, 124). *Panama cgl.*, a massive cgl. of quartz pebbles (almost always lens-shaped) and sand, the proportion of sand to pebbles being much larger than in many purely conglomeratic masses of NW. Pa. The rock at Panama, Chautauqua Co., N. Y., where it is best exposed, is made up, from top to bottom, of alternating layers of ss. and cgl., and is 69 ft. thick. It rests on bluish-green shales of Chemung group. Assigned to Chemung. [Now considered to be younger than Chemung.] Horizon is 200 to 300 ft. lower than Salamanca cgl.

This cgl. is now generally considered to correspond to Wolf Creek cgl. lentil of Cattaraugus fm., although it has been correlated by some geologists with the younger Salamanca cgl. G. H. Chadwick stated (Geol. Soc. Am. Bull., vol. 36, p. 457, 1925) that Panama cgl. can be traced into Le Boeuf ss. of Pa. and that it underlies his Amity sh. K. E. Caster, 1933 (Geol.

Soc. Am. Bull., vol. 44, No. 1, p. 203) and 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 77–83), also said it is same as Le Boeuf cgl., Venango 3d oil sand, and Wolf Creek cgl., and that it underlies Amity sh. of Chadwick and rests on Chemung group.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 580). Panama cgl. makes base of true Cattaraugus fm. in McKean and western Potter Counties, Pa.

Panama formation.

Miocene: Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 244). [Age not given. Later repts by several other geologists assign the deposits to Mio.]

Panamint metamorphic complex.

Pre-Cambrian and lower Paleozoic (?): Southeastern California (Inyo County).

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). *Panamint metamorphic complex.*—A series of metamorphic crystalline rocks, including gneisses, schists, marble, ls., qtzite, etc., of unknown thickness, presumably in large part sedimentary. The only metamorphic rocks of known igneous origin are sheared granite gneiss and hornblende schist. The rocks have been injected by granite and aplite and cut by diabase dikes. Oldest fm. in S. part of Panamint Range, where it covers large area. Is pre-Camb. and lower Paleozoic (?). Underlies—probably uncon.—Marvel dolomitic ls.

Panamintan series.

A term applied by C. [R.] Keyes, 1923 (Pan.-Am. Geol., vol. 40, pp. 51, 53, 80), to 2,400 to 3,000 ft. of qtzites and sss. in eastern Calif., Nev., and Utah, said to be of early Camb. age and much older than Prospect Mtn qtzite. Named for Panamint Mtns, eastern Calif.

Pandermitan series.

Lower Cambrian: Great Basin (Utah and Nevada).

C. [R.] Keyes, 1927 (Pan-Am. Geol., vol. 48, p. 68). Taconic section [Lower Camb.] of Great Basin divided into (descending): Uncon.; Uintan series (7,000 ft. of qtzites); uncon.; Monon series (3,000 ft. of lss.); uncon.; *Pandermitan series* (3,000 ft. of qtzites); uncon.; Pintoan series (2,000 ft. of lss.); uncon. [Derivation of names not stated.]

†Panhandle beds.

Pliocene: Panhandle of Texas.

J. W. Gidley, 1903 (Am. Mus. Nat. Hist. Bull., vol. 19, pp. 634–635). *Panhandle beds.*—Deposits, which seem to be at least partially of lacustrine origin, of nearly uniform thickness [thickness not stated], forming practically whole area of Staked Plains and westward to Rocky Mtns in N. Mex. Underlie Clarendon beds and overlie Triassic. Fossils indicate middle or lower Mio.

W. D. Matthew, 1925 (Geol. Soc. Am. Bull., vol. 36, p. 221). *Panhandle beds* of Gidley are almost barren of fossils, but recent work by Am. Mus. party showed that their base is in places Lower Pleist., and that in other places they are contemp. in upper part with Blanco beds [middle Plio.] and in lower part with Clarendon beds [upper Mio. and Plio.]; also that they are earlier than Rock Creek beds and are uncon. on Triassic. "We consider this fm. essentially a consolidated eolian loess."

May be named for Panhandle of Tex. or for town in Carson Co., where the beds are exposed.

Replaced by *Ogallala fm.* (*Plio.*). No Mio. in this part of Tex., according to more recent studies.

Panoche formation.

Upper Cretaceous: Southern California (Diablo Range).

R. Anderson and R. W. Pack, 1915 (U. S. G. S. Bull. 603). *Panoche fm.*—Lower fm. of Chico group. Rests uncon. on Franciscan fm. and is conformably overlain by Moreno fm., the upper fm. of Chico group. Consists of alternating beds of dark thin-bedded clay sh. and massive gray concretionary ss. aggregating 9,500 to over 20,000 ft. in thickness. The fm. also includes some aren. sh., platy ss., and beds of coarse cgl., which locally attain great thicknesses. The lowest beds here included in Panoche fm. are nonfossiliferous and may represent Knoxville fm., which, however, is believed to be absent. Named for development in Panoche Hills, Fresno Co.

Panola formation.

Devonian and Silurian: Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 2). *Panola fm.*—Coarse yellow ss., 0 to 30 ft. thick, at base; fine blue sh., usually interbedded with thin beds of rusty brown impure ls. carrying Niagara fossils, in middle; heavy-bedded brown ls. of Dev. age at top. In places whole fm. is only 1 ft. thick; in other places appears to be absent. Where fully represented is 70 ft. thick, and corresponds to Clinton and Niagara groups, Oriskany ss., and Corniferous ls. of earlier Ky. repts. Underlies Chattanooga sh. and overlies Richmond fm.

Named for Panola, Madison Co.

Panther conglomerate. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 185). *Panther cgl.*—Massive cgl. to heavy- and current-bedded grayish-white to brown ss. Carries large white quartz pebbles, ovoidal and rounded. Is prominent cliff maker. Thickness 40 to 100 ft. Lies 1 to 5 ft. below Lower Douglas coal and 0 to 10 ft. above Iaeger B coal. Exposed at Panther, McDowell Co. [W. Va. Geol. Surv. Fayette Co. Rept., 1919, says this is Upper Nuttall ss.]

Also called *Panther ss.*

Panther tongue (of Star Point sandstone).

Upper Cretaceous: Central eastern Utah (Book Cliffs).

F. R. Clark, 1928 (U. S. G. S. Bull. 793). *Panther tongue.*—Basal part of Star Point ss. First appears in outcrop in Soldier Creek, Wellington quad., where it consists of impure ls. concretions and thin beds of buff ss. and sandy sh. Thickens to W. and material gets coarser and more sandy. At W. edge of Wellington quad. it is 30 to 40 ft. thick, and consists of friable, sugary cliff-forming ss., massive at top and grading down through sandy sh. to sh. Varies in thickness from 0 to 125 ft. Probably laid down in Mancos sea, but to W. and SW. it unites with Star Point ss. of Mesaverde group. Exposed in Panther Canyon, SE. of Castlegate, Carbon Co.

Panther Creek limestone member (of Ochelata formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

P. V. Roundy, K. C. Heald, and G. B. Richardson, 1922 (U. S. G. S. Bull. 686Z, p. 397, pl. LV). *Panther Creek ls.*—Either rests on Torpedo ss. or is separated from it by a thin sh. Is named for Panther Creek, in SW. part of T. 26 N., R. 12 E., where it is well exposed along valley rim to E. and to W. This ls. was called "Stanton (?) ls." in rept on T. 26 N., R. 11 E., but from evidence now at hand it appears to be considerably lower than true Stanton ls. of Kans. In some sections it attains a thickness of 14 ft. Usually the lower part is a rather siliceous impure ls. that weathers to orange color. The upper part is a purer and lighter-colored ls., in places almost white. The entire ls. contains abundant crinoid-stem segments and some other fossils. At top is a very fossiliferous bed, partly argill.

Panther Mountain shale and sandstone.

Middle Devonian: Eastern New York (Schoharie, Susquehanna, Cherry, and Unadilla Valleys).

G. A. Cooper, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 544, 550). *Panther Mtn sh. and ss.* is suggested for an interval of rock having a slightly different age along its range from Schoharie Valley to Unadilla Valley. In Schoharie Valley this name is to include rocks btw. Otsego memb. below and Portland Point memb. above. It thus includes upper part of Marcellus and overlying Skaneateles and Ludlowville, which cannot be separated lithologically. For convenience it is suggested this name be used in Susquehanna and Cherry Valleys also, for interval btw. Solsville and Portland Point members, where the Pecksport and Mottville are lithologically indistinguishable, and Skaneateles and Ludlowville fms. cannot be separated on this basis. In Unadilla Valley the Mottville clearly defines base of the Skaneateles, but it is not possible to separate this fm. lithologically from the Ludlowville, and it is therefore proposed to use *Panther Mtn* in this valley also. This broad definition includes a succession of aren. shales, sss., and cross-bedded sss. In Schoharie Valley there are fingers of continental beds at several levels in the Panther Mtn. Estimated thicknesses of the Panther Mtn are: Susquehanna Valley, 830 ft.; Bear Gulch, 1,097 ft.; Schoharie Valley, 1,303 ft.; and Berne-Durham quads (where much of section is composed of red beds), 1,400 ft. Type section is in face of Panther Mtn along the "Towpath" about ½ mi. S. of Fultonham and up Panther Creek to its head, where the Portland Point is exposed on property of T. Wayman, 3½ mi. E. of Summit. Replaces Moheganter shales and sss. of Grabau. (See under *Moheganter*.)

Panuco gray limestone.

Upper Cretaceous: Northern Mexico.

E. A. Trager, 1926 (A. A. P. G. Bull., vol. 10, No. 7, pp. 679–681, 688). [Name applied to a very light-gray hard, dense, slightly sandy microcrystalline ls., 100 to 200 ft. thick (but absent in Boca del Abra region), forming middle memb. of his Lower San Felipe (=lower part of San Felipe fm.).]

Paoli limestone.

Mississippian: Southern Indiana and central northern Kentucky.

M. N. Elrod, 1899 (Ind. Acad. Sci. Proc. for 1898, pp. 258–267). *Paoli ls.*—Massive close-textured ls., slightly broken at top by beds of calc. sh. and near middle by included chert nodules; generally the groundmass is lithographic. Includes all rocks below first Kaskaskia ss. and above Lost River chert. On paleontologic ground assigned to St. Louis group. Thickness 60 to 90 ft.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, pp. 408, 506–507, 515). Elrod's *Paoli ls.* includes Ste. Genevieve ls. and Gasper oolite. It is proposed here to restrict name to the representative of lower Gasper in Ind. Extreme top of the Mitchell appears to be a memb. of Gasper oolite and is here called *Paoli ls.* It is lowest memb. of Chester series in Ind., and consists of compact oolitic ls. of dark-gray to nearly white color. Very fossiliferous in places. Overlies Fredonia oolite and underlies Mooretown ss.

Named for Paoli, Orange Co., Ind.

Paoli limestone.

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). [See under *Iola ls.*]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 51–54). *Paoli ls.*, basal memb. of Iola ls. Underlies Muncie Creek sh. memb. Consists of single layer of very dense dark bluish-gray ls., very brittle, weathering in angular blocks. Upper surface highly irregular and pitted. Thickness uniformly 1½ ft. Named for Paoli, Miami Co., Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 114). *Paoli ls.*, basal memb. of Iola ls., is identified near Independence, southern Kans., and persists N. as far as the Iola is known.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Paonia shale member (of Mesaverde formation).

Upper Cretaceous: Central western Colorado (Delta County region).

W. T. Lee, 1909 (U. S. G. S. Bull. 341, pp. 20, 23). *Paonia sh. memb. of Mesaverde fm.*—Sh. (carbonaceous in places) and ss. with plant remains and fresh-water invertebrates. Thickness 400+ ft. Top is 2,000± ft. below top of Mesaverde fm. Rests conformably on Bowie sh. memb. of Mesaverde at E. end of Grand Mesa coal field, but is uncon. on older Rollins ss. memb. of the Mesaverde in central part of field. At W. end of field the Paonia is uncon. on Bowie sh. Named for Paonia, Delta Co.

Papagallos formation.

Cretaceous: Mexico.

E. T. Dumble, 1911 (Sci., n. s., vol. 33, p. 233).

This name has had considerable usage, but Trager states (A. A. P. G. Bull., vol. 10, No. 7, 1926, p. 681) it is now called "Mendez fm." by Tampico geologists, and that it is Upper Cret.

Papagayos formation.

Cretaceous: Mexico.

J. L. Tatum, 1931 (A. A. P. G. Bull., vol. 15, p. 875).

Papantla formation.

Miocene: Mexico (Vera Cruz).

H. E. Thalmann, 1935 (Eclogae geol. Helvetiae, vol. 28, No. 2, p. 545).

Papoose sand.

A subsurface sand, of Pocono (Miss.) age in SW. Pa. that is lower than Squaw sand and higher than Murrysville sand.

Papoose sand.

Name applied to an oil-bearing sand in Papoose oil field, Okfuskee and Hughes Counties, Okla. Top lies at depth ranging from 3,250 to 3,350 ft. Thickness 60 to 80+ ft. Has been correlated by some geologists with Wapanucka ls. (Penn.) and by other geologists with Pitkin ls. (Miss.), the former correlation being based on strat. position, the latter on fossils found in well samples. According to L. Roark, 1926 (Okla. Geol. Surv. Bull. 36), it is Miss., correlates with Pitkin ls., has been correlated with Cromwell sand and with Lyons-Quinn sand, and is main producing sand of Papoose field. According to A. I. Levorsen, 1927 (A. A. P. G. Bull., vol. 11, No. 7), Cromwell sand is older than Pitkin ls. According to A. I. Levorsen, 1928 (Okla. Geol. Surv. Bull. 40BB, pp. 17, 43), the Cromwell sand is basal sand of the Penn. J. P. Boyle, 1929 (Okla. Geol. Surv. Bull. 40KK), assigned both Cromwell and Papoose to basal Penn. (Morrow) horizon. According to J. P. Boyle, 1930 (Okla. Geol. Surv. Bull. 40XX), the *Papoose-Cromwell horizon* (200 to 400 ft. thick) is older than Wapanucka ls. and uncon. above Caney sh. to S. and Pitkin ls. to N. According to R. V. Hollingsworth (Geol. Soc. Am. Proc. 1933, p. 364, 1934) the Papoose, Cromwell, and Lyons-Quinn sands are same, and are middle memb. of Wapanucka ls. (early Penn.).

†Parachucla marl.

†Parachucla shale.

Miocene (lower): Southeastern Georgia and southwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 15–16, 18, names only, not defined); 1908 (S. C. Geol. Surv. ser. 4, Bull. 2, pp. 435, 464, 466). *Parachucla phase.*—This phase [of his Olig. period] is made to comprise a marl and its immediately overlying sh. The Parachucla marl has been definitely discriminated at two points—Porter's Landing [Ga.] and Marl Lake. It consists of approx. 5 ft. of a light-yellow porous marl which includes numerous discoidal quartz pebbles, and fossil shells (notably *Carolia floridana*). It rests on undulating surface of Combahee shales [a facies of Alum Bluff]. The Parachucla shales are exposed along W. bank of Savannah River interruptedly from Marl Lake to vicinity of Purysburg. It is well exhibited at Porter's Landing overlying the Parachucla shales [marls] and underlying the Mark's Head marl, on which is superimposed the Edisto phase of the marl. The Parachucla shales constitute an alumino-siliceous sh., more or less indurated by siliceous solutions, and slightly stratified; in color they range from dove to dark gray. The mass includes indurated portions with a concentric structure. No fossil forms sufficiently defined for discrimination have been observed.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). These beds are lower Mio. and compose part of Hawthorn fm. Names are abandoned.

Named for exposures along Savannah River in vicinity of Parachucla, a locality in SE. Ga.

Parachute Creek member (of Green River formation).

Eocene: Northeastern Utah (Uinta Basin) and northwestern Colorado (Garfield and Rio Blanco Counties).

W. H. Bradley, 1931 (U. S. G. S. P. P. 168). *Parachute Creek memb. of Green River fm.*—Contains most of the rich oil sh. beds of Green River fm. Thickness 175 to 1,000+ ft. Divided into: (1) Upper oil sh. group, 87 to 730 ft. thick, consisting of 29 to 38 percent of oil sh. and the rest slightly organic marlstone and paper sh., and including the "mahogany ledge," the principal oil sh. horizon of the Green River; (2) transitional beds, 43 to 118± ft. thick, consisting chiefly of marlstone, nearly barren of organic matter, weathering buff to gray, and, locally, some ls. and ss.; (3) lower oil sh. group, 45 to 200 ft. thick, chiefly hard platy marlstone with smaller amount of somewhat softer flaky sh. and a small amount of ls. Underlies Evacuation Creek memb. and overlies Garden Gulch memb. Reaches max. thickness, and probably also max. richness, in vicinity of Parachute Creek, Garfield Co., Colo., hence name.

Paradise conglomerate.

Carboniferous: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 295–298). *Paradise coarse cgls.*—The continuous exposures of the coarse cgls. forming E. side of Eastons Point terminate northward at Sachuest Beach. The same series farther N. forms Paradise Rocks.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped the rocks of the areas mentioned as Purgatory cgl.

†Paradise limestone.

Silurian (Niagaran): Northeastern Utah (northern Wasatch Mountains).

E. Blackwelder, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 517–542), in a paper on geol. of Wasatch Mtns, mentioned E. M. Kindle's identification of a ls., containing Sil. fossils, conformably underlying Jefferson ls., and in table on p. 519 he called this fm. *Paradise ls.*, but he did not describe it, nor give its thickness or type loc., and no geographic feature bearing that name is shown on his maps or mentioned in his paper. In 1913 G. B. Richardson applied *Laketown dol.* to the Sil. of northern Wasatch Mtns, and fully defined the fm.

F. F. Hintze, Jr., 1913 (N. Y. Acad. Sci. Annals, vol. 23, pp. 107–108). No name has yet come into general use for the Sil. strata of the northern Wasatch, as they have been little studied, but the one employed by Blackwelder, viz, *Paradise ls.*, might serve. In the central Wasatch this is apparently wanting altogether.

Same as Laketown dol., which was fully defined by G. B. Richardson in 1913.

Paradise formation.

Mississippian (upper): Southeastern Arizona (Chiricahua Mountains).

A. A. Stoyanow, 1926 (Am. Jour. Sci., 5th, vol. 12, pp. 316–320). *Paradise fm.*—A group of strata markedly different, both lithologically and paleontologically, from anything so far described from Carbf. of Ariz. Occurs on E. face of Chiricahua Mtns, not far from Paradise, an abandoned mining camp 45 mi. NE. of Bisbee and 10 mi. W. of N. Mex. line. Consists of black and gray moderately thick- and thin-bedded crystalline ls. that weathers olive and yellow, alternating with ss., sh., oolite, cross-bedded calc. ss., and aren. ls. Preponderant color of fm. is yellow. Thickness 134 ft. Fossils prove its upper Miss. age (late Meramec and early Chester). Underlies Naco ls. (Penn.) and overlies Escabrosa ls. (lower Miss.).

R. M. Hernon, Dec. 1935 (Jour. Pal., vol. 9, No. 8, pp. 653–694), divided Paradise fm. of Stoyanow into 8 lithologic members; gave detailed sections of the fm.; described, listed, and figured its fauna; and correlated its members with Miss.

POLITECHNIKA G... ZAKŁAD GEOLOGII

Valley, Ark., and Okla. fms. ranging in age from St. Louis(?) ls. up to Glen Dean ls. of Chester group.

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 509–511), gave very detailed section of his Paradise fm. and listed its fossils.

Paradox formation.

Pennsylvanian (lower): Southeastern Utah and western Colorado.

A. A. Baker, 1933 (U. S. G. S. Bull. 841). *Paradox fm.*—Salt, gyp., and anhydrite, with interbedded black and brown sh. and some ls. Exposed in a few small areas in Moab dist., Utah, where overlying rocks were relatively thin and have been ruptured by upward movement of the relatively plastic salt and gyp. Base not exposed. Type loc. is Paradox Valley, Montrose Co., SW. Colo. In Moab dist., Utah, it underlies Hermosa fm. (Penn.), but it may be=basal part of typical Hermosa fm. of SW. Colo. although its lithology is totally different from Hermosa lithology. Is believed to be younger than Molas ls. of SW. Colo.

This is an intrusive fm. Also described in U. S. G. S. Bull. 863, 1935, by C. H. Dane. Has been itentified in parts of western Colo. as far E. as central part of Eagle Co., according to J. B. Reeside, Jr. (personal communication, 1935).

Parian group.

Tertiary or Cretaceous: Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geol. of Trindad, pp. 33–60). [Divided into older group and newer group, and assigned to Tert.]

H. B. Milner, 1921 (Min. Mag., vol. 25, p. 144), assigned these deposits to Cret.

Paris formation.

Middle Ordovician: Central Kentucky.

J. M. Nickles, 1905 (Ky. Geol. Surv. Bull. 5, p. 15). [*Paris* used (in table only, without any description or thickness) for fm. in Lexington group underlying Perryville and overlying Wilmore of Lexington group.]

According to A. F. Foerste (Ky. Geol. Surv. Bull. 7, 1906) the Paris is 75 ft. thick and overlying Perryville is 0 to 35 ft. thick. According to Foerste, 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21), the Paris includes Benson, Brannon, and Bigby lss. of his classification.

Named for Paris, Bourbon Co.

†Paris shale.

Pennsylvanian (Allegheny): Western Arkansas coal field.

A. J. Collier, 1907 (U. S. G. S. Bull. 326, pp. 12, 20–21, map). *Paris sh.*—Sandy sh. with thin beds of shaly ss.; Paris coal 200 to 300 ft. above base and about 400 ft. below top. Thickness 600 to 700 ft. Underlies Savanna ss. and overlies Fort Smith fm. Top fm. of McAlester group.

Named for Paris, Logan Co.

This name has been discarded, as explained under *McAlester fm.*

Paris moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17.

Parita formation.

Age (?): Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 263).

Park shale.

Middle Cambrian: Central northern Montana (Fort Benton quadrangle) and central southern Montana (Little Belt Mountains quadrangle and to west).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Park shales and ls. cgls.*, several hundred ft. thick, overlie Meagher ls. and underlie Pilgrim ls.; all included in Barker fm.

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Park sh.*—Very thin-bedded soft, crumbly rock, often containing glistening grains of mica, mostly of greenish-gray color, but also showing various shades of red and purple. Overlies Meagher ls. and underlies Pilgrim ls.; all included in Barker fm. [Derivation of name not stated, but Barker fm. is mapped over large part of Belt Park, in NW. corner of Little Belt Mtns quad. and SW. corner of Fort Benton quad., and is also mapped on E. and W. sides of Big Park, same quad.]

W. H. Weed, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 286). Greater part of Camb. rocks seen in mtn area of Little Belt Mtns probably belong to *Park sh.* Lower strata are gray or greenish micaceous shales. Higher up these contain intercalated thin layers of impure lss., which often consist of flat ls. pebbles—a true intraformational cgl. Well exposed in road cuttings at head of Sheep Creek, in valleys of Dry Wolf, Pilgrim, and Tenderfoot Creeks, and near Barker. Estimated thickness 800 ft.

Park granite.

Tertiary: Southern British Columbia and central northern Washington (Okanogan batholith).

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). Very conspicuous on N. spurs of Park Mtn [B. C. or Wash.?].

Park sandstone.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 37). *Park ss.*—Sss., 300 ft. thick, underlying Heber lss. and overlying Argenta lss. Middle fm. of Aubreyan series in Utah. [Derivation of name not stated.]

Park City formation.

Permian and Pennsylvanian: Northeastern Utah (northern and central Wasatch Mountains).

J. M. Boutwell, 1907 (Jour. Geol., vol. 15, pp. 439–458). *Park City ls.* (also *Park City fm.*).—Largely calc., but includes several sss. and qtzites. In general it comprises a thick ls. in its lower part, several minor lss. in its upper part, and a number of thin calc. beds toward base, with intercalated qtzites and sss.; some cherty lss. in lower part. Thickness of fm. 590 ft. Conformably underlies Woodside sh. and conformably overlies Weber qtzite. Named for Park City dist., Utah, in recognition of fact that it has yielded the bonanzas that have made that dist. famous.

This name was later used in SW. Wyo. and SE. Idaho, but in 1912 the Perm. beds of SE. Idaho that represent the upper 2 members of typical Park City fm. of Park City dist., Utah, were named *Phosphoria fm.*, the underlying Penn. rocks were named *Wells fm.*, and the use of *Park City fm.* in SE. Idaho and adjacent parts of northern Utah was discontinued. Later the name *Park City fm.* was discontinued by U. S. Geol. Survey in SW. Wyo., where the rocks formerly designated by that name are now called *Phosphoria fm.* and *Wells fm.* (The Wells fm. includes the equiv. of the Penn. part of Park City fm. and the underlying Weber qtzite, also Penn.) *Phosphoria fm.* has been applied (by A. A. L. Mathews, 1931) to upper (Perm.) part of Park City fm. in its typical region, and *Park City fm.* to lower (Penn.) part, but this usage has not been adopted by U. S. Geol. Survey.

Parker slate.

Lower Cambrian: Northwestern Vermont (Franklin County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 371). *Parker sl.*—This fm. is named for its excellent exposures around the sides of Parker Cobble and on old Parker farm, where it contains large numbers of Lower Camb. fossils and is the celebrated locality from which Walcott was able to make his first analysis of Taconic system of Emmons and demonstrate the existence of beds older than Upper Camb. It has long been the most important Camb. fm. of region. It is the same as that previously called "*Colchester*" by writer, and is renamed because of the poor exposure of the fm. in Colchester and, indeed, anywhere S. of Parker Cobble, where a full section of fm. is exposed, together with overlying and underlying fms. It is uncon. overlain by Milton dol. and underlain by Mallett dol. [According to Keith (personal communication) Parker Cobble is 2 mi. NW. of Georgia Center, which would locate it in St. Albans quad.]

Parker formation.

Pennsylvanian: Southwestern Indiana (Knox County) and adjacent parts of Illinois.

M. M. Fidlar, 1933 (Ind. Acad. Sci. Proc., vol. 42, pp. 137, 139), gave following succession (downward order) of outcropping fms. in Knox Co., Ind., and adjacent parts of Ill.: *St. Wendell ss.*, 45 ft.; *Parker fm.* (underclay, coal, black sh., ls.), 20 ft.; Merom ss., 60 to 100 ft.; Ditney fm., 0 to 10 ft.; West Franklin fm., 15 ft. Derivation of new names *St. Wendell ss.* and *Parker fm.* not indicated.

Parker quartz diorite.

Late Jurassic (?): Southern California (San Gabriel Mountains).

W. J. Miller, 1934 (Univ. Calif. at Los Angeles, Pub. in Math. and Phys. Sci., vol. 1, No. 1, map, pp. 37–65, 83). *Parker quartz diorite.*—Typical occurrence in Parker Mtn, W. of Acton. Of different mineralogical composition from Lowe granodiorite and Wilson diorite, but may be a facies of the Lowe. Assigned to late Jurassic (?).

Parker Hill schist.

Pre-Devonian (?): Northwestern New Hampshire (Ammonoosuc River region).

F. H. Lahee, 1916 (Jour. Geol., vol. 24, pp. 366–381). *Parker Hill white schist* is taken as representative of the "tuff-like schists" of Lyman group. It is associated with *Parker Hill dark schist*, and is undoubtedly a metamorphosed clastic; it certainly was never a normal clastic in ordinary sense of term. Locally contains angular blocks and sometimes isolated pebbles. Grades into fine variety of Lyman cgl. schist, which is not younger than Dev. and may be older. Might be called an arkose schist, because of abundant clastic feldspar. I classify the rock as metamorphosed tuff.

Probably named for the Parker Hill in NW. corner of Moosilauke quad.

Parkhead sandstone member (of Jennings formation).

Upper Devonian: Northeastern West Virginia and western Maryland.

G. W. Stose and C. K. Swartz, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Parkhead ss. memb. of Jennings fm.*—Fine quartz cgl. and gray and red ss. interbedded with buff sh. Thickness 400 to 800 ft. Is a memb. in middle of Jennings fm. Contains Portage fossils. Underlain by thin band of dark-red sh. Named for exposures at Parkhead Station, Washington Co., Md.

Parkman sandstone member.

Upper Cretaceous: Northern Wyoming and southern Montana.

N. H. Darton, Nov. 17, 1906 (U. S. G. S. P. P. 51, pp. 13, 58, etc.). *Parkman ss.*—Soft massive buff ss. with harder darker concretions. Thickness 300 to 500 ft. Grades into overlying Piney fm. and rests on Pierre sh. Supposed to represent Fox Hills ss. Named for Parkman Station.

This name also appeared in the following other repts by Darton, published in 1906: Geol. Soc. Am. Bull., vol. 17, Dec. 31, 1906, p. 544; U. S. G. S. Bald Mtn-Dayton folio, No. 141, and Cloud Peak-Fort McKinney folio, No. 142. As thus originally defined the Parkman was treated as a distinct fm. Later it was treated as a memb. of Pierre fm. in Salt Creek and neighboring oil fields in Wyo. In 1917 it was treated as top memb. of Claggett fm. in N. part of Bighorn Basin. Later it was decided to treat it as a distinct fm. in Crow Indian Res., Mont., where it is overlain by Bearpaw sh. and underlain by Claggett sh. (See U. S. G. S. Bull. 856, 1935.) In central Wyo. the Parkman ss. is basal memb. of Mesaverde fm., as traced northward from Colo.

Named for exposures near Parkman, Sheridan Co., Wyo.

Parks Creek limestone. (In Pottsville formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307-316). *Parks Creek ls.*—Cap rock above Seville (No. 1) coal of Pottsville fm. in Fulton Co. Thickness 0 to 20 ft. There is erosional uncon. at top of this ls. in Fulton Co., and it is proposed to treat that uncon. as div. line btw. Carbondale and Pottsville fms. Fossils correspond closely with those of Curlew ls. of SE. Ill. [Derivation of name not stated, but is probably a creek in Fulton Co.]

Parks Mountain sandstone member (of Thrifty formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 410). *Parks Mtn bed.*—Massive ss. and cgl., 10 to 70 ft. thick. Memb. of Cisco div. Overlies Lohn bed and underlies Chaffin bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132), include this bed in Thrifty fm., of Cisco group.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, p. 232). Parks Mtn cgl. of Drake is a conglomeratic phase of Avis ss.

Wallace Lee and C. O. Nickell (Univ. Tex. Bull. soon to be published) adopted *Parks Mtn ss. memb. of Thrifty fm.* for Colorado River region, underlying Chaffin ls. memb. and overlying Lohn sh. memb., and adopted Avis ss. for basal memb. of Thrifty fm. of Brazos River region.

Named for Parks Mtn, Coleman Co., in Waldrip quad.

†Parkville limestone. (In Kansas City formation.)

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., p. 51). *Parkville ls.*—Many bedded cherty fossiliferous ls. forming cap rock of coal No. 1.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 105), placed *†Parkville ls.* under synonymy of Cement City ls., but stated: Identifiable only by reference to localities cited. Appears to be erroneously placed in section or miscorrelated with other lss.

Named for exposures at Parkville, Platte Co.

†Parkville shale.

Pennsylvanian: Northwestern Missouri and southwestern Iowa.

C. R. Keyes, 1898 (Am. Geol., vol. 21, p. 349). *Parkville sh.*—Shales, 75 ft. thick, best exposed near station of Parkville, N. of Kansas City. Underlies Plattsburg ls. and overlies Iola ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 118). †Parkville sh. of Keyes included beds btw. top of Argentine ls. (his Iola) and base of Plattsburg ls.

Named for exposures at Parkville, Platte Co., Mo.

Parkwood formation.

Mississippian (upper 500 ft. may be Pennsylvanian): Northern Alabama.

C. Butts, 1910 (U. S. G. S. Bull. 400, pp. 15, 20; U. S. G. S. Birmingham folio, No. 175, p. 8). *Parkwood fm.*—Prevailingly gray or greenish sandy sh. and ss.; no calc. beds. Thickness, knife edge to 2,000 ft. Overlies Pennington sh. and uncon. underlies Brock coal bed, basal bed of Pottsville fm. in Cahaba coal field, northern central Ala. Occurs in Shades Valley. Its basal memb. is the ss. that makes Little Shades Mtn and Bald Ridge.

Is now considered by C. Butts (Ala. Geol. Surv. Spec. Rept. No. 14, 1926) to be=upper part of Pennington sh. of Tenn.; also to correspond to hiatus btw. the Pennington and the Pennsylvanian in northern Appalachian region.

Named for exposures at Parkwood, Jefferson Co.

Parma sandstone.

Pennsylvanian (Pottsville): Southern Michigan.

A. Winchell, 1861 (Mich. Geol. Surv. 1st Bien. Rept. Prog., pp. 112, 138). *Parma ss.*—White or slightly yellowish quartzose glistening ss. containing occasional traces of vegetable remains. Overlies the Carbf. ls. [Bayport ls.], and underlies Coal Measures [Saginaw fm.]. Thickness 24 to 105 ft. [Later repts give thickness 0 to 200 ft.]

Named for exposures at Parma, Jackson Co.

Parnell limestone.

A name applied locally (see Am. Inst. Min. and Met. Engrs. Trans., vol. 70, 1924, pp. 859–883, by R. N. Hunt; pp. 884–889, by A. N. Winchell; and pp. 908–926, by O. A. Peterson) to a ls., 30 to 50 ft. thick, in upper part of Bingham qtzite (Penn.) of Bingham dist., Utah. Lies 300 ft. below York-Petro ls. and 220 ft. above Bullard ls. Probably named for Parnell mine.

Parrish limestone lentil (of Cashaqua shale).

Upper Devonian: West-central New York.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63, pp. 31–32). *Parrish ls.*—Singular concretionary ls., continuous in character, in a mass of red and greenish kramenzel abounding in goniatites and *Orthoceras*. Thickness 6 in. Named because it is distinctive in color, contents, and composition. Exposed in Parrish Gully at Parrish, Ontario Co. Is a lentil in Cashaqua sh. about 50 ft. below its top. [On map accompanying this rept. the town is spelled *Parish*, but the ls. has been consistently spelled *Parrish* in the literature.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 75). *Parrish ls.* is recognized from type section in Canandaigua Lake region to Seneca Lake.

Parrsboro formation.

Pennsylvanian: Nova Scotia.

H. C. Hyde, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 395) and 1915 (Summ. Rept. 1914, pp. 107–108).

Parson Bay group.

Triassic: British Columbia.

J. A. Bancroft, 1913 (Canada Geol. Surv. Mem. 23, p. 75).

Parsons formation. (In Pleasanton group.)

Pennsylvanian: Southeastern Kansas.

G. I. Adams, 1903 (U. S. G. S. Bull. 211, p. 33). *Parsons ls.*—In Iola quad. consists of 8 to 15 ft. of ls. underlying Dudley sh. and overlying Bandera sh. To S. thickens and consists of two lss. separated by 15 ft. of sh. [In Independence quad. the fm. is 80 ft. thick, the upper ls. being 20 ft. thick, the middle sh. 45 ft. thick, and the lower ls. (Altamont ls.) 15 ft. thick.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 64). Parsons fm. (discarded) included Altamont ls. at base and Lenapah ls. at top.

The U. S. Geol. Survey has not yet had occasion to consider abandonment of Parsons fm.

Named for Parsons, Labette Co.

Parting quartzite member (of Chaffee formation).

Upper Devonian: Leadville district, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230), 1883 (U. S. G. S. Leadville Atlas), and 1886 (U. S. G. S. Mon. 12). A descriptive term applied to the white qtzite, 10 to 70 ft. thick, separating Blue [Leadville] ls. above from White ls. [Ord.] below.

In some repts has been treated as upper memb. of †Yule ls., but is now considered to be of Dev. age.

E. Kirk, 1931 (Am. Jour. Sci., 5th, vol. 22, pp. 228–229). *Chaffee fm.* introduced for the Dev. rocks of Colo. to N. and E. of areas (in SW. Colo.) where *Ouray ls.* and *Elbert fm.* have been applied. In Leadville dist. the Chaffee fm. includes Parting qtzite memb. and overlying lss. of Dev. age which have formerly been included in Leadville ls. The name Parting Spur has been applied to the spur extending NW. from Dyer Mtn toward West Dyer Mtn. It is in Lake Co. and E. of Leadville. The Parting qtzite is exposed on this spur.

The descriptive term *parting qtzite* has been applied to qtzites in other parts of Colo., without intending to imply correlation with the well-known Parting qtzite of Leadville dist.

Partridge slate.

Pre-Silurian (Upper Ordovician?): Northwestern New Hampshire (Ammonoosuc River region).

M. Billings, 1934 (Sci., Jan. 19, vol. 79, No. 2038, pp. 55-56). *Partridge sl.*—Black sl., 0 to 2,000 ft. thick, of pre-Sil. (Upper Ord.?) age. Uncon. underlies Clough cgl. and overlies Ammonoosuc volcanics in Littleton and Moosilauke quads. [Appears to replace what he called *West Bath sl.* in his Feb. 1933 paper (Am. Jour. Sci., 5th, vol. 25, No. 146, p. 149).]

M. Billings, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 413-415), mapped *Partridge sl.* at and around Partridge Lake, Littleton quad., and other parts of Littleton and Moosilauke quads.

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., maps and pp. 12, 21). *Partridge fm.* is proposed for a group of black slates that overlie Ammonoosuc volcanics and underlie Clough and Fitch fms. Named for Partridge Lake, Littleton Twp. The fm. is largely sl., although locally somewhat sandy. Lower 25 ft. in some places consists of interbedded black sl. and fine-grained light-colored qtzite, in beds ¼ to 1 inch thick, and in other places this basal memb. has thin beds of schistose soda-rhyolite tuff similar to those in Ammonoosuc volcanics. Believed to be Upper Ord.

Partridge Point formation.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524-526). *Partridge Point fm.*—Gray and bluish argill. lss. and gray calc. shales, containing many crinoids and blastoids. Thickness exposed, 14 ft. Separated from overlying Squaw Bay ls. by 3-ft. covered interval and from underlying Potter Farm fm. by covered interval of 70 ft. Is top fm. of Thunder Bay stage of Traverse group. Type loc., E. shore of Partridge Point, 3 mi. S. of Alpena.

Pasadena formation.

Miocene: Southern California (San Gabriel Mountains).

R. Arnold and A. M. Strong, 1905 (Geol. Soc. Am. Bull., vol. 16, p. 188). *Pasadena fm.*—A conformable series of cgls., sss., and shales of either lower or middle Mio. age. Flanks San Rafael Hills on S. and underlies S. part of city of Pasadena. The cgls. rest on and are composed of the San Gabriel plutonic and metamorphic rocks.

Pasayten formation.

Cretaceous (Lower): Central northern Washington.

G. O. Smith and F. C. Calkins, 1904 (U. S. G. S. Bull. 235). *Pasayten fm.*—Proposed as a substitute for *Similkameen fm.* of Russell (Cret.), which is preoccupied. *Consists of sed. rocks without contemp. volcanic material.* East of main fork of Pasayten River ss. appears to be dominant rock. Most instructive exposures are along main divide N. of Barron, where fm. consists of (ascending): (1) At least 1,000 ft. of black sh. exposed along crest of Hozomeen Range; (2) sandy cgl. with pebbles from 1 to 8 in. diam., 500 ft. exposed; (3) ss.; (4) black sh. Thickness of fm. 6,000± ft. It contains a few thin and discontinuous beds of ls. Assigned to Lower Cret.

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329-376). *Pasayten Lower Cret. beds* are 30,000 ft. thick btw. Pasayten and Skagit Rivers. In part composed of debris from the granodiorites.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 14, 120° 30′ to 121°), mapped *Pasayten series* (*Shasta-Chico*), as consisting of (downward): Memb. L (black argillite); memb. K (green and gray ss. with interbeds of sh. and cgl.); memb. J (coarse cgl.); and members B to I, crossed by Pasayten River (chiefly arkose and ss., with cgl. and sh.). He also mapped *Pasayten volcanic fm.* (*Lower Cret.*), consisting of andesitic breccia, crossed by Pasayten River. This volcanic fm. apparently was not included in Pasayten fm. of Smith and Calkins. In 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 479-506) R. A. Daly used *Pasayten volcanic fm. or memb. A of Pasayten series*, and stated that it occurs in only one part of Bdy belt, on densely thicketed slopes of Pasayten River Valley.

Pasayten volcanic formation.

See 1912 entry under *Pasayten fm.*

Pasayten andesite.

Lower Cretaceous: Southern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 14, 120° 30′ to 121°). *Pasayten volcanic fm.*—Andesitic breccia; Lower Cret. [Pasayten River, B. C.-Wash., crosses this mass.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 474). *Pasayten andesite*, Cret., Wash. and B. C.

Pascagoula clay.

Miocene (upper): Mississippi, southwestern Alabama, and Louisiana.

W J McGee, 1891 (U. S. G. S. 12th Ann. Rept., pt. 1, p. 409). Name selected by L. C. Johnson. In SE. Miss., particularly along Pascagoula River, Johnson has brought to light a series of deposits resembling somewhat in material the typical Grand Gulf fm., though the bedding is more definite, and alternating layers of sand and clay partially replace the prevailing mudstones. The series appears to correspond in strat. position either with upper part or with whole of the Grand Gulf, and carries a moderately abundant fauna of rather recent (apparently late Neocene) aspect, which has not yet been studied in detail. Pending determination of precise relations, [L. C.] Johnson has designated this series of deposits *Pascagoula fm.* Still farther eastward the deposits characteristic of the Pascagoula Basin disappear, but whether by feathering out or by gradual transition has not been ascertained. [As thus defined probably included Hattiesburg and Pascagoula clays of current nomenclature, although Hattiesburg clay is not developed along Pascagoula River, but occurs a short distance N. of that river.]

E. A. Smith, 1892 (Sketch of geology of Ala., Birmingham, Ala., Roberts & Son, pam. of 36 pp.). Among materials brought up by an artesian boring in Mobile recently are some shells that have been recognized as characteristic of the Mio. Inasmuch as no marine shells have as yet been found in Grand Gulf beds, it seems best to give a distinct name to this Mobile shell-bearing stratum. A fossiliferous stratum with the same shells as those from the Mobile boring has lately been discovered by L. C. Johnson, of U. S. Geol. Survey, on Pascagoula River, in Miss. This bed lies immediately over strata of undoubted Grand Gulf characters, and may be a marine phase of the Grand Gulf but withal so entirely different from the other beds of this fm. as to be worthy of a name of its own, and Mr. Johnson has suggested *Pascagoula*, from the original locality. Mr. Johnson has also recently traced the Mio. fossiliferous deposits of Alum Bluff, on Chattahoochee River, Fla., westward and northward to within a few mi. of S. bdy of Covington Co. It seems altogether probable this phase of the Mio. will be found to extend into Ala., and it may turn out to be identical with our Pascagoula, as above defined. [The Alum Bluff group is now known to be older than Pascagoula clay, and to be of middle and lower Mio. age.]

L. C. Johnson, 1893 (Sci., vol. 21, pp. 90-91). A fourth phase of the Mio. or Grand Gulf group manifests itself below Leakesville on the Chickasawhay, on Lower Leaf River and Pascagoula, being clays of a more tenacious quality, abounding in specks and nodules of calc. material, and in a few places holding shells of mollusks. One locality of the last, where first discovered, is the Shell Landing below Roberts Bluff, 4 mi. SW. of Vernal P. O. This is the *Pascagoula phase or fm.* It extends into Ala. in wells, being reached at 600 ft. in Mobile wells. [Appears to consider Pascagoula younger than Hattiesburg clay.]

W. H. Dall, 1903 (Wagner Free Inst. Sci. Phila. Trans., vol. 3, pt. 6, pp. 1541-1620), definitely classified Pascagoula clay as younger than Hattiesburg clay.

G. C. Matson, 1916 (U. S. G. S. P. P. 98). *Pascagoula clay*, in part marine, uncon. underlies Citronelle fm. (Plio.) and uncon. overlies Hattiesburg clay. Consists of a series of blue, green, and gray clays, locally calc., with interbedded sands and, more rarely, sss. Thickness 250 ft. in Ala., 450 ft. in western Miss. and eastern La., and 250 or 300 ft. in western La. and eastern Tex. Pascagoula clay as here used differs from Johnson's Pascagoula phase or fm. by including the portion of his Fort Adams or Ellisville phase extending from Tunica, La., to Columbia, Miss.

Type loc. is, however, the same, and the difference is largely due to a more thorough understanding of distribution of fm. [This is present approved definition, except that the use of the name in Tex. has been discontinued.]

Named for exposures along Pascagoula River, in Jackson Co., Miss.

Paskapoo formation.

Upper Cretaceous and Eocene (?): Alberta and Saskatchewan, Canada.

J. B. Tyrrell, 1887 (Canada Geol. Surv., n. s., vol. 2, pp. 74E, 84E, 127E, 135E–137E). *Paskapoo series.*

Some Canadian geologists assign this fm. to Tert., others to Cret. It is considered=Lance fm. or Lance and Fort Union fms. of Mont.

†Paskenta formation.

Lower Cretaceous (Shasta series): Northern California (Tehama County).

F. M. Anderson, 1902 (Calif. Acad. Sci. Proc., 3d ser., Geol., vol. 2, No. 1, pp. 43–47). *Knoxville (Paskenta) horizon, the true Knoxville.*—The 4,000 ft. of dark or yellowish Cret. clay sh. forming upper part of Knoxville of previous repts contains a typical subtropical fauna with abundant *Aucella*, which are apparently confined to this interval. The underlying 15,000 ft. of beds heretofore included in the Knoxville are probably pre-Cret., and for lack of better name are here designated *sub-Knoxville*. Few organic remains other than *Aucella* have been obtained from these beds. It is not yet possible to say where exact limits btw. this sub-Knoxville and the Knoxville horizon may be drawn, and it may not be possible to establish one more than theoretically in Tehama and Shasta Counties. But there appears to be sufficient evidence that the Knoxville as here restricted was inaugurated by some profound movements felt elsewhere if not in this basin. The sub-Knoxville has not yet been clearly recognized outside of Sacramento Valley, either in Calif. or Oreg. Nearly if not quite all occurrences of *Aucella*-bearing rocks in Coast Ranges have shown themselves by their fossil remains other than *Aucella* to belong wholly to Knoxville (Paskenta) horizon. The true Knoxville rests conformably on the sub-Knoxville, and the latter rests uncon. on Franciscan series. The Paskenta horizon is especially well represented in vicinity of Paskenta, Tehama Co.

J. P. Smith, 1909 (Sci., n. s., vol. 30, pp. 346–351), divided *Knoxville fm.* into Upper Knoxville beds (Neocomian) and Lower Knoxville beds (Portland and Aquilonian).

F. H. Knowlton, 1910 (Am. Jour. Sci., 4th, vol. 30, pp. 33–64), expressed opinion, based on fossil plants, that most of *Knoxville fm.* is Jurassic.

J. P. Smith, 1910 (Jour. Geol., vol. 18, No. 3, pp. 217, 220), 1915 (Nature and sci. on Pacific coast, Elder & Co., p. 51) and 1916 (Calif. State Min. Bur. Bull. 72), treated the Knoxville as a unit and assigned it to Lower Cret. (Neocomian).

The name *Knoxville fm.* continued to be applied to all beds btw. Horsetown fm. above and Franciscan fm. below. In 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770) B. L. Clark called attention to Anderson's name *Paskenta* for the upper part of Knoxville and restriction of *Knoxville* to lower part of the Knoxville of previous repts, and stated: "Although use of *Paskenta* has not been generally recognized, yet in writer's opinion this horizon is very important. Several paleontologists, including J. P. Smith and F. H. Knowlton, have held that line btw. lower and upper Knoxville is true line btw. Jurassic and Cret. But this is a debatable point. Over large areas, owing to lack of detailed work, *Knoxville* and *Paskenta* have not been differentiated, and in such cases the undiff. series has been called *Knoxville*."

F. M. Anderson, 1932 (Min. in Calif., vol. 28, Nos. 3 and 4, pp. 313–323), included *Paskenta beds* in Shasta group, gave their geographic distribution, assigned them to Valangian and Infravalangian of European classification, and gave their thickness as 4,880 ft. "Overlie Knoxville group [restricted] and underlie Horsetown beds."

N. E. A. Hinds, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, pp. 79–122), described and mapped the rocks of part of northern Calif., and applied *Paskenta fm.* to upper part of Knoxville of the literature and restricted *Knoxville fm.* to lower part of Knoxville. He stated that neither base nor top of Paskenta fm. (Lower Cret.) has been determined in this region, although F. M. Anderson stated [see Pan-Am. Geol., vol. 60, No. 3, pp. 175–188, 1933] that there is a conspicuous uncon. btw. Paskenta and underlying Knoxville [restricted], which latter he assigned to Upper Jurassic.

F. M. Anderson, 1933 (Min. in Calif., vol. 28, Nos. 3 and 4, pp. 311–326), assigned his *Paskenta beds* to Valangian and Infravalangian of Lower Cret. European classification, gave their thickness as 4,880 ft., and discussed their geographic distribution and probable relations to underlying *Knoxville group*, as he would restrict it. He gave thickness of his restricted Knoxville as 14,280 to 16,000 ft., and assigned it to the Aquilonian and Portlandian of Upper Jurassic of European classification.

N. E. A. Hinds, 1934 (Am. Jour. Sci., 5th, vol. 27, p. 185), recognized Horsetown and *Paskenta fms.* (Lower Cret.) and *Knoxville fm.* (?) (Upper Jurassic).

These proposed modifications of terminology have not yet been adopted by U. S. Geol. Survey.

Paskenta horizon.

See 1st entry under *Paskenta fm.*

Paso Robles formation.

Pliocene and lower Pleistocene (?): Western California (San Luis Obispo County and neighboring areas).

H. W. Fairbanks, 1898 (Jour. Geol., vol. 6, pp. 565–566). *Paso Robles fm.*—Fresh-water cgls. and sandy and marly clays, usually slightly consolidated. Overlap uncon. upon upturned and sharply folded San Pablo fm. Fill Salinas Valley as far up as Atascadero. Are characteristically exposed about town of Paso Robles [San Luis Obispo Co.], from where they extend W. toward Santa Lucia Mtns and for many miles N. and E. of that place, filling valley of the Estrella and its tributaries, and may reach into the Great Valley. Are of later Neocene age.

Paspotansa greensand marl member (of Aquia formation).

Eocene: Eastern Maryland and Virginia.

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Paspotansa memb. or substage.*—Upper 10 to 17 ft. consists of thick-bedded layers and interstratified greensand marl; lower 30 ft. consists of light greenish-gray greensand. Top memb. of Aquia fm. Overlies and is faunally separable from Piscataway memb. or substage. Named for Paspotansa Creek, Va.

B. L. Miller, 1912 (U. S. G. S. Choptank folio, No. 182). *Paspotansa greensand marl memb.*—Top memb. of Aquia fm. Overlies Piscataway indurated marl memb.

Patapsco formation. (In Potomac group.)

Lower Cretaceous: Eastern Maryland, Delaware, and Virginia.

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, pp. 156, 191). *Patapsco fm.*—Chiefly highly colored and variegated clays which grade over into lighter-colored sandy clays. Sandy bands of coarser materials are at times interstratified. The sands frequently contain much decomposed feldspar and rounded lumps of clay occur at times. The sands are often cross-bedded, and all deposits give evidence of shallow-water origin. Thickness 200± ft. Rich Cret. flora. Uncon. underlies Raritan fm. and uncon. overlies Arundel fm., all included in Potomac group. Named for occurrence in valley of Patapsco River.

The Raritan fm. has been proved to be of Upper Cret. age, and is no longer included in Potomac group. The Patapsco fm. is therefore now topmost fm. of Potomac group.

Patara schist (also Patara series).

Pre-Cambrian: Ontario (Abram Lake region).

F. J. Pettijohn, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 3, pp. 481–483). [On p. 481: *Patara series*, 0 to 2,500 ft. of cgl., breccia, and sed. schists, of pre-Abram age, included in Keewatin, but "in part post-Keewatin." On pp. 482–483 these rocks are called *Patara schists*, from Patara Lake.]

F. J. Pettijohn, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 12, pp. 1895, 1896, map, etc.). *Patara sedi-volcanics*, 1,250 to 1,500 ft. thick.

Patillas quartz monzonite.

Age (?): Puerto Rico.

C. R. Fettke, 1924 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 2, p. 161).

Pato red member (of Vaqueros formation).

Miocene (lower): Southern California (Cuyama Valley).

W. A. English, 1916 (U. S. G. S. Bull. 621, pp. 191–215). *Pato red memb.*—Gray and red clay sh. and ss., 1,300 ft. thick, forming basal memb. of Vaqueros fm. Upper 500 ft. are of brilliant crimson color and composed of material eroded from adjacent land at time the red beds were being deposited. Conformably below these bright-red beds is about 800 ft. of gray and red clay, which forms lower part of memb. The Pato memb is overlain, in places uncon., by massive white ss. of the Vaqueros. Rests with marked uncon. on pre-Monterey sh. Named for exposures in Pato Canyon, Cuyama Valley.

According to W. S. W. Kew (Calif. Univ. Pub., Dept. Geol. Bull., vol. 12, pp. 1–21, 1919) the *Pato red memb.* is older than true Vaqueros and corresponds to Sespe fm., of Olig. and upper Eo. age.

Patoot beds.

A name long in use for Upper Cret. rocks in Greenland that overlie Atane beds (also Upper Cret.).

Patrician drift.

A name that has been applied to red drift of Patricia ice sheet of Wisconsin stage of Pleist. in Patricia dist., Canada.

Patrick greenstone.

Cretaceous (?): Northwestern California (Del Norte County).

J. H. Maxson, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, p. 134 and map). *Patrick greenstone.*—Fine-grained intrusive diorites and andesites containing green hornblende and sodic plagioclase with smaller amounts of sericite and pyrite. Intrudes Siskiyou granodiorite (Jurassic). Is believed to be of Cret. age. [Map shows Patrick Creek cutting across this fm.]

Patriot limestone. (In Conemaugh formation.)

Pennsylvanian: Eastern Ohio.

D. D. Condit, 1909 (Ohio Nat., vol. 9, p. 484). *Patriot ls.*—Thin, nodular, fossiliferous ls., 6 to 18 inches thick, separated from underlying Patriot coal by 3 ft. of black sh.

Probably named for Patriot, Gallia Co.

Patsy gas sand.

A subsurface sand, of Perm. age, 10± ft. thick, in central southern Okla., which is correlated with a part of Wichita fm.

Patterson limestone member (of Shady dolomite).

Lower Cambrian: Southwestern Virginia (Wythe County region).

C. Butts, 1933 (Va. Geol. Surv. Bull. 42, p. 3 and columnar section on geol. map of Appalachian Valley of Va.). Shady dol. is almost wholly dol., much like the Tomstown, but has rather more of the coarse light-gray rock (saccharoidal memb.) and in basal part considerable ls. (*Patterson ls. memb.*) that varies much in thickness and distribution. At the top in vicinity of Ivanhoe, Wythe Co., is a thick ls. (*Ivanhoe ls. memb.*).

L. W. Currier, 1935 (Va. Geol. Surv. Bull. 43). *Patterson ls. memb.*—Chiefly dark-gray dense ls. and dol., both with characteristic type of "ribbon" structure; ribbon ls. and dol. mutually gradational in all directions. At base transition beds of dark-gray sandy dol. or of light-gray crystalline dol. Thickness 700 to 800± ft. Basal memb. of Shady dol. in SW. Va. lead and zinc region. Rests conformably on Erwin qtzite. Grades into overlying saccharoidal dol. memb. of Shady dol. Named by C. Butts, for extensive exposure at Patterson, Wythe Co., where 100± ft. of it is exposed in bluff on W. side of Little Reed Island Creek.

Patterson sand.

A subsurface sand, of Upper Cret. age, in Greasewood field, Weld Co., NE. Colo. Tentatively correlated with Muddy sand of drillers.

Patton shale member (of Pocono formation).

Mississippian: Western Pennsylvania.

M. R. Campbell, 1904 (U. S. G. S. Latrobe folio, No. 110). *Patton sh. memb. of Pocono ss.*—Red or green sh., 0 to 80 ft. thick, not known in outcrop in this quad., but believed to correspond to a bed of red sh. cropping out on Redbank Creek, at Patton, near W. line of Jefferson Co. It is first bed of red material below top of Pocono ss., lying 350 to 500 ft. below top of that ss. Carries Pocono flora.

C. Butts, 1904 (U. S. G. S. Kittanning folio, No. 115), introduced *Burgoon ss.* for the massive sss. of Pocono fm. that overlie Patton sh. memb.

Patton limestone. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 450, 480). *Patton ls.*—Shaly and sandy at top, but in middle and lower portions it is hard and blue, weathering gray with occasional nodules of black chert. Scattered marine fossils; plants in middle. Thickness 100 to 275 ft. Underlies Lower Taggard sh. and overlies Patton sh.; all members of Greenbrier series [ls.]. Type loc. on S. side of Second Creek, just S. of Patton, Monroe Co. Also observed in Mercer Co., W. Va. Present in Giles Co., Va., and increases in thickness to SW. until it reaches 475 ft. in Washington Co., Va. Recognized as far N. as head of Greenbrier River, Pocahontas Co., W. Va.

Patton shale. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 450, 483). *Patton sh.*—Gray and highly calc.; abundant plants, also marine fossils; 10 to 25 ft. thick. Underlies Patton ls. and overlies Sinks Grove ls.; all members of Greenbrier series [ls.]. Named for association with Patton ls., but was not observed at type loc. of latter. Type loc. may be considered as in Monroe Co., NE. of Union, along Pickaway-Hillsdale road 0.8 mi. SE. of Pickaway, where it is 25 ft. thick and consists partly of yellow shaly ls. and partly of calc. sh. Also observed in Giles Co., Va., and as far to SW. as Washington Co., Va., where it is 180 ft. thick.

Patuxent formation. (In Potomac group.)

Lower Cretaceous: Eastern Maryland, Delaware, and Virginia.

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, pp. 156, 190). *Patuxent fm.*—Mainly sand, sometimes quite pure and gritty, but generally containing considerable kaolinized feldspar, producing a clearly defined arkose. Clay lumps in considerable numbers are scattered through the aren. beds. The sands frequently pass over gradually into sandy clays, and these into argill. materials, commonly of light color, but often highly colored and locally not unlike the variegated clays of Patapsco fm. The more aren. deposits were cross-bedded, and whole fm. gives evidence of shallow-water origin. Underlies Arundel fm. and overlies crystalline rocks of Piedmont Plateau. Named for development in upper valleys of Little and Big Patuxent Rivers.

Paulian till.

A term that has been applied to a till sheet of early Wisconsin age "having its ground moraine in central Minn. down to the vicinity of St. Paul." (See C. [R.] Keyes, Pan-Am. Geol., vol. 58, pp. 203, 217, 1932, and vol. 60, p. 55, 1933.)

Paupack sandstone. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania (Wayne and Pike Counties).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 59, 68, 169, 170, 199, 200). *Paupack ss.*—Greenish-gray or sometimes bluish-green serpentinelike rock, 25 ft.

thick, in layers 4 to 8 in. thick. Quarried extensively. Named for Paupack Falls, on Wallenpaupack Creek, Palmyra Twp, Pike Co. Underlies Montrose red sh. and overlies Paupack shales.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 94, 99–101). In Pike and Monroe Counties the *Paupack ss.* cannot be differentiated but forms a part of *Delaware River flags*, which underlie Montrose red sh. and rest on New Milford red sh. [See under *Delaware River flags*.]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 585–587), retained *Paupack ss.* for upper memb. of his Shohola fm., and replaced White's Paupack shales with *Barryville memb.*, the lower memb. of his *Shohola fm.* He stated: Paupack ss. is wholly or partly post-Chemung and—part or all of the New Milford.

Paupack shales. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania (Wayne and Pike Counties).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 68). About 200 ft. of greenish-gray current-bedded sss. interstratified with green, olive, and occasionally red shales, underlie Paupack quarry rock and spread throughout the dist. in a manner so uncharacteristic that I hesitate to propose a name for them. [In table on p. 59 he applied *Paupack shales, red and green, and ss.* to the 200 ft. of beds underlying his Paupack ss. and overlying his New Milford group.]

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 94, 99–101). [See quotation under *Delaware River flags*.]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 586). *Barryville memb. of Shohola fm.* is introduced for the 200 ft. of red and green sss. and shales underlying Paupack ss. and which White described as "so uncharacteristic that I hesitate to propose a name for them."

Pawhuska limestone. (In southern part of area **Pawhuska formation.**)

Pennsylvanian: Northeastern and central northern Oklahoma.

J. P. Smith, 1894 (Jour. Geol., vol. 2, p. 199). *Pawhuski ls.*—Massive fossiliferous ls., 100 ft. thick, in Upper Coal Measures. Overlies heavy-bedded sss. and caps hills 3 mi. NW. of Pawhuski [Osage Co.].

G. I. Adams, 1903 (U. S. G. S. Bull. 211, pp. 61–65). *Pawhuska ls.* of Smith consists of 3 distinct members. It is possible they are—Lecompton, Deer Creek, and Hartford fms.

L. C. Snider, 1911 (Okla. Geol. Surv. Bull. 7, pp. 208–226). *Pawhuski ls.*, 165 ft. thick, overlies Elgin ss. and is basal fm. of Ralston group.

K. C. Heald, 1918 (U. S. G. S. Bull. 691C). *Pawhuska ls.*—A series of ls. beds separated by sh., with some associated lenses of ss. It rests on Elgin ss., and consists of (descending): (1) Ls. ("red lime"), 7 to 10± ft.; (2) sh. with in places ss. and a thin ls., 20 ft.; (3) a succession of light-gray lss. and shales with lenses of ss., 100 to 123 ft.; (4) red sh. which probably corresponds to Tecumseh sh. of Kans.; (5) Lecompton ls. memb., 6 to 14 ft.; (6) sh. and thin red ss., 20 to 35 ft. Is overlain by a series of sss.

L. C. Snider, 1920 (Oil and gas in Midcontinent fields, pp. 78–84). *Pawhuska ls.*, 130 to 180 ft. thick, rests on Elgin ss. It consists of lss. with intervening shales and some ss. lenses. The ls. at Pawhuska is about midway of the series.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 78). *Pawhuska fm.*—Consists of 3 beds of heavy gray lss. with intervening shales; ss. and sh. constitute large part of fm. near S. end of its exposure. Thickness varies up to 180 ft. Includes all beds btw. Elgin ss. below and Buck Creek fm. above.

The top of the "red lime," or its approx. equiv. where the "red lime" is not identifiable, is top of Pawhuska fm. This div. line lies from 46 to 66 ft. below Turkey Run ls. memb. of Buck Creek fm. (See U. S. G. S. Bull. 686 (M and R), 1919.)

The town for which this fm. was named is now spelled *Pawhuska*.

Pawhuska sand.

A subsurface sand, of Penn. age, in central northern Okla. that is correlated with upper part of Cherokee sh.

Pawhuska lime.

A subsurface ls. bed, 10 to 40 ft. thick, lying in midst of Pawhuska fm. of central northern Okla.

Pawhuska series.

Pennsylvanian: Northeastern Oklahoma.

D. A. McGee and W. W. Clawson, Jr., 1932 (A. A. P. G. Bull., vol. 16, No. 10). "Pawhuska" is field name for a very prominent and persistent series of beds that occur at approx. 3,200 ft. depth in Oklahoma City oil field, NE. Okla. Overlies Hoover sand and lies 930 ft. below Neva ls. Consists of (descending): (1) Massive white to gray finely crystalline ls., 30 ft.; (2) gray bedded sh. with a 20-foot sand near top and thin ls. and ss. stringers in basal part, 110 ft.; (3) ls. like No. 1, 70 ft.; (4) gray bedded sh., 30 ft.; (5) medium- to coarse-grained angular sand with white angular chert fragments, 70 ft.; (6) ls. like No. 1, 45 ft.; (7) gray bedded sh., 60 ft.; (8) sand and chert cgl. at base.

Pawhuski limestone.

See *Pawhuska ls.*, present spelling of town in Okla. for which the ls. was named.

Pawling gneiss.

Pre-Cambrian: Southeastern New York.

T. N. Dale and L. M. Prindle, 1904 (N. Y. State Mus. 23d Ann. Rept., map; text is by F. J. H. Merrill). *Pawling gneiss (pre-Camb.)*.—[Mapped over part of Pawling Twp. Dutchess Co., but not near village of Pawling. The rept. is on Beekman and Pawling Twps of Dutchess Co. The text description, by F. J. H. Merrill, does not mention Pawling gneiss, but describes the *Precambrian gneiss* as "a great formation of banded gneiss, cut and injected at many points by later eruptives," and as extending from N. Y. City northward through Dutchess Co. and into Conn.]

Pawling limestone.

See under †*Poughquag ls.*, where is cited only record of name.

Pawnee limestone. (Distinct formation in Kansas and Oklahoma.)
Pawnee limestone member (of Henrietta formation) in Missouri.

Pennsylvanian: Northwestern Missouri, eastern Kansas, and northeastern Oklahoma.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., p. 24). *Pawnee ls.*—Heavy-bedded porous and compact coarse and fine drab, brown, and bluish-gray cherty, concretionary, and mottled fossiliferous ls., 20 to 25 ft. thick, forming bed No. 203 of geol. section of eastern Kans. and top memb. of Pawnee ls. series. Overlain by Marais des Cygnes coal series. [This is Pawnee ls. of current classification.]

The generally accepted definition treats Pawnee ls. as top memb. of Henrietta fm. in Mo., overlying Labette sh. memb. and underlying Bandera sh. memb. of Pleasanton fm. In Kans. the Henrietta is treated as a group by U. S. Geol. Survey and the Pawnee ls. as a fm. In Okla. also the Pawnee ls. is treated as a distinct fm. The Kans. Geol. Surv. has recently abandoned Henrietta fm. and now treats Pawnee ls. as a fm. in its Marmaton group. (See R. C. Moore, Kans. Geol. Surv. Bull. 22, 1936.) This changed classification has not been considered by U. S. Geol. Survey for its publications.

Named for exposures on Pawnee Creek, near village of Pawnee, Bourbon Co., Kans.

†Pawnee limestone series.

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., pp. 24–25). *Pawnee ls. series*.—Series of fossiliferous lss., sl., and shales, 112½ ft. thick, including beds 203 to 211, inclusive, of geol. section of eastern Kans. Underlies Marais des Cygnes coal series, overlies Fort Scott ls., and includes Pawnee ls. as its top memb.

Includes Pawnee ls. and Labette sh.

Probably named for its top memb., the Pawnee ls.

Pawnee limestone.

Pennsylvanian (?): Central northern Oklahoma (Pawnee County).

N. F. Drake, 1897 (Am. Phil. Soc. Proc., vol. 36, pp. 326–387). *Pawnee ls.*, 2 to 4 ft. thick, included in Perm. Separated from underlying Pawhuska ls. by 100 ft. of gray clay sh. Named for Pawnee, Pawnee Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 62). Pawnee ls. of Drake probably corresponds to Foraker ls. of present classification.

†Pawnee Creek beds.

Miocene (middle) and lower Pliocene: Northeastern Colorado.

W. D. Matthew, 1900 (Am. Mus. Nat. Hist. Bull., vol. 12, pp. 24–25). *Pawnee Creek beds* would be a better geographic name for lower horizon (*Cyclopidus* beds) of Loup Fork in Colo.

W. D. Matthew, 1901 (Am. Mus. Nat. Hist. Mem., vol. 1, pt. 7, pp. 355–374, 444). *Pawnee Creek beds.*—Upper beds are clearer and coarser sand, sometimes hardly consolidated and sometimes consisting of coarse cross-bedded gray sss.; lower beds are fine muddy sand, semiconsolidated, with sometimes one or more layers of coarse shingle; in places a shingle layer separates upper beds from lower beds. Uncon. overlies White River fm.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 114). *Pawnee Creek beds* belong to middle Mio. *Ticholeptus* zone.

H. F. Osborn 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, p. 19). *Pawnee Creek series* appears to include 2 levels. The "Upper Pawnee Creek" occurs at Sand Canyon, also at localities W. of Grover, Colo. It belongs to *Protohippus-Hipparion* zone (Lower Plio.). The typical "Pawnee Creek" is true *Meryohippus* zone (upper Middle Mio.).

Named for Pawnee Creek, Logan and Weld Counties.

Pawpaw sandy member (of Denison formation).

Lower Cretaceous (Comanche series): Northeastern Texas and central southern Oklahoma.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 302, 303, 328–335). *Pawpaw shales or clays.*—Fossiliferous light-drab, very thinly laminated clays, inseparable from Quarry ls. (in top of underlying North Denison sands). Overlain by Main Street ls. [broad sense], top memb. of Denison beds.

R. T. Hill, 1901. (See under *Weno clay memb.*)

The so-called "Quarry ls." mentioned above is treated by U. S. Geol. Survey as basal bed of Pawpaw memb., which rests on Weno clay memb. and is overlain by Main Street ls. memb. of the Denison. (See L. W. Stephenson, U. S. G. S. P. P. 120H, 1918.) This is definition followed by Tex. Geol. Surv. (See Univ. Tex. Bull. 3232, 1933, p. 375.)

Named for Pawpaw Creek, in southern and eastern part of Denison, Grayson Co., Tex.

Pawtucket shale.

Pennsylvanian: Eastern Rhode Island (Providence County).

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 159–164). *Pawtucket shales.*—Chiefly coal-bearing shales exposed in several troughs [described] about Providence. Thickness of beds here included under this term (if we place here all soft beds in the troughs described) cannot be safely stated but may reach 3,500 ft. Well exposed in banks of Blackstone River on Division St., Pawtucket, and at Valley Falls. Underlie Sockanosset sss. Both Pawtucket shales and Sockanosset sss. belong to Cranston beds, the basal div. of Rhode Island Coal Measures.

Is a part of Rhode Island fm.

†Pawtucket formation.

Pennsylvanian: Eastern Rhode Island.

C. H. Warren and S. Powers, 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 439–475). *Pawtucket fm.*—Name introduced to replace "Coal Measures" of Woodworth. Largely sss. and shales with some cgls. Underlies Dighton group and overlies Wamsutta fm.

Named for Pawtucket, R. I.

Replaced by *Rhode Island fm.* (See U. S. G. S. Bull. 597, 1917, p. 54.)

Paxton quartz schist.

Carboniferous: Central Massachusetts, northern Connecticut, and central southern New Hampshire.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). [*Paxton whetstone schist* appears in Worcester County column of strat. table.]

B. K. Emerson and J. H. Perry, 1903 (Geol. of Worcester, with map). *Paxton schist.*—Quartzose mica schist of brownish-gray color and frequently containing alternating lighter bands of greenish color. Because of abundance of this mixture of mica and hornblende schists in the ledges of Paxton the mixture may be called *Paxton schist.* The Paxton schist and Bolton gneiss are equiv., or simply parts of one extensive fm.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 60–62, 86–87, 234, and map). *Paxton quartz schist.*—A chocolate-colored, highly micaceous whetstone, which contains small green hornblendic lenses, also small beds of mica schist and ls. It is distinctly qtzitic and some of it is highly graphitic. To W. is divided into Quabin qtzite and Ewing hornblende schist. To E. grades into Oakdale qtzite. Considered to be older than Brimfield schist. Named for development at Paxton, NW. of Worcester, Mass.

E. Callaghan, 1931 (N. Y. Acad. Sci. Annals, vol. 33, pp. 29, 63, 64, 67, 73, 74). *Paxton schist* redefined and given significance as a fm. rather than a rock type. Retained for the 2 thick members of feldspathic biotite schist and the thin middle memb., which in its easternmost exposure in Wachusett-Coldbrook tunnel is largely feldspathic but which is mainly biotite schist to W. Thicknesses: Upper feldspathic biotite schist to E., 1,300 ft., to W., 275 ft.; middle memb., 400 ft. to E., 175 ft. to W.; lower feldspathic biotite schist, 450 to 1,600 ft. Overlies Ware schist; underlies Brimfield schist as here restricted and redefined.

The U. S. Geol. Survey has not yet had occasion to consider, for its publications, Callaghan's redefinition.

Payette formation.

Miocene: Southeastern Oregon and western Idaho.

W. Lindgren, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 632–634). During earlier part of Neocene (Mio.) a large fresh-water lake occupied at least lower part of Snake River Valley, and its sediments are now prominent features of region. For these lake beds *Payette fm.* is proposed, and their age is determined as upper Mio. This fm. is probably not same as Cope's *Idaho fm.*, to which a Plio. age was assigned and which appears to be connected with later basalt flows. (Footnote: From results of more extended surveys during summer of 1897, it has become evident that the Payette and Idaho fms. represent two successive stages of the lake, the often deformed shore line of former being found at elevations of 4,200 to 5,000 ft., and those of latter at max. elev. of 3,000 ft. To separate the deposits of the two fms. is not always easy.) The extent of the fm. is shown in pl. 57, from which it is seen that it lies in front of Boise Mtns and occupies whole lower part of ridge btw. the Boise and the Payette. It extends over large areas to N. of the Payette, along the flood plains of Snake River, and is seen to occupy vast areas in Oreg. btw. mouth of Owyhee River and Weiser, where Snake River Canyon begins. On both sides of lower Snake River the bluffs of Payette fm. attain height of over 800 ft. In Payette Valley S. of Emmett the sharply defined bluff of Payette beds rises 600 ft. above the alluvium. Smaller masses, detached by erosion, or uplifts, lie in intermontane valleys as far E. as Idaho Basin. Along Boise Mtns the Payette beds rest against the irregularly eroded and sharply sloping surface of the granite, and top stratum attains height of 4,100 ft. A total thickness of 1,000 ft. is exposed near Boise, and wells bored show several hundred ft. of similar strata below the surface. Over larger part of its extent the fm. lies nearly horizontal or dips only a few degrees. The sediments consist chiefly of granitic light-colored sands, locally cemented by hot-spring deposits to hard sss. (as at Table Mtn near Boise) or clayey semiconsolidated sss. Heavy masses of cgls. and gravels begin to appear at Table Mtn and reach their greatest development opposite mouth of Boise River, in high ridge extending westerly. Purely clayey deposits are rarer, occurring only in convenient sheltered locations near the shore line or in places where volcanic eruptions took place. In basal part of fm., at Horseshoe Bend, Jerusalem, and other localities along the Payette, are small coal seams. Fm. rests uncon. on granite. F. H. Knowlton identifies the fossil plants from it as upper Mio. During time of max. extension of Payette Lake its surface stood at present elev. of 4,200 ft. Its deposits, over 1,000 ft. thick near the shore, rested against abrupt slope of Boise Mtns and filled old canyon of the Boise to same depth. The canyon must have formed a fiord, the branches of which reached as far back as Idaho Basin. The data are not at present sufficient to determine extent of Payette Lake, though it is probable it was confined to Snake River Valley, enclosed on W. by Blue Mtns and on E. by divide toward Salmon River. Near base of Payette fm. sheets of rhyolite and rhyolite tuff occur, but this eruption was of limited extent. These flows are contemp. with the lake beds and are interbedded with them. After attaining its highest stage Payette Lake was drained by establishment of present course of Snake River below Weiser. The lake receded as the canyon was rapidly cut by the mighty volume of water, and erosion has steadily proceeded since end of Mio. or beginning of Plio. The broad valleys of the Boise, the Payette, and the lower Snake were eroded in the soft lake beds. A new course was established for Payette River, which evidently did not debouch at its present position before Payette epoch. The Boise River, on contrary, maintained its old course. The accumulated gravels were scoured out from its canyon, and before the Plio. basaltic eruptions its channel in the canyon was deepened nearly to its present level. There was, however, at least one temporary check in this process of draining. For considerable interval of time the lake remained stationary at present elev. of 2,800 to 3,000 ft. The deposits and basalt flows of this epoch are regarded as late Neocene (Plio.) and belong to *Idaho fm. of Cope.*

F. H. Knowlton, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, p. 736), assigned fossil plants of Payette fm. to upper Mio.

W. Lindgren, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 93–94, 97–98). The highest (Mio.) stage of the lake near Boise reached elev. of 4,200 ft., while the lower (Plio.) stage is indicated by terrace of shore gravels at 3,000 ft. The beds deposited by the lake at its high stage were named *Payette fm.* in U. S. G. S. 18th Ann. Rept., pt. 3, pp. 632, 665, et seq.), while for the lower beds the name *Idaho fm.*, proposed by Cope, was retained, as all fossils studied by him were evidently found in this division. Near Prospect Peak, 20 mi. NW. of Boise, the upper lake beds reach elev. of 4,600 ft. North of Emmett, on the Payette, the lower stage is indicated by shore gravels at elevations of 2,800 ft. It is clear that a certain amount of post-Mio. deformation has taken place, and position of the old shore lines, whenever determinable within reasonable limits of error, will measure the relative amount of this deformation. Naturally the upper line is easier to determine than the lower stage, the latter being carved in soft lake beds and disintegrating gravels. As a consequence of this, the distinction btw. the older and younger lake beds, or in other words, btw. Payette (Mio.) and Idaho (Plio.) fms., is often difficult. It is rarely possible to draw exact contact lines, and the two fms. have been indicated on map by one color. The younger beds were laid down nearly conformably on the older, and in fact largely consist of their detritus.

I. C. Russell, 1902 (U. S. G. S. Bull. 199), mapped Tert. lake beds over broad area in SW. Idaho, extending from N. of Weiser SE. through Canyon, Ada, SW. Elmore, northern Owyhee, and western Lincoln Counties, to within 20 mi. of Shoshone Falls.

J. C. Merriam, 1917 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 10, No. 22, pp. 431–443). Idaho fm. is not yet satisfactorily separated from Payette (Eo. or Mio.) and from *a Mio. or Plio. stage which may intervene btw. the Payette and the Idaho.* The Idaho is either latest Plio. or earliest Pleist.

J. P. Buwalda, 1923 (Idaho Bur. Mines and Geol. Pam. 5). Payette fm. in Snake River Valley of SW. Idaho is overlain by 1,000 ft. of rhyolite flows. These rhyolite flows are immediately overlain by *Poison Creek fm.*, of lower Plio. or later age. The mammals of Idaho fm. (which lies in middle and flatter part of the valley) indicate Pleist. age. The Idaho fm. is generally made up of cream-tinted silt and volcanic ash, and rests uncon. on underlying fms. [Idaho fm. as used in previous repts included all Plio. beds overlying Payette fm. (Mio.), from which it was "separated with difficulty."]

V. R. D. Kirkham, 1931 (Jour. Geol., vol. 39, No. 3, pp. 198–201, 235–239). [See 1931 entry under *Idaho fm.*]

Whether Payette fm. is upper, middle, or lower Mio. is still a debated question among paleontologists. The Idaho fm. is Plio. and Pleist.

Payne sandstone.

Permian: Central Oklahoma.

C. T. Kirk, 1904 (Okla. Dept. Geol. and Nat. Hist. 3d Bien. Rept., pp. 9–11). *Payne ss.*—Ledge of red ferruginous ss., which in Payne Co. and to S. replaces and is a continuation of Wreford ls. Roughly nodular in places, in other places smoothly bedded. In many places known as "iron rock," from its red and almost vitrified appearance, due to ferric oxide. Thickness 10 to 30 ft. Basal fm. of Perm. in Okla.

C. N. Gould, 1927 (Obsolete Okla. names: Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 6, pt. 2, p. 235). *Payne ss.* proposed by Kirk for ss. assumed to represent Penn.-Perm. contact in Okla. red beds. The name never came into popular use.

Named for Payne Co.

Payne Branch sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 352). *Payne Branch ss.*—Usually greenish gray or reddish brown and shaly, 20 to 35 ft. thick. Underlies Lower Avis sh. and overlies Payne Branch sh.; all members of Hinton group [fm.]. Type loc. on N. side of Payne Branch of Fivemile Creek 0.8 mile SW. of Caperton School and 2.2 mi. N. of Hatcher, Mercer Co. Also observed in Summers Co.

Payne Branch shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 353). *Payne Branch sh.*—Red and variegated, 15 to 20 ft. thick. Underlies Payne Branch ss. and overlies Hackett ss.; all members of Hinton group [fm.]. Type loc. same as Payne Branch ss. Also observed in Summers Co.

Paynes Creek basalt.

Late Pleistocene or Recent: Northern California (Chico quadrangle).

H. Hamlin, 1921 (Dept. Int., U. S. Reclamation Service in cooperation with State of Calif. and Iron Canyon Project Association, App. 1, pp. 47, 50, 58, pl. 2). *Paynes Creek basalt.*—A very porous fm. of basaltic lava, few ft. thick at edges of flow to 70 ft. thick in old valley of Paynes Creek. It flowed down old valley of Paynes Creek, completely filling it, and also filling Iron Canyon for at least 1 or 2 mi. and possibly much farther. Paynes Creek has since cut a new canyon through the basalt and underlying fms. down to and nearly through aggl. No. 1. The basalt is underlain by old stream gravels, which rest on upper tuff, which in turn rests on aggl. No. 1.

C. A. Anderson, 1933 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 23, No. 7, pp. 240, 243, 245). *Paynes Creek basalt* followed present course of Paynes Creek to Sacramento River, possibly filling Iron Canyon for short distance. Since then all traces have been removed from Iron Canyon. Paynes Creek was displaced by the lava, and has since cut a new canyon through the basalt and into underlying Tuscan fm. for depth of 50 ft. This flow is much later in age than Red Bluff fm. and many of the other basalt flows of region. It may be very late Pleist. to Recent.

†Peabody granite.

Devonian or Carboniferous: Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.), applied *Peabody granite* to granite which he in 1921 (U. S. G. S. Bull. 704) included in Quincy granite, as did B. K. Emerson in 1917 (U. S. G. S. Bull. 597). The Quincy granite covers a large part of Peabody Twp, Essex Co., where it is quarried under name "Peabody granite."

†Peaceable sand.

See under *Gerty sand.*

Named for exposures along Peaceable Creek, Pittsburg Co., Okla.

†Peace Creek beds.

Pliocene (lower): Southern Florida.

W. H. Dall, 1891 (Phila. Acad. Nat. Sci. Proc. for 1891, p. 120). *Peace Creek beds.*—Have been exploring Peace Creek, where the fossil bones are found, and have determined strat. relation of beds they come from. They are under marine Plio. beds corresponding to part of Caloosahatchee beds and overlie or are mixed with older Plio. phosphatized rock which has many of the Caloosahatchee shells in it but which on the whole seems rather older. The bones from Peace Creek, which are derived from one original stratum not over 2 ft. thick, are older Plio. beyond question.

A local facies of Alachua fm. (See G. C. Matson and F. G. Clapp, Fla. Geol. Surv. 2d Ann. Rept., p. 133, 1909.)

Named for exposures on Peace Creek, De Soto Co.

Peace River sandstone.

Cretaceous: Alberta.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 216). [Assigned to Cret. or Tert., but all later Canada Geol. Surv. repts assign it to Cret., and Allan and Rutherford, Alberta Research Coun. Rept. 30, 1934, p. 14, assign it to Lower Cret.]

Peach Bottom slate.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania and western Maryland.

J. P. Lesley and P. Frazer, Jr., 1880 (2d Pa. Geol. Surv. Rept. C_5, map of Lancaster Co.). *Peach Bottom roofing sl.* [Shown as older than Chikis [Chickies] qtzite and younger than chlorite schist.]

J. P. Lesley, 1885 (2d Pa. Geol. Surv. Rept. X, map 35), mapped *Peach Bottom roofing sl.* in Lancaster Co., Pa., as overlying chlorite schist and underlying Chikis qtzite.

E. B. Mathews, 1904 (Am. Jour. Sci., 4th, vol. 17, p. 143), showed *Peach Bottom slates* overlying Cardiff quartz cgl.

W. B. Clark, 1904 (Md. Geol. Surv. map of Harford Co., Md.) *Peach Bottom.*—Blue-black roofing slates, bedding obscured by cleavage. Thickness 1,000 ft. Overlie Cardiff.

E. B. Knopf and A. I. Jonas, 1922 (Am. Jour. Sci., 5th, vol. 5, pp. 45–49, 61–62). *Peach Bottom sl.* is top fm. of Glenarm series, and overlies Cardiff cgl.

Named for exposures at Peach Bottom, York Co., Pa.

The Glenarm series was formerly classified by U. S. Geol. Survey as "Algonkian," but, that term having been discarded as a time term, the Glenarm is now classified as *pre-Camb.*

Peach Lake diorite.

Age(?): Eastern New York (Dutchess County).

R. Balk, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 5, pl. 1, etc.).

Peach Orchard sandstone. (In Pottsville formation.)

Pennsylvanian: Northeastern Kentucky (Morgan County).

L. C. Robinson, 1927 (Ky. Geol. Surv., ser. 6, vol. 26, p. 239). *Peach Orchard ss.*, a cliff-forming ss. memb. of Pottsville series of Morgan Co. that is well developed where the "Fossil Lime" is found. Is rather dense and fine grained ss. overlying the "Fossil Lime." Lies lower in Pottsville than Homewood ss. [Type loc. not stated.]

Peacock formation. (Of Double Mountain group.)

Permian: Central northern Texas (Stonewall and adjacent counties).

L. T. Patton, 1930 (Univ. Tex. Bull. 3027, p. 45). *Peacock fm.*—The part of Double Mtn group lying above Blaine fm. and below Triassic. Named for exposures at town of Peacock, in W. part of Stonewall Co. A prominent gyp. memb. (Swenson gyp. memb.) is taken as base of fm. The Peacock consists almost entirely of brick-red sandy sh., argill. fine-grained friable sss., a few gyp. beds, and very few thin and nonpersistent beds of dol. Some gray and blue shales and sss. occur. About 100 ft. above Swenson gyp. occurs Oriana gyp. memb. With exception of these two gyp. members there are no other prominent gyp. beds in Peacock fm. Upper fourth of fm. has been eroded away all over county except in SW. part, where it is protected from erosion by overlying Triassic and Cret. Thickness 700 to 850 ft., the upper 300 ft. of which has been removed by erosion over most of county. [Some geologists apply name *Blaine fm.* to all beds below Whitehorse ss. (which overlies Dog Creek sh.) and above Chickasha fm.]

N. H. Darton, 1932 (unpublished statement). The division btw. Dog Creek sh. and Peacock fm. is at top of the Dog Creek, which intergrades with the Blaine, and the two cannot be separated. [This definition is the one adopted by U. S. G. S. See 1937 geol. map of Tex.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). Swenson gyp. of Patton is apparently same as Childress dol. and gyp. memb. of Blaine fm. and is discarded.

Peacock sand.

Local name for 1,400-foot sand (in Shawnee group, Penn.) of Cowley Co., Kans.

Peale formation.

Mississippian: Northern California (Taylorsville region).

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Peale fm.*—Of variable character. Reddish to brown slaty sh., sometimes gray or greenish, passing into tuffaceous ss. and fine cgl., is most common. The fine cgl. contains much volcanic material, with occasional red lapilli and small lenses of calc. matter. Thin beds of gray qtzite also occur, and masses of black, gray, or red chert form prominent ledges. The tuffaceous beds are well exposed and fossiliferous on horse trail from Wards Creek to Peale diggings, also beyond Hosselkus and to within about a mile of Lucky S road. The chert is best exposed near forks of road just E. of Hosselkus, where there is a prominent ledge of red-banded chert full of quartz veins, but no considerable amount of hematite with it, as on Houghs Peak. Red siliceous sl. and chert occur near summit along trail from Wards Creek to Peale diggings, as well as in divide at head of Hinchman Ravine. [Fossils listed.] The fm. is almost completely surrounded by igneous rocks, meta-andesites, and is in part made up of pyroclastic material of same sort. It evidently represents an epoch of volcanic activity, although the immediately enveloping rock may be in large part intrusive. Thickness 1,400 ft. Is overlain by Reeve meta-andesite. Is older than Robinson fm. and younger than Shoofly fm.

Pearisburg limestone.

Lower and Middle (?) Ordovician: Southwestern Virginia.

R. S. Bassler, 1907 (Min. res. of Va., by T. L. Watson, pp. 137–138, 144, 148). *Pearisburg ls.*—At Pearisburg, [Giles Co.,] Va., consists of (descending): (1) Light-gray compact ls. with gastropods abundant in lower beds and Ostracoda in upper part, 60 ft.; (2) fine-grained dove ls., 20 ft.; (3) embedded mag. ls., 25 ft.; (4) light- to dark-gray, moderately fine-grained ls. in lower part and massive cherty beds in upper div., 65 ft.; (5) dark bluish-gray ls., subcrystalline or earthy in upper part and slightly cherty in lower beds, with a *Girvanella* very abundant, 50 ft.; (6) dark-gray, mottled massive fossiliferous ls. leaving a deep-red chert upon weathering, 250 ft. Underlies Moccasin ls. and overlies Knox dol.

R. S. Bassler, 1909 (Va. Geol. Surv. Bull. 2A, p. 171). In northern part of SW. Va., in place of the marbles and thin-bedded lss. of the Holston, heavily bedded gray and dark-blue ls. is found, the exact equivalency of which has not been determined, and in "Min. res. of Va." the provisional new name *Pearisburg ls.* was employed. It is a ms. name of M. R. Campbell several years ago.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). *Pearisburg ls.* occurs in Pearisburg trough. Largely contemp. with Heiskell sh. Underlies Moccasin ls. Uncon. overlies Holston ls. Is of late Chazyan (post-Stones River) age.

†Pearl shale. (In Sumner group.)

Permian: Eastern Kansas and southeastern Nebraska.

J. W. Beede, 1909 (Kans. Acad. Sci. Trans., vol. 21, pt. 2, p. 255). *Pearl shales.*—Succession of red, blue, and green shales, 70 ft. thick, overlying Herington ls. and underlying Abilene cgl. All included in Marion stage.

In 1927 the beds previously called "Pearl sh. memb. of Marion fm." were transferred to overlying Wellington fm., because of difficulty of separating them from the Wellington, and Pearl sh. memb. was abandoned by both Kans. Geol. Survey and U. S. Geol. Survey. (See under *Wellington fm.*, N. W. Bass, 1929.) However, the 1932 revised classification of Perm. rocks of Kans. and Nebr. by R. C. Moore and G. E. Condra excluded Pearl sh. from Wellington and treated it as a distinct fm., as did

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12). Moore also restricted *Wellington sh.* to upper part of the Wellington of prior usage and applied new name *Donegal ls.* (divided into 3 members) to the beds overlying Pearl sh. (also restricted) and underlying his restricted Wellington fm.

See Kans.-Nebr. Perm. chart compiled by M. G. Wilmarth, 1936.

Named for exposures at Pearl, Dickinson Co., Kans.

Pearlette ash.

Pleistocene: Southwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 53, 54). *Pearlette ash.*—Widespread horizon of white to brownish, rarely greenish, volcanic ash, 13 ft. thick, underlying Kingsdown marls and overlying Meade gravels. Supposed to be late Plio. and to belong to Tule div. of Cummins (*Equus* beds of Cope). Named for old post office of Pearlette, Meade Co.

E. Haworth, 1897 (Univ. Geol. Surv. Kans. vol. 2). As it is yet open question regarding true nature of material of Pearlette ash of Cragin, and much more so regarding its mode of deposition, it is hardly desirable to draw many conclusions from their supposed origin, and it is less desirable to group the little isolated patches together and assign them to a geologic terrane including nothing else.

Pearl Harbor series.

Pliocene: Hawaiian Islands.

C. H. Hitchcock, 1912 (Geol. Soc. Am. Bull., vol. 23, p. 71).

Pearl River series.

Pliocene: Hawaiian Islands.

C. H. Hitchcock, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 31–34).

Peay sandstone member (of Frontier formation).

Upper Cretaceous: Northern Wyoming (Bighorn County) and southern Montana (Carbon, Bighorn, Stillwater, and Yellowstone Counties).

F. F. Hintze, Jr., 1915 (Wyo. State Geol. Bull. 10, p. 21). *Peay ss.*—Light-gray and light-brown ss., with large sandy concretions in central part and conglomeratic layer at top, but no interbedded cgls. Thickness 150 to 200 ft. Is *ss. A* of Washburne. Separated from overlying Torchlight ss. (top bed of Benton) by 350 to 400 ft. of Upper Benton sh. (consisting of black adobe sh. and sandy sh. with bentonite, and, at base, a thin bed of rather fine cgl.), with which it is discon. Rests conformably on Lower Benton sh., which contains Mowry sh. near top.

C. T. Lupton, Jan. 21, 1916 (U. S. G. S. Bull. 621, pp. 167, 169, 171, etc.), treated *Peay ss.* as a *memb.* of Frontier fm.; stated that it is 45 ft. thick in Basin oil field, where it lies 292 ft. below Torchlight ss. memb. and 138 ft. above Mowry sh.

Named for Peay Hills, Bighorn Co., Wyo.

Peay sand.

Drillers' name for subsurface sands lying at or near horizon of Peay ss. memb. of Frontier fm.

Pecan Gap chalk member (of Taylor marl).

Upper Cretaceous: Northeastern Texas and (?) southeastern Oklahoma (McCurtain County).

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120H, p. 156). *Pecan Gap chalk memb. of Taylor marl.*—About 50 ft. of bluish-gray, slightly bituminous, more or less argill. and sandy chalk, weathering light gray and white. Lower 10 ft. is typically exposed in a cut of Gulf, Colorado and Santa Fe Ry ½ mi. E. of Pecan Gap, Delta Co. Rests on Wolfe City sand memb.

C. W. Honess, 1927 (Okla. Geol. Surv. Bull. 40R). *Pecan Gap chalk* and associated shales and sands are at present concealed, but undoubtedly are present across southern tip of McCurtain Co., Okla.

C. H. Dane and L. W. Stephenson, 1928 (A. A. P. G. Bull., vol. 12, pp. 41–58), changed name to *Pecan Gap tongue of Annona chalk,* and defined it as resting on Wolfe City sand memb. of Taylor marl.

L. W. Stephenson, 1929 (A. A. P. G. Bull., vol. 13, p. 1330). *Pecan Gap tongue of Annona chalk* in NE. Tex. is separated, both from Wolfe City sand memb. of Taylor marl below and from typical Taylor marl above, by unconformities, marked everywhere by phosphatic nodules and casts of fossils.

The name of this unit now in use by U. S. Geol. Survey is *Pecan Gap chalk memb. of Taylor marl.*

Pecatonica dolomite member.

Middle Ordovician (Black River): Northwestern Illinois, southern Wisconsin, northeastern Iowa, and southeastern Minnesota.

O. H. Hershey, 1894 (Am. Geol., vol. 14, p. 175). The *Buff ls.* underlies a narrow strip skirting St. Peter ss. of NW. Ill. on S. and W. sides. It is moderately thick bedded buff or light-brown dol., argill., and nearly free from fossils. Thickness 20 ± ft.; thins out to NE. Grades into overlying Blue ls. and down into St. Peter ss. Designation *Buff ls.* is deceptive, for under cover it is as frequently blue as the Trenton above it. Perhaps *Pecatonica ls.* would be more appropriate, as it is best exposed in Pecatonica Valley, near Wis. line, and northward.

O. H. Hershey, 1896 (Am. Geol., vol. 18, p. 72), used, in table, *Pecatonica ls., 40 ft. thick,* beneath Trenton ls. and above St. Peter ss.

See also O. H. Hershey, 1897, Am. Geol., vol. 20, pp. 66–67.

This name appears not to have been again used until revived by A. C. Trowbridge et al., 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., figs. 1, 2, pp. 64, 70, 71), who divided their expanded *Platteville ls.* near Dubuque and at other places in Iowa into (descending) Spechts Ferry sh. memb., McGregor ls. memb., *Pecatonica dol. memb.* (*"Lower Buff"*), and Glenwood sh. memb. Thickness of *Pecatonica memb.* 16 ft. at Guttenberg and McGregor, Iowa; 30 ft. near Dubuque, Iowa; absent in southern Minn. On p. 286 of this Conf. Rept. G. M. Kay described *Pecatonica or Lower Buff memb. of Platteville fm.* as composed of heavy ledges, up to 7 ft. thick, of rather dense blue, buff-weathering mag. ls. or dol., which in northern Ill., SW. Wis., and NE. Iowa succeed Glenwood memb. of Platteville fm. and underlie McGregor memb. of the Platteville. From max. of 30± ft. in northern Ill., it thins to 15 ft. in Winnebago Co., Ill., and is absent at Preston, Minn. On p. 286 he gave thickness of *Pecatonica* (*"Lower Buff"*) *memb.* near Platteville, Wis., as 21 ft. 8 in. Kay also stated that Pecatonica ls. of Hershey is Lower Buff ls., and that it was named for Pecatonica River, Winnebago Co., Ill. On p. 297 of this Conf. Rept. C. A. Bays and G. O. Raasch stated: Writers are opposed to use of *Pecatonica* for *Lower Buff.* As originally proposed Pecatonica included Glenwood horizon and had no specific type loc. It seems preferable that a new term with a specific description and no confusing antecedents be introduced for this memb. [but they do not propose a substitute].

Pecatonica till.

A term applied by C. [R.] Keyes to a pre-Wisconsin till sheet in Ill. (See Pan-Am. Geol., vol. 58, pp. 203, 217, 1932.)

Pecksport member.

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 134, 219, etc.). *Pecksport memb. of Marcellus fm.*—The hard resistant Solsville memb. of Marcellus is succeeded by Pecksport memb., consisting of soft aren. sh. that crumbles to small fragments when exposed. In Morrisville quad. this bed is characterized by *Leiorhynchus laura* in association with many typical Hamilton fossils. Type section is in Livermore Gully, 1 mi. E. of railroad switch at Pecksport, where it is 153 ft. thick. Eastward the memb. thins to 90 ft. at Button Falls, S. of Leonardsville. At this place it is a coarse sandy sh. abounding in typical Hamilton pelecypods, especially *Grammysia alveata.* Grades into overlying Mottville memb. of Skaneateles sh. The Peckport can be identified to W. of type section only as far as Pine Woods. It is thus coextensive with the Solsville. To W. of Pine Woods it grades laterally into fine aren. shales characterized by *Leiorhynchus laura*, forming upper part of Cardiff sh. and not divisible from it.

Pecos shale.

Permian (?): New Mexico.

C. R. Keyes, 1909. [See under *Cimarronian series*. Derivation of name not given.]

†Pecos formation.

Permian: Southeastern New Mexico (Roswell artesian basin).

A. G. Fiedler and S. S. Nye, 1933 (U. S. G. S. W. S. P. 639). *Pecos fm.*—A lithologic unit consisting chiefly of red beds, gyp., anhydrite, impure ls., light-colored fine sand, and intercalated thin beds of mag. or dolomitic ls. and dol. Uncon. underlies the Triassic E. of Pecos River and overlies Picacho ls., with uncon. locally. Base of fm. varies considerably in strat. position, being lower N. of Salt Creek and notably higher a few mi. S. of mouth of Seven Rivers than it is within the artesian basin. Near top, in Seven Rivers region, it is penetrated laterally by Carlsbad ls. tongue of Capitan ls., which is underlain by Seven Rivers tongue of Pecos fm., which to S. becomes replaced laterally by Capitan ls. Upper part of Pecos fm. has been eroded away W. of Pecos River, but lower part extends a few mi. W. of river. Thickness of fm. 1,066 ft. in one section. Named for exposures E. of Pecos River. The strata constituting the Pecos fm. are represented on Darton's 1928 geol. map of N. Mex. as *Chupadera fm.* N. of Lake McMillan and as Castile fm. SE. of Lake McMillan. The beds here named *Picacho ls.* are believed by geologists working in this region to be strat. equiv. of San Andres ls. of Lee and Girty, and have been referred to by that name for years.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Pecos fm.* abandoned, being here divided into (descending): Pierce Canyon red beds, Rustler fm., Salado halite, Castile anhydrite (thin lateral extension of upper part of Castile anhydrite of Delaware Basin), and Chalk Bluff fm. Latter fm. includes equivalents of (descending) Seven Rivers gypsiferous memb., Queen ss. memb. and underlying beds that are=Dog Canyon ls. Picacho ls. is here abandoned for San Andres ls. The Pierce Canyon redbeds are now classified as Triassic.

Pecos Canyon sandstone.

Permian: Northeastern New Mexico (Santa Rosa to Tucumcari).

J. K. Knox, 1920 (A. A. P. G. Bull., vol. 4, pp. 99–101). *Pecos Canyon ss.*—A massive ss. that divides the red beds, which overlie Magdalena group into two groups—the *upper "Red Beds"* and the *lower "Red Beds"*—in Santa Rosa-Tucumcari region.

Pecosan series.

Pecosian series.

Terms introduced by C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 14, pp. 223–228, 1907) to cover his late Tert. *Llano Estacado sands* along Rio Pecos of western Tex. and eastern N. Mex. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 10. "Includes essentially all of the Plio. section of the Llano Estacado region.")

†Pecos Valley red beds.

Permian and Triassic: Southeastern New Mexico.

J. W. Beede, 1910 (Am. Jour. Sci., 4th, vol. 30, pp. 131+). *Pecos Valley red beds.*—Thin lss. and covered slopes apparently composed of soft sss. or clays. Overlies Guadalupian series in Carlsbad region.

C. L. Baker, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 99–126). The *Pecos Valley red beds* outcrop along foot of E. flank of Sacramento Mtns and underlie alluvium in lower Pecos Valley. The N. limit of outcrop is not known at present. They extend S. into Toyah Basin, Tex., and E. under Llano Estacado. Near E. base of Guadalupe Mtns the Capitan ls. changes along the strike into *Pecos Valley red beds*. The transition is well seen in walls of Rocky-Arroyo, 20 mi. W. of Carlsbad. On E. flank of Sacramento Mtns and N. flank of Guadalupe Mtns the Pecos Valley red beds lie on San Andres ls.

Includes †Pecos fm. (Perm.) and overlying Triassic red beds.

Pecursian series.

Picursian series.

Terms introduced by C. [R.] Keyes to cover upper part of old pre-Camb. rocks in N. Mex. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 10.)

Pedee group.

Peedee group.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 97). *Peedee group.*—Sh. and thin ls. up to 100 ft. or more thick locally, that overlie Stanton ls. and underlie pre-Virgil uncon. Includes (descending) Hardesty sh., Iatan ls., and Weston sh. The Weston and Iatan are defined as previously. The sh. overlying the Iatan and occurring beneath the uncon. is designated *Hardesty sh.*, from a locality in Smithville quad., Mo. In some places, as along Kansas River, no representative of Peedee group remains, and basal ss. and cgl. of Virgil series rests directly on Stanton ls.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 79). For the dominantly shaly strata btw. Stanton ls. and base of overlying Virgil series Moore is introducing *Pedee*, from stream near Weston, opp. Leavenworth, on Missouri River. [In letter dated Sept. 3, 1935, Newell stated this *creek* is spelled *Pedee* (not Peedee).]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 137–138). The strata btw. top of Stanton ls. and discon. that defines top of Missouri series are included in Pedee group. These beds were formerly included in Douglas group, but it is clear they should be separated from the rocks that discon. overlie them. The Pedee beds are designated a separate group, rather than an addition to Lansing group, because latter beds are a well-characterized compact strat. unit consisting mainly of ls., and because the conformable upper bdy of Lansing group, as previously drawn and here accepted, is a more usable strat. datum in mapping and in subsurface studies than the uneven surface of the post-Missouri discon. The Pedee group contains 2 fms., Weston sh. below and Iatan ls. above. It is probable that in some places where Iatan ls. is present there is a certain thickness of sh. above the Iatan that belongs below the post-Missouri discon. and therefore should be included in Pedee group. Such conditions may exist along Missouri River in vicinity of Iatan and Weston, where part of the poorly bedded sandy and clayey beds btw. top of Iatan ls. and base of Sibley coal possibly belong to Missouri series. Evidence of exact position of bdy btw. Missouri and Virgil deposits is lacking here, but inasmuch as thickness of zone in which bdy belongs is only 5 to 20 ft., this uncertainty is not of great importance. In any case the bdy at top of Iatan ls. is practically the most useful, and accordingly Pedee group is regarded as including no beds above Iatan ls. The term *Hardesty sh.* is therefore abandoned. It was not properly defined. Thickness of Pedee group 100± ft. SE. of St. Joseph, Mo.; it has been removed by erosion throughout much of Platte Co., Mo., and in Kansas River Valley; in southern Kans. it is 200 ft. thick in places; is well represented in east-central and SE. Kans.

Pedro bentonite bed. (In Pierre shale.)

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Pedro bentonite bed.*—Hard white massive clay and tuff, locally 20 ft. thick, but not widespread. Lies at base of Gammon ferruginous memb., the basal memb. of Pierre sh. in NE. Wyo. and SE. Mont. Named for exposures near Pedro, sec. 5, T. 45 N., R. 63 W., Weston Co., Wyo.

Pedroian.

A time term used by J. E. Eaton (A. A. P. G. Bull., vol. 12, p. 138, 1928) to cover San Pedro fm. as restricted by him (to basal part of original San Pedro) and his overlying Hall Canyon fm., or to all of lower Pleist.

Peebles dolomite.

Silurian (Niagaran): Southwestern Ohio (Adams and Highland Counties).

A. F. Foerste, 1929 (Ohio Jour. Sci., vol. 29, No. 4, pp. 168–169). *Peebles dol.* of Highland and Adams Counties is=Guelph of Canada, and therefore belongs above the Cedarville of Springfield area, which is=Racine of Wis., the Racine being directly under the Guelph in that State.

A. F. Foerste, 1931 (Ky. Geol. Surv. ser. 6, vol. 36, p. 191). *Peebles fm.* is typically exposed at Peebles, Ohio, where it includes the part of the Niagaran which intervenes btw. top of the Bisher W. of town and base of the Greenfield 2 or 3 mi. eastward. At Hillsboro the Lilley fm. intervenes btw. the Bisher and the Peebles. Fossils listed. Fauna is Guelph. Peebles fm. can be traced S. as far as Ohio River, in Adams Co., where characteristic Guelph fossils occur on the hills facing the river. Not exposed S. of Lewis Co.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 134), stated *Peebles dol.* underlies Greenfield dol. (Cayugan) and overlies Bisher fm., and that none of them is known S. of Lewis Co., Ky. On p. 138 he stated Niagaran section at Hillsboro, Ohio, consists of (descending) Peebles dol., Lilley fm., Bisher fm., Ribolt sh., Alger clay sh., and Dayton ls. Other details are given on other pp. of this paper, especially 137–144. On p. 143 he stated type section is btw. Peebles, Ohio, and base of Greenfield dol. several mi. to E.

Peedee formation.

Upper Cretaceous: Coastal Plain of eastern South Carolina (Florence and Horry Counties) and North Carolina.

E. Ruffin, 1843 (Agric. Surv. S. C., 1st Rept., pp. 6–7, 24–27). The marls of S. C. which are sufficiently abundant to be valuable for use are of four different fms. or geological ages, and each of distinct and marked character in regard to certain minor pecularities, though all agreeing in main chemical and agricultural characteristics, as defined above, and which only are of importance to the value of marl. That which I shall term *Peedee bed* is oldest marl, and is part of great secondary fm. (and that div. called the Cret., and which is so fully developed in N. J.), as is manifest from its characteristic fossils (principally *Belemnites Americana* and *Exogyra costata*). This bed, so far as I have yet ascertained, is limited to land bordering on part of great Peedee River and some of its tributaries, as Black River; all the fm. being connected and lying in Marion, Williamsburg, and Georgetown districts. The next oldest fm. of marl is that which I shall designate *Great Carolinian bed.* It extends from E. of the Santee to far across the Savannah. Though this fm. is separated from the Mio. marl (or middle Tert.) in the geological series, or in regard to age, by the interval of two entire periods, or intervening successive fms. (the newer Cret. and the Eocene or lowest and oldest of the Tert., both of which are here entirely wanting), still the former two are so united in position near the Peedee that it would be difficult to describe either alone without referring continually to the other. Therefore, in the description that will be given of the secondary or Peedee bed, the overlying and connected bed of Mio. marl will be also embraced, so far as regards its position and visible thickness; leaving its other characteristic to be considered separately, as part of the whole Mio. fm. of the State. It is the secondary fm. in that vicinity only to which I give the name of *Peedee bed.* This peculiar fm. is known as low on Peedee River as Britton's ferry, at line dividing Georgetown and Williamsburg districts. The Peedee bed is of peculiar character and very different in appearance from all other fms. in S. C. It occurs in alternate layers of hard marlstone and soft marl, sundry of which are to be seen in one section. Both these, wherever they underlie the Mio., and also higher up than the latter extends, are of a dark bluish-gray color; and each is of homogeneous texture, the marl like an impure clay and the marlstone like a compact and close-grained hard stone. Lower down the river than any Mio. is seen, the upper marlstone of the secondary or Peedee bed is yellowish. The marl is poor compared to most of those of the great Carolinian bed and to the adjacent Mio., usually not more than from 30 to 40 percent. The marlstone, however, is rich, varying from 66 to 68, and the little that has been tried burnt to white and excellent lime. The characteristic fossils, *Belemnites* and *Exogyra costata,* are not found diffused generally, but are very abundant at particular places, of which the bluff at Birch's ferry is the best supplied.

The present definition of Peedee fm. corresponds to Ruffin's definition in lithology and paleontology. It is uppermost of the Upper Cret. fms. of S. C. and N. C.; it uncon. overlies Black Creek fm. and is everywhere uncon. overlain by Tert. or Quat. deposits; and it consists chiefly of dark-green or gray, finely micaceous, more or less glauconitic and argill.

sands, many layers of which are calc. and some sufficiently calc. to form an impure ls. Irregular concretionary masses of impure calcium carbonate occur in places. Dark marine clays are interstratified with the sand. Thickness 0 to 886 ft. In some repts it has been called *Peedee sand*, but that lithologic term is not strictly applicable. It is a marine fm., of Ripley age. (See L. W. Stephenson, N. C. Geol. Surv., vol 3, 1912.)

Named for exposures on Great Peedee River, S. C., the exposure at Burches Ferry, on W. side of Peedee River in Florence Co., being a typical one. According to C. W. Cooke (U. S. G. S. Bull. 867, 1936), Burches Ferry may be taken as type loc. of Peedee fm., although the beds containing *Exogyra cancellata*, which in N. C. form base of Peedee fm., are absent at Burches Ferry.

†Peedee marl.

Miocene (upper): Northeastern South Carolina (Darlington and Florence Counties).

E. Ruffin, 1843 (Agric. Surv. S. C. 1st Rept., p. 28). [Although on earlier pages of above rept Ruffin distinctly stated that he applied *Peedee bed* to the secondary [Cret.] marl, on p. 28 he referred to the marls along Peedee River as *Peedee miocene marl* and *Peedee secondary marl*, "the two being difficult to separate."]

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, 19). *Pee Dee marls* (also *Pee Dee phase*).—This phase is interruptedly exhibited along Pee Dee River area from Darlington to Allisons Ferry; it also extends very interruptedly up Lynches River to Sparrow Swamp. At Davis Bluff it comprises 9 ft. of marl, in two layers, overlying 5 ft. of Goose Creek marl. The layer immediately resting on Goose Creek marl presents about 3 ft. of tough porous yellow marl consisting of a matted mass of shells (principally *Chama congregata* and *Arca incile*); the upper 6 ft. has been indurated in places almost to crystalline form (comprises large numbers of *Pecten eboreus*, etc.). The *Arca incile* layer is the one principally observed along Lynches River.

Name conflicts with Peedee fm. of the Cret. The Mio. bed is Duplin marl, according to studies of C. W. Cooke.

Named for exposures in Peedee River region, NE. S. C., from Darlington to Allisons Ferry.

Peedee group, Pennsylvanian, Kans. See *Pedee group*.

†Peedee River marls.

Upper Cretaceous: Eastern South Carolina.

F. S. Holmes, 1870 (Phosphate rocks of S. C., pp. 12, 13).

Same as Peedee fm.

Peeker sand.

The subsurface Second Cow Run or Peeker sand of Washington Co., Ohio, is Lower Freeport ss., and the Peeker sand of Morgan, Athens, and western Washington Counties is Lower Freeport ss. (W. Stout et al., Geol. of nat. gas, A. A. P. G., 1935, pp. 900-901.)

Peekskill granite.

Pre-Cambrian: Southeastern New York (east of Peekskill).

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, p. 377). [*Peekskill granite* mentioned only in table, where it is placed below Cortlandt series and above Harrison diorite, and both Peekskill granite and Cortlandt series are assigned to "*Lower Siluric*" (Ordovician).]

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146, p. 53). *Peekskill granite*.—White or pink massive, very coarse-grained, soda granite, occupying about 4 sq. mi. 2 mi. E. of Peekskill. Believed to be genetically related to Cortlandt series.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, map and passim). *Peekskill granite*.—Light-gray medium- to coarse-grained acid granite composed of quartz, white feldspar, striated and nonstriated, muscovite, and biotite. Of same age as Cortlandt series. Cuts Manhattan schist. [In many places is called *Peekskill or Mohegan granite.*] Type loc. about 3 mi. E.-NE. of Peekskill.

Peekskill phyllite.

Ordovician: Southeastern New York (Peekskill region).

C. R. Fettke, 1914 (N. Y. Acad. Sci. Annals, vol. 23, pp. 245–257). *Peekskill phyllite.*—Dark-gray to black phyllite, of rather fine texture. Well exposed on NW. side of Peekskill Creek Valley. Thickness probably much more than 1,000 feet. Rests on 1,000 ft. of blue to white crystalline ls. believed to be Wappinger ls. If the ls. is Wappinger ls., then the phyllite correlates with Hudson River series, but there is possibility the Peekskill phyllite may represent a less metamorphosed phase of Manhattan schist, the age of which is still in doubt. [The age of Manhattan schist is now rather generally accepted as pre-Camb.]

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226), mapped the rocks on NW. side of Peekskill Creek Valley as *Hudson River shales and phyllites,* and the underlying ls. as *Wappinger ls.*

Peekskill diorite.

Same as Peekskill diorite gneiss.

Peekskill diorite gneiss.

Pre-Cambrian: West Point quadrangle, southeastern New York.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225–226, p. 28). *Peekskill diorite gneiss or Pochuck gneiss.*—An old injection or impregnation type of diorite gneiss of uncertain relation to the other types except that it is intimately associated with the Grenville and is judged to be the oldest intrusive [in West Point quad.]. [In most places in rept the rocks are called either *Pochuck gneiss* or *Pochuck diorite,* while the name *Peekskill* is applied to a younger granite.]

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68), classified this gneiss as of post-Glenarm pre-Camb. age.

Type loc. along Peekskill Creek, Westchester Co.

Peekskill norite.

Age (?): Eastern New York (Dutchess County).

R. Balk, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 5, pl. 1, etc.).

Peekskill Creek limestone.

Name casually applied by C. R. Fettke (N. Y. Acad. Sci. Annals, vol. 23, p. 201, 1914), in 2 places, to Wappinger ls. of Peekskill Creek section of eastern N. Y. In 1921 (N. Y. State Mus. Bull. 225–226) C. P. Berkey and Marion Rice mapped this ls. as Wappinger ls.

Peerless sandstones. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., pp. 281, 282). *Peerless ss.*—Bluish-gray fine-grained, frequently micaceous ss. or sandy sh., 80 to 150 ft. thick, lying 5 to 10 ft. below Cedar Grove coal and frequently including Campbells Creek ls.; lies higher than Peerless coal. *Lower Peerless ss.*—Massive bluish-gray ss., 25 ft. thick, lying 10 ft. below Peerless coal and 27 ft. above No. 2 Gas coal. The Peerless coal was named for small mining village (now abandoned) on S. side of Kanawha River just E. of Lewiston, Kanawha Co.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 103, 183). *Peerless ss.*—Massive, persistent, 10 to 46 ft. thick. Underlies Little Alma coal and lies 1 to 5 ft. above Campbell Creek ls.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co., p. 274). *Peerless ss.*—Usually massive, medium-grained, micaceous, greenish gray to bluish gray, 25 to 70 ft. thick. Is same as Lower Cedar Grove ss. of Logan-Mingo Co. Rept. Overlies Alma coal, the Alma A coal being absent. The ledge in *Logan and Mingo Counties* that was erroneously correlated with Peerless ss. is here renamed *Lower Monitor ss.*

Peerless shale member (of Sawatch quartzite).

Upper Cambrian: Central Colorado.

C. H. Behre, Jr., 1932 (Colo. Sci. Soc. Proc., vol. 13, No. 3, p. 58). *Peerless sh. memb. of Sawatch qtzite.*—Sandy and shaly dolomitic beds and calc. shaly beds, with prominent fucoid markings, forming top memb. of Sawatch qtzite in Weston Pass dist. In earlier repts called "transition sh." Thickness at Weston Pass 50 ft. Typical occurrence on NW. slope of Peerless Mtn, 6 mi. E.-SE. of Leadville. Grades into overlying Manitou ls. (Ord.). Underlain by qtzites.

The "transition sh." of Alma dist. consists of (descending): (1) Shaly beds, 12 to 27 ft.; (2) dolomitic and sandy ls. with sh. partings, 15 to 30 ft.; (3) shaly beds, 18 to 30 ft.; (4) dolomitic ls. with sh. partings, 15 to 30 ft.; (5) purple qtzite containing tiny angular quartz pebbles, 2 to 15 ft.; the aggregate thickness of the memb. being 62 to 132 ft.

Peers Spring formation.

Mississippian (lower and middle ?): Eastern Nevada (Pioche district).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171, pp. 7, 20, map, etc.). *Peers Spring fm.*—Outcrops are mainly black dense fine-grained aphanitic ls., weathering gray or white; some bands weather rusty. Brown calc. sh. is probably the more common facies, but outcrops of it are not so numerous. Gray thick-bedded ls. is interbedded in lower part. Is separated from other Carbf. fms. by fault boundaries, but in Dutch John Mtn section its strat. position btw. Bristol Pass ls. (below) and Scotty Wash qtzite (above) is clearly shown. Thickness at least 500 ft. and may be 2,500 ft. Fossils (of Madison age) are listed. Named for occurrence in hills E. and N. of Peers Spring, 3 mi. NW. of Bristol Pass.

Pegram limestone.

Middle Devonian: Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 400, 425). In valley of Harpeth River, btw. Newsom and bridge W. of Pegram, all exposures of Louisville fm. are overlain by Dev. ls., the *Pegram ls.* Its thickness increases toward W. At Newsom it is 3 ft. thick; at bridge 1½ mi. W. of Pegram it is 8 ft. thick; at its most western exposure, in quarry N. of railroad, the total thickness is 12 ft. In Harpeth River region it is usually very white and crystalline. At bridge W. of Pegram this white ls. is overlain by 6 to 12 in. of dark earthy rock, and above that lies the Black sh. Top of Pegram ls. seems to correspond to Sellersburg ls. of Ind. and Hamilton of N. Y., while lower part indicates at least one characteristic Corniferous [Onondaga] fossil.

Overlies Camden chert uncon., and uncon. underlies Hardin ss. memb. of Chattanooga sh. See C. O. Dunbar, 1919 (Tenn. Geol. Surv. Bull. 21).

E. R. Pohl, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 195; Tenn. Acad. Sci. Jour., vol. 5, pp. 54–63), divided Pegram ls. into Sellersburg ls. (above) and Jeffersonville ls. (below) and discarded *Pegram*.

Named for exposures at Pegram, Cheatham Co.

Pekanatui series.

Pre-Cambrian: Canada (Northwest Territories).

C. Lausen, 1929 (Canadian Min. and Met. Bull. 202, p. 376).

Pekin formation. (In Newark group.)

Triassic (Upper): Central North Carolina.

M. R. Campbell and K. K. Kimball, 1923 (N. C. Geol. and Econ. Surv. Bull. 33, pp. 20–25). *Pekin fm.*—Prevailingly red ss. and sh., with a remarkable gray cgl. at base, called millstone grit and composed of white quartz pebbles up to 2 in. in diameter. Rocks carry considerable hematite. Is lowermost fm. of Newark group. Underlies Cumnock fm. Rests uncon. on ancient schist and sl. Has generally been referred to as "Lower red ss." Thickness 1,000 to 2,000 ft.

Named for exposures at Pekin, Montgomery Co., which lies in midst of the fm.

†Pelham limestone.

Upper, Middle, and Lower Ordovician: Alabama.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, p. 152, section opp. p. 162, and map). *Trenton or Pelham ls.*—Lower part usually impure shaly ls. with great numbers of *Maclurea magna*, characteristic Chazy fossil. Upper part mostly pure ls., with Trenton fossils. In places the pure ls. is overlain by calc. shales and shaly lss. often full of graptolites. Max. thickness 800 ft. or more. Overlies Knox dol. and underlies Clinton or Red Mountain fm.

As defined is same as Chickamauga ls. The ls. at Pelham, type loc., is now, however, known to include beds of Trenton and Chazy age and in addition 1,200 ft. of beds of Beekmantown age, according to studies of C. Butts. The latter beds belong to Knox dol. as defined and elsewhere used. *Chickamauga ls.* is an almost simultaneous name for the lss. of Trenton, Black River, and Chazy age in southern Appalachians, which had been mapped under that name in many repts before their essential equivalency to †Pelham ls. of Ala. was established.

Named for Pelham, Shelby Co., in Bessemer quad.

Pelham granite.

Late Carboniferous or post-Carboniferous: Western central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 48). [Shows *Pelham gneiss* in SW. wall of Pelham asbestos quarry, and describes the *gneiss of Pelham* on pp. 42–45.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 94, 127–128, 248–250, and map). *Pelham granite.*—Gray biotitic gneissoid granite. Covers large part of Pelham Twp.

†Pelham quartzite.

Late Carboniferous or post-Carboniferous: Western central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18, and map, pl. 34). *Pelham qtzite.*—Aren. actinolitic qtzite. Crosses Pelham Twp.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 250–252 and map). [The rocks mapped as "Pelham qtzite" in Mon. 29 were in Bull. 597 mapped as "Northfieldite (pegmatitic, aplitic, or vein quartz border on Pelham granite)," and the name "Pelham qtzite" was discarded.]

†Pelham saxonite.

Late Carboniferous or post-Carboniferous: Western central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pp. 47–55, and map, pl. 34). *Pelham saxonite.*—Black olivine-enstatite-magnetite rock with serpentine and steatite beds.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 209, 215–217). [The patches of rock in Shutesbury and Pelham Twps which were mapped as "Pelham saxonite" in Mon. 29 were here mapped as *saxonite and peridotite*, and the geographic name was discarded.]

†Pelham serpentine.

Name applied by B. K. Emerson (U. S. G. S. Mon. 29, 1898, p. 55) to an exposure of serpentine at "asbestos" mine in Pelham, Mass., and later discarded by him. Not mentioned in his U. S. G. S. Bull. 597, 1917.

Pelican shale.

Pelican sandstone.

Upper Cretaceous: Alberta.

R. G. McConnell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 28D to 29D). [Both included in Colorado group.]

Pella beds.

Mississippian: Central southern and southeastern Iowa.

H. F. Bain, 1895 (Am. Geol., vol. 15, p. 318). *Pella beds or substage.*—Clay marls, clay shales, and ls., 75 ft. thick, forming top memb. of St. Louis fm. in SE. Iowa. Overlie Verdi beds (middle memb. of St. Louis) and uncon. underlie Coal Measures.

According to later repts, by S. Weller and F. M. Van Tuyl, these beds carry a Ste. Genevieve fauna and are discon. separated from underlying true St. Louis ls.

Named for exposures near Pella, Marion Co.

Pellisier granite.

Age (?) : Central eastern California (Inyo Range).

G. H. Anderson, 1935 (Pan-Am. Geol., vol. 64, No. 1, p. 66). The batholith which forms core of northern Inyo Range is composed chiefly of 2 granites which are designated *Pellisier* and *Boundary Peak granites*. The Pellisier is of variable composition and texture, but may be described as hornblende granite with monzonitic tendencies. The Boundary Peak granite, of more uniform appearance and composition, contains no hornblende and has a lower percentage of other ferromagnesian minerals. [Age and derivation of names not stated.]

Pellville sand.

A subsurface sand, of Chester (Miss.) age, in S. part of Hancock Co. and N. part of Ohio Co., Ky.

Pelly gneiss.

Pre-Cambrian: Northeastern Alaska and Yukon Territory, Canada.

A. J. Collier, 1903 (U. S. G. S. Bull. 218, p. 16). Oldest rocks in Yukon River region are of gneissoid character, and for these *Pelly gneisses* has been suggested by Brooks and accepted by McConnell. These gneisses are an intricate series of crystalline rocks whose genesis is doubtful. A part are altered intrusives, and further study will undoubtedly show that some of them are younger than the sediments they are supposed to underlie. Everywhere show profound metamorphism. Uncon. overlain by quartz schists and qtzites called by Spurr the *Birch Creek series*.

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). *Pelly gneiss* intrudes Birch Creek schist. Consists mainly of granitic rocks, but locally includes darker varieties of monzonitic, dioritic, and even gabbroic character. Probably pre-Camb. but possibly Paleozoic.

Named for exposures on Pelly River.

Pelodian.

Pre-Cambrian: General.

J. D. Whitney and M. E. Wadsworth, 1884 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 7, geol. ser. vol. 1, No. 11, p. 562), proposed the following "chronological arrangement of crystalline (Azoic) rocks" (descending): *Pelodian* (argillites); *Glacian* (cgls.); *Taconian* (lss.); *Crystallian* (qtzites, quartz schists); *Montalban* (mica schists); *Huronian* (diorites, diabases, melaphyrs, chlorite schists); *Porphyrian* (porphyrites); *Arvonian* (felsite, quartz porphyry, petrosilex, jaspilite); *Norian* (gabbros, coarse diabases, and diorites); *Ophian* (peridotites, including serpentines); *Siderian* (magnetite, hematite, menaccanite); *Laurentian* (granites, gneisses, syenites). Derivation of names not stated.

Pelona schist.

Pre-Cambrian (?) : Southern California (Los Angeles County).

O. H. Hershey, April 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pl. 1, map). [*Pelona schists* on legend of map lie btw. gneiss below and Archean gneiss above.]

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 273–290). *Pelona schist series*.—Three thousand ft. of dark-colored and more schistose mica schist underlain by 2,000 ft. of light-yellowish coarse angular mica schist. Assigned to pre-Camb. (?). Named for Sierra Pelona, Los Angeles Co.

O. H. Hershey, 1912 (Am. Jour. Sci., 4th, vol. 34, pp. 271–273). Another area of *Pelona series* constitutes greater part of Rand Mtns near Randsburg, Kern Co. This series is youngest important Archean series. I propose to extend the name over Abrams and Salmon fms. of Klamath region.

E. C. Simpson, 1934 (Calif. Jour. Mines and Geol., vol. 30, No. 4). *Pelona schist series*, 7,500+ ft. thick in Elizabeth Lake quad., is probably Archean. Identical in lithology and structure with Rand schist of Randsburg quad.

Pelton basalt member (of Deschutes formation).

Late Tertiary (Miocene or Pliocene) or early Pleistocene: Central northern Oregon (Deschutes Basin).

H. T. Stearns, 1931 (U. S. G. S. W. S. P. 637, p. 139). *Pelton basalt memb. of Deschutes fm.*—Name suggested by Ira A. Williams. The memb. usually consists of several beds laid down in rapid succession, and it is not unlikely they were all poured out during a single eruption. Thickness 130 to 150+ ft. Lies near lower part of Deschutes fm. Exposed in Deschutes Canyon from line btw. Twps 12 and 13 S., R. 12 E., to N. bdy of area. Not traced beyond this point but known to continue several mi. downstream. In N. part of T. 11 S., R. 12 E., it forms bench nearly ¼ mi. wide on both sides of Deschutes River. Also extends N. and underlies former R. R. station of Pelton.

Pembina beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 130).

Pembina Mountain.

Name applied by G. M. Dawson (Geol. and res. 49th par., 1875, p. 81) to Pierre sh.

Pembroke formation.

Silurian: Southeastern Maine.

E. S. Bastin and H. S. Williams, 1913 (Maine Water Storage Comm. Third Ann. Rept., p. 168; Geol. Soc. Am. Bull., vol. 24, pp. 378, 379). [Name mentioned but not defined. Refers to Eastport folio.]

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, p. 6). *Pembroke fm.*—A conformable alternation of rhyolitic and diabasic volcanic rocks with gray and dark-red shales. Southeast of Leighton Point the sed. rocks are subordinate in amount. Northwest of Leighton Point the fm. consists chiefly of two sh. members, Leighton gray sh. memb. below and Hersey red sh. memb. above. Thickness about 6,000 ft. Conformably overlies Edmunds fm. and conformably underlies Eastport fm. Fossils indicate Rondout age. Named for exposures near Pembroke, Washington Co.

Pembroke moraine.

Name applied to a Pleist. moraine in N. Y. (See F. Leverett, U. S. G. S. Mon. 41, pp. 685–688, 1902, who described them as *Pembroke ridges*, but H. L. Fairchild (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 627–662, 1932) refers to the deposit as *Pembroke moraine*.)

Pemigewasset series.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Ammonoosuc River region) and White Mountains.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 142–148, 257–261). *Labrador system or Pemigewasset series of granites, ossipytes, compact feldspars, etc.*—Chiefly eruptive. In vol. 1 I stated I believed the following belong to one grand system, arranged according to age, youngest at top: (1) Compact and crystalline feldspars or porphyries, 600 ft.; (2) ossipyte or labradorite rocks; (3) Chocorua granite; (4) Albany granite, 1,000 ft.; (5) Conway granite, 600 ft.; (6) breccia granite, 300 ft. I find that there are difficulties in way of accepting these views and desire to investigate subject further before committing the rept to this view. The Pemigewasset granites cut the andalusite slates and are of later origin, either Eozoic or Paleozoic. The series overlies Franconia breccia, which is younger than Montalban group, and older than Pequawket or Mount Mote breccias and porphyries. Named for Pemigewasset River, along which the rocks are exposed over large areas. The Conway granite caps Mount Pemigewasset. The Labrador system is considered the probable equiv. of Labrador system of Logan and Hunt.

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, No. 3, pp. 67–137), assigned the granites enumerated above, also the Pequawket and "Mount Mote" (Moat) breccias and porphyries, to Dev. (?), and stated that Pequawket breccia of Hitchcock consists of clastic rocks interbedded with quartz porphyry and trachyte flows. In 1935 he assigned all these intrusives to late Dev. or late Carbf. (See under names of subdivisions.)

Pemmican River formation.

Upper Cambrian (?): Greenland.

C. Poulsen, 1927 (Meddelelser om Grønland, Bd. 70, pp. 244, 341).

Peña Blanca marls.

Oligocene: Panama.

E. Howe, 1907 (Isthmian Canal Comm. Rept., p. 113).

Pen Argyl beds. (In Martinsburg shale.)

Upper Ordovician: Southeastern Pennsylvania (Northampton County).

C. H. Behre, Jr., 1926 (Jour. Geol., vol. 34, pp. 485–487) and 1927 (Pa. Geol. Surv., 4th ser., Bull. M9, pp. 33, 104–107, and maps). By studying in detail the beds laid bare in the quarries, it has been possible to divide the uppermost or soft sl. memb. of Martinsburg fm., 3,000 ft. thick, into two parts. As lower part has been quarried at Bangor it is distinguished as *Bangor beds*. The upper part is exposed at Pen Argyl and is designated *Pen Argyl beds*. The only difference is that the slates of Bangor beds are slightly harder than those of Pen Argyl beds and do not attain such great thickness. [Jour. Geol. paper gave 1,500 ft. as thickness of each.] The two sets of beds are separated by a somewhat more sandy phase of sedimentation, which is shown on Slateford Creek, about 1 mi. W. of Slateford, and which is with difficulty recognized; it is assigned to Bangor beds.

Penasco quartzite.

Pre-Cambrian: Central northern New Mexico (Santa Fe region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 10). *Penasco qtzite.*—Main body of siliceous section exposed near Pecuris, N. of Santa Fe. Thickness 400 ft. [Derivation of name not given.]

Pence ferruginous slate member (of Ironwood formation).

Pre-Cambrian (upper Huronian): Northwestern Michigan and northwestern Wisconsin (Gogebic district).

W. O. Hotchkiss, 1919 (Eng. and Min. Jour., vol. 108, pp. 501, 505). *Pence ferruginous sl. memb.*—Dominantly thin- and even-bedded ferruginous sl.; at base a "flatwise" cgl. believed to represent uncon. Thickness 80 to 130 ft. Is a memb. of Ironwood fm., underlying Anvil ferruginous chert memb. and uncon. overlying Norrie ferruginous chert memb. Named for Pence mine, W. of Hurley, Wis.

Pencil Cave.

A descriptive term applied by drillers to certain clay or shale fms. which cave in drilling and which have a tendency to break up easily into long pencil-like forms. The name has been applied in western Pa. to beds, 5 to 40 ft. thick, in midst of Mauch Chunk sh. or Greenbrier ls. (both Miss.), underlying Little lime and overlying Big lime of that region. The Pencil Cave of drillers of central Tenn. (Crossville region) is a volcanic ash (bentonite) of Ord. age, lying near bdy btw. lss. of Trenton and Black River age. It is also called "Green Pencil Cave." The Pencil Cave of W. Va. is, according to D. B. Reger, without much doubt the Lillydale sh. (in the Mauch Chunk).

Pendleton sandstone.

Middle Devonian: Indiana.

E. T. Cox, 1879 (Ind. Geol. Surv. 8th, 9th, and 10th Ann. Repts., p. 62). *Pendleton ss.*—Heavy-bedded soft white ss., 15 ft. thick, upper part containing Schoharie fossils, according to James Hall; assigned to Corniferous. Overlain by buff sandy Corniferous ls. and underlain by Niagara ls.

E. M. Kindle, 1901 (Ind. Dept. Geol. and Nat. Res. 25th Ann. Rept., pp. 558–561). *Pendleton ss.*, 15 ft. thick at Pendleton, is strat. equiv. of Jeffersonville ls. Locally there is a cgl. bed in top.

E. R. Cumings, 1922 (Hdb. Ind. Geol. pt. 4, Sep. Pub. 21, p. 464). *Pendleton ss.*—The Schoharie is represented in Ind. by a single outcrop of ss. at Pendleton [Madison Co.]. Underlies Jeffersonville ls.

W. N. Logan, 1923 (Pan-Am. Geol., vol. 40, btw. pp. 111 and 136). *Pendleton ss.*—Locally conglomeratic. Is evidently a true basal ss. Very doubtful whether it is actually the western representative of Schoharie grit. [In tables this ss. is placed beneath Jeffersonville ls.]

Pendleton zone.

Name applied by C. B. Claypool (The Wilcox group of central Tex., Abstract of thesis, Univ. Ill., 1933, pp. 6, 10), to a marine zone in the Wilcox group of La., which he correlated with Holly Springs sand of Miss., Tuscahoma fm. of Ala., and the nonmarine Rockdale fm. of Tex. Geol. Survey. Named for outcrops at Pendleton Bluff, on Sabine River, where large marine fauna was collected.

Pend Oreille group.

Carboniferous (?) and older (?): Southern British Columbia and northeastern Washington (Stevens County).

O. E. Le Roy, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 142).

R. A. Daly, 1912 (Canada, Geol. Surv. Dept. Mines Mem. 38, maps 7, 8, 117° to 118°). *Pend D'Oreille ls.* (Carboniferous?) overlies *Pend D'Oreille schist* (?Carboniferous to Ordovician).

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 271). *Pend d'Oreille group.*—Schistose sediments and lss. that are believed to be mainly of upper Paleozoic age. Thickness 5,500 ft. The lower schists may include sediments of any age from Carbf. to Sil. inclusive. The group can be divided into two parts, *Pend d'Oreille schists* (including greenstone and amphibolite as well as phyllite and qtzite) and *Pend d'Oreille marbles.* They are primarily not strat. subdivisions so much as purely lithological ones. Rests conformably on Summit series and uncon. underlies Rossland and Beaver Mtn groups of sediments and volcanics. No fossils. The wild canyon of Pend d'Oreille River in lower 20 mi. of its course has been excavated in rocks of this group. [Pend d'Oreille River empties into Columbia River just N. of Wash.-B. C. bdy.]

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 48). *Pend Oreille group.*—Group of qtzites, amphibolites, Stevens Co., Wash. No fossils. Lie in zone of intense deformation and crushing. In many ways difficult to distinguish from older Summit series. Because of lithologic similarity to Cache Creek group of B. C., of Carbf. age, is tentatively correlated with Penn., but lower schists may include sediments of any age from Carbf. to Sil. inclusive. On W. side of Columbia River the group underlies Rossland volcanic series. Overlies Summit series, with no apparent uncon. but rather with possible gradation.

Penholoway formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Florida (?) to Delaware.

In 1925 (Ga. Geol. Surv. Bull. 42, pp. 24–26) C. W. Cooke named and described the Penholoway terrace, citing as type an area in Wayne Co., Ga., extending from Hortense northeastward to Penholoway Bay and Penholoway Creek. In 1931 (Wash. Acad. Sci. Jour., vol. 21, pp. 509–510) he stated that the Penholoway terrace was formed when the sea stood about 70 ft. higher than its present level, and that its shore line can be traced for long distances in both directions from type loc. In 1932 (16th Int. Geol. Cong. Guidebook 12, pp. 5, 8) he applied the name *Penholoway fm.* to the deposits formed when the sea stood 70 ft. above its present level. The other Pleist. terrace fms. now recognized across the Atlantic Coastal Plain from Del. to Fla., as explained on pp. 2 and 5 of Guidebook 5 and in Guidebook 12, 1932 (table opp. p. 4, pp. 14, 15, etc.), are enumerated under *Columbia group.*

Peninsula formation.

Lower Cretaceous: Southwestern British Columbia (Harrison Lake region).

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of Dissert. 1924–26, vol. 1, p. 132).

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, pp. 487, 488). *Peninsula fm.*—Ss., 1,200 ft. thick, yielding *Aucella canadiana.* Assigned to Lower Cret. Underlies Brokenback Hill fm. and uncon. overlies Agassiz Prairie fm. (Upper Jurassic).

†Peninsular limestone.

Eocene (upper): Northern Florida.

W. H. Dall, 1903 (Wagner Inst. Sci. Trans., vol. 3, pt. 6, p. 1554). In order to promote clearness and avoid confusion it is probably advisable to adopt a distinct name for the Orbitoidal phase or fm., for which I would suggest the term *Peninsular ls.* This is intended, not as a permanent fm. name, but as a general term for the fundamental plateau ls. of Fla., in which a close and thorough study in the future may result in discrimination of more than one horizon or zone. It seems probable the Orbitoidal ls., which has in this work and in the literature generally been called *Vicksburg ls.*, may really form a different horizon altogether from the typical Vicksburgian and be intermediate btw. the latter and the nummulitic Ocala ls.

Later work by C. W. Cooke has proved this ls. to be the upper Eocene Ocala ls. The latter name has priority. (See Fla. Geol. Surv. 20th Ann. Rept., 1929.)

Named for development in peninsular Fla.

Has also been called †*Peninsula ls.*

†Pennell sandstone.

Upper Cretaceous: Eastern Utah.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 64, 65). *Pennell ss.*—Sss., 200 ft. thick, composing basal fm. of Laramian series in Utah. Underlie 1,000 ft. of unnamed shales, and uncon. overlie Masukian shales. Is Masuk ss. of Gilbert, which is replaced because Masuk is retained for the shales. Named "from Mount Pennell, overlooking as its piedmont the Masuk Plateau," eastern Utah.

Penney sand.

Name applied to a subsurface sand, of probable Dev. age, in SW. N. Y. See N. Y. State Mus. Bull. 239, 240, map opp. p. 16, 1922. (See also *Penny sand.*)

Pennine system.

Name proposed by H. S. Williams (U. S. G. S. Bull. 80, 1891, pp. 75–82) as geographic designation for *Carboniferous system*. Named for Pennine Range of northern England, where all of Carbf. system and overlying so-called "New Red ss." are present and exposed, resting on the underlying "Old Red ss." [Dev.]. The Pennine Range was type loc. of Carbf. system of Conybeare, 1822.

Pennington shale (also **Pennington formation**).

Mississippian (late Chester): Southwestern Virginia, eastern Kentucky and Tennessee, northern Alabama, and northwestern Georgia.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 37). *Pennington sh.*—Red and green shales, with beds of ss., 1,100 ft. thick, forming upper fm. of Miss. series in Bigstone Gap coal field of Va. and Ky. Overlies Newman ls. and underlies Lee cgl. Named for Pennington Gap, Lee Co., Va., where it is 1,025 ft. thick. It has same thickness at Big Stone Gap.

In some subsequent repts several hundred ft. of calc. beds properly belonging to Newman ls. were erroneously included in Pennington sh. According to C. Butts (Ky. Geol. Surv., ser. 6, vol. 7, 1922, pp. 125, 161, 168, 178) the Newman ls. includes St. Louis ls. at base and Glen Dean ls. at top, and Pennington sh. should be [and now is] restricted to beds of post-Glen Dean age. It includes equivalents of Bluestone fm., Princeton ss., and Hinton fm., according to some geologists, but C. Butts (Va. Geol. Surv. Bull. 42, 1933, pp. 44, 46) expressed opinion that Pennington and Hinton are same fm. In some repts *Pennington group* has been used to include Bluestone fm., Princeton cgl., Hinton fm., and Bluefield sh., but that usage has been discontinued.

The Newman ls. of SW. Va. and adjacent areas in SE. Ky. and NE. Tenn. is now divided into several fms., the upper of which is Glen Dean ls.; in Early Grove region of SW. Va. it is the Cove Creek ls. In Crossville quad. of central Tenn. the Pennington sh. is 250± ft. thick and rests on 350 ft. of Bangor ls. restricted. In northern Ala. it reaches a max. thickness of 200± ft. and rests on Bangor ls. restricted. In NW. Ga. and in Chattanooga region of SE. Tenn. its thickness has been reported as 500± ft., and there also it rests on Bangor ls. restricted. C. Butts (Ala. Geol. Surv. Spec. Rept. No. 14, p. 199, 1926) described Pennington fm. of Ala. as consisting of 200± ft. of mainly argill., partly cherty ls., with beds of sh., some of which are red, "the red sh. being the striking and characteristic feature of Pennington fm. to N."

Pennsylvanian epoch (or **series**).

The middle epoch of Carboniferous period and the rocks formed during that epoch. For definition see U. S. G. S. Bull. 769, pp. 72–73. Some geologists now treat the Penn. deposits as a system.

Penny sand.

A subsurface sand, of probable Dev. age, in western N. Y., lying higher than Bradford and Richburg sands. (See also *Penney sand.*)

Penobscot formation.

Cambrian (?): Central southern Maine (Penobscot Bay quadrangle).

G. O. Smith, E. S. Bastin, and C. W. Brown, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 3). *Penobscot fm.*—Metamorphosed shaly sediments (slates, schists, qtzites) typically developed along nearly whole length of W. shore of Penobscot Bay. Vary from light gray through steel gray and purplish gray to black, the darker grays being predominant. Locally injected and metamorphosed by granite and diorite. Weathered surfaces usually rusty. In a few places only the rock exhibits a very perfect slaty cleavage, highly inclined to bedding planes. Conformably overlies Battie qtzite. Assigned to Camb (?). Named for exposures along W. shore of Penobscot Bay, especially btw. Belfast Bay and Sandy Point, Waldo Co.

On 1933 geol. map of Maine, by A. Keith, this fm. is included in Ord. and Camb. block.

Penobscot Bay granite.

Silurian (late) or early Devonian: Maine.

F. W. Toppan, 1932 (Geol. of Maine, Dept. Geol. Union Coll., Schenectady, p. 44).

†Penokee series.

Pre-Cambrian (upper Huronian): Northwestern Wisconsin and northwestern Michigan.

E. T. Sweet, 1876 (Wis. Acad. Sci., Arts, and Lett. Trans., vol. 3, pp. 40–55). *Penokie series*, of the Huronian, lies directly below the Copper-bearing series. Consists of 4,000 ft. of siliceous schists, black slates, iron-bearing beds, siliceous marble, and fine-grained white quartz. Rests uncon. on granitic and gneissic rocks supposed to be=Canadian Laurentian.

T. C. Chamberlin, 1883 (Geol. Wis., vol. 1, pp. 81–84). *Penokee series*, of the Huronian, is 13,000 ft. thick in Penokee region, Wis. Consists of (descending): (1) Mica schists, 8,000 ft.; (2) black slates, schists, and diorites, 3,500 ft.; (3) iron-bearing and siliceous schists and qtzites which now form crest of Penokee iron range, 800 ft.; (4) quartz schist and argill. mica schist, 400± ft.; (5) white granular qtzite; (6) crystalline mag. ls., 130 ft.—lowest memb. exposed to view.

Applied to all of Huronian series in Penokee dist. In some later repts the Bad River ls. was both excluded from and included in †Penokee series.

†Penokee-Gogebic series.

A term applied in some early repts (see U. S. G. S. 21st Ann. Rept., pt. 3, 1901) to the upper Huronian rocks of NE. Wis. and NW. Mich.

Penrod sand.

A subsurface sand in upper part of Chester group (Miss.) of Muhlenburg Co., western Ky. Composed of two members separated by about 10 ft. of sh. Occurs at depth of about 650 ft.

Pensauken formation. (In Columbia group.)

Pleistocene: New Jersey.

R. D. Salisbury, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, pp. 57–60, 67–72). *Pensauken fm.*—The second stage of the yellow gravel. Consists of gravel, sand, loam, clay, and marl derived from underlying Beacon Hill fm. and Cret. beds. Thickness 0 to 60± ft. Named for exposure at mouth of Pensauken Creek, at Hylton's pits. Uncon. overlies Beacon Hill sand and gravel and uncon. underlies Jamesburg [Cape May] fm.

R. D. Salisbury, 1898 (N. J. Geol. Surv. Ann. Rept. State Geol. 1897, pp. 13–15), introduced *Bridgeton fm.* for beds underlying Pensauken fm. [restricted] and overlying Beacon Hill gravel. He stated that in some places the Bridgeton fm. "seems not to be clearly separable from Beacon Hill fm., which preceded, while in others it is not easily distinguishable from Pensauken which follows," but that in other places "it is distinctly separable from the Pensauken and in still others from the Beacon Hill."

R. D. Salisbury, 1901 (N. J. Geol. Surv. Ann. Rept. State Geol. 1900), stated that Bridgeton fm. was included in Pensauken fm. of 1895 and earlier repts, and that Pensauken fm. is uncon. overlain by Cape May fm. and uncon. underlain by Bridgeton fm. This is present accepted definition of Pensauken fm., which is now classified as middle fm. of Columbia group in N. J. It is of nonglacial origin, and considered to be approx.=in age to Jerseyan drift.

Pentagon shale.

Upper or Middle Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 38 and passim). *Pentagon sh.*—Is sh. and shaly lss. only in immediate vicinity of Pentagon Mtn. but in all other sections it is generally massive ls. Thickest (290 ft.) at type loc.; thins most rapidly S.-SE. to Prairie Reef-White Ridge area, where it consists of tan to chocolate-gray massive thick-bedded ls. with small amount of clay disseminated as flakes. Lower 92 ft. is calc. gray to buff-gray, rather thick-bedded platy sh. interbedded with platy blue-gray argill. lss. in thin beds. Overlying 150 ft. is platy, irregularly bedded argill. ls., blue gray to tan gray in upper part. Above these platy lss. come 22 ft. of black-gray paper sh. interbedded with a few thin lss. in lower part. Top of fm. consists of 26 ft. of nodular platy interbedded chocolate and white-gray argill. lss. Overlies Pagoda oolite and underlies Gordon Mtn ls. Type loc. on Continental Divide in NE¼ sec. 24, T. 25 N., R. 12 W. Named for Pentagon Mtn., which lies approx. 2 mi. NW. of type loc.

†Pentamerus limestone.

Silurian (Niagaran): New York.

T. A. Conrad, 1839 (N. Y. Geol. Surv. 2d Rept., pp. 62–63). Underlies Rochester shales and overlies green sl., lenticular iron ore, etc. Contains *Pentamerus elongatus* (*P. oblongus?*).

Paleontologic name of a ls. in Clinton fm.

Has also been called "First Pentamerus ls." and "Lower Pentamerus ls."

†Pentamerus limestone.

Lower Devonian: New York.

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 237–238). Pentamerus ls. overlies Tentaculite ls. [Manlius ls.], which rests on the Water lss.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 376). Pentamerus ls. overlies Manlius waterlime group and underlies Delthyris shaly ls. [New Scotland ls.].

Paleontologic name of ls. later named *Coeymans ls.*

Penters chert.

Devonian (probably Lower): Central northern Arkansas (Batesville district).

H. D. Miser, 1920 (U. S. G. S. Bull. 715G). *Penters chert.*—Gray and bluish chert, upper part dark-colored at places. Thickness 0 to 91 ft. Uncon. underlies Chattanooga sh. and uncon. overlies Lafferty ls. No fossils. Named for exposures at Penters Bluff Station, Izard Co.

Pentozoic.

A time (life) term applied by E. Hitchcock (Geol. Vt., 1861, vol. 1, p. 19) to the Tertiary.

†Pentremital limestone.

Pennsylvanian: Northwestern Arkansas.

Paleontologic term now replaced by Brentwood ls. memb. of Bloyd sh.

Peñuelas shale.

Cretaceous: Puerto Rico.

G. J. Mitchell, 1922 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 3, p. 251).

Penyon Blanco agglomerate.

Probably lower Mesozoic: Sierra Nevada, California.

N. L. Taliaferro, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 149). *Penyon Blanco aggls.*, 9,000 ft. thick, are included in Tuolumne group (probably lower Mesozoic). Underlie Agua Fria slates, lss., cherts, and tuffs and overlie Hunter Valley cherts and tuffs.

Peoples sand.

A subsurface sand, of Penn. age and 100± ft. thick, in central northern Okla. Originally correlated with part of Ochelata fm. In Cleveland and Hominy pools it lies 200 to 500 ft. above Layton sand. N. W. Bass and L. E. Kennedy show (Subsurface geol. of Osage Co., Okla.) this sand belongs in Nellie Bly fm., instead of in Ochelata fm.

Peorian stage of deglaciation, also **Peorian loess** (Pleistocene).

Peorian stage is name which for many years has commonly been applied to the interglacial stage succeeding Iowan stage of glaciation and preceding Wisconsin stage of glaciation. The name was proposed by F. Leverett (Jour. Geol., vol. 6, pp. 244–249, 1898), in the form of *Peorian soil and weathered zone*, also *Peorian interglacial stage*, with statements that the name was applied "to the interval between the Iowan loess and the Shelbyville till sheet, a till sheet which appears to be the earliest of the Wisconsin series" [stage], and that it is "best displayed east of Peoria, Tazewell Co., Ill." Subsequently the loess was included in Peorian interglacial stage, and the name *Iowan* was restricted to the preceding glacial stage. Later work led Leverett to opinion that "this weathering interval, and also the time of the loess deposition, are parts of the third [Sangamon] interglacial stage," and that the Iowan stage of Keewatin ice sheet may be of same age as Illinoian stage of Labrador and Patrician ice sheets. This, however, is still a moot question.

G. F. Kay and M. M. Leighton (1933) included Peorian loess and Iowan glacial stage in Wisconsin stage, and somewhat modified the definition of Peorian. See under *Wisconsin stage.*

A. L. Lugn, 1934 (Nebr. State Mus., vol. 1, Bull. 41, pp. 350–351). *Peorian loess* occurs as an almost unbroken mantle of yellowish eolian silt and clay over 42,000 sq. mi. of Nebr. It mantles the eroded Loveland fm., on an irregular surface.

Thickness in eastern Nebr. 10 to 100 ft.; in south-central Nebr. 30 to 200 ft.; to N. of Platte River 30 to 250 ft. Writer is not in agreement with recent suggestions to eliminate Peorian as a stage of the Pleist., as proposed by M. M. Leighton (Jour. Geol., vol. 39, pp. 45–53, 1931, and Sci., n. s., vol. 77, 1933) and by G. F. Kay and Leighton (Geol. Soc. Am. Bull., vol. 44, pp. 669–674, 1933).

Pepino formation.

Miocene: Puerto Rico.

R. T. Hill, 1899 (Nat. Geog. Mag., vol. 10, p. 109).

Pepper formation.

Upper Cretaceous (Gulf series): Eastern Texas (Trinity and Brazos River regions).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 417–422). *Pepper fm.*—The basal noncalc. blue-purplish clay sh. that extends southward from the Woodbine outcrop proper in McLennan Co. and underlies the *Acanthoceras flags* (Tarrant fm.) of the Eagle Ford. It is a distinct strat. unit, separated from underlying Grayson (Del Rio) by an uncon. represented by a pebble cgl. Its top is marked by a sharp break in character of sedimentation, the overlying Tarrant fm. being an aren. flaggy ls. containing much fish debris, phosphatic bodies, and fossil wood, and showing many evidences of shallow-water deposition. The Pepper sh. has a distinct fauna. In the past it has been referred to either Woodbine or Eagle Ford. It may be a part of Woodbine. Type loc., an exposure on a small branch of Pepper Creek just S. of Belton-Temple highway, Bell Co., and 1.6 mi. E. of easternmost of two underpasses of the highway under Santa Fe Railway.

Peppersauce sandstone.

Peppersauce Canyon sandstone.

Upper Cambrian: Southeastern Arizona (Santa Catalina Mountains).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 476–477, 480, 481, 482). *Peppersauce Canyon ss.*—Thin-bedded alternating brown porous siliceous ss. and hard pinkish qtzite, 21 ft. thick; Upper Camb. fossils near top. Overlies Abrigo fm. [restricted] in Peppersauce Canyon, Santa Catalina Mtns. [In table on p. 477 he calls it *Peppersauce ss.*] Correlated with Rincon ls. of Whetstone Mtns and with Copper Queen ls. of Bisbee dist. The 3 fms.—*Copper Queen ls.*, *Rincon ls.*, and *Peppersauce Canyon ls.*—are of very limited depositional areas, each with its own faunal and lithological aspect, which are altogether different from anything observed with the Abrigo fm. [as here restricted].

Pepple sand.

A subsurface sand, lying at 1,850 and 1,900 ft. depth, in Lawrence Co., Ill.

†Pequanac shale.

Middle Devonian: Northern New Jersey.

H. B. Kümmel, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). *Pequanac sh.* introduced to replace "Monroe sh." [preoccupied] of repts of N. J. Geol. Survey. Extensively developed along upper Pequanac River. Thickness 1,000 ft. Overlies Kanouse ss. Contains Hamilton fossils.

Cornwall sh. having been published in 1907, as a name to replace "Monroe shales" in N. Y., the name "Pequanac" was in 1914 (U. S. G. S. Raritan folio, No. 191) discarded in favor of *Cornwall sh.*, now in use in both States.

Pequawket breccia.

Devonian (?): Northern New Hampshire (North Conway quadrangle, White Mountains).

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 235, 239, 262, 675, pl. 11, etc.). The last of the groups of rock among White Mtns to be considered are *Mount Pequawket or Mount Mote breccias and porphyries*. The breccia was formed by dismemberment of the andalusite sl., and the feldspathic injection was of later origin. The Pequawket and Mote areas are alike in composition and may have been parts of same original mass, cut in two subsequently by Saco River. In W. part of Albany and Waterville are other breccias, perhaps to be referred to same eruptive period.

If so, the porphyry period is probably coeval with it. There is an extensive area of brecciated porphyries similar to those just described upon the two mtns W. of North Conway, btw. Saco and Swift Rivers, known as Mote Mtns. [The mtns referred to by Hitchcock are now known as North *Moat* Mtn and South *Moat* Mtn. See U. S. G. S. North Conway topog. map, 1927.] The identity of the Mount Mote with Mount Pequawket breccia seems well established. The breccia is younger than Albany, Conway, and Concord granites.

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, No. 3, map, pp. 72, 89, 98, etc.). *Pequawket breccia*.—A group of clastic rocks, varying greatly in composition and appearance, and interbedded with the quartz porphyry and trachyte flows of Moat volcanics. On Mount Pequawket the whole southern slope and the two main peaks are zones of clastic rocks. [On map *Pequawket group* is used, bracketed opp. two blocks, the upper one labeled *breccia (rich in clay sl.)* and the lower one *tuffs and breccias (includes some comendite)*.] Pequawket breccia as here used=Pequawket breccia of Hitchcock, and the South Moat flows of this rept is=quartz porphyry of Hitchcock. [See under *Moat volcanics*, which he assigned to Dev. (?).]

Percé formation.

Lower Devonian: Quebec (Percé).

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 204). *Perce fm.*, Silurian, Canada.

J. M. Clarke, 1908 (N. Y. State Mus. Mem. 9, p. 62). *Percé massive*, Dev., Quebec.

J. M. Clarke, 1915 (N. Y. State Mus. Bull. 177, p. 149). *Percé ls.*, Dev., Quebec.

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 173–175). *Percé fm.* is Oriskanian (Lower Dev.).

Percha shale.

Upper Devonian: Southern New Mexico to southwestern Texas.

C. H. Gordon, 1907 (Am. Jour. Sci., 4th, vol. 24, pp. 58–64; Sci., n. s., vol. 25, pp. 824–825; Jour. Geol., vol. 15, pp. 91–92). *Percha sh.*—Sh. underlying Lake Valley ls., overlying Mimbres ls., and carrying an Upper Dev. fauna in lower part. Is 200 ft. thick in Sierra Co. and 500 ft. thick in Grant Co. At Lake Valley it consists of 60 ft. of grayish-yellow and blue shales underlain by 100 ft. of black fissile sh.

Named for Percha Creek, Sierra Co., N. Mex.

Perchan series.

See under *Martinian series.*

Perdrix shale.

Upper Devonian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 294, 295, 300). *Perdrix sh.*—Black fissile sh. with occasional thin beds of ls. and some concretions. Thickness 600 ft. Overlies Flume dol. (Middle Dev.) and underlies Boule dolomitic ls. (Upper Dev.). Named for Roche à Perdrix, but typical section is on Roche Miette.

Perkasie shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Bucks and Montgomery Counties).

B. S. Lyman, 1893 (Pa. Geol. Surv. geol. and topog. map of Bucks and Montgomery Counties) and 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, pp. 2589–2638). *Perkasie sh.*—Green and dark-red or gray shales, 2,000 ft. thick near Perkasie tunnel. Underlie Pottstown shales and overlie Lansdale shales.

Corresponds to middle part of Brunswick sh. of Newark group. (See also under *Sanatoga memb.*)

Perkins volcanics.

Cretaceous: Canada (Yukon).

D. D. Cairnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 50). [Age not assigned, but Cockfield, Canada Geol. Surv. Summ. Rept. 1922, pt. A, 1923, p. 2, assigned these rocks to Cret.]

Perkins group.

Devonian (?): British Columbia.

D. D. Cairnes, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 34).

Permian epoch (or **series**).

The last epoch of Carboniferous period and the rocks formed during that epoch. For definition see U. S. G. S. Bull. 769, pp. 70–72. Some geologists now classify the Perm. deposits as a system.

†Permo-Carboniferous.

A term employed in early geologic repts to include Perm. and Penn. rocks.

Perris quartz diorite.

Late Jurassic (?): Southern California (Riverside County).

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, map, pp. 491, 501). *Perris quartz diorite* is most common and widespread rock type of Perris block, parts of Elsinore and Corona quads., Riverside Co.

Perry formation.

Upper Devonian: Southeastern Maine and New Brunswick.

C. H. Hitchcock, 1861 (Maine Bd. Agr. 6th Ann. Rept., pp. 247–256). *Red sss. of Perry and vicinity.*—In vicinity of Perry there is a fine deposit of red sss. and cgls. which indisputably belongs to highest part of Dev. At Point Pleasant, in SE. part of Perry, the Sil. strata crop out from beneath the red sss., illustrating the complete unconformability of the two sets of strata, also the small thickness of the Dev. strata. [In a few places author casually uses *Perry rocks* and *Perry sss.*, but he evidently did not propose Perry as a fm. name.]

N. S. Shaler, 1886 (Am. Jour. Sci., 3d, vol. 32, pp. 48–51). *Perry series.*—Series of coarse red sss., cgls., and reddish shales, certainly over 2,000 ft. thick. Overlies Cobscook series, but in places rests on the older Campobello series. Appears to be much less cut up by dikes than underlying Cobscook series. Was clearly formed in shallow water in immediate proximity to land. May be of upper Dev. or Sub-carbf. age.

G. O. Smith and David White, 1905 (U. S. G. S. P. P. 35, pp. 10, 25, 28). *Perry fm.* as exposed in towns of Robbinston and Perry is divisible into four members. Two members consist of sedimentary strata, while the other two are interbedded lavas and associated volcanic breccia. Members are: (1) Upper lava (green lava with columnar parting and amygdaloidal texture, including one bed of cgl. and ss.); (2) Upper ss. (coarse red and brown ss. and cgl., with small amounts of sh., including one flow of lava near base); (3) Lower lava (basaltic lava and breccia, including one thin bed of cgl. near top); (4) Lower cgl. (coarse cgl. and red ss., with thin beds of sandy sh.). Thickness of members undet. At N. end of Perry Basin the Perry fm. is in contact with granite; at S. end it uncon. overlies strata believed to belong to "Cobscook series" of Shaler and "Mascarene series" of Bailey and Matthew. The Perry is an estuarine fm., is distinctly Dev., and probably Chemung. Named for development at Perry, Washington Co., and elsewhere in Perry Basin.

E. S. Bastin, 1914 (U. S. G. S. Eastport folio, No. 192). *Perry fm.* is Upper Dev. and correlates with Chemung and Catskill fms.

On 1933 geol. map of Maine, by A. Keith, these rocks are assigned to Mississippian.

Perry formation.

Middle Devonian: Central Pennsylvania (Perry County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 1236–1237). The name *Perry fm.* would be unexceptionable for the middle ss. div. of the Hamilton, because in Perry Co. it is magnificently developed as mountainous outcrops. [He also suggests using *Ludlow ss.* for this ss., "an abbreviated form of Ludlowville sh. of N. Y."]

†Perry limestone.

Silurian and Devonian: Eastern Missouri, along Mississippi River.

C. R. Keyes, 1896 (Mo. Geol. Surv. vol. 11, p. 41). *Perry ls.*—Light-grayish or bluish ls., some clay, 300 ft. thick, exposed only in E. part of Mo. along Mississippi River. Some beds doubtless=so-called Niagara of other parts of Mississippi Basin, but faunas are not closely enough related to admit of covering both sets of strata by a common name. Name *Perry ls.* seems preferable to reviving Worthen's name *Clear Creek*, though it covers nearly same space. Underlies Grand Tower ls. and overlies Girardeau ls. (Ord.). Assigned to Sil.

Preoccupied. Includes several fms. (See Mo. chart.)

Named for Perry Co.

Perryman sand.

A subsurface sand, of Penn. age and 28 to 30 ft. thick, in Okla., lying lower than Oswego lime and higher than Bartlesville sand. Correlated with Squirrel and Prue sands.

Perryville formation.

Middle Ordovician (Trenton): Central Kentucky.

J. M. Nickles, 1905 (Ky. Geol. Surv. Bull. 5, p. 15). [*Perryville* used (in table only, without any description or thickness) for topmost part of Lexington group, overlying Paris [fm.] and underlying Winchester group.]

According to A. F. Foerste (Ky. Geol. Surv. Bull. 7, 1906) the *Perryville* is 0 to 35 ft. thick, underlies Greendale bed, and overlies Paris bed. According to E. O. Ulrich (Geol. Soc. Am. Bull., vol. 22, pp. 416–417, 1911) *Perryville ls.* underlies Catheys fm. and overlies Flanagan ls. According to A. F. Foerste (Denison Univ. Sci. Lab. Bull. 17, 1912) *Perryville memb. of Lexington ls.* in Boyle and Mercer Counties, Ky., consists of 5 to 8 ft. of fine-grained dove-colored ls. above and more richly fossiliferous fine-grained whitish ls., termed Faulconer div., below, and is overlain by Cornishville ls. memb. of Lexington ls. and underlain by Paris bed of Lexington. In 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21) Foerste (also A. M. Miller) included Cornishville ls. in Perryville fm., dividing the Perryville into (descending) Cornishville ls. memb., 5 ft.; Salvisa ls. memb.; and Faulconer ls. memb. In 1924 (Canada Dept. Mines Geol. Surv. Mem. 138, geol. ser. No. 121, chart opp. p. 58) Foerste divided the Perryville into Cornishville ls. (above) and Faulconer ls. (below), without explaining in which division the Salvisa ls. memb. was included; but Miller up to 1925 (Ky. Geol. Surv., ser. 6, vol. 21, pp. 126–142) continued to divide Perryville into Cornishville, Salvisa, and Faulconer members, and to exclude it from Cynthiana fm.

Named for Perryville, Boyle Co., Ky.

Perseverance slate.

Triassic or older: Southeastern Alaska (Juneau region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 93–94). *Perseverance sl.*—Unfossiliferous clay sl., possibly 3,000 ft. thick, underlying Gastineau volcanic group and overlying Clark Peak schist. Is of Triassic or older age.

Named for Perseverance Camp, just E. of Juneau.

Peru limestone.

Middle Devonian: Central Pennsylvania (Juniata County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, p. xix). *Peru ls.*—The bottom layers of the corniferous sh. (which underlies Upper Helderberg ls.) take on a special aspect for several mi. E. and W. of Peru [Juniata Co.], in Tuscarora Valley, that of a hard thin-bedded ls. breaking up into long, narrow blocks.

Peru sandstone.

Middle or Lower Devonian: Central Pennsylvania (Juniata County).

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. F, p. xix). *Peru ss.*—A 3-foot layer of fragile rock occurs at Peru, Juniata Co., overlying typical Oriskany ss., but very distinct from it. It has yielded no fossils and therefore cannot be named Caudagalli grit. Southwest of Peru fragments of it, scattered upon the surface, contain pebbles as large as a chestnut and from that down to a grain of sand. Pockets of iron ore have been found in this rock at Orbisonia and elsewhere.

Peru beds.

Pleistocene: Northeastern Illinois.

C. O. Sauer, 1916 (Ill. Geol. Surv. Bull. 27). *Peru beds.*—A type of stratified drift along sides of valley W. of Peru [near W. line of La Salle Co.] unlike that common at surface elsewhere. Suggests pre-Wisconsin drainage. Consists of (descending): (1) Rotted gravels, coarse and fine, sharply separated from overlying fresh high-level gravel by a line of rust that marks oxidized surface of older bed, 30 to 40 ft.; (2) loess, 2 ft.; (3) fine gravel and sand, 15 ft.; (4) clay silt, dark blue [thickness not stated]. Is uncon. on Coal Measures.

Peru sand.

A subsurface sand, of Penn. age and 0 to 50± ft. thick, in Okla., which is correlated with upper part of Labette sh. The name has also been misapplied to a higher and to a lower sand in same region.

†Pescadero series.

Upper Cretaceous, Eocene, Miocene: Western California (Santa Cruz Mountains region).

G. H. Ashley, 1895 (Jour. Geol., vol. 3, pp. 435–439). *Pescadero series.*—A great series of sss., shales, and cgls. having considerable prominence in Santa Cruz Mtns. They consist in part of the San Francisco ss. of previous writers. The section near Pescadero gives questionable thickness of over 10,000 ft. The rocks have been greatly disturbed and faulted. Their age has been shown to be in part Mio., and is thought to extend down through the Eo. and possibly into Cret. Uncon. underlies Monterey series and rests, probably uncon., on pre-Cret. metamorphic ss.

Named for exposures at Pescadero Point and near Pescadero, San Mateo Co.

Peshastin formation.

Pre-Tertiary: Central Washington (Mount Stuart and Snoqualmie quadrangles).

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Peshastin fm.*—Black sl., with grit or cgl., bands of black chert, and lenses of light-gray ls. interbedded. No fossils. Tentatively assigned to Paleozoic, possibly Carbf., based on resemblance to the Carbf. rocks of Sierra Nevada and B. C. Uncon. underlies Swauk fm. (Eocene). Is younger than Easton schist.

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Peshastin fm.* rests on Hawkins fm. without any marked evidences of uncon., but in places rests uncon. on Easton schist. Is of great thickness. Named for canyon of Peshastin Creek, near mouth of Negro Creek, Mount Stuart quad.

C. E. Weaver, 1911 (Wash. Geol. Surv. Bull. 6). *Peshastin fm.* seems to correspond most closely to Cache Creek series of B. C. and Calaveras fm. of Calif. and is therefore tentatively assigned to Carbf. or older.

W. S. Smith, 1915 (School Mines Quart., vol. 36, pp. 154–169). There is fossil evidence that the ls. of *Peshastin series* is Paleozoic.

W. S. Smith, 1916 (Jour. Geol., vol. 24, pp. 559–583). *Peshastin fm.* correlates with a series of sed. rocks containing definite Trenton fossils that occur in Skykomish Basin, to west.

Petaluma formation.

Pliocene (lower): Northern California (north of San Francisco Bay region).

R. E. Dickerson, 1922 (Calif. Acad. Sci. Proc., 4th ser., vol. 11, No. 19, with maps). *Petaluma fm.*—Chiefly lacustrine deposits of clays, clay sh., and sss. Characterized by great abundance of clays, but only in certain stream canyons is there opportunity to observe them. Is a fresh-water and brackish-water phase of marine San Pablo fm., and is confined to NE. corner of Petaluma quad. and SE. corner of Santa Rosa quad. Is uncon. overlain by Merced group or its correlative the Sonoma group. Is probably underlain by Monterey group at many localities. [Apparently named for exposures in vicinity of Petaluma, Sonoma Co.]

R. R. Morse and T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 10, pp. 1437–1455). *Petaluma fm.*, 4,000+ ft. thick, is divided into 2 mapped units, called *Upper Petaluma fm.* and *Lower Petaluma fm.* The *Upper Petaluma* is of fluviatile or lacustrine origin, consisting chiefly of poorly stratified clays with thick lenses of ill-sorted sands and gravels. The characteristic gray-green clays are only indistinctly bedded. The sands are usually greenish gray and intricately cross-bedded; irregular lenses of sands, up to 200 ft. thick, are common, and often grade laterally into gravels of predominantly Franciscan material. Small nests of gravel and scattered boulders are common throughout. Grades into *Lower Petaluma fm.*, which is 500 to 600 ft. thick; of estuarine origin; consisting of dark laminated clay shales and thin sands with, at several horizons, an abundance of smooth-valved ostracodes and fish debris, and with, locally, thin beds of gray ls. interbedded in the sh.; at base a transition zone, of alternating volcanics and ostracode sh., 122 to 168 ft. thick, which grades into underlying Tolay volcanics. Is overlain, with angular uncon., by Sonoma volcanics (of upper or middle Plio. age), and is correlated with Orinda fm. in its broader sense, as recognized in Mount Diablo region. Assigned to Lower Plio. A better description of Petaluma fm. could scarcely be given than in Lawson's words describing the Orinda.

Pete terrane.

Cretaceous: Kansas.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 255). *Pete terrane*, shales, 50 ft. thick. Underlies Brookville terrane (sss.) and uncon. overlies Mentor terrane, top of Comanchean. Included in Dakotan. [Derivation of name not stated.]

†Peter sandstone.

An abbreviation of *St. Peter ss.* introduced by C. [R.] Keyes. (See Pan-Am. Geol., vol. 38, No. 4, 1922, pp. 313–326, and subsequent volumes.)

Petermann series.

Lower Cambrian: Eastern Greenland.

C. Teichert, 1933 (Meddelelser om Grønland, Bd. 95, No. 1, p. 26).

Petersburg formation.

Pennsylvanian: Southwestern Indiana.

M. L. Fuller and G. H. Ashley, 1902 (U. S. G. S. Ditney folio, No. 84, p. 2). *Petersburg fm.*—Alternating sss. and shales with persistent bed of ls. at top. Thickness 80 ft. Underlain by Brazil fm. and overlain by Millersburg fm. Limited below by base of Petersburg coal, and above by base of Millersburg coal (No. 7).

Redefined by E. R. Cumings in 1922 (Ind. Geol. Surv. Sep. Pub. 21) so as to include coal No. 7 at top, and at base all beds down to top of coal No. 4. As thus redefined it is discon. overlain by Shelburn fm. and discon. underlain by Staunton fm.

This name was used by F. W. DeWolf in Ill. (Ill. Geol. Surv. Bull. 16, 1910, pp. 178–181) for beds extending from top of coal No. 6 to base of coal No. 5, the underlying beds down to base of coal No. 2 being called by him *LaSalle fm.* The Petersburg and LaSalle of DeWolf comprise Carbondale fm. of present nomenclature.

Named for Petersburg, Pike Co.

Petersburg granite.

Pre-Cambrian: Eastern Virginia.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Petersburg granite.*—Coarse to fine gray biotite granite with coarse pink porphyritic facies intruded by fine bluish granite in Fredericksburg, Richmond, and Emporia areas. Mapped over large area including Petersburg.

Petersburg sand.

A subsurface sand in Mooretown ss. (Miss.) of Cumings in Ind.

Peters Creek schist.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania, northern Maryland, and northeastern Virginia.

A. I. Jonas and E. B. Knopf, 1921 (Wash. Acad. Sci. Jour., vol. 11, p. 447). An upper member of Wissahickon fm. that is less highly anamorphosed than the Wissahickon itself has been separated and named by the writers the *Peters Creek schist*. It may represent Harpers schist memb. of Mont Alto qtzite of central Pa.

E. B. Knopf and A. I. Jonas, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 40–62). [See quotation under *Wissahickon fm.*]

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.), mapped *Peters Creek qtzite* over a large but disconnected area in NE. Va.

Named for exposures along Peters Creek, which enters Susquehanna River at Peach Bottom, Lancaster Co., Pa.

Peters Mountain sandstone. (In Pocono formation.)

Mississippian: Central Pennsylvania.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 573). Pocono fm. is usually tripartite. At its base occur locally Griswolds Gap cgl. or, to W., Knapp cgl. or ss. Overlying these is massive conglomeratic "Berea" ss. A similar massive pebbly memb., the Burgoon ss., forms highest third of fm. A middle platy div., *Peters Mtn ss.*, intervenes btw. the "Berea" and the Burgoon. This trifid character is distinctive throughout central Pa. *Peters Mtn ss.* was proposed by writer in rept. on Miss. system of Pa. submitted in 1935 to National Research Council. Named for Peters Mtn, Dauphin Co.

Peterson limestone. (In Gannett group.)

Cretaceous (?): Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98, pp. 76, 82). *Peterson ls.*—Massively bedded near top; very persistent throughout region, forming prominent ridges that can be followed by the eye for miles from some of higher summits. Thickness 205 ft. Underlies Bechler cgl. and overlies Ephraim cgl.; all in Gannett group. Named for exposures E. of Peterson's ranch, along Tygee Creek, sec. 34, T. 7 S., R. 46 E., Boise meridian. May be Jurassic.

Peterson Creek syenite.

Jurassic (?): British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 82).

Petersville shale.

Mississippian: Northeastern Kentucky.

W. C. Morse and A. F. Foerste, 1912 (Ky. Geol. Surv. Bull. 16, p. 24). *Petersville sh.* proposed as substitute for hyphenated term *Bedford-Berea sh.*, because S. of Vanceburg, Lewis Co., the Bedford and Berea cannot be separated.

Named for Petersville, Lewis Co.

†Pethtle rocks.

A name applied locally in W. Va. to Gilmore ss. memb. of Greene fm. (See I. C. White, W. Va. Geol. Surv., vol. 1, 1899, pp. 197–213.)

Petit-Bourg series.

Age (?): West Indies.

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 513).

Petitcodiac series.

Pennsylvanian: New Brunswick.

W. J. Wright, 1922 (Canada Geol. Surv. Mem. 129, p. 25). [Assigned to Carbf. by Wright; but G. W. H. Norman, 1932 (Canada Geol. Surv. Econ. Geol. ser. No. 9, p. 172) assigned it to Penn.]

Petoskey limestone.

Middle Devonian: Michigan (northwestern part of Lower Peninsula).

A. W. Grabau, 1902 (Mich. Geol. Surv. Rept. 1901, pp. 201, 210). *Petoskey ls.*—Lss. and dolomites, 360 ft. thick, underlying 45 to 50 ft. of chert beds forming top div. of Traverse group and overlying *Acervularia* and *Stropheodonta nacrea* beds, all of which are included in Traverse group.

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14). *Petoskey fm.* was first applied by Grabau, to beds largely equiv. to the fm. herein proposed, but without proper delimitation. Since the term is particularly applicable it has been here adopted to the usage proposed. Thickness 13 to 100+ ft. Consists of lss. with some beds of sh. Forms top div. of Traverse group in northern counties of Lower Peninsula. Overlies, with uncon. and overlap, Charlevoix stage of Traverse group. [Gives details of beds and faunal zones. See also under *Charlevoix stage.*]

Probably named for exposures at Petoskey.

†Petro limestone lentil (of Bingham quartzite).

A name inadvertently used on map and in places in text of U. S. G. S. P. P. 38, 1905, for the Tilden ls. lentil of Bingham qtzite in Bingham dist., Utah. The Tilden is the ls. in Petro mine.

Petro oil sand.

Name locally applied to a sand (in Carbondale or in Pottsville fm.) lying about 230 ft. below Herrin (No. 6) coal, in Wamac field of Centralia area, Marion Co., SE. Ill. It is 30 ft. thick.

Petrolia 1st sand.

Drillers' term for a sand in Pocono fm. of Butler Co., Pa., which lies about 120 ft. above Butler 2d sand.

Petrolia shale.

Devonian: Ontario.

C. R. Stauffer, 1915 (Canada Geol. Surv. Mem. 34, pp. 4, 192).

Petrolia shale member (of Hamilton formation).

Devonian: Ontario.

W. Malcolm, 1915 (Canada Geol. Surv. Mem. 81, p. 42).

Pettus sand.

A subsurface sand in the upper Eocene of Driscoll pool, Duval Co., Tex. It is said to belong to Yegua fm. (See A. A. P. G. Bull., vol. 15, No. 7, pp. 778–782, 1931.) A. Deussen and E. W. K. Andrau (A. A. P. G. Bull., vol. 20, No. 5, 1936, p. 540) assign it to uppermost part of Yegua fm. in Pettus dist., where it lies 170 ft. above Tuleta sand.

Petty Hill moraine.

Pleistocene (Wisconsin stage): Northeastern New York (Essex County). Named for Petty Hill. See N. Y. State Mus. Bull. 187, 1916.

Pewabic amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. Pumpelly, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 21–25, 28). [Called *Pewabic copper-bearing bed.*]

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 58, 86, and chart). [Called *Pewabic lode* and *Pewabic cupriferous bed,* and said to consist of amygdaloid.]

Belongs to Ashbed group. The mineralized part is the Pewabic lode. Named for occurrence in Pewabic mine, Houghton Co.

Pewabic flow.

Includes Pewabic amygdaloid and underlying trap.

Pewabic quartzite.

Pre-Cambrian (Huronian): Northeastern Minnesota (Gunflint Lake region).

N. H. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept., pp. 79, 86). *Pewabic qtzite.*—A great qtzite near top [?] of the Animikie in region of Gunflint Lake to Ogishke Muncie Lake. Named for Chippewa word meaning *iron.*

N. H. Winchell, 1891 (Minn. Geol. Nat. Hist. Surv. 18th Ann. Rept.). *Pewabic qtzite* is considered to overlie Animikie black sl., unless there are two great qtzites.

N. H. and H. V. Winchell, 1891 (Minn. Geol. Nat. Hist. Surv. Bull. 6). At base of Animikie series is a fragmental quartz ss. 300 ft. thick—the *Pewabic qtzite*. Includes iron ore beds.

N. H. Winchell, 1893 (Minn. Geol. Nat. Hist. Surv. 20th Ann. Rept.) *Pewabic qtzite* at base of Animikie series lies uncon. on all older rocks. In many places it is conglomeratic. It includes the qtzite of Pokegama Falls, on Mississippi River, and of Pipestone Co.

H. V. Winchell, 1893 (Minn. Geol. Nat. Hist. Surv. 20th Ann. Rept.), correlated *Pewabic qtzite* of Gunflint Lake with Pokegama qtzite of Mississippi River.

A. H. Elftman, 1894 (Minn. Geol. Nat. Hist. Surv. 22d Ann. Rept., pp. 150–180). The so-called *Pewabic qtzite* btw. Birch Lake and Gunflint Lake belongs to middle memb. (iron-bearing) of the Animikie. The *Pewabic qtzite* is lower memb. of the Animikie. It disappears entirely in vicinity of Iron Lake.

J. E. Spurr, 1894 (Minn. Geol. Nat. Hist. Surv. Bull. 10). So far as yet definitely known the *Pewabic qtzite* is basal memb. of Animikie series.

U. S. Grant, 1894 (Minn. Geol. Nat. Hist. Surv. 22d Ann. Rept., pp. 67–78). The name "Pewabic qtzite" was proposed for and applied to the iron-bearing rocks of Akeley Lake (N. H. Winchell, 16th Ann. Rept., p. 86, 1888). [Akeley Lake lies W. of Gunflint City.] Subsequently this term has been applied quite extensively to qtzite memb. at base of Animikie on western Mesabi range, so that now the term Pewabic usually refers to this qtzite, which, however, in the Minn. repts has been considered as=the iron-bearing rocks of Akeley Lake. Writer would refer these rocks to the iron-bearing memb., if they belong to the Animikie.

U. S. Grant, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, pp. 166–190). Pokegama qtzite is called at times *Pewabic qtzite*. It is a persistent horizon at base of Animikie series.

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, pp. 181, 398). *Pewabic qtzite* belongs with Keewatin, but whether to Lower or Upper Keewatin is not known. Pokegama qtzite belongs to the Animikie. It blends into the iron fm. and to E. is replaced by Pewabic qtzite. The Pokegama is associated with taconitic iron ore and the Pewabic with jaspilitic. The Pokegama is not known to be titaniferous; the Pewabic is usually distinctly titaniferous. The Pokegama qtzite is never associated with the peculiar muscovadyte, but the Pewabic is never without it. The Pokegama qtzite, with its taconitic companion, is known to be overlain by the black slates of the Animikie, and occurs only westward from Iron Lake. The Pewabic qtzite is overlain and underlain invariably by muscovadyte, or by "gabbro," where the alteration was intense, and occurs only eastward from vicinity of Iron Lake.

Pewabic West conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 82 and chart). *Pewabic West cgl.* is cgl. No. 16 of Houghton Co.

Is in Ashbed group.

Probably named for occurrence in old Pewabic West mine, Houghton Co.

Peyotes division.

Cretaceous: Mexico.

E. Ordóñez, 1908 (Min. and Sci. Press, vol. 96, p. 363).

Pfeifer shale member (of Greenhorn limestone).

Upper Cretaceous: North central Kansas.

N. W. Bass, 1926 (Kans. Geol. Surv. Bull. 11, p. 32). *Pfeifer sh. memb.*—Chalky sh. interbedded with soft thin chalky lss.; the "fence-post ls." forms top bed. Thickness 19 to 21 ft. Top memb. of Greenhorn ls. in Russell to Hamilton Counties. Overlies Jetmore chalk memb. of Greenhorn ls. and underlies Fairport chalky sh. memb. of Carlile sh.

Named for exposures 2½ mi. NW. of Pfeifer, Ellis Co.

Phalen Lake volcanics.

Tertiary (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 101; map). *Phalen Lake volcanics.*—Series of lavas, tuffs, and breccias over 1,000 ft. thick. Do not resemble

Rossland volcanics, but may possibly be in part correlative with Rossland. Not metamorphosed and, except for surficial alteration, appear relatively fresh. Tuffaceous phases light-colored and have grayish-white tint, fine-grained, and greatly indurated. Occupy 11± sq. mi. in north-central part of county, 7 mi. S. of Rossland volcanics. Rest uncon. on upturned and eroded edges of Mission argillites and Northport ls. Form steep escarpment overlooking W. side of Phalen Lake. Assigned to Tert. [See *Rossland volcanic fm.*]

Phanerozoic eon.

A term that has been proposed (see C. Schuchert and C. O. Dunbar, Textbook geol., pt. 2, p. 70, 1933) to include Cambrian and all subsequent time. Derived from the Greek *phaneros*, visible.

†Phelps sandstone.

Devonian (?): Southwestern Missouri.

E. M. Shepard, 1898 (Mo. Geol. Surv. vol. 12, pt. 1, pp. 49, 77–82). *Phelps ss.*—Soft, irregularly bedded coarse-grained ss., 0 to 4 ft. thick, uncon. overlying Sac. ls. and uncon. underlying so-called (not typical) Louisiana ls., of Kinderhook group. Top fm. of Hamilton stage of Dev. in Greene Co., Mo.

S. Weller, 1901 (Jour. Geol., vol. 9, pp. 130–148), included *Phelps ss.* in Kinderhook.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, pp. 41–42), assigned *Phelps ss.*, 10 ft. thick, to Hamilton (Dev.), and correlated it with Sylamore ss. of Ark.

G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, p. 67), assigned *Phelps ss.* to Hamilton, as did Otto M. Smith and Paul C. Standley, 1907 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, pp. 73–74).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29), correlated *Phelps ss.*, Sac ls., and King ls. with Louisiana ls., and assigned all to Kinderhook.

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser., p. 177), assigned *Phelps ss.* to Miss. In southern and western Mo. it occupies a strat. position near that of Hannibal sh. of NE. Mo.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.), assigned *Phelps ss.* to Kinderhook group.

E. B. Branson, 1923 (Mo. Bur. Geol. and Mines vol. 17, 2d ser.), stated *Phelps ss.* is=Sylamore ss.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., p. 108). Sylamore ss. was called *Phelps ss.* in earlier Mo. repts.

Named for Phelps mines, Greene Co.

Phi Kappa formation.

Ordovician (Lower and later?): Central Idaho (Hailey quadrangle).

L. G. Westgate and C. P. Ross, 1930 (U. S. G. S. Bull. 814, pp. 10, 18). *Phi Kappa fm.*—Upper 4,600 ft. consists of a series of dark shales and interbedded yellow shaly sss.; lower 4,800 ft. consists of medium and fine-grained qtzitic sss. and flinty argillites, commonly black, weathering to rusty slabs. Graptolites of lower and upper parts indicate late Chazy age. Uppermost 25 ft. contains fauna that may be late Middle or Upper Ord. In fault contact with overlying Trail Creek fm. (Sil.). Rests on argillites carrying Lower Ord. (Beekmantown) fossils. Named for exposures along Phi Kappa Creek, Hailey quad.

Philadelphia brick clay.

Pleistocene: Southeastern Pennsylvania and southwestern New Jersey.

H. C. Lewis, 1881 (Phila. Acad. Nat. Hist. Sci. Proc., vol. 32, pp. 258–272, 296–309). *Philadelphia brick clay.*—Of large extent and with numerous boulders. Is confined to river valley. Rests uncon. on both Philadelphia red gravel and the Fossiliferous gravel, now called Glassboro gravel. Philadelphia is in part built on this clay. Thickness about 15 ft.

F. D. Chester, 1884 (Am. Jour. Sci., 3d, vol. 27, pp. 189–199). Yellow brick clay, sand, loam, or loamy gravel, 5 to 20 ft. thick, which "we shall call *Philadelphia clay*, after Prof. H. C. Lewis." Overlies the Red Gravel.

Is a part of Cape May and Pensauken fms., according to U. S. G. S. Philadelphia folio (No. 162), 1909, and both underlies and overlies the "Red gravel."

†Philadelphia mica schists and gneisses.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania.

C. E. Hall, 1881 (2d Pa. Geol. Surv. Rept. C_6, map and pp. 28–31). *Philadelphia mica schists and gneisses* [on map], *Philadelphia group* of mica schists and gneisses [in text]. Extends from Delaware River at Trenton westward across Schuylkill River into Delaware Co.

Replaced in part by Wissahickon fm.

Philadelphia red gravel.

Pleistocene: Southeastern Pennsylvania.

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc., vol. 32, pp. 258–272, 296–309). *Philadelphia red gravel.*—Stratified clayey gravel composed of pebbles on the Fossiliferous gravel (Glassboro gravel) mixed with fragments of Triassic red sh. and other rocks brought down Delaware Valley. Rests on decomposed gneiss. Philadelphia is in part built on this gravel. It might be called *University gravel* for distinction, as good sections of it are seen near University of Pa. Thickness 20 ft. Uncon. underlies Philadelphia brick clay.

Is a part of Pensauken fm., according to U. S. G. S. Philadelphia folio (No. 162), 1909.

Philadelphia moraine.

Pleistocene (Wisconsin stage): Northwestern New York (Jefferson County).

Named for Philadelphia, Jefferson Co. (See Jour. Geol., vol. 32, 1924, pp. 645, 660.)

A. F. Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 44–45). Extends from near Philadelphia, Jefferson Co., to 1 mi. E. of Antwerp, Jefferson Co.

Philipsburg series.

Phillipsburg series.

Lower Ordovician and older (?): Southern Quebec and northwestern Vermont.

W. E. Logan, 1863 (Geol. Surv. Canada, pp. 273–280, 844–854), described the rocks of Philipsburg, Quebec, region, but did not definitely name them. Assigned them to Quebec group.

R. W. Ells, 1896 (Canada Geol. Surv., n. s., vol. 7, pp. 16J to 17J, 30J to 32J). *Phillipsburg series*, Cambro-Silurian, Quebec, Canada. Included in Quebec group. Includes Lower Phillipsburg (Calciferous), Upper Phillipsburg (Chazy). [Later Canada repts spell this name with one *l*.]

H. W. McGerrigle, 1931 (17th Rept. Vt. State Geol., pp. 184–186). The term "*Philipsburg series*" is meant to include a group of 13 fms. ranging in age from Ozarkian to Chazy and extending from about latitude of Highgate Springs, Vt. northward across Quebec-Vt. bdy for about 20 mi. Named for village of Philipsburg, Quebec, where the lower fms. of the series are well exposed. Logan has given most complete account of Philipsburg series, and his table of fms. (p. 273 of rept cited above) has been the standard of reference for other workers in the field. Following outline of his table is given (descending):

D3. Gray and black striped slates, 1,500.
D2. Black and greenish argill, slates, 1,000.
D1. Ls. cgls., at least 2 bands, separated by slates, 300.
C2. Black slates or thin-bedded black lss., 170.
C1. Black massive, pure lss., 150.
B5. Black lss., mag. beds at base, 350.
B4. Black slaty thin-bedded lss., 300.
B3. Dark bluish-gray thin-bedded lss., 150.
B2. Dark lss., some mag. beds, 120.
B1. White and dove-gray pure lss., some mag. beds, 120.
A3. Reddish gray and black dolomites, some thin-bedded black lss., 200.
A2. White and dove-gray pure compact lss., 100.
A1. Dark-gray and yellowish-white dolomites, 400.
Total thickness, 4,860 ft.

In this rept only fms. A1 to B3 inclusive are considered. During writer's work on Philipsburg series N. of Int. Bdy it was found advisable to make some changes over Logan's section from A1 to B3, as outlined below:

Logan's section:		Revised section (all mapped in Vt.):
B3, 150		Luke Hill 160
B2 (summit bed)	120	Naylor Ledge 30
B2 (below summit bed)		Hastings Creek 260
B1, 120		
A3, 200		Morgans Corners (dol.) 150 Wallace Creek fm. (interstratified thin-bedded shaly lss. with thicker bedded lss.) 200-250
A2, 100		Strites Pond 400
A1, 400		Rock River 500

Philipsburg series is older than his Highgate Springs series. [Type localities of all of above newly named fms. are in Quebec.]

†Philipsburg formation.

Lower Ordovician: Northwestern Vermont and eastern New York.

R. P. Whitfield, 1890, suggested this name for same beds that have been called "Cassin fm." and "Fort Cassin fm." (See explanation under *Beekmantown group*.)

Phillips formation.

Pre-Cambrian: Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 2, 114°30′ to 115°). *Phillips fm.*—Purplish to red thin-bedded metargillite and qtzite. Underlies Roosville fm. and overlies Gateway fm.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 108, table at p. 178). *Phillips fm.*—Chiefly dark-purplish or brownish-red fine-grained to compact metargillite and metasandstone in alternating thin beds. At base 3 massive beds of gray qtzitic ss., 4, 10, and 20 ft. thick, are intercalated. Thickness 550 ft. Conformably underlies Roosville fm. and grades into underlying Gateway fm. Named for occurrence on two summits about 2 mi. N. of Phillips Creek.

Phillips sand.

A subsurface sand lying 600± ft. below top of Colorado sh. in Bowdoin dome, NE. Mont. See under *Martin sandy zone*.

Phillips moraine.

Pleistocene (Wisconsin stage): Northeastern New York (Essex County). Named for Phillips place. See N. Y. State Mus. Bull. 187, 1916.

Phillipsburg series. See *Philipsburg series*.

Philson limestone. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Somerset County).

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, pp. 286, 292). *Philson ls.*, underlies Philson (or Rose) coal, and lies about 40 ft. above Gallitzin coal. Thickness 3 ft.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q. pp. 303–305). Brush Creek ls. is same as *Philson ls.* of Somerset Co.

J. D. Sisler, 1925 (Pa. Geol. Surv. 4th ser., Bull. M_2, pp. 268, 331). [Gives following downward sequence of beds in Conemaugh of Somerset Co.: Elk Lick coal, Elk Lick ls., Berlin coal, Berlin ls., Platt coal, Price coal, Coleman coal, Coleman ls., Philson (Rose) coal, *Philson ls.*, Johnstown iron ore, Brush Creek (Gallitzin) coal, Mahoning ss.]

Probably named for exposures at or near Philson, Somerset Co.

Phipsburg limestone.

Age (?): Maine.

C. T. Jackson, 1838 (Rept. on geol. of Maine, vol. 2, pp. 61–62), refers in several places to *Phipsburg ls.* of Phipsburg Basin. This is an econ. rept.

Phoenix beds.

A name that has been used, but not defined, by F. M. Anderson (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 1-62, 1902) for a part of lower beds of Chico age in southern part of Oregon Basin.

Phoenix limestone lentil (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 44, map, and sections). *Phoenix ls. lentil of Bingham qtzite.*—White or light-colored siliceous marble. Thickness 0 to 300 ft. [Sections show it some distance above Tilden ls. lentil. Crops out at mouth of Phoenix mine.]

Phoenix volcanic group.

Mesozoic (?) and older (?): Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 9, 10, 118° to 119°). *Phoenix volcanic fm.*—Flows and pyroclastic deposits of augite andesite, etc. Carbf. to Triassic.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 383, 385, 377-388). *Phoenix volcanic group.*—Pyroclastic flows (?) and contemp. intrusions of porphyrite. The town of Phoenix is in midst of this large though interrupted area of basic volcanics. *Phoenix volcanics* are possibly largely Mesozoic and contemp. with andesitic members of Rossland group. Uncon. is believed to exist btw. Phoenix group and Attwood series. [See *Rossland volcanic fm.*]

Phoenix or Schroeppel shale.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327-368). *Phoenix or Schroeppel sh.*—Olive-colored sh. and intercalated sss. underlying Donnelly ore and Lakeport ls. and overlying Kirkland iron ore or ls. Thickness 62 ft. at South Granby and Lakeport, from which place the beds are connected by numerous outcrops with the upper sandy layers at Clinton and Utica. Westward the sandy layers at this horizon drop out and thin limy ones come in, increasing until finally the division seems to merge into Irondequoit ls. Fossils listed. Type loc. at Phoenix, on Oswego River [Oswego Co.]. Since *Phoenix* has been used for ls. in Utah and for volcanic fm. in B. C., recourse may be had, if necessary, to *Schroeppel*, the Twp in which Phoenix lies.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 191, 347). Clinton fm. in Lakeport, N. Y., region divided into (descending): Sh. of Rochester age, 29 ft.; Lakeport ls. (of Rochester age), 17 ft.; Donnelly ore (of Rochester age); *Schroeppel sh.*, 62 ft.; ls. of Irondequoit age, 6 ft.; *Brewerton sh.*, 36 ft.; *Williamson sh.*, 105 ft.; Wolcott ls., 18 ft.; Sodus sh., 31 ft.; *Reynales ls.*, 7 ft.; and Maplewood sh., 7 ft. [*Schroeppel sh.* is shown as=lower part of Rochester sh. and underlying Irondequoit ls., as younger than *Williamson sh.*, and as pinching out E. of Wolcott, where Irondequoit ls. rests on *Williamson sh.* and *Williamson sh.* rests on Wolcott ls. This is position assigned to *Williamson sh.* by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10).]

†Phoenix Mine group.

Pre-Cambrian (Keweenawan): Northern Michigan (Keweenaw County).

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 175-178). Beneath the Greenstone (bed 108), and separated from it by a red clay seam, which is known locally as "The Slide" and is a thin cgl. bed farther E. and W., a few hundred ft. of rock are exposed to view in Phoenix mine, which is one of the numerous workings just beneath the Greenstone on N. and S., or crossing veins. The total thickness of these beds, which I may appropriately call *Phoenix Mine group*, is 685 ft., in beds ranging from 9 to 160 ft. Overlies Kingston cgl., from which it is separated by a covered space of 2,325 ft.

Includes upper part of Central Mine group.

Phoenix Park quartz latite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). Lava flows and tuff breccias of a fairly uniform rock. Thickness 0 to 500 ft. Is a fm. in Alboroto group of Potosi volcanic series. The main body rests on a fairly regular surface of Campbell Mtn rhyolite, and uncon. underlies Mammoth Mtn rhyolite. Another body of similar rock occurs as a lens btw. flows of Campbell Mtn rhyolite, and it is believed there was an interbedding of the two types of material. Named for development about Phoenix Park.

†Phoenixville shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Bucks and Montgomery Counties).

B. S. Lyman, 1894 (Am. Phil. Soc. Proc., vol. 33, pp. 197–215). *Gwynedd and Phoenixville shales.*—In great part hard, dark or greenish gray and blackish, partly dark red, at Gwynedd and Phoenixville tunnels, with traces of coal. Thickness 3,500 ft. Underlie Lansdale shales and overlie Norristown shales.

Same as Lockatong fm., of Newark group.

Phosphoria formation.

Permian: Northeastern Utah, eastern Idaho, central western, central southern, and southwestern Montana, and western Wyoming.

R. W. Richards and G. R. Mansfield, 1912 (Jour. Geol., vol. 20, pp. 683–689). *Phosphoria fm.*—Phosphatic shales, with some thin lss., and, at top, Rex chert memb. In region of Bannock overthrust (SE. Idaho and NE. Utah) thickness of fm. is 75 to 627 ft. and thickness of Rex chert memb. 0 to 450 ft. Is=upper two members of Park City fm. of Park City dist., Utah, namely the phosphate shales and the "overlying chert." Overlies Wells fm. (Penn.) and underlies Woodside sh. (Triassic). Named for Phosphoria Gulch, which joins Georgetown Canyon 2.5 mi. N. 16° W. of Meade Park, Idaho, in which the fm. is typically exposed. [Complete detailed section at type loc. given and fossils listed.]

Piasa limestone. (In McLeansboro formation.)

Pennsylvanian: Southwestern Illinois (Jersey, Macoupin, *or* Madison Counties).

H. E. Culver, 1925 (Ill. Geol. Surv. Coop. Min. Ser. Bull. 29, p. 20). In S. part of 3d dist. are one or more lss. in McLeansboro fm. which can be traced considerable distances. The most important of these are *Piasa ls.*, named for Piasa Creek, on which it is most excellently exposed, and *Golden Eagle ls.*, well known in Calhoun Co. These beds are of considerable value in strat. work, since they constitute horizon markers which can be positively identified over relatively large areas. [Position within McLeansboro fm. not defined.]

Piasa Creek runs through SE. corner of Jersey Co., SW. corner of Macoupin Co., and NW. corner of Madison Co.

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, pp. 129–138). *Piasa ls.* overlies coal No. 7 and is 5 to 6 ft. thick in places in Jersey Co. Is older than Lonsdale ls.

†Picacho limestone.

Permian: Southeastern New Mexico (Roswell artesian basin).

A. G. Fiedler and S. S. Nye, 1933 (U. S. G. S. W. S. P. 639). *Picacho ls.*—A lithologic unit consisting dominantly of ls. and dolomitic ls. but including minor amounts of ss., sh., gyp., and anhydrite, whose upper and lower limits are variable with respect to strat. position and time. Throughout most of Roswell artesian basin the Picacho ls. is underlain, apparently conformably, by Nogal fm., but in SE. part of basin the Nogal gives place laterally to a thick ls. section, which is tentatively included in Picacho ls., and there the Picacho rests on the older Abo ss. Thickness of fm. 800 to 1,200 ft. where it underlies Pecos fm. and overlies Nogal fm., but top of fm. is locally eroded away. Named for town in vicinity of which lower part is well exposed. The beds here named *Picacho ls.* are believed by geologists working in this region to be strat. equiv. of San Andres ls. of Lee and Girty, and have been referred to by that name for years.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Picacho ls.* here abandoned for *San Andres ls. memb. of Chupadera fm.*, and *Nogal fm.* here abandoned, being replaced by Hondo ss. memb. of Chupadera fm. (above) and Yeso memb. of Chupadera fm. (below). [As originally defined and heretofore used San Andres ls. rested on the Yeso. The recognition of Hondo ss. involves slight redefinition of both Yeso and San Andres.]

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Picacho de Calera formation.

Devonian: Southeastern Arizona.

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 485, 488). *Picacho de Calera fm.*—In Picacho de Calera Hills, 25 mi. NW. of Tucson, consists of 73 ft. of beds (descending): (1) Fossiliferous calc. brown ss., 2 ft.; (2) black dol., 25 ft.; (3) yellow crystalline ls., largely of small calcified algal bodies and interbedded with thin flaggy blue ls., some fossils, 2 ft.; (4) blue ls. in beds 2 to 4 ft. thick, fossiliferous, 40 ft.; (5) yellow calc. ss., probably subeolian, 4 ft. It is there discon. underlain by Rincon ls. (Upper Camb.) and conformably overlain by Martin ls. [restricted]. Has been traced 75 mi. eastward into Rincon and Whetstone Mtns. Is Upper Dev.

Martin ls. (250 to 350 ft. thick) as originally defined and heretofore used included all Dev. of SE. Ariz., and has long been classified by U. S. Geol. Survey as *Upper and Middle Dev.* The foregoing newly described fm. appears to correspond to lower part of Martin ls. of previous repts.

Picayune volcanic group. (In Silverton volcanic series.)

Tertiary (Miocene): Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). *Picayune andesite.*—Augite andesite in tuff, breccia, or aggl., and massive flows; pronounced porphyritic texture. Thickness 0 to 500+ ft. Is basal div. of Silverton volcanic series. Uncon. underlies Eureka rhyolite and uncon. overlies San Juan tuff.

W. Cross, 1911 (U. S. G. S. Bull. 478, pp. 20, 24–26). *Picayune volcanic group.*—The earliest of lavas of Silverton volcanic series is a dark augite andesite occurring in relatively small exposures in Animas Valley and its minor tributary, Picayune Gulch, and named in Silverton folio the *Picayune andesite*, after latter locality. It is now known that andesite of Picayune Gulch is but one of the rock varieties erupted in first part of Silverton time, and that the complex group of early lavas is most prominent in country btw. Henson Creek and head of Lake Fork and in valleys of these streams. The name *Picayune* will be retained for the group, since it is already in use, and since relations of these rocks to overlying Eureka rhyolite are well shown in original locality. The Picayune volcanic group consists largely of andesite of type first observed, but includes also several kinds of more siliceous lava. The various elements are so irregularly associated as to make it clear the exposed rocks of the group belong to a central volcanic mass made up of surface lava streams, pyroclastic breccia and tuff, and intrusive bodies. The massive rocks have in many places been shattered and dislocated by volcanic shocks.

Picayune andesite.

See 1st entry under *Picayune volcanic group.*

Pic d' Aurore series.

Devonian: Quebec.

J. M. Clarke, 1915 (N. Y. State Mus. Bull. 177, pp. 149, 150).

Pickaway limestone. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 450–473). *Pickaway ls.*—Very dark, hard, sandy, stylolitic through most of Monroe Co. Scanty marine fossils. Thickness 175 to 400 ft. Underlies Union ls. and overlies Upper Taggard sh.; all members of Greenbrier series [ls.]. Type loc. along State road btw. Pickaway and Union, Monroe Co. Also observed in Mercer Co., and traced to NE. until it disappears in N. part of Pocahontas Co., W. Va. To SW. it increases in thickness to nearly 700 ft. in Washington Co., Va., but wholly disappears before Ky. and Tenn. lines are reached.

Pickens sandstone.

Pennsylvanian: Northern West Virginia.

J. A. Taff and A. H. Brooks, 1896 (U. S. G. S. Buckhannon folio, No. 34). *Pickens ss.*—White or gray massive ss. and cgl. at base; light-gray or white ss. at top; and a series of brown sss., shales, and coals in medial portion. Thickness 400 to 500 ft. Overlies Canaan fm. [Mauch Chunk sh.] and underlies Pugh fm. Named for town of Pickens, Randolph Co., which is located near its top.

Corresponds to New River "group" of later W. Va. repts.

Pickering gneiss.

Pre-Cambrian: Eastern Pennsylvania and New Jersey.

B. L. Miller, 1912 (Econ. Geol., vol. 7, p. 767). *Pickering gneiss.*—Graphitic gneisses. Name proposed by Miss Bascom, who intends to separate out the graphitic gneisses from the nongraphitic gneisses, both of which she included in Baltimore gneiss in Trenton folio.

B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M., pp. 61–66). Observations at several places in Piedmont Plateau lead writer to believe Franklin ls. and Pickering gneiss constitute a single fm. similar to Grenville fm. of N. Y. and Canada. The Franklin ls. or marble is coarsely crystalline, white, with graphite and numerous silicate minerals. The *Pickering gneiss* is banded gneiss or schist containing lenses of highly graphitic schists.

F. Bascom, 1932 (U. S. G. S. West Chester-Coatesville folio, No. 223). Several years ago the writer, in mapping the rocks of Phoenixville quad., Pa., separated the graphitic gneisses from the nongraphitic gneisses and proposed to apply to them the geographic name "Pickering gneiss," restricting the name *Baltimore gneiss* to the nongraphitic rocks, and that name and definition were published in an article by B. L. Miller in Econ. Geol. (vol. 7, p. 767, 1912). More recent work, however, on the pre-Camb. gneisses of SE. Pa. and Del., has led writer to consider the graphitic gneiss associated with recognized Baltimore gneiss as essentially a facies of that fm. and not a distinct fm. In this folio and other repts in preparation, therefore, the graphitic gneiss is included in Baltimore gneiss and name "Pickering gneiss" is dropped.

In 1934 the U. S. Geol. Survey decided to adopt *Pickering gneiss* for the pre-Camb. sed. rocks associated with Franklin ls.—a white, coarsely crystalline ls. or marble, more or less contemp. with Pickering gneiss, with which it is found interbedded as well as apparently overlying. This gneiss is a medium-grained quartz-feldspar-mica rock, usually light-colored, owing to paucity of dark-colored constituents, and pinkish or greenish in tone, owing to abundant altered feldspar. The rock is always gneissic, but in absence of contrasting constituents this texture is not conspicuous. The feldspar is orthoclase, microperthite, microcline, and a sodic plagioclase, albite or andesine. Graphite-bearing beds are an important feature of the fm. in Phoenixville and Honeybrook quads. Uncon. underlies Lower Camb. Thickness unknown. Named for fact that Pickering Creek, Chester Co., lies almost wholly within this gneiss area. This is definition now followed by F. Bascom.

Pico formation. (Of Fernando group.)

Pliocene (upper): Southern California (Los Angeles and Ventura Counties).

B. L. Clark, 1921 (Jour. Geol., vol. 29, pp. 608–609 and chart opp. p. 586). Over fairly large area in Los Angeles region there is a marked difference in dip and strike btw. the lower and middle Fernando, now referred to *Pico fm.* by U. S. Geol. Survey, and what has previously been referred to as *upper Fernando.* (Footnote: A paper by Dr. W. S. W. Kew, of U. S. Geol. Survey, is now in press in which the Fernando is considered a group composed of Pico and Saugus fms. separated by an uncon.) The beds of this upper horizon contain very large percentage of recent species. The Geol. Survey proposes to use *Saugus fm.* for the upper Fernando section, which is herein referred to as *Saugus group.*

W. S. W. Kew, 1923 (A. A. P. G. Bull., vol. 7, pp. 411–420). The author's name *Pico fm.*, for lower fm. of Fernando group, first appeared in print in 1921, in brief paper by B. L. Clark on Los Angeles region. The fm. is well exposed in Pico Canyon, Los Angeles Co., from which it is named. It is also well exposed in Santa Clara Valley and in San Fernando Valley, where it rests uncon. on Modelo fm. and lies uncon. below Saugus fm. Is entirely of marine origin and contains fauna belonging to base of the Plio.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753). *Pico fm.*, the lower fm. of Fernando group, consists of fine-grained gray ss., interbedded with coarse ss. and cgl., and is about 4,000 ft. thick. Along S. side of Fernando Valley and westward to Las

Virgenes Canyon it consists of laminated gray sandy clay and fine-grained ss. with zones or lenses of white diatomaceous soft sh.; the upper strata largely medium-grained soft ss. with some cgl.

J. E. Eaton, 1926 (Oil and Gas Jour., Nov. 11, 1926, p. 72; Oil Age, Nov. 1926, p. 16). Santa Paula fm., 10,000 ft. thick, previously unrecognized, underlies Pico fm. and uncon. overlies Modelo fm. [See under *Santa Paula fm.*]

In 1932 (16th Int. Geol. Cong. Guidebook 15) *Pico fm.* was restricted to middle and upper Plio. beds and *Repetto fm.* was adopted for lower Plio. beds. The overlying Saugus fm. was also restricted to beds of lower Pleist. age, the beds of upper Plio. age previously included in it being transferred to Pico fm. (See W. P. Woodring, pl. 2 and p. 35; R. D. Reed, p. 31; W. S. W. Kew, p. 49.)

W. P. Woodring now (March 1937) classifies Pico fm. as upper Plio., and this is present age designation of U. S. Geol. Survey.

Picton granite.

Pre-Cambrian: Northern New York (Alexandria Bay, Grindstone, and Clayton quadrangles).

J. M. Clarke, 1909 (N. Y. State Mus. Bull. 133, pp. 9–10). *Picton granite.*—Coarse red granite. Seems to be latest rock in dist. (Alexandria Bay, Grindstone, and Clayton quads.). Outcrops of considerable extent occur on Grindstone and Wellesley Islands, also in Canada, but in N. Y. it occurs chiefly as dikes cutting all other rocks. Assigned to pre-Cambric; later than Laurentian and later than Grenville schists.

H. P. Cushing et al., 1910 (N. Y. State Mus. Bull. 145, p. 11, maps). *Picton granite.*—A coarse, rather bright-red granite, with fine-grained phases. Red feldspars constitute 75 percent of mass. Named for Picton Island (called Robbins Island on all maps) [in St. Lawrence River]. Younger than Alexandria syenite, as it holds inclusions of that rock. Assigned to pre-Camb.

Picton formation.

Ordovician: Ontario.

P. E. Raymond, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 348).

Replaced by *Cobourg ls.*, q. v.

Pictou freestones.

Carboniferous: Nova Scotia.

H. M. Ami, 1899 (Brit. Assoc. Adv. Sci. Rept. 1899, p. 756).

Pictou formation.

Carboniferous: Canada.

H. M. Ami, 1900 (Canadian Rec. Sci., vol. 8, pp. 162–163).

†Picturecliff sandstones.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, p. 279).

Same as Pictured Cliffs ss.

Pictured Cliffs sandstone.

Upper Cretaceous (of Montana age): Southwestern Colorado and northwestern New Mexico.

W. H. Holmes, 1877 (U. S. Geol. and Geog. Surv. Terr. 9th Ann. Rept., for 1875, pp. 248, 250, 251, pl. 35). *Pictured Cliffs group*, also *Pictured Cliff ss.*—Overlies Sand Shale group [later named Lewis sh.] and underlies Laramie (?) group. Assigned to Fox Hills epoch. [In pl. 35 is described as consisting, in valley of Rio San Juan, of 130 ft. of massive sss.; on pp. 247–248 is described as consisting, btw. Pinon Mesa and Mesa Verde, of 30 ft. of white ss. followed [downward] by 100 ft. of brownish and yellowish sss. and shales; on p. 251 is described as consisting, as exposed on San Juan down to Great Hogback, of 40 ft. of white ss. and 60 to 80 ft. of yellowish-gray ss., underlain by 30 to 40 ft. of brownish laminated sss.]

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). Holmes evidently restricted *Pictured Cliffs ss.* to the massive ledges and excluded the interbedded sh. and sss. beneath them, which writer believes should be included, and which he does include, making total thickness of fm. 281 ft. It grades into underlying Lewis sh. and into overlying Fruitland fm., of late Montana age. The Pictured Cliffs ss. has not been recognized outside of San Juan Basin, where it is of variable thickness. It contains a littoral marine fauna of Montana age. [In pl. 4 he correlates it with uppermost part of Pierre sh.]

Named for Pictured Cliffs of San Juan River, in NW. N. Mex.

Picursian series. See *Pecursian series.*

†Piedmont group.

Cambrian and pre-Cambrian: Western North Carolina (Piedmont Plateau).

W. C. Kerr, 1869 (N. C. Geol. Surv. Rept. 2, pp. 13–35). *Piedmont group.*—A series of metamorphic gneissoid rocks, which are essentially a repetition of Buncombe group. It consists of a succession of feldspathic, hornblendic, and micaceous slates and gneiss, the most conspicuous of which is the broad belt of light-colored and gray feldspathic gneiss, sometimes fine, generally coarse-grained and porphyroidal, which extends along W. side of the fm. from upper French Broad to the Catawba in Burke Co. This fm. extends eastward to the King's Mtn slates, being limited in that direction by a line connecting that mtn with the Pilot, in Surry Co., occupying nearly the whole of the piedmont plateau. It may therefore appriately be named *Piedmont group*, although it extends across the Blue Ridge into Henderson and Transylvania Counties.

The rocks described are now divided into many fms. See North Carolina correlation chart.

Named for development in Piedmont Plateau of N. C.

†Piedmont sandstone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland and northern West Virginia.

C. A. Ashburner, 1877 (Am. Phil. Soc. Proc., vol. 16, pp. 519–560). *Piedmont ss.*—Upper memb. of *Pottsville (Seral) cgl.* Thickness 160 ft. Upper part consists of white and reddish-white and gray flaggy ss. and cgl.; in middle part cgl. predominates; lower part is principally thinly bedded and conglomeratic ss. [Appears to include more than Homewood ss. memb. of Pottsville fm.]

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, p. 180, pls. 10 and 11). *Piedmont ss.*, "the upper portion of the Pottsville cgl. (No. XII), the name Piedmont being derived from the Cumberland Basin."

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q. pp. 308–316). *Piedmont (Upper Homewood) ss.* underlies Brookville coal.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2, p. 77). *Piedmont (Tionesta) ss.* is=Homewood ss. [See quotation under †*Tionesta ss.*]

Probably named for Piedmont, Mineral Co., W. Va., where it is well exposed. See U. S. G. S. Piedmont folio, No. 28, 1896, in which Pottsville fm. is mapped as *Blackwater fm.*, and its upper ss. [Homewood=Piedmont] is said to be 110 ft. thick.

†Piedmont crystallines.

†Piedmont gneiss.

†Piedmont granite.

Terms applied by W J McGee, in early repts, to the basement rocks of Atlantic Coastal Plain. In 45th Ann. Rept. Bd. Regents Smithsonian Inst., pp. 72–74, 1891, he says *Piedmont gneiss* "is a vast complex of crystalline rocks extending from Ala. to N. J."

†Piedra formation.

Upper Cretaceous: Southwestern Colorado.

W. Cross, 1899. [See 1899 entry under *Lewis sh.*]

This name probably was intended to apply to so-called Laramie fm. of later repts on SW. Colo. and to include Pictured Cliffs ss., Fruitland fm., and Kirtland sh. of present nomenclature.

Piedra rhyolite (also **Piedra group**). (In Potosi volcanic series.)

Miocene: Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 36). *Piedra fm.*—Top fm. of Potosi volcanic series. In Platoro-Summitville dist. is overlain by Fisher quartz latite and underlain by Huerto fm.

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). In Platoro-Summitville dist. the *Piedra fm.* consists of 0 to 2,000+ ft. of volcanic flows with subordinate tuff, predominantly of rhyolite and quartz latite, and is uncon. on Huerto fm. In Creede dist. the Piedra becomes a *group*, divided into 8 or 9 fms., and is uncon. overlain by Creede fm. and uncon. underlain by Alboroto group, the intervening Huerto fm. being absent there. Named for exposures in Piedra Peak, San Cristobal quad.

E. S. Larsen, 1935 (U. S. G. S. Bull. 843), changed name to *Piedra rhyolite*.

Pie Knob andesite.

Pleistocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, pp. 403–404 and map). *Pie Knob andesite.*—Andesite, 180 ft. thick on Pie Knob, occurring in lower part of Campan series, about 250 ft. above it base. Forms large part of Pie Knob, N. of University Campus, Berkeley.

Pierce limestone. (In Stones River group.)

Lower Ordovician: Central Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 258–267). *Pierce ls.*—Thin-bedded, flaggy fossiliferous lss., with generally a heavy-bedded layer near base. Thickness 27 ft. Included in Trenton or Lebanon [Stones River] group. Underlies Ridley ls. and overlies Central [Murfreesboro] ls.

Named for Pierce's mill, on Stones River, in Rutherford Co.

Pierce shales.

Pennsylvanian (?): Northwestern Arizona (mouth of Grand Canyon).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 337). *Pierce shales* is name especially applied to the sandy basal red beds of Supaian section, as shown at mouth of Grand Canyon, near Pierce's ferry. Thickness 100 ft.

Pierce Canyon redbeds.

Triassic: Delaware Basin and Pecos River Valley, southeastern New Mexico and western Texas.

W. B. Lang, 1935 (A. A. P. G. Bull., vol. 19, No. 2, pp. 262–270). *Pierce Canyon redbeds.*—Series of fine sandy to earthy redbeds, polka-dotted with green reduction spots and usually irregularly veined with thin secondary selenite fillings. Thickness over most of basin 350 ft., excepting the marginal areas and the Pecos Valley of Reeves Co. No favorable exposures, but a fair outcrop is in vicinity of Pierce Canyon, SE. of Loving, N. Mex. Rests on Rustler fm. Appears to be last definite evidence of Perm. sedimentation in the Southwest.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7), discriminated *Pierce Canyon redbeds* much farther N. in Pecos Valley of N. Mex., where they rest on Rustler fm. Age changed to Triassic, on basis of lithology and uncon. at base.

Piercefield gneiss.

Pre-Cambrian: Long Lake quadrangle, Adirondack Mountains, New York.

H. P. Cushing, 1907 (N. Y. State Mus. 60th Ann. Rept., pt. 2, pp. 463, 469–470). *Piercefield gneiss.*—Green syenite gneiss and red granite gneiss, with other gneisses present in minor quantity. Age relations to Long Lake gneiss and Grampus gneiss undet.

Named for exposures about Piercefield, St. Lawrence Co.

Pierpont sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 218). *Pierpont ss.*—Heavy- to current-bedded medium-grained micaceous bluish to light-gray cliff-forming ss. Thickness 40 to 60 ft. Lies 0 to 5 ft. below Pocahontas No. 7 coal, and 0 to 40 ft. above Pocahontas No. 6 coal. Forms cliffs flush with Virginia Railway grade for a short distance SE. from Pierpont, Wyoming Co.

†Pierran series.

A term applied by C. R. Keyes to Pierre sh. and its supposed equivalents.

Pierre shale. (In Montana group.)

Upper Cretaceous: South Dakota, North Dakota, eastern Wyoming, eastern Montana, eastern Colorado, Nebraska, western Minnesota.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 419, 424). *Fort Pierre group (Formation No. 4 of Cretaceous).*—Thickness 700 ft. in Nebr. [which then included Wyo., Mont., and Dakotas]. Underlies Fox Hills beds and overlies Niobrara div. Consists of (descending): (1) Dark-gray and bluish fossiliferous plastic clays exposed on Sage Creek, on Cheyenne River, and on White River above Bad Lands; (2) middle zone, nearly barren of fossils, which occurs at Fort Pierre and out on to Bad Lands—down the Missouri on high country to Great Bend; (3) lower fossiliferous zone, which occurs at Great Bend of the Missouri below Fort Pierre; and (4) dark bed of very fine unctuous clay containing much carbonaceous matter, with veins and seams of gyp., masses of sulphuret of iron, and numerous small scales of fishes, and occurring near Bijou Hill, on the Missouri.

Rocky Mtn Ass. Pet. Geol. (by its Committee, composed of T. S. Lovering, H. A. Aurand, C. S. Lavington, and J. H. Wilson), 1932 (A. A. P. G. Bull., vol. 16, No. 7, pp. 702–703). After a field conference with *J. B. Reeside, Jr.*, of U. S. Geol. Survey, *the Rocky Mtn Ass. Pet. Geol. has agreed to restrict the term Fox Hills as follows:* The base of Fox Hills fm. shall be considered as the horizon below which the section is predominantly gray marine clay shales and sandy shales of Pierre age, and above which the section changes rapidly to a buff to brown ss. containing numerous large gray to brown hard sandy concretions. This lower concretionary memb. is commonly overlain by a series of light-gray to brown sss. and sandy shales. The top of Fox Hills fm. shall be considered as the horizon above which the section is composed predominantly of fresh-and brackish-water deposits accompanied by coals and lignitic shales, and below which it is predominantly marine.

Lower fm. of Montana group.

Named for exposures at old Fort Pierre, in either Stanley or Hughes Co., S. Dak. The exact location of the old fort is not known.

Pierson limestone.

Mississippian (Osage): Southwestern Missouri.

S. Weller, 1901 (Jour. Geol., vol. 9, pp. 140, 144). *Pierson ls.*—Fine-grained buff-colored gritty ls., 3 to 30 ft. thick, forming top fm. of Kinderhook group in SW. Mo. Overlies Northview ss. and sh. Frequently nonfossiliferous, but often fossiliferous. Represents only upper part of Chouteau ls. of central Mo.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser.), correlated Pierson ls. with Fern Glen ls., which is now included in Osage group.

Named for Pierson Creek, Greene Co.

Pierson Point shale. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 80). *Pierson Point sh.*—Basal bed of McKissick Grove sh. memb. of Wabaunsee fm. Bluish argill. sh. and some sand; upper part, and at places lower part, nearly black. Thickness 8 to 10 ft. in Nebr. and Kans. Overlain by Maple Hill ls. and underlain by Tarkio ls. memb. Named for Pierson's Point, SE. of Falls City, Nebr.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), discarded McKissick Grove sh. and treated its subdivisions as *fms.* in Wabaunsee group.

Pigeon slate.

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 2). *Pigeon sl.*—Sl., of great uniformity, bluish gray when fresh, but weathers dull yellow. Mainly argill., occasionally banded by thin seams of coarser siliceous material. A few thin beds of fine white ss. occur at various parts of fm., notably toward top. Thickness 1,300 to 1,700 ft. Overlies Citico cgl. and underlies Cades cgl.

Equivalent to upper part of Hiwassee sl.

Named for exposures near West Fork of Little Pigeon River, Sevier Co., Tenn.

Pike gravel member (of Trinity formation).

Lower Cretaceous: Southwestern Arkansas.

H. D. Miser and A. H. Purdue, 1918 (U. S. G. S. Bull. 690B). *Pike gravel memb. of Trinity fm.*—Irregularly bedded pebbles and cobbles up to 10 in. diam. Thickness 100 ft. Basal memb. of Trinity fm. in Caddo Gap and De Queen quads. Rests uncon. on Atoka fm. (Penn.). Named for Pike, Pike Co.

H. D. Miser, 1927 (A. A. P. G. Bull., vol. 11, No. 5, pp. 443–453). Near Ark.-Okla. line the Pike gravel memb. and the younger Ultima Thule gravel memb. merge.

Pike sand.

A subsurface sand in Pottsville fm. of Knox, Knott, and Pike Counties, SE. Ky.

Pike Creek volcanic series.

Tertiary (late): Southeastern Oregon (Steens Mountain).

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, pp. 7–130). *Pike Creek volcanic series.*—Series of alternating acidic flows and stratified tuffs, 1,500+ ft. thick, in S. part of Steens Mtn. Includes, (descending): (1) Biotite dacite, 500+ ft.; (2) upper tuffs, 40± ft.; (3) *Little Alvord Creek rhyolite* (exposed in Little Alvord Creek); (4) upper laminated rhyolite flow, 250 to 500 ft.; (5) middle tuffs, 200 to 300 ft.; (6) lower laminated rhyolite, 200± ft.; (7) lower tuffs, 200+ ft. Overlies Alvord Creek beds (middle Mio.). Best exposed in valley of Pike Creek, on E. scarp of Steens Mtn.

Appears to be of approx. same age as his Steens Mtn andesitic series of N. part of Steens Mtn.

Pike River granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. granite in Wis. (area not stated).

Pikes Peak granite.

Pre-Cambrian: Eastern Colorado (Pikes Peak region).

W. Cross, 1894 (U. S. G. S. Pikes Peak folio, No. 7). *Pikes Peak granite.*—The mass of Pikes Peak is principally made up of a single granite type, belonging to what is apparently one great body, extending for many mi. in all directions. The main type is a very coarse-grained biotite granite or granitite, in most places red. In the Pikes Peak type proper biotite is quite subordinate, but on either side of Platte River, and in several places in SW. part of dist., a large increase in black mica greatly changes appearance of rock. The Pikes Peak type is cut by a fine, even-grained reddish or pinkish granite poor in mica.

E. B. Mathews, 1900 (Jour. Geol., vol. 8, pp. 214–240), divided the "Algonkian or early Cambrian granites" of Pikes Peak quad. into (descending order of age) fine-grained type, *Cripple Creek type*, *Summit type*, and *Pikes Peak type*. The Pikes Peak type was named for its prominence in constitution of Pikes Peak massif. Is characterized by relatively large size of its feldspar and quartz grains and its tendency to form conspicuous feldspar phenocrysts that often attain diam. of several inches. Texture presents all grades of transition. The coarse-grained granite, in which the feldspar phenocrysts are large and generally well formed, is sometimes called "*Raspberry Mtn granite*," from its conspicuous development on that mtn.

W. Lindgren and F. L. Ransome, 1906 (U. S. G. S. P. P. 54). *Pikes Peak granite* is intrusive into the gneiss and schist and probably into Spring Creek granite.

L. C. Graton, 1906 (U. S. G. S. P. P. 54). *Pikes Peak granite.*—Light pink to red, coarse-grained; consisting largely of alkali feldspar. Undoubtedly older than Cripple Creek granite.

G. B. Richardson, 1915 (U. S. G. S. Castle Rock folio, No. 198). *Pikes Peak granite* is intrusive into Algonkian qtzites and is pre-Camb.

The terms "Algonkian system" and "Archean system" were discarded by U. S. Geol. Survey in 1934. For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

Piketon gravel.

Tertiary: Southeastern Missouri.

C. F. Marbut, 1902 (Mo. Univ. Studies, vol. 1, No. 3, pp. 18, 27, 32). *Piketon gravels.*—Stratified gravels, often showing current bedding, composed of chert, qtzite, and quartz pebbles mixed with reddish sand. Thickness not stated. The qtzite pebbles are different from any rock in Mo., and their worn condition shows they have traveled long distance, probably from northern United States. Of late Tert. (Lafayette) age [also calls them *Lafayette gravels*]. Uncon. overlain by loess, and underlain, probably uncon., by Benton or Lafayette sands.

Named for exposures at Piketon, Stoddard Co.

Pikian series.

Name employed by C. [R.] Keyes (Pan-Am. Geol., vol. 41, pp. 281, 284, 1924) to cover "the Pikes Peak granitic intrusives," the "latest Proterozoic rocks in Colo."

Same as Pikes Peak granite.

Pilarcitos sandstone. (In Franciscan group.)

Jurassic(?): Western California (San Francisco region).

R. Arnold, 1902 (Sci., n. s., vol. 15, table on p. 416). *Pilarcitos ss.*, 790 ft. thick. A fm. of the Franciscan. [Shown in table as underlying volcanics that are older than Calera ls.]

A. C. Lawson, 1903 (Geol. Soc. Am. Bull., vol. 13, pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). [Maps Franciscan rocks along Pilarcitos Creek and Pilarcitos Lake, both in San Mateo Co., as *Cahil ss.*, of which the Calera ls. is a memb.]

Pilgrim limestone.

Upper Cambrian: Central southern Montana (Little Belt Mountains), central northern Montana (Fort Benton quadrangle), and central western Montana.

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55, and Little Belt Mtns folio, No. 56). *Pilgrim ls.*—Dense gray rocks, massively bedded, containing shaly layers, often spotted with green glauconite remains; frequently carrying fossils on the surface. The layers are often cgls. formed of flat pebbles of green or buff lss. showing no definite arrangement. Thickness 140 ft. in Fort Benton quad. Overlies Park shales and ls. cgls. Underlies Dry Creek sh. Exposed in broad valley of Pilgrim Creek [SW. corner of Fort Benton quad.].

Pillar Falls mud flow.

Miocene ? (upper Miocene?): Southern Idaho (Twin Falls and Jerome Counties).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Pillar Falls mud flow.*—Well-rounded gravel and huge boulders several ft. diam. Contains andesitic pebbles and boulders intermingled with ash and soil. Fills irregularities in surface of Shoshone Falls andesite. Thickness 0 to 40± ft. Older than Neeley lake beds. Exposed at Pillar Falls, on Twin Falls-Jerome Co. line.

Pilot shale.

Mississippian: Eastern Nevada (Ely district).

A. C. Spencer, 1917 (U. S. G. S. P. P. 96, pp. 24, 26, map, etc.). *Pilot sh.*—Exposed a short distance W. of Ely, in middle slopes on S. side of Robinson Canyon, also in open country just N. of Copper Flat, and in several places in NW. part of quad.

It breaks down at surface. From a few pits and tunnels it appears to be composed entirely of soft, highly carbonaceous sh., drab to nearly black. Thickness 100 to 400 ft. Underlies Joana ls. and overlies Nevada ls. (Dev.). No fossils found, but is believed to be of Miss. age. Named for Pilot Knob, in W. part of Ely quad.

Pilot Knob conglomerate.

Upper Cambrian: Southeastern Missouri.

C. R. Keyes, 1894 (Mo. Geol. Surv. vol. 4, pp. 30, 31). *Pilot Knob cgl.*—Cgl., 0 to 40 ft. thick, more or less perfectly bedded; only known occurrence on Pilot Knob [Iron Co.]. Assigned to Algonkian. Uncon. underlies Fourth Mag. ls. and is younger than Iron Mtn porphyry.

H. F. Bain and E. O. Ulrich, 1905. [See 1905 entry under *Lamotte ss.*]

J. Bridge, 1930 (personal communication). In a few instances certain basal true cgls. at Pilot Knob have been included in *Pilot Knob cgl.* or have been referred to under this name. These were economically important and are of same age as Iron Mtn cgl.

Pilot Knob formation.

Pre-Cambrian: Southeastern Missouri.

E. R. Buckley, 1908 (Am. Min. Cong. Rept. Proc. 10th Ann. Sess., p. 286), and 1909 (Mo. Bur. Geol. and Mines, 2d ser., vol. 9, pt. 1, pp. 15–17). *Pilot Knob* assigned to Huronian (?). Is uncon. below Lamotte and uncon. above Laurentian diabase, granite, and rhyolite. Consists of sl. and cgl. 200 ft. thick.

C. [R.] Keyes, 1914 (Scheme of strat. succession in Mo.). *Pilot Knob* assigned to Animikian. Consists of 50 ft. of cgls. underlying Ironton sl.

J. Bridge, 1930 (personal communication). If name *Pilot Knob* is to be retained in literature it should be changed to *Pilot Knob aggl.* or *Pilot Knob tuff*, and should be classed as *Algonkian*.

Pilot Knob iron formation.

Pre-Cambrian: Southeastern Missouri.

G. W. Crane, 1912 (Mo. Bur. Geol. and Mines vol. 10, 2d ser.). *Pilot Knob iron fm.*—Breccia and tuff, 140 ft. thick.

Pilot Knob sandstone.

Pennsylvanian: Northern Tennessee coal field.

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 23, 33, 319). *Pilot Knob ss.*—Very prominent cliff-making coarse gritty ss., 20 to 40 ft. thick in Briceville region, where it lies 300 to 320 ft. above the Big Bench, and 80 ft. thick on Pilot Knob, where it lies about 250 ft. above the Big Bench. Is basal memb. of Anderson fm. Its base is 450 ft. beneath highest point on Pilot Knob. Is believed to be uncon. on Scott fm.

Pima sandstone.

Middle Cambrian: Southeastern Arizona (Whetstone Mountains).

A. A. Stoyanow, Apr. 30, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 466, 482). *Pima ss.*—Buff hard ss., 4 ft. thick, containing *Micromitra pannula*. Underlies Cochise fm. and overlies Bolsa qtzite. In places contains inclusions of Bolsa qtzite. Been traced 60+ mi., from Whetstone Mtns, Cochise Co., to Picacho de Calera Hills, Pima Co. Is Middle Camb. [Derivation of name not stated. His table on p. 482 shows it absent in Bisbee dist.]

Pimienta beds.

Jurassic (?): Mexico.

A. Heim, 1926 (Eclogae geol. Helvetiae, vol. 20, p. 86).

Pimple Hill conglomerate.

Upper Devonian or Mississippian: Northeastern Pennsylvania (Monroe, Pike, and Wayne Counties).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 578, etc.). *Pimple Hill cgl.*—Persistent cgl., distinguished by red quartz pebbles, in upper part of Cherry Ridge red beds (Upper Dev.). Forms small ridges and hills concentric to eastern escarpment of Pocono Plateau. Named for Pimple Hill, a knob in Monroe Co. Has not been identified W. of Wayne Co. In Bradford Co. serves as key to identify presence of Catskill. [Table on p. 571 shows Pimple Hill cgl. *below* Dyberry glomerate, but text (p. 578) says Pimple Hill is in *upper* part of Cherry Ridge and Dyberry glomerate in *lower* part. For further information see 1936 entry under *Cherry Ridge group*. This name replaces *Cherry Ridge cgl.* of I. C. White.]

Pinal schist.

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Pinal schists.*—Crystalline schists of pre-Camb. age. The oldest rocks in Globe quad. Are broken by granite intrusions into very irregular masses. Are at least in part derived from quartzose sediments. Are abundantly present and well exposed in Pinal Mtns, whence their name. The largest single body of schistose rocks is that underlying greater part of W. slope of the range. Are uncon. overlain by Apache group.

F. L. Ransome, 1904 (U. S. G. S. Globe folio, No. 111). *Pinal schist* consists of quartz-sericite and quartz muscovite schists.

F. L. Ransome, 1904 (U. S. G. S. Bisbee folio, No. 112). *Pinal schist.*—Light to dark-gray or greenish schists; very fine-grained; uniform texture; imperfect cleavage; surfaces commonly have a satinlike sheen; essential constituents quartz and sericite; biotite and tourmaline rare; amphibole not observed. General character indicates the schist was at one time arkosic sands or silts. Vastly older than Camb. May = Vishnu schist of Grand Canyon. Thickness unknown.

Pinar schist.

Pre-Jurassic (?): Cuba.

J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, p. 534). Assigned to pre-Jurassic.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 522), assigned this fm. to Jurassic.

Pina Vititos sandstone.

Name applied by C. [R.] Keyes (Conspectus of geol. fms. of N. Mex., 1915, pp. 2, 10) to "basal memb. of the Montanan coal-bearing series around the southern end of the Rocky Mtns." Thickness 250 ft. Derivation of name not stated. On p. 10 is spelled *Pino Vititos*.

Pinckneyville granite.

Post-Carboniferous: Eastern Alabama.

W. F. Prouty, 1922 (Elisha Mitchell Sci. Soc. Jour., vol. 38, p. 16; also Ala. Geol. Surv. map of Clay Co.) and 1923 (Ala. Geol. Surv. County Rept. No. 1, pp. 51–62). Biotite granite, covering large area about Pinckneyville, Clay Co. As mapped it includes the belts of biotite granite "locally designated as Bluff Springs granite." Intrudes Talladega phyllites.

On 1922 geol. map of Clay Co. the granite and town are spelled *Pinkneyville*. The map accompanying 1923 rept cited above spells the town and granite *Pinkneyville*, but throughout text the spelling *Pinckneyville* is used. The latter spelling is used on 1926 geol. map of Ala.

Pine sandstone member (of Pottsville formation).

Pennsylvanian: Central Alabama.

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175, p. 10). *Pine ss. memb.*—Quartzose, coarse, and thick-bedded ss. at base, but finer-grained and more flaggy at top. Thickness 250 ft. Is a memb. in lower part of Pottsville fm. in Cahaba and Coosa coal fields. Immediately or closely overlies Roper coal.

Named for Pine Ridge, Jefferson Co.

Pinean series.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 55, 80). *Pinean series* is essentially the White Pine sh. of Hague (1888), of Eureka dist.

Derivation of name not stated, but apparently it is an abbreviation and adaptation of the geographic name *White Pine*.

†Pine Barren beds.

A name applied in some early Ala. repts to the basal Eocene beds now known as *Clayton fm.*, which are "best seen in eastern Wilcox Co., on Pine Barren Creek and in adjoining part of Butler Co. in Little Texas region."

Pine Bluff quartz porphyry.

See under *Seneca quartz porphyry.*

Pine Canyon limestone.

Mississippian: Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Pine Canyon ls.*—Beds of nearly black, dense, rather thin-bedded ls. with large black chert nodules and occasional thin beds of black chert, alternating with beds of medium- to light-gray medium- to coarse-grained, distinctly cross-bedded ls. Thickness 1,000 ft. Fossils from most of fm. are of Madison age, according to G. H. Girty, but he tentatively regards upper 300 ft. as of upper Miss. age. Underlies Humbug fm. and overlies Gardner dol. Exposed in Pine Canyon, btw. Godiva Mtn and Sioux Peak.

Pinecate formation.

Oligocene: Southern California (San Benito County).

P. F. Kerr and H. G. Schenck, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 470, 472 and map). *Pinecate fm.*—Chiefly massive yellowish pebbly ss. with interbedded cgl. Cross-bedding common. Thickness about 1,000 ft. Fossils rare, but when found indicate marine origin. Lies on San Juan Bautista fm. with probable discon. Underlies Vaqueros fm., probably uncon. Is upper fm. of San Lorenzo series. Typically exposed at Pinecate Peak, 4 mi. NW. of San Juan, and also near San Juan Cement Works.

Pine City moraine.

Pleistocene (Wisconsin stage): Eastern Minnesota (Pine County).

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 79–80). Oldest moraine of Rush Lake morainic system. Named for development at Pine City, Pine Co.

†Pine Creek limestone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 32). *Pine Creek (Coleman?) ls.*, 2 ft. thick. Lies 40 ft. below Bakerstown coal and overlies Buffalo ss. [In places this ls. lies 26 ft. above Buffalo ss.]

Same as Cambridge ls. memb., which has priority. The Pa. Geol. Survey, however, uses Pine Creek ls. instead of Cambridge ls.

Named for Pine Creek [Allegheny Co.?], Pa.

†Pine Creek sandstone. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania (Armstrong County).

J. P. Lesley, 1880 (2d Pa. Geol. Surv. Rept. H_5, pp. xxi, 319). [See under *Kittanning ss. memb.* Lesley proposed *Pine Creek ss.*, also *Worthington ss.*, for a ss. lying in interval below Middle Kittanning coal and above Lower Kittanning coal.]

Replaced by unpreoccupied name *Worthington ss. memb.*

Pine Creek conglomerate.

Cretaceous (?): Southeastern Iowa.

J. A. Udden, 1899 (Iowa Acad. Sci. Proc., vol. 6, pp. 54–56). *Pine Creek cgl.*—Coarse, brown to yellow pebbly ss., 16 or more ft. thick, in Muscatine Co. Of post-Carbf. and preglacial age. Regarded by Calvin as identical in nature with Rockville cgl. of McGee; also resembles Cret. cgl. in Guthrie Co. Overlain by loose yellow sand.

Named for Pine Creek, Muscatine Co.

Pinecrest formation.

Lower Triassic: Central northern Utah (central Wasatch Mountains).

A. A. L. Mathews, 1929 (Chicago Univ., Walker Mus. Mem., vol. 1, No. 1, p. 1). The Lower Triassic rocks outcrop in Fort Douglas area in two localities, one on N. limb of a syncline btw. Red Butte and Dry Canyons and on S. limb of same structure near Mill Canyon. They comprise lower div. of Thaynes group and are referred to here as *Pinecrest fm.* This fm. is named after Pinecrest Ridge, which lies btw. N. and S. forks of Red Butte Creek. The fm. contains a very rich marine fauna, consisting primarily of pelecypods and cephalopods. [Fossils described, but fm. not described nor thickness given.]

A. A. L. Mathews, 1931 (Oberlin Coll. Lab. Bull., n. s., No. 1, Feb.). *Pinecrest fm.*—Chiefly dark bluish-gray dense massive brittle, resistant ls. intercalated with beds of calc. ss. and massive light blue-gray or olive-drab ls.; some thick massive beds of brittle ls. near base, and a thick resistant ss. at base. Thickness 607 ft. Conformably underlies Emigration fm. and grades into underlying Woodside sh. Is lower part of Thaynes ls. The upper part of the fm. is present in Thaynes Canyon. The overlying Emigration fm. is upper part of Thaynes ls.

Pinedale glacial stage.

Pleistocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310, 324–340). *Pinedale stage.*—The youngest moraines, which for convenience may be called *Pinedale drift*, are conspicuous around each of the large lakes near Pinedale on SW. side of Wind River Range.

E. Blackwelder, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 865–922) correlated this drift with Wisconsin glacial stage.

Pine Hill quartzite.

Lower Cambrian: Southwestern Vermont (Rutland County).

J. E. Wolff, 1891 (Geol. Soc. Am. Bull., vol. 2, btw. pp. 331 and 338, in a description of Rutland, Vt., and vicinity), stated that the *Pine Hill qtzite* (not defined) underlies Rutland ls. Pine Hill is a short distance NW. of Rutland and a short distance SE. of Proctor, in Proctor Twp, Castleton quad.

Pine Hill quartzite.

Silurian: Southeastern New York (Orange County).

E. C. Eckel, 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 1, pp. r144 to r150). *Pine Hill qtzite* is here proposed for a series of qtzite beds overlying Green Pond cgl. [restricted] and underlying Longwood shales. Transition beds btw. the qtzite and cgl. and btw. the qtzite and shales occur, but in general the lithologic distinctions btw. the fms. are evident. The fm. is well shown in Pine Hill, E. of Highland Mills, Orange Co.

These beds form upper part of Green Pond cgl. as originally defined by Darton and as still used by geologists generally, and there is no other record of Pine Hill qtzite.

Pinelog conglomerate.

Lower Cambrian: Northwestern Georgia (Cartersville district).

L. LaForge, 1919 (Ga. Geol. Surv. Bull. 35, p. 40). *Cgl. gneiss that Hayes called* [unpublished ms.] *Pinelog cgl.*—A rather heterogeneous fm. of cgl., arkose, qtzite, siliceous phyllite, and graphitic sl., all much sheared and largely altered to sericite schist and gneiss; its base is in places an arkose. Rests on Corbin granite and underlies a sl. regarded by Hayes as = Wilhite sl. of Tenn.

J. P. D. Hull, 1920 (Ga. Geol. Surv. Bull. 36, pp. 19–28). *Pinelog cgl.* borders the area of Corbin granite on all sides but the SE., and forms Pinelog, Pine, and E. part of Brushy Knob and Signal Mtns.

†Pine Mountain group. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky.

A. R. Crandall, 1889 (Ky. Geol. Surv. Whitley Co. Rept.). *Pine Mtn group.*—Name provisionally applied to cgls., 1,500 ft. thick, interbedded with shales and shaly sss. at intervals of 100 to 200 ft., overlying Chester group and extending to recognized top of the cgl. of the Coal Measures. Overlain by later Coal Measures. Greatly thickened equiv. in Pine Mtn region of Rockcastle group.

The rocks of Pine Mtn were, in U. S. G. S. P. P. 49, 1906, mapped as *Lee fm.*, but they probably include some beds younger than true Lee, according to geologists who have worked in the region.

Named for Pine Mtn, SE. corner of Ky.

Pine Mountain formation.

Cambrian or pre-Cambrian: Central western Georgia (Pike to Harris Counties).

S. L. Galpin, 1915 (Ga. Geol. Surv. Bull. 30, pp. 74–76). *Pine Mtn fm.*—The qtzites and associated schists which are found on Pine Mtn and the ridges nearby are here grouped under a single fm. name, which is taken from the most conspicuous physiographic feature of region. The qtzites give place to siliceous and micaceous schists about the Monroe-Pike Co. line, and the continuation of these fms. far into Monroe Co. was not noted. Mica schists may usually be found enclosing the qtzite layers, and in some instances, as on the ridges of northern Upson Co., there is a gradual transition from one rock type to the other. In most places there is no great width to these schists, but in NW. part of Upson Co. excavations along Macon & Birmingham R. R. expose them almost continuously from a point 6½ mi. NW. of Thomaston to near Flint River. Within this distance the strike changes from N. 35° E. on SE. to N. 25° W. on NW. There are also changes of dip indicating existence of one or two synclines. The qtzite layers are of medium to fine grain, usually containing considerable secondary mica. In some places disseminated crystals and groups of pyrite are found. The schists are usually of fine and rather even texture and are composed mainly of mica and quartz. Small lenses and stringers of secondary quartz are very abundant. No positive evidence as to age, but absence of intrusions of Roan gneiss, presence of one intrusion of a later dioritic rock showing some metamorphism, and nature of fm. would seem to favor its tentative classification as either pre-Camb. or early Camb.

Named for development on Pine Mtn, from W. part of Harris Co. to E. part of Pike Co.

Pine Mountain complex.

Name applied by D. Modell (Geol. Soc. Am. Bull., vol. 47, 1936, p. 1911) to a subsidiary stock (chiefly granite porphyry) in Pine Mtn-Rocky Mtn area of Belknap Mtns, N. H.

Pine Nut limestone member (of Gold Hill formation).

Cambrian? (Upper Cambrian?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Pine Nut ls. memb.*—White impure crystalline ls. carrying little knots of silicate minerals. Thickness 10 ft. Lies below middle of Gold Hill fm. and 140 ft. lower than Morning Glory ls. memb. Exposed on Pine Nut claim.

Pine Point limestone.

Devonian: Northwest Territories, Canada.

A. E. Cameron, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 26).

†Pine Ridge sandstone member (of Chemung formation).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 535), is a misprint for *Piney Ridge ss. memb.*

Pine Ridge sandstone member (of Mesaverde formation).

Upper Cretaceous: Southeastern Wyoming (Rock Creek field).

C. E. Dobbin, H. W. Hoots, C. H. Dane, and E. T. Hancock, 1929 (U. S. G. S. Bull. 806, p. 140). *Pine Ridge ss. memb.*—Light-gray slabby to massive sss., interbedded with gray sandy sh., carbonaceous sh., and four coal beds, one of which, near top, is locally 8 ft. thick. Forms top memb. of Mesaverde fm. in Rock Creek oil field. Thickness 80 ft. near Rock River and 450 ft. in Medicine Bow dome. Probably=Teapot ss. memb. of Mesaverde in other parts of Wyo. Named for exposures in Pine Ridge, about 2 mi. SE. of town of Rock River, Albany Co.

Pine River formation.

Jurassic (?): British Columbia.

E. M. Spieker, 1922 (A. A. P. G. Bull., vol. 6, pp. 112–126). [Assigned to Jurassic (?), but M. Y. Williams and J. B. Bocock, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 206), assigned this fm. to Upper or Middle Jurassic.]

Pine Run sand.

A subsurface sand, of early Miss. or Upper Dev. age, in western Pa., lying at or above horizon of Nineveh sands. Said to be older than Hundred-foot sand.

Pinetop chert.

Middle Devonian: Southeastern Oklahoma (Ouachita Mountains).

H. D. Miser, 1934 (A. A. P. G. Bull., vol. 18, No. 8, pp. 974, 975). *Pinetop chert.*—Named for Pinetop School, sec. 5, T. 2 N., R. 15 E. [in Pittsburg Co.], about 20 mi. due S. of McAlester, Okla., where 50± ft. of fossiliferous chert and ls. of Onondaga age are exposed. Replaces Brushy Creek chert of Ulrich, which is preoccupied. Underlies Woodford chert in Ti-Valley-Choctaw belt of Ouachita Mtns, Okla.

Pineville sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 211). *Pineville ss.*—Massive to current-bedded, medium-grained, buff to bluish gray, 50 to nearly 100 ft. thick. Forms cliffs nearly 100 ft. high at Pineville, Wyoming Co. Underlies Little Fire Creek coal and lies 0 to 5 ft. above Pocahontas No. 9 coal.

Piney formation.

Upper Cretaceous: Northern Wyoming (Bighorn Mountains region).

N. H. Darton, Nov. 17, 1906 (U. S. G. S. P. P. 51, pp. 13, 59–60, etc.). *Piney fm.*—Gray and brown ss. and shales, 2,000 to 3,000 ft. thick, underlying Kingsbury cgl. and overlying Parkman ss. in Bighorn Mtns. Is Upper Cret. Named for Piney Creek, NW. of Buffalo.

This name also appeared in several other repts, by Darton, published in 1906, and listed under *Parkman ss.* In U. S. G. S. Bull. 856 (1935), on Crow Ind. Res., Mont., is statement that Piney fm. as mapped by Darton in U. S. G. S. folio 141 appears to correspond to Bearpaw sh., Lennep ss., and Lance fm. as mapped in Crow Ind. Res.

Named for exposures on Piney Creek, NW. of Buffalo, Wyo.

Piney Creek conglomerate. (In Pottsville group.)

Pennsylvanian: Southern West Virginia (along New River).

D. White, 1895 (Geol. Soc. Am. Bull., vol. 6, pp. 305–320). [The massive conglomeratic ss. at top of Piney Creek section is called *upper Piney Creek cgl.* and the lower cgl. on Piney Creek, 75± ft. thick, is called *Piney Creek cgl.* and *lower Piney Creek cgl.* According to later repts of W. Va. Surv. the *upper Piney Creek cgl. of D. White* is Raleigh ss.]

Piney Ridge sandstone member (of Chemung formation).

Upper Devonian: Central Pennsylvania (Blair and Huntingdon Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 535). *Pine* [y] *Ridge ss. memb.* lies in lower part of Chemung fm., some distance below Allegrippis ss. memb.

C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227, in press). *Piney Ridge ss. memb.*—Consists of several rather thick sss. separated by soft greenish clay sh. Thickness 50 ft. Lies 30 to 200 ft. above base of Chemung fm., and 1,400 ft. below Allegrippis ss. memb. of Chemung.

Named for exposures along Piney Ridge, Huntingdon Co.

Pinguico rhyolites.

Age (?): Mexico.

C. W. Botsford, 1909 (Eng. and Min. Jour., vol. 87, p. 692).

Pinkard formation.

Upper Cretaceous: Southeastern Arizona (Clifton region).

W. Lindgren, 1905 (U. S. G. S. P. P. 43). *Pinkard fm.*—Several hundred ft. of sss. and shales. Lowest part consists of black shales, which occupy considerable areas in Silver Basin. Upper part is made up of alternating shales and yellowish-gray sss., in places calc. Rests uncon. on Modoc ls. Exposed in vicinity of Pinkard Gulch, W. of Morenci.

†Pink Cliff series.

Eocene: Southwestern and central southern Utah.

C. E. Dutton, 1880 (Geology of High Plateaus of Utah, pp. 143–159, 188–210). *Pink Cliff series*.—Consists of (descending) upper white ls. and calc. marl, 300 ft.; pink calc. ss., 800 ft.; pink cgl. 550 ft. The Pink Cliffs [N. part of Kane Co.] are exposures of the fine-grained calc. ss. forming middle memb. of the Bitter Creek. This series of beds in Markágunt and Paunságunt Plateaus is identical with Bitter Creek beds of Uinta Mtns, although actual continuity is doubtful. They rest on Cret.

These beds are now recognized as a southern development of Wasatch fm., by which name they are called. (See U. S. G. S. P. P. 164, pp. 114–116, 1931.)

Pinkerton sandstone.

Mississippian: Northeastern West Virginia.

G. W. Stose and C. K. Swartz, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Pinkerton ss.*—Massive white ss. and quartz cgl., in part cross-bedded, with a thin coal seam. Thickness more than 125 ft. Top fm. of Pocono group. Rests on Myers sh. Is about 125 ft. thick on Pinkerton Knob, Berkeley Co. Contains Pocono plants.

Pinkneyville granite.

See *Pinckneyville granite.*

Pinnacle.

Pliocene or Pleistocene: Southeastern Alaska (St. Elias region).

I. C. Russell, 1891 (Nat. Geog. Mag., vol. 3, pp. 167–175). *Pinnacle system*.—Thin-bedded dark-colored sh., cgl., ls., ss., best exposed in cliffs of Pinnacle Pass and along N. and W. borders of Samovar Hills. Faulted and upheaved. Thickness at Pinnacle Pass at least 1,750 ft. Plants and invertebrates indicate Plio. or Pleist. age. Relations to Yakutat system undet.

Pinnacle graywacke.

Cambrian: Southern Quebec.

See under *West Sutton sl.*, 1931.

Pinney Hollow schist.

Lower Cambrian: Southeastern Vermont (Windsor County).

E. L. Perry, 1927 (15th Rept. Vt. State Geol., p. 161). *Pinney Hollow schist*.—A uniform pale-green quartz-chlorite-sericite schist, usually intensely plicated and resembling Bethel schist in lithology and origin. Lies stratigraphically below Ottauquechee fm. and above a group of light-brown or gray qtzites. Assigned to Camb. (?). Type exposures in Pinney Hollow, in Plymouth [Windsor Co.].

E. L. Perry, 1929 (16th Rept. Vt. State Geol., pp. 1–61). *Pinney Hollow schist*, probably late Camb., is 3,500± ft. thick. Typically exposed in Pinney Hollow [Woodstock quad.] from Pinney Hollow School westward nearly to Plymouth village. Lies uncon. on series of pre-Camb. or older Camb. qtzites, cgls., dol., and schists.

C. H. Richardson and E. J. Foyles, 1929 (16th Rept. Vt. State Geol., p. 288), assigned this schist to Lower Camb.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 405), assigned this fm. to Lower Camb.

Pinoche formation.

Misprint for *Panoche fm.*

Pinole tuff.

Pliocene: Western California (San Francisco region).

R. Arnold, 1902 (Sci., n. s., vol. 15, table on p. 416). *Pinole*, 1,000 ft. (pumiceous, fossiliferous tuffs). [Shown as underlying Orindan fm. and overlying San Pablo fm.]

A. C. Lawson, 1903 (Geol. Soc. Am. Bull., vol. 13, table on pp. 544–545). *Pinole tuffs*, 1,000 ft. (fossiliferous, pumiceous). [Shown as underlying Orindan fm. and overlying San Pablo fm.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). The *Pinole tuff* in most of its deposits is distinctly stratified. Consists almost wholly of whitish or light-yellowish pumice, partly in fragments ranging from 1 to 50 mm and partly in fine dust. Occurs only in small exposures in Concord and San Francisco quads, but is more extensively exposed in Coast Ranges farther N. Stratigraphically it lies chiefly btw. San Pablo fm. below and Orinda fm. above, but is in part interbedded with basal sediments of the Orinda, with which it is more closely associated than with the marine San Pablo. On shores of San Pablo Bay it contains fresh-water fossils and bones of terrestrial mammals. Thickness 0 to 1,000 ft. Rests, with probable uncon., on San Pablo fm. Named for exposures near town of Pinole, on San Pablo Bay.

†Pinos Altos limestones.

Ordovician: Southwestern New Mexico.

C. R. Keyes, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 360–362). *Pinos Altos fm.* consists of 400 ft. of lss. of Ord. age, underlying Dev. Chloride fm. (lss.) and overlying Camb. sss.

Probably named for town in Grant Co., and probably includes Fusselman ls. (Sil.) and Montoya and El Paso lss. (Ord.).

Pino Vititos sandstones.

See under *Pina Vititos ss.*

†Pinto limestone.

Upper Cretaceous (Gulf series): Southwestern Texas.

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 222, 229, 230). *Pinto ls.*—Fossiliferous chalky lss. separated by bands of laminated limy shales, calc. clays, and purer clays. Thickness 1,500 ft. Same as Austin ls. Underlies Eagle Pass div. and overlies Val Verde flags.

Same as Austin chalk, older name.

Named for Pinto Creek, Val Verde Co.

Pinto diorite.

Age (?): Central Montana (Little Belt Mountains quadrangle).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Most noticeable rock of Neihart mining dist. At once recognized by spotted appearance. Intrudes Archean rocks; is probably Cret. [Derivation of name not stated, and no geographic feature of that name shown.]

P. A. Schafer, 1935 (Mont. Bur. Mines and Geol. Mem. 13, pp. 7, 9, map, etc.). The younger pre-Beltian rocks of Neihart dist. comprise a group of metamorphosed igneous rocks collectively called *Pinto diorite*. Although several varieties occur, they are related in origin and belong to same intrusive episode. The distinction btw. varieties is petrographic rather than genetic or structural, since all belong to one igneous mass and gradations occur btw. them. There are 2 principal rock types—one a spotted porphyritic-looking rock for which the name *Pinto diorite* was chosen; the other a dense black amphibolite, associated with the metadiorite and forming a characteristic border phase of that rock. Within these 2 facies are numerous variations. The Pinto diorite, including the amphibolite facies, is intrusive into the earlier gneisses and schists. [Derivation of name not stated.]

Pinto sandstone.

Cretaceous (probably all Upper Cretaceous): Southwestern Utah (Iron Springs region).

C. K. Leith and E. C. Harder, 1908 (U. S. G. S. Bull. 338, p. 37). *Pinto ss.*—Includes some sh., cgl., and ls. lenses. Thickness 1,500 ft. Underlies (uncon.) Claron ls. (Eocene) and overlies (uncon.) Homestake ls. (Carbf.). [Evidently named for Little Pinto Creek, which appears to cross the fm. just S. of Iron Springs quad.]

Pinto formation.

Pleistocene: Southern California (Riverside County).

D. Scharf, 1935 (Southwest Mus. Papers, No. 9, pp. 11–20). *Pinto fm.*—Lacustrine clays, sss., and gravels interstratified with basalt flows, and represented in part by very coarse fangl. Occurs in Pinto Basin, north-central part of Riverside Co. Composes Eagle Mtns; also exposed in hill btw. Eagle Mtns and the Coxcombs, and in Pinto Wash. Rests uncon. on old crystalline rocks. Horse and camel remains establish Pleist. age.

Pintoan series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 51, 53, 80), to 2,000 ft. of lss. in Calif. and Nev., said to be of basal Camb. age and much older than Prospect Mtn qtzite.

Named for Pinto Mtns, near Waucoba Springs, in White Mtn Range, Calif. Keyes has also included under this name 900 ft. of shales (which he named *Holliday*) composing basal fm. of Camb. of Utah.

Pinyon conglomerate.

Eocene: Yellowstone National Park.

W. H. Weed, 1896 (U. S. G. S. Yellowstone Nat. Park folio, No. 30). *Pinyon cgl.*—A series of cgl. beds with local intercalations of ss., resting uncon. on upturned Laramie (Cret.). Best exposed on Pinyon Peak. Found only in S. end of Park. Assigned to Eo.

Pinyon series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53), to Eureka qtzite (Middle Ord.) and the overlying lss. of Ord. age in Nev. Also to Fishhaven dol. (Upper Ord.) and Eureka qtzite. Derivation of name not stated.

†Pinyon Mesa group.

Eocene and older (?): Southwestern Colorado and northwestern New Mexico.

W. H. Holmes, 1877 (U. S. Geol. and Geog. Surv. Terr. 9th Ann. Rept., for 1875, pp. 248, 249, 251). *Pinon Mesa group*, also *Pinon Mesa sss.*—Chiefly coarse yellowish sss., alternating with thin beds of variegated marls. Thickness 1,200 ft. Overlies Bad Land fm. ("Puerco marls"). Forms escarpment of Pinon Mesa [in NW. part of San Juan Co., N. Mex.]. [On pl. 35 he includes these beds in Wasatch and calls them *Canyon Largo of Newberry*, but Newberry never published *Canyon Largo*.]

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, p. 6), showed Holmes' 1877 use of *Canyon Largo series of Newberry* included Wasatch, Torrejon, and Puerco fms. and Ojo Alamo ss.; and his Puerco marls as = McDermott fm.

†Pinyon Peak conglomerate.

Eocene: Yellowstone National Park.

A. Hague, 1899 (U. S. G. S. Mon. 32, pt. 2, pp. 184+), applied this term to the cgl. named *Pinyon cgl.* by Weed in 1896.

Pinyon Peak limestone.

Devonian (Upper ?): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Pinyon Peak ls.*—Shaly ls., 0 to 150 ft. thick. Conformably overlies Bluebell dol. and uncon. underlies Victoria qtzite. Exposed along upper eastern slope of Pinyon Peak from its blunt eastern spur southwestward to its base. Not seen in N. spur of the peak. Only recognized Dev. rock in Tintic dist. Fossils indicate Upper Dev. (Threeforks?) age, but this correlation is not certain.

Pioche shale.

Lower Cambrian: Western Utah (House Range) and eastern Nevada (Pioche region).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9–12). *Pioche fm.*—Aren. and argill. shaly layers with some thin layers and bands of ls. more or less irregularly interbedded and limited in horizontal distribution. Is 210 ft. thick at Pioche, Nev. [1,120 ft., according to measurements of L. G. Westgate, U. S. G. S. P. P. 171, 1932]; 170 ft. thick on W. face of Highland Range, 18 mi. W. of Pioche. In Eureka dist., Nev., 135 mi. NW. of Pioche, this fm. lies btw. Prospect Mtn qtzitic ss. and the great ls. series, and is 200± ft. thick. In House Range, Utah, 105 mi. N-NE. of Pioche, it is 125 ft. thick, and overlies Prospect Mtn fm. and underlies Howell fm. Contains Lower Camb. *Olenellus* fauna. Type loc. SE. of Pioche, Nev., on road to Panaca, Utah.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1812), recognized btw. Howell fm. and Pioche sh., in House Range, 205 ft. of bluish-gray aren. ls. which he called *Langston (?) ls.*

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. and Met. Engrs. Trans., No. 1647, pp. 3–8) and 1932 (U. S. G. S. P. P. 171, pp. 8+, etc). *Pioche sh.*—Comprises 1,120± ft. of shales and interbedded lss., which are doubtless the same as Pioche fm. of Walcott, although writers found thickness much greater than that given by Walcott. The sh. is yellow or brown, rarely red argill. sh., usually distinctly micaceous; in places so fine-grained that individual mineral grains do not show. In Ely Range the rock is coarser, more micaceous, and more quartzose, in some places approaching schist in appearance. Contains interbedded lss. and sss., especially in middle and upper parts. A carefully measured section on ridge N. of Lyndon Gulch gave thickness of 1,120 ft. Fossils listed. Rests conformably on Prospect Mtn qtzite and is conformably overlain by Lyndon ls. (Middle Camb.).

Pioneer shale. (Of Apache group.)

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Pioneer sh.*—Dark reddish-brown aren. shales, 200± ft. thick, overlying Scanlan cgl. and underlying Barnes cgl. in Globe dist. The basal 25 ft. are distinctly arkose, containing abundant fragments of pink feldspar. Toward top the shales become more quartzose, but are probably nowhere quite free from particles of granitic feldspar. Named for exposures at old mining settlement of Pioneer, just S. of Globe quad.

Pioneer sandstone.

Pennsylvanian: Northern Tennessee coal field.

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 18–19, 21, 22). A massive ss. that in many places outcrops in prominent cliffs and usually has a broad bench just above it. In Briceville region this ss. is very prominent and the bench immediately above it is known locally as Brayden Bench. The ss. is believed to be same as the ss. in gap at Old Pioneer, in Campbell Co., and has been called by writer *Pioneer ss.* It forms topmost memb. of Jellico fm. In some places, as near Briceville and southwestward toward Windrock, the Pioneer ss. at the base [of Scott fm.] is prominent and forms Brayden Bench, and over it there is another prominent ss. in lower part of the [Scott] fm. that forms Dougherty Bench. [On p. 32 is statement that Pioneer ss. is basal memb. of Scott fm., and on p. 51 is statement that W. of Briceville the Pioneer ss. forms the Dougherty Bench. On p. 316 is following statement: Where it [the Pioneer ss.] is in average development it forms projecting cliffs and underlies a bench that about Petros is prominently developed and known as Dougherty Bench. About Briceville, in Anderson Co., the corresponding bench is known as Brayden Bench and another bench 200 to 225 ft. higher is there locally known as Dougherty Bench. Writer evidently intended to make his Pioneer ss. the top memb. of his Jellico fm.]

Pipe Creek shale member (of Wiscoy sandstone).

Upper Devonian: Western New York.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [See 1923 entry under †*Silver Creek sh.*]

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, pp. 95, 96, 98, 193, 198, 199, 276, 278, 351, 357). *Pipe Creek black sh.* underlies Hanover sh. and overlies Portage ("Nunda") ss. Traceable from Lake Erie to Genesee River. Only 2 ft. thick on Walnut Creek, beneath type section of Hanover sh., but thickens eastward. At East Aurora it rests on Angola sh. Well exposed in Pipe Creek Glen, West Falls [Erie Co.].

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 352), included this sh. in Chemung group.

In Steuben and adjacent counties of south-central N. Y. the Pipe Creek sh. is treated by U. S. Geol. Survey as basal memb. of the Wiscoy, which in this area is a ss. and is called *Wiscoy ss.*

Pipes fanglomerate.

Upper Pliocene or lower Quaternary (mapped as Pliocene): Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 379–380, and map). *Pipes fangl.*—A flat-lying sedimentary deposit. Lower 15 ft., soft gray ss. containing many rounded pebbles. This grades upward into reddish cgl., for most part of rounded granite, aplite, and quartz pebbles up to 6 inches in diam., but containing considerable angular material. Larger part of mass on hill ½ mi. SE. of The Pipes is rather well cemented and more resistant to weathering than underlying granite, so that it forms a distinct bench near top of the ridge. Total thickness on this hill is 50 ft. Total thickness at table-topped hill directly E. of The Pipes is 60 ft. on S. side, but less than 20 ft. on N. side. Overlain by basalt. Is younger than Hathaway fm.

Named for The Pipes, a watering place in San Bernardino Co., near which it occurs.

Pipestem shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 294, 322). *Pipestem sh.*—Sandy sh., usually with streaks of ss. and with plant fossils at base; also contains marine fossils. Thickness 30 to 45 ft. Underlies Glady Fork ss. and overlies Pipestem coal. All included in Bluestone group [fm.]. Type loc. in Tallery Mtn road near foot of Davy Knob, 1$\frac{1}{10}$ mi. NE. of Pipestem, Summers Co.

†Pipestone quartzite.

Pre-Cambrian (Huronian): Southwestern Minnesota (Pipestone County).

N. H. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 2, p. xxii), shows *New Ulm and Pipestone qtzites* as older than red shales and red sandrock underlying Hinckley ss.

Later repts state that it is same as Sioux qtzite.

Pipestone formation.

Devonian: British Columbia.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 75, p. 51).

Pipestone beds.

Oligocene: Montana.

See *Pipestone Creek beds.*

†Pipestone Creek beds.

Oligocene (lower): Western central Montana (Jefferson County, Boulder region).

E. Douglass, 1902 (Am. Phil. Soc. Trans., vol. 20, n. s., pt. 3, pp. 237–245). *Pipestone beds*, the White River (Olig.) deposits on Pipestone Creek, just above Piedmont, Jefferson Co. Local name given for convenience till correlation is established.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 22, 60, 65). White River deposits along Pipestone Creek, Mont. (Douglass, 1902), are lower Olig.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, p. 9), called these beds *Pipestone Creek beds* and assigned them to lower Olig.

Piqua stone.

Silurian (Niagaran): Southwestern Ohio (Miami County).

John Hussey, 1878 (Ohio Geol. Surv. vol. 3, p. 478). *Piqua stone.*—Fine-grained, mostly sedimentary stone, few ft. thick, without large proportion of fossils. *Quarried* at Piqua, Miami Co. Extremely local. Belongs in Niagara. Rests on uneven surface of undoubted Clinton [not Clinton, but Brassfield ls.].

†Piqua limestone member.

Pennsylvanian: Southeastern Kansas.

G. I. Adams, 1904 (U. S. G. S. Bull. 238, p. 20). *Piqua ls.*—Heavy-bedded lss., 50 ft. thick, overlying Vilas sh. and forming top fm. exposed in Iola quad.

Same as Stanton ls., older name.

Named for Piqua, Woodson Co.

Piran series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 289). *Piran series.*—Qtzites, 2,700 ft. thick, underlying [Mount] Whyte shales and overlying [Lake] Louise shales. Of early Cambric age. [Apparently same as St. Piran fm.]

Pirate Cove formation.

Upper Devonian: Quebec.

F. J. Alcock, 1935 (Canada Dept. Mines Geol. Surv. Bur. Econ. Geol. Mem. 183, p. 86).

†Piscataway sands.

Eocene: Eastern Maryland.

A. Heilprin, 1884 (Phila. Acad. Nat. Sci. Jour., 2d ser., vol. 9, pt. 1, pp. 120, 124–127). *Piscataway sands*, Eocene. Underlie Upper Marlborough or Marlborough rock. "Uncertain whether they represent Claibornian, Buhrstone, or Eo-Lignitic."

Piscataway as above used is said to probably correspond to Aquia fm. of present nomenclature, and "Upper Marlborough" to Nanjemoy fm.

Piscataway indurated marl member (of Aquia formation).

Eocene: Eastern Maryland and Virginia.

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Piscataway memb. or substage.*—Basal memb. of Aquia fm. Characterized by greensands and greensand marls; lower beds often quite argill. Thickness generally exceeds 50 ft. Underlies and is faunally separable from Paspotansa or upper memb. of Aquia fm. Rests uncon. on Cret. Named for Piscataway Creek, Md.

B. L. Miller, 1912 (U. S. G. S. Choptank folio, No. 182). *Piscataway indurated marl memb.*—Basal memb. of Aquia fm. Underlies Paspotansa greensand marl memb. Rests uncon. on Cret.

Pisgah member (of Kincaid formation). (In Midway group.)

Eocene: Northeastern to southwestern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 535, 536, 540, 550). *Pisgah ls. memb. of Kincaid fm.*—Clay, glauconitic clay, and glauconitic sand containing lentils of ls. Top memb. of Kincaid fm., extending from top of Littig glauconite memb. of the Kincaid up to basal glauconite of Wills Point fm. Thickness 115 ft. In NE. Tex. it outcrops from Limestone Co. to Hopkins Co. and contains Lone Oak, Rocky Cedar Creek, and Tehuacana ls. lentils, the latter ls. at top and 40 ft. thick. In SW. Tex. it is somewhat different from typical exposures in NE. Tex.; in Medina Co. the clay is thinner, the basal glauconite bed is thicker, and the gray ls. near its top is more persistent than the lentils in NE. central Tex.

J. Gardner, 1935 (Univ. Tex. Bull. 3301), divided Kincaid fm. into (descending) Tehuacana memb. (more inclusive than Tehuacana ls. of Plummer), *Pisgah memb.* [restricted], and Littig glauconitic memb. This is adopted definition of U. S. Geol. Survey.

Named for exposures on Pisgah Ridge, Navarro Co., on road btw. Richland and Wortham, 6 mi. N. of Limestone Co. line.

Pismo formation.

Miocene (upper): Southern California (San Luis Obispo region).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *Pismo fm.*—Siliceous sh., diatomaceous earth, and thick beds of soft ss., with a memb. of ss. and cgl. at base. Thickness about 3,000 ft. Occurs in S. part of area mapped, and is considered to be contemp. with Santa Margarita fm. of N. part of area, though the two fms. are not known to have been connected. Uncon. overlain by Paso Robles fm. and uncon. underlain by Monterey sh.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 787). *Pismo fm.* is now known to be=Etchegoin fm. and therefore of Plio. age.

Named for exposures at town of Pismo, San Luis Obispo Co.

Pit shale.

Middle and Upper Triassic: Northern California (Shasta County).

H. W. Fairbanks, July 1894 (Am. Geol., vol. 14, p. 28). *Pitt shales.*—Siliceous slates, of which nearly 2,000 ft. are exposed at Silverthorne's ferry [on Pit River, approved spelling], containing fossils regarded by J. P. Smith as Middle and possibly Lower Triassic. It is intended to apply term *Pitt shales* to these rocks, which, together with some Upper Carbf. strata (McCloud shales), 20 mi. above the Fisheries, shall be embraced under designation *Pitt fm.*

J. P. Smith, October 1894 (Jour. Geol., vol. 2, pp. 592, 601–604). The *Pitt fm.* (H. W. Fairbanks ms.) overlies conformably McCloud ls., and consists of about 3,000 ft. of siliceous and calc. shales, cgls., and tuffs. The rocks in most places are highly metamorphosed, very poor in fossils, and folded to such degree that the strat. is obscure. The fm. is largely developed in region near junction of Pitt and McCloud Rivers. Contains both Carbf. and Triassic rocks, in apparently conformable series. Divided into Pitt shales, 2,000 ft. thick, of Middle and Upper Triassic age, and McCloud shales, 1,000 ft. thick, of Upper Carbf. age. Underlies Swearinger slates. The Pitt shales consist of siliceous shales and cgls. containing Triassic fossils about 1,500 ft. below their top, underlain by several hundred ft. of shales and cgls. without fossils.

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Pit sh.*—Largely dark and gray shales, thin-bedded sss., and many layers of tuffs. Thickness probably more than 2,000 ft. Conformably underlies Hosselkus ls. and rests on volcanic rocks called *Bully Hill rhyolite* and *Dekkas andesite*, the latter being in part interbedded with lower beds of Pit sh. Fossils indicate Upper and Middle Triassic age.

†Pit formation.

†Pitt formation.

Pennsylvanian to Upper Triassic: Northern California (Shasta County).

See definition under *Pit sh.* The U. S. Geol. Survey does not use the broad definition of *Pit*, which included Pit sh. and Nosoni fm. of present terminology.

†Pithole grit.

Mississippian: Northwestern Pennsylvania.

J. F. Carll, 1880 (2d Pa. Geol. Survey Rept. I_3, pp. 82, 93, 121, 130). The Third Mountain sand will receive in this report a new name, the *Pithole grit*. It was first recognized as a persistent ss. in Pithole oil wells, being well developed in all that country [in and around Pithole, Venango Co.], and making conspicuous outcrops along Allegheny River on S. and along Oil Creek on W. Is probably=Berea grit. A persistent band of red sh., sometimes 125 or more ft. thick, underlies Pithole grit all the way from S. line of Warren Co. [Pa.] to John Smith well in Butler Co. The Pithole grit lies near middle of Crawford shales.

I. C. White, 1881 (2d Pa. Geol. Survey Rept. Q_4). *Pithole grit* is Berea grit.

Pitkin limestone.

Mississippian (Chester): Northern Arkansas and eastern Oklahoma.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 27, 109). *Pitkin ls.*—Fossiliferous ls., 0 to 90 ft. thick, heretofore called "Archimedes ls." by Ark. Geol. Survey. Sometimes has associated with it ss. beds which contain same fossils as the ls. Highest Miss. fm. Late Chester fauna. Overlies Fayetteville sh. and uncon. underlies Morrow group (Penn.).

Named for Pitkin, Washington Co., Ark.

†Pitt formation. See *Pit sh.*

Pitt series.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed *Pitt series* as a geographic name for *Middle Triassic series*.

Pittsburg. Appalachian region. See *Pittsburgh*.

†Pittsburg formation.

Eocene: Western Washington (Puget Sound region).

B. Willis, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 424–430). *Pittsburg fm.*—Sss., shales, and a few coal beds. Top fm. of Puget group. Thickness 4,770 to 7,000 ft. Overlies Wilkeson fm. Is comparatively barren of fossils. Named for town. [On p. 424 he said this fm. is exposed on South Prairie Creek. On p. 429 he called the deposits *South Prairie fm.* On pp. 426, 430, etc. *Pittsburgh fm.* and *South Prairie fm.* are used interchangeably.]

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54), applied name *Burnett fm.* to top fm. of Puget group (probably because Pittsburg was preoccupied), but continued to use *South Prairie fm.* interchangeably with *Burnett fm.*

G. O. Smith, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, pp. 483–487), treated Puget as a fm., and applied *Pittsburg memb.* to upper 7,000± ft. of the Puget, and *Wilkeson memb.* to underlying 1,000 ft.

Foregoing are only recorded uses of *Pittsburg* for this Eocene fm.

Pittsburg Bluff sandstone.

Oligocene: Northwestern Oregon (Columbia County).

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, p. 254), used *Pittsburg Bluffs* for lower Olig. in Oreg. column, but did not define it. On pp. 250–254 they discussed fossils collected at that place by different geologists.

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12, pp. 450, 457, 458, 459). [The "sandstone at Pittsburg Bluffs" is mentioned on p. 450. The "sandstone at Pittsburg Bluff" is mentioned on p. 457. On pp. 458 and 459 *Pittsburg Bluff ss.* is used. The ss. at Pittsburg Bluff is said to overlie Keasey sh., and it is assigned to middle Olig. All of definition.]

H. G. Schenck, 1928 (Calif. Univ. Dept. Geol. Sci. Bull., vol. 18, p. 36). *Pittsburg Bluff ss.*—Massive ss. that outcrops at Pittsburg Bluff, in SW¼ NE¼ sec. 23, T. 5 N., R. 4 W. Believed to rest on Keasey sh. Is overlain by massive sandy sh. containing admixture of tuffaceous material and a number of diatoms. Fossils (listed) correlate with Eugene, Tunnel Point, and Yaquina sss.

†Pittsburgh series.

Pennsylvanian: Central western Pennsylvania.

H. D. Rogers, 1839 (Pa. Geol. Surv. 3d Ann. Rept. pp. 88–108), applied *Pittsburg series* to the rocks overlying *formation XIII* (*Coal Measures*) in 5th dist. of Pa., "embracing the country west of Chestnut Ridge and Allegheny River." "It is believed that no part of the dist. contains rocks superior in their order of stratification to those just described, if we except the narrow belt of country a few miles in width, which forms the dividing land between the Ohio and Monongahela Rivers, and which extends from town of Washington southward, through Greene County to Dunkard's Creek, on Virginia line." [Corresponds to Perm. of present nomenclature.]

H. D. Rogers, 1840 (Pa. Geol. Surv. 4th Ann. Rept., p. 150). The Monongahela series, or Upper Coal Measures, which rest on Allegheny series, "includes the beds entitled the *Pittsburg series* in my last annual rept." [Includes Perm. and Monongahela fm. (Penn.) of present nomenclature.]

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3). *Upper Productive Coal Measures or Pittsburg group* overlies Lower Barren Measures in Somerset Co. Thickness 200 ft. Includes at top a ss. which lies 50 ft. above Great Pittsburg ls. Extends up to base of Pittsburg coal. [Corresponds to Monongahela fm.]

J. P. Lesley, 1886 (Am. Inst. Min. Engrs. Trans., vol. 14, pp. 631–652). "The Lower Barren Measures, or Barren measures proper of First Survey, which I may call the *Pittsburg series*, for all the hillsides in sight of us are made of upper half of this series and the lower half of it lies immediately beneath our feet" [at Pittsburgh]. Extends from top of Upper Freeport coal up to base of Pittsburgh coal. [Corresponds to Conemaugh fm. of present nomenclature. Has had considerable usage in this sense, being called *Pittsburgh group* in some repts.]

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed that the Pennsylvanian *system* (as he called it) be divided into two *series*, the upper one to be called *Pittsburgh series* and to include Monongahela, Conemaugh, and Allegheny *groups* (as he called them), and the lower one to be called *Pottsville series*.

†Pittsburgh limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 628–635). *Pittsburg ls.* is at top of Lower Barren Measures and immediately beneath Pittsburg coal. It consists of blue and black ls. 25 ft. thick, in 6 to 10 layers separated by sh. [As thus defined the term probably included both Upper Pittsburgh ls. memb. and Lower Pittsburgh ls. memb. of current classification. In subsequent repts, however, the name has by many geologists been restricted to Upper Pittsburgh ls. memb.]

J. J. Stevenson, 1873 (Am. Phil. Soc. Trans., vol. 15, n. s., pp. 20–21). Under term *Pittsburg ls.* I include all the ls. [of "Monongahela River series"] below the Waynesburg coal, although I am aware that it does not rightly cover so much. The total thickness [of ls.] is about 100 ft. in 350 ft. of strata. Color varies from light blue to almost black. Most of strata are quite compact. [This usage of name has not withstood the test of time.]

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. 88, 100). *Pittsburg ls. group* includes Uniontown ls. at top and Redstone ls. at base.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 87). *Lower Pittsburgh ls.* lies a short distance above Connellsville ss. It is thicker and more persistent than Upper Pittsburgh ls. The Little Pittsburgh coal lies a few ft. above L. P. ls. and is overlain by *Upper Pittsburgh ls.*, 3 to 5 ft. thick. Both of these lss. are known under general name of *Pittsburgh ls.*

In some U. S. G. S. repts the *Upper Pittsburgh ls. memb.* has been called *Pittsburgh ls. memb.*, but that usage is no longer followed.

Pittsburgh sandstone member (of Monongahela formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 503–507). *Pittsburg ss.*—Massive ss., irregularly stratified. Thickness 25 to 50 ft.; 25 ft. in Greene Co., Pa., and at Pittsburg. Is older than Redstone coal, and separated from underlying Pittsburg coal by 35 ft. of brown sh. [This definition apparently applied the name to same ss. that is now designated as *Pittsburgh ss. memb.*]

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Upper Pittsburg ss.*—Ss. or sandy sh., 40 ft. thick. Separated from overlying Redstone coal by 0 to 10 ft. of ls., and from underlying Pittsburg coal by 0 to 10 ft. of sh. [No Lower Pittsburg ss. was mentioned, and the ss. defined above has for many years been called *Pittsburgh ss.*]

F. Platt, 1876 (2d Pa. Geol. Surv. Rept. L, p. 20). The *Pittsburg ss.* (*Morgantown?*) is a great deposit of sh. above, sand in middle, and pebble rock at bottom, 70 ft. thick, extremely variable in composition in different parts of county. Lies 40 ft. below Connellsville ss. [The Pittsburgh ss. is now known to be a much younger bed than Connellsville ss., and Morgantown ss. is older than the Connellsville.]

J. J. Stevenson, 1877 (2d Pa. Geol. Surv. Rept. K_2, p. 409). Pittsburg ss. is *Upper Pittsburg ss.*, and is separated from underlying Pittsburg coal by 6 to 10 ft. of dark sh.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 63). Where Redstone ls. is absent or poorly represented there is often present a coarse massive ss. immediately above Pittsburg coal to which H. D. Rogers long ago gave name of *Pittsburg ss.* It is usually coarse, friable, and often pebbly, and 25 to 70 ft. thick.

Pittsburgh (Lower) sandstone. (In Conemaugh formation.)

In some repts of Pa. Geol. Surv. the name *Lower Pittsburgh ss.* is applied to a ss. underlying Upper Pittsburgh ls. memb. and lying not far above Lower Little Pittsburgh coal. In W. Va. Geol. Surv. Rept. Tucker Co., 1923, the name *Lower Pittsburgh ss.* is applied to 10 to 20 ft. of gray ss. lying 35 ft. below Morantown coal and overlying 4 ft. of dark sh. occupying the horizon of Upper Pittsburgh ls. In other repts the thickness of this Lower Pittsburgh ss. is given as 65 ft.

Pittsburgh red beds.
Pittsburgh red shale. (In Conemaugh formation.)
Pittsburgh Reds.

Pennsylvanian: Western Pennsylvania and Maryland, northern West Virginia and eastern Ohio.

Names commonly applied in Pa., Ohio, Md., and W. Va. repts to the red shales occurring in interval btw. Harlem coal above and Saltsburg ss. memb. below.

Named for exposures along the grade lines of many railroads at Pittsburgh, Pa.

Pittsburgh member. (In Monongahela formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include, as "prominent beds," Pittsburgh ss. and Pittsburgh coal.

Pittsford shale member (of Salina formation).

Silurian: Western to east-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Bull. 69, p. 867). Thin layer of black shales forms horizon at base of Salina shales. Exposed by excavations in Erie Canal near Pittsford [Monroe Co.] in 1897. Contains unique collection of heretofore unknown fossils. So distinctive is character of fm. and its fauna that we are distinguishing the layer at *Pittsford sh.* [According to Clarke's Hdb. 19, 1903, Pittsford sh. is basal bed of Salina, underlies Vernon sh., overlies Guelph dol., and consists of black sh. and interbedded platten dol. with profusion of eurypterids.]

In later repts thicknesses of 10 and 20 ft. are given for Pittsford sh. Is basal memb. of Salina fm.

The foregoing definition of *Pittsford sh.* continued to be followed for many years. In 1928 (N. Y. State Mus. Bull. 275, p. 21) H. L. Alling stated: "Pittsford" is only a local faunal phase of Vernon sh.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 337). *Pittsford sh.*—Black sh., 10 to 20 ft. thick. Basal part of Salina series in western and central N. Y. Underlies Vernon sh. and overlies Lockport dol. Was separated from the other shales because of fauna. [She described Vernon sh. as mainly red and green, but also as containing gray gypsiferous shales and thin flaggy dolomites.]

Piutean series.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 80). *Piutean series.*—The Plio. section of the Borate sediments in Death Valley dist. and best developed perhaps under Piute Point, in Furnace Canyon [E. of Death Valley, Inyo Co., Calif.]. [Negra clays are only fm. included in the series. On p. 61 these clays are "tentatively considered as Mio. in age." The series and the clays are both listed as present in Nev.]

Placentia.

See under *Terra Nova*.

Placerita formation.

Pre-Cretaceous (pre-Cambrian?): Southern California (San Gabriel Mountains).

W. J. Miller, 1934 (Univ. Calif. at Los Angeles Pub. in Math. and Phys. Sci., vol. 1, No. 1, pp. 3–12, 63–65, 83, map). *Placerita* (*metasedimentary*) *fm.*—Oldest known rocks of SW. San Gabriel Mtns; pre-Cret., probably pre-Camb. Profoundly altered from shales, sss., and lss. into various kinds of schists, qtzites, and crystalline lss. [On map a separate block is labelled *Placerita crystalline ls.*] Named for good exposures in Placerita Canyon, at W. end of San Gabriel Mtns. Thickness 800 to 2,500± ft. No fossils. Presumably is older than San Gabriel mixed fm., but the two are intimately associated and relations are not clear. The Placerita metasediments form part of San Gabriel fm. [On p. 35 he calls his Placerita a memb. of San Gabriel fm.] Noble has correlated this fm. with Pelona schist of Hershey, but writer believes it is older than Pelona schist. If the Pelona is pre-Camb. or possibly early Paleozoic, the Placerita is almost certainly pre-Camb. and probably older pre-Camb. (Archeozoic). Is intruded by Rubio diorite and Echo granite.

Placerita crystalline limestone.

See under *Placerita fm.*

†Placer Mountain group.

Upper Cretaceous: Central northern New Mexico.

F. V. Hayden, 1869 (U. S. Geol. and Geog. Surv. Terr. 3d Ann. Rept., pp. 90, 190). The next group of coal strata occurs in Placer Mtns, N. Mex., about 30 mi. S. of Santa Fe. Lithological characters of the beds are very similar to those of lignite group farther N., but evidence in regard to age or parallelism with lignite group is not so clear. While I regard the true coal beds of West as lower Tert., yet these Placer Mtn beds present appearance of greater antiquity than the coal beds farther N. Still the numerous varieties of deciduous leaves which I have obtained from rocks just overlying the coal beds indicate they are lower Tert. With this belief I have named them *Placer Mtn group*. The Gallisteo sand group overlies them in valley of Gallisteo Creek, and Cret. No. 4 underlies them.

Probably approx. same as Mesaverde fm.

Placid shale member (of Brad formation).

Pennsylvanian: Central Texas (Colorado River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 35; Univ. Tex. Bull. 2132, pp. 109–110, 115). *Placid sh.*, 30 to 50 ft. thick, is a memb. of Brad fm. in Colorado River Valley. Underlies Ranger ls. of the Brad and overlies Clear Creek ls. memb. of Brad. In places contains lentils of ss. Is "bed No. 7" of Drake [which Drake reported to be 25 to 100 ft. thick]. Named for town of Placid, McCulloch Co., which is located on its outcrop.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104 112). [See 1933 entry under *Brad fm.*]

F. M. Bullard and R. H. Cuyler, 1935. [See 1935 entry under *Brad fm.*]

Lower or ls.-bearing part of this memb. is now included in Winchell memb. of Nickell and Wallace Lee, which is top part of Graford fm. as redefined by Sellards (Univ. Tex. Bull. 3232, 1933) and by Wallace Lee and C. O. Nickell. The upper 111± ft. of Placid sh. of Plummer and Moore is still included in Brad. fm. (See Wallace Lee and C. O. Nickell, rept completed and soon to be published by Tex. Geol. Survey.)

Placita marl.

Tertiary? (probably Pliocene and Miocene): Central northern New Mexico.

E. D. Cope, 1875 (Ann. Rept. Chief Engrs U. S. A., Rept. Secy War to 44th Cong., vol. 2, pt. 2, p. 997). *Placita marls* underlie gravel mesas and overlie Cret. Nos. 4 and 3 in region from Zandia [Sandia] Mtns to and beyond village of Placita.

E. D. Cope, 1877 (U. S. Geog. Surv. W. 100th Mer., vol. 4, pt. 2, pp. 24–25). In intervals btw. the hills [Algodones to Sandia Mtns] there is a deposit of indurated clay, 40 ft. thick, of post-Plio. age, carrying shells which indicate its lacustrine character, which I have called *Placita marl*.

A. B. Reagan, 1903 (Am. Geol., vol. 31, pp. 87, 89). The patches of Pleist. deposits in inner valley of Rio Grande (20+ ft. thick and resting on cgl.) may be designated *Rio Grande marl;* btw. San Felipe and Placita they are called *Placita marl*, after Cope. Younger than Albuquerque marl.

Placitos limestone.

Pennsylvanian: Central northern New Mexico.

C. R. Keyes, 1903 (Ores and Met., vol. 12, p. 48). *Placitos ls.*—The lower black ls. in Sandia Mtns, of middle Carbf. age. Overlies Sandia qtzites. [Derivation of name not stated.]

†Plainfield schist.

Ordovician: Western Massachusetts.

R. Pumpelly, 1894 (U. S. G. S. Mon. 23, pp. 29–30), from [unpublished] rept of B. K. Emerson. *Plainfield schist*, the "upper hydromica schist." Thickness 9,000 ft. Overlies Chester amphibolite and underlies Conway schist. [According to personal communication from B. K. Emerson this name was published by Pumpelly as a quotation from unpublished work by Emerson, who, instead of using *Plainfield*, divided the rocks into *Hawley schist* and *Savoy schist*.]

Named for occurrence in Plainfield Twp.

Plainfield quartz schist.

Pre-Cambrian: Eastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 132, and map). *Plainfield quartz schist.*—Highly quartzose, but varies in texture from a finely divided quartz schist to an almost massive qtzite, and also to a dark-colored rock resembling sl. Crosses Plainfield Twp. Believed to be only a prominent and clearly marked variation of Putnam gneiss. It seems to be part of a series that includes Putnam gneiss and to be the oldest sed. fm. in the region. Resembles Poughquag qtzite.

G. F. Loughlin, 1910 (Am. Jour. Sci., 4th, vol. 29, pp. 448–451). *Plainfield quartz schist* may be Carbf.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the continuation into R. I. of Plainfield quartz schist of Conn. Survey as Westboro qtzite (pre-Camb.).

L. H. Martin, 1925 (Conn. Geol. and Nat. Hist. Surv. Bull. 33, with map), assigned *Plainfield quartz schist* to pre-Camb.

†Plains marl.

Pleistocene, Pliocene, and Miocene: Western Kansas.

R. Hay, 1893 (Kans. State Bd. Agric. 8th Bien. Rept., p. 101). Tert. deposits of Kans. consist of *plains marl* (Plio.), 175 ft. thick, and Loup Fork (Mio.), 50 ft. thick.

R. Hay, 1895 (U. S. G. S. 16th Ann. Rept., pt. 2, p. 570). *Plains marl* is composed of lime, sand, and clay. It is a surface deposit on the high prairie, but is sometimes found forming the bottom land of valleys, and sometimes occurs in patches on the slopes. Thickness few ft. to 200. I regard it as Plio. as to its inception, and probably its latest deposits were laid down in Quat. time. Where thickest its lower parts are often more aren. than the upper. It overlies Mio. grit.

E. Haworth, 1897 (Univ. Kans. Geol. Surv., vol. 2, pp. 257–280). *Plains marls* and *mortar beds* of Cragin have no definite strat. position, but are convenient terms to designate difference in physical properties. The *mortar beds* occur at all positions from base to summit of Tert. They contain Loup Fork fossils in some places and Pleist. fossils in other places, as do the *plains marls.*

N. H. Darton, 1905 (U. S. G. S. P. P. 32, pp. 149–155). Ogallala fm. of western Kans. comprises the Tert. grit, mortar beds, etc. It consists of calc. grit, sandy clay, and sand, underlying *Equus* beds and overlying Pierre sh.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3). Ogallala fm. [Plio. and Mio.] occupies all of High Plains of western Kans. Has been called "mortar beds." It is 0 to 300 ft. thick, overlies Pierre sh., and underlies Pleist. glacial deposits.

N. H. Darton, 1920 (U. S. G. S. Syracuse-Lakin folio, No. 212). [See 1920 entry under *Ogallala fm.*]

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7, pp. 163–180). *Sanborn fm.*—Proposed for the Pleist. loess, with some gravel and sand at base, which is widely distributed on the divides in western Kans. The name is intended as a substitute for "Tertiary marl" or "Plains marl," introduced for this fm. by Robt. Hay. Major part of Sanborn fm. consists of this *Pleist. loess.* It seems to writer that only the loess that covers the divides can be considered to be Pleist., the loess of the valley slopes and bottoms being largely if not wholly redeposited from the divides, the redeposition having taken place probably for most part in late Pleist. and Recent times.

A. L. Lugn, 1934 (Nebr. State Mus., vol. 1, Bull. 41, p. 355). "Sanborn fm." (Elias, 1931) of western Kans. is a composite of sand, gravel, and loess, ranging in age from early Pleist. (Kansan or perhaps older) to Peorian or younger (the "yellow dirt"). The separate parts of "Sanborn fm.," especially the loess, are differentiated in Nebr. and should not have been grouped together as a fm.; at least a new fm. name should not have been assigned.

†Plains series.

Pleistocene and Recent: Nebraska.

A. L. Lugn, 1935 (Nebr. Geol. Surv. Bull. 10, 2d ser., charts, pp. 128, etc.). *Plains series* is, as a whole, a unit in that the several fms. are of like origin and similar lithology, except the Sand Hills fm., and have all been more or less derived from common sources. The eolian genesis of this Plains or loess and Sand Hills series, its great areal extent of more than 62,000 sq. mi. in Nebr., and also the great thickness and large quantity of the deposits, make this grouping of eolian materials into a series a desirable and convenient expedient in classifying the Pleist.

geol. of the State. It is also separated from underlying Platte series by a great uncon., which is as widespread as are the fms. in Nebr. and adjoining States. It corresponds to (descending) Recent, Wisconsin, Peorian, Iowan, Sangamon, and Illinoian stages of Iowa classification.

Plaisance limestone.

Eocene: Haiti.

W. P. Woodring, 1922 (Prel. rept. Republic Haiti) and 1924 (Geol. Republic of Haiti, p. 99).

†Planorbis rock.

Pleistocene and Pliocene: Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 143, 157, 333). *Planorbis rock.*—Hard rock characterized by abundance of *Planorbis.* Uppermost Plio. bed of Fla.

This name is also applied to Pleist. rocks in Fla. (See Fla. Geol. Surv. 2d Ann. Rept., 1909, and U. S. G. S. W. S. P. 319, 1913.)

†Plant beds.

A name applied by J. W. Powell (Geology of eastern portion of Uinta Mtns, 1876) to upper part of Green River fm., overlying Tower ss., in Sweetwater Co., Wyo. These beds were later named *Morrow Creek memb.*

Plateau gravel phase.

Quaternary: Southwestern Arkansas.

See *Centre Point division.*

Plateau Valley beds.

Eocene (lower): Central western Colorado (Mesa County).

B. Patterson, 1936 (Geol. Soc. Am. Proc. 1935, p. 397). [Lists fossils from "*Titanoides* level in Mesa Co., Colo.," and says:] The assemblage is certainly upper Paleocene and probably either a Clark Fork or a Tiffany equiv. The name *Plateau Valley beds* is given to the upper Paleocene fm. in the area. [All of definition.]

†Platte series.

Upper Cretaceous: From Rocky Mountains eastward.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 49). *Platte series.*—Upper Cret. series of the Plains, into which shales and sss. more largely enter than in Comanche or Lower Cret. series, but which also has some important ls. fms. Includes Dakota, Benton, Niobrara, Fort Pierre, Fox Hills, and Laramie. Area of typical occurrence that segment of North American Interior Plateau which extends from Rocky Mtns eastward and constitutes the higher portion of the Plains. Named for Platte River, which in Colo. and Nebr. cuts all divisions of the series.

Platte shale.

Pennsylvanian: Southwestern Iowa and northwestern Missouri.

C. R. Keyes, 1898 (Am. Geol., vol. 21, p. 349). *Platte shales.*—Shales, 105 ft. thick, underlying Forbes ls. and overlying Plattsmouth ls.

Equivalent to Tecumseh sh. memb., Lecompton ls. memb., and Kanwaka sh. memb. of Shawnee fm.

Named for exposures at mouth of Platte River at Nebr.-Iowa bdy; also well exposed along Platte River (another stream) of NW. Mo.

†Platte series.

Pleistocene: Nebraska.

A. L. Lugn, 1935 (Nebr. Geol. Surv. Bull. 10, 2d ser., charts, pp. 88+). *Platte series.*—Is made up of Holdrege, Fullerton, Grand Island, and Upland fms. They constitute the Pleist. fluviatile deposits W. of the till border in Nebr. This series is=Grandian and Ottumwan of Iowa and eastern Nebr. The Upland fm. is=Yarmouth stage, the Grand Island is=Kansan stage, the Fullerton is=Aftonian stage, and the Holdrege is=Nebraskan stage. The several fms. are exposed in and near Platte River Valley, and they have a very significant relation to nature and history of Platte River and its valley. In addition, these 4 fms. have a generic unity in relation to the Nebraskan and Kansan glaciations in Nebr., which makes this grouping of them into a series logical. The fms. are extensively distributed over 15,000 to 20,000 or more sq. mi. of State, and occur as continuous layers under both the plains and Platte River Valley. Platte River flows on these fms. "*in situ*" for most part on Grand Island sand and gravel, from near North Platte to near Columbus. The deposits uncon. overlying the Platte series are= (ascending) Illinoian, Sangamon, Iowan, Peorian, Wisconsin, and Recent stages of Iowa and are here named *Plains series*.

Platte River formation.

A name loosely applied by H. Engelmann (Eng. Dept. U. S. Army, J. H. Simpson's Expl. of Great Basin of Terr. of Utah, 1876, pp. 247, 281–282) to exposures in bluffs along Platte River, Nebr., of so-called "Lignite fm.," which he assigned to Eo. or Upper Cret., and stated that it overlies Cret. No. 3 of Nebr. and is separated from his so-called "Scotts Bluff fm." by "a series of Tert. strata." (See also under †*Scotts Bluff fm.*)

Platteville limestone.

Middle Ordovician (Black River): Southwestern Wisconsin, southern Minnesota, Iowa, and northwestern Illinois.

H. F. Bain, 1905 (U. S. G. S. Bull. 246, pp. 18–19). *Platteville ls.*—The beds heretofore called "Trenton ls." in Miss. Valley region, but older than Trenton. Consists of (descending): (1) 10 to 20 ft. of thin beds of ls. and sh.; (2) 25 to 30 ft. of thin-bedded brittle ls. breaking with conchoidal fracture and at times called "glass rock;" (3) 20 to 25 ft. of buff to blue mag. heavy-bedded ls., frequently a dol.; and (4) 1 to 5 ft. of blue sh. and sandy sh. Overlies St. Peter ss. and underlies the massive Galena ls. The fm. is typically exposed in vicinity of Platteville, Grant Co., Wis., and entire thickness may be seen along Little Platte River W. of that town. The black shales of No. 1 are locally termed "oil rock," but the main bed of chocolate-colored sh., or the "oil rock" of the lead and zinc dist., lies just at base of overlying Galena. [E. O. Ulrich assigned these pre-Galena beds to the Black River and the Galena to the Trenton in 1879. See under *Galena dol.*]

As above defined included at top the beds later (1906) named *Decorah sh.* and now treated as a distinct fm. Some writers now exclude from base the sh. which has been named *Glenwood sh.* The U. S. Geol. Survey and the 1935 Conf. Rept. Kans. Geol. Soc. include this sh. in Platteville ls.

G. M. Kay, 1928 (Sci., n. s., vol. 67, p. 16), introduced *Spechts Ferry memb.* for lower part of his Decorah sh., and included in it the "glass rock" and some overlying beds. In 1931 (Jour. Geol., vol. 39, p. 370) he redefined his *Spechts Ferry memb. of Decorah fm.* by excluding the "glass rock," which he transferred to Platteville ls.

V. T. Allen, 1932 (Jour. Geol., vol. 40, No. 3, pp. 259–269), proposed to draw line btw. Platteville and Decorah at base of a 1- to 3-inch layer of metabentonite, which he reported as present 12 to 18 inches above base of Decorah in Minn., Iowa, and Wis.

G. M. Kay and G. I. Atwater, 1935 (Am. Jour. Sci., 5th, vol. 29, Feb., p. 101), include their Spechts Ferry memb. ("of late Black River age") in the Decorah, but later in 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 286–287) Kay included his Spechts Ferry memb. in Platteville ls., leaving his Guttenberg memb. (15 ft. thick near Platteville, Wis.) the sole representative of Decorah sh. near Platteville. On p. 288 he stated that in Minn. and northern Iowa it is "more convenient to consider the Spechts Ferry as a lowest memb. of Decorah fm." Kay stated (p. 286) his restricted Spechts Ferry memb. includes a thin bed of metabentonite 18 inches above its base. On p. 295 he showed an uncon. btw. his Guttenberg and Spechts Ferry members in Minn. and Ill.

See also 1935 entries under *Spechts Ferry memb.*

The U. S. Geol. Survey has for many years excluded the "glass rock" from Platteville ls. and included it in overlying Decorah sh., but *Decorah sh.* as recently defined by Kay et al. is applied to beds stated to have heretofore been included in Galena dol. (See under *Decorah sh.*)

†Platteville stage.

A term employed by S. Calvin (Iowa Geol. Surv. vol. 16, pp. 60, 84, 1906) to include Platteville ls. and Decorah sh.

Plattford shale. (In Scranton shale.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 41, 58). *Plattford sh.*—Underlies Cass ls. and overlies South Bend ls., all in Scranton sh. Thickness 16 ft. Named for outcrops along Platte River in Plattford Twp, Sarpy Co., Nebr.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). *Plattford sh.* is abandoned, another name having priority.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12). *Plattford sh.* same as Weston sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 210). *†Plattford sh.* abandoned. Does not belong in Scranton sh. [Does not state where it does belong.]

Plattin limestone.

Middle Ordovician (Lowville): Eastern Missouri, central western and southwestern Illinois, and central northern Arkansas.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 111). *Plattin ls.*—Fine-grained ls. overlain by Kimmswick ls. and underlain by Joachim or "First Mag." ls. Generally called Trenton or lower Trenton. [Later repts give thickness of 150 to 350 ft.]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), showed *Plattin ls.* as including beds of Lowville age at top and beds of upper Stones River age at base; as uncon. underlying Decorah sh. (of post-Lowville age) and uncon. overlying Joachim ls. in eastern Mo.; and as substantially = Platteville ls.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2), showed *Plattin ls.* all of Lowville age, as = Platteville ls., and as older than Decorah sh.

C. L. Fenton, 1928 (Am. Midland Nat., vol. 11, No. 2). Upper 32 ft. of *Plattin fm.* in Ste. Genevieve Co., Mo., consists of thinly bedded cherty lss., highly fossiliferous, underlying Decorah fm.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., pp. 104–110). The higher beds of *Plattin ls.* as originally defined consist of shales with more or less subordinate ls. layers, which contain same fauna as Decorah sh. of upper Miss. Valley and are undoubtedly exact equiv. of that fm. in Iowa. The name *Decorah sh.* is therefore applied to this sh. in SE. Mo., where it is 0 to 35 ft. thick, and it is here treated as a distinct fm. overlying Plattin ls. Locally the Plattin ls. is conspicuously cherty, nearly the entire mass of the ls. being replaced.

V. T. Allen, 1932 (Jour. Geol., vol. 40, No. 3, pp. 259–269). In Minn., Iowa, and Wis. there lies, from 12 to 18 in. above base of Decorah fm., a layer of metabentonite 1 to 3 in. thick. This bed is good horizon marker of bdy btw. Platteville ls. and Decorah fm. In Jefferson Co., Mo., a bed (7 to 10 in. thick) of metabentonite of similar petrographic and chemical characters lies at or 4 in. above base of Decorah fm., and confirms Weller's assignment of the overlying shales and lss. to Decorah sh., and their removal from Plattin ls., in which they were originally included.

See under *Decorah sh.*, last entry.

Named for exposures near mouth of Plattin Creek, Jefferson Co., Mo

Plattsburg limestone. (In Lansing group, Kansas.)

Plattsburg limestone member (of Lansing formation).

Pennsylvanian: Northwestern Missouri, southeastern Nebraska, eastern Kansas, and southwestern Iowa.

G. C. Broadhead, 1868 (St. Louis Acad. Sci. Trans., vol. 2, pp. 317, 327). *Plattsburg ls.*—Coarse gray and ashy-blue ls., 13 to 23 ft. thick, forming bed 134 of detailed section of Coal Measures from NW. corner of Mo. to Glasgow, Howard Co., Mo. Rests on brownish calc. ss. Is overlain by sandy sh. Included in Plattsburg group.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). *Plattsburg ls. memb. of Lansing fm.* underlies Vilas sh. memb. and overlies Lane sh. memb.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 70–75). *Plattsburg ls.* is basal memb. of Lansing group as restricted by R. C. Moore. The Lane sh. of Hinds and Greene is much younger than true Lane sh., and upper part of their so-called Lane sh., upon which the Plattsburg rests, has been named *Bonner Springs sh.*

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for exposures at Plattsburg, Clinton Co., Mo.

†Plattsburg group.

Pennsylvanian: Northwestern Missouri.

G. C. Broadhead, 1868 (St. Louis Acad. Sci. Trans., vol. 2, pp. 317, 327). *Plattsburg group.*—Group E of previous repts. Includes beds Nos. 134 to 146. Thickness 134 ft. Most important memb. of group is Plattsburg ls., at top.

Includes lower part of Lansing fm. and Iola ls. memb. of Kansas City fm.

Named for exposures at Plattsburg, Clinton Co.

Plattsmouth limestone.

Pennsylvanian: Northwestern Missouri, southwestern Iowa, eastern Kansas, and southeastern Nebraska.

C. R. Keyes, 1898 (Am. Geol., vol. 21, pp. 349, 350). *Plattsmouth ls.*—Ls., 30 ft. thick, underlying Platte sh. and overlying Lawrence sh. along Missouri River btw. Kansas City, Mo., and Omaha, Nebr.

For many years this ls. was believed to be same as Oread ls., but according to G. E. Condra (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 37, 1927) it represents only top 28 to 30 ft. of Oread ls. in Nebr., rests on Heebner sh. bed of the Oread, and one of its best developments is in Weeping Water Valley, at Snyderville. Condra said: "The bed has been known by this name since the days of Meek and Hayden, but has not been closely defined, there being more or less misunderstanding regarding its relation to Oread memb. as a whole." Condra gave thickness in Mo. 19 to 21 ft. and in Kans. 16 to 21 ft.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). Oread ls. divided into (descending) Kereford ls. memb., Heumader sh. memb., Plattsmouth ls. memb., Heebner sh. memb., Leavenworth ls. memb., Snyderville sh. memb., and Weeping Water ls. memb.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12). Oread ls. divided into (descending) Kereford ls., Heumader sh., *Plattsmouth ls.* (17 to 18 ft. thick), Heebner sh., Leavenworth ls., Snyderville sh., and Weeping Water (Toronto) ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 167). According to my observations in July 1934, of type Plattsmouth exposures near Plattsmouth, Nebr., and of excellent section in Snyderville quarry, W. of Nehawka, Nebr., which is regarded by Condra as showing uppermost beds of Plattsmouth ls. that are eroded at Plattsmouth, it appears that Condra's definition of this unit includes equivalents not only of "upper" Oread ls. of Kans., but also of Kereford ls. memb. of Oread, Clay Creek ls. memb. of Kanwaka sh., and other lss. that appear in N. part of Kanwaka sh. If this is true the name *Plattsmouth* is not applicable to "upper" Oread ls. alone unless restricted to use in this sense. Since it was evidently Condra's intention to designate only "upper" Oread ls. memb. as Plattsmouth, and since the Kereford and other strat. units in type Plattsmouth section can be recognized, it seems best to restrict *Plattsmouth* to ls. beds btw. Kereford (Heumader sh. absent at Plattsmouth) and Heebner members of Oread. [See further remarks in 1936 entry under *Spring Branch ls.*]

See also G. E. Condra and E. C. Reed, Nebr. Geol. Surv. Bull. 11, 2d ser., p. 60, 1937.

Named for exposures near Plattsmouth, Cass Co., Nebr.

Pleasant Hill limestone.

Middle Cambrian: Central Pennsylvania (Blair County).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 528, 534, 537). *Pleasant Hill ls.*—Thick-bedded fossiliferous ls., underlain by argill. thin-bedded ls. that weathers to sh. Thickness 600 ft. Underlies Warrior ls. and overlies Waynesboro fm.

Upper part is well exposed at Pleasant Hill Church, 1 mi. NW. of Henrietta, Blair Co.

Pleasanton formation (**group** in Kansas).

Pennsylvanian: Eastern Kansas and northwestern Missouri.

E. Haworth, 1895 (Kans. Univ. Quart. vol. 3, p. 274 and pl. opp. p. 290; Am. Jour. Sci., 3d, vol. 50, p. 457 and pl. opp. p. 466). *Pleasanton shales*.—Shales (with much ls. in places and with two coal beds), 180 to 250 ft. thick, overlying Pawnee and Oswego lss. and underlying Erie or Triple ls. system. [R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 63, 77), says Hertha ls. is basal bed of †Erie ls. of Haworth and Kirk, 1894.]

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), defined *Pleasanton fm.* of Mo. as underlying Hertha ls., overlying Pawnee ls. memb. of Henrietta fm., and as top fm. of Des Moines group. This definition was followed for many years.

In 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. chart) R. C. Moore restricted Pleasanton sh. of Kans. to beds overlying Altamont ls. and separated from Hertha ls. by sh. and channel ss., with which he reported it is uncon. In 1932 he dropped Pleasanton from the Kans. classification, and in his 1936 rept (Kans. Geol. Surv. Bull. 22) he discarded the name altogether. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.) The 1933 (57th Bien.) and 1935 (58th Bien.) repts of Mo. Bur. Geol. and Mines continued to use *Pleasanton fm.* as defined by Hinds and Greene, which is definition at present followed by U. S. Geol. Survey.

Named for exposures at Pleasanton, Linn Co., Kans., where the schoolhouse hill is composed principally of these shales.

Pleasant Valley formation.

Pre-Cambrian: British Columbia (Cariboo district).

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 15). [Assigned to pre-Camb. (?), but later repts, by several geologists, assign it to pre-Camb.]

Pleasantview sandstone. (In **Carbondale formation**.)

Pennsylvanian: Northwestern Illinois (Mercer County) and central western Illinois.

H. R. Wanless, 1929 (Ill. Geol. Surv. Bull. 57, pp. 49, 90–91, 124). Olive-gray to blue-gray ss., medium-grained, very micaceous, cross-bedded. Thickness in Alexis quad. [Mercer Co.] 0–50+ ft. Is here designated *Pleasantview ss.*, a name proposed by Walter Searight (personal communication) for a ss. in similar strat. position along Mill Creek, near Pleasantview, Schuyler Co. Local distribution and marked irregularity of basal surface of this ss. suggest it is largely a group of channel deposits. Lies 17± ft. below eroded top of Carbondale fm. in Alexis quad., and 0 to 21± ft. above Colchester (No. 2) coal or 0 to 12½ ft. above Francis Creek sh. Is probably=Vergennes ss. of southern Ill.

H. R. Wanless, 1931 (Ill. Geol. Surv. Bull. 60, pp. 179–193). *Pleasantview ss.* overlies Purington sh. and in places cuts out all underlying beds down to coal No. 2.

Pleiocene.

An early spelling of Pliocene.

Pleistocene epoch (or **series**).

The early epoch of Quaternary period and the deposits formed during that epoch. Commonly called "Glacial epoch," and popularly known as the Great Ice Age, the later part of Quaternary period being known as Recent epoch (or series). For definition of *Pleistocene* see U. S. G. S. Bull. 769, pp. 45–49. Some geologists still apply Pleistocene to all of Quaternary period. It is commonly divided into (descending) Wisconsin stage of glaciation, Peorian stage of deglaciation, Iowan stage of glaciation, Sangamon stage of deglaciation, Illinoian stage of glaciation, Yarmouth stage of deglaciation, Kansan stage of glaciation, Aftonian stage of deglaciation, and Nebraskan (or pre-Kansan) stage of glaciation. G. F. Kay and M. M. Leighton, 1933 (Geol. Soc. Am. Bull., vol. 44, pp. 669–673, Aug. 31), proposed a slightly different classification (see under *Wisconsin stage*) and applied *Pleistocene* to all of the Quaternary.

†Pleito formation.

Oligocene: Southern California (Kern County).

C. M. Wagner and K. H. Schilling, 1923 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 14, pp. 235–252). *Pleito fm.*—Upper fm. of San Lorenzo group in San Emigdio region. Discon. overlies San Emigdio fm., the lower fm. of San Lorenzo group, and is uncon. overlain by Monterey group. At Caraera Pass, E. of Pleito Creek, it consists of 350 ft. of brownish and pearl-gray fine sss., the lower portion medium-grained and white; underlain by 600 ft. of massive dark-brown and buff sss, with fossiliferous layers and light bluish-gray massive cgls. toward base; the basal 50 ft. consists of dark brick-red coarse sss. and cgls. grading into gray toward W. Exposed on Pleito Creek, Kern Co. The Pleito and San Emigdio are littoral deposits but faunally distinct, the faunas being more closely related to each other than either one is to the faunas of overlying and underlying fm.

Is a faunal zone in San Lorenzo fm., according to H. W. Hoots.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 761, pl. 15). Thickness of *Pleito fm.* in San Emigdio region is 2,375 ft., and it is of upper and middle Olig. age.

Pliocene epoch (or **series**).

The last epoch of Tertiary period and the rocks formed during that epoch. For definition see U. S. G. S. Bull. 769, pp. 51–53.

Plomosas formation.

Age (?): Mexico.

R. H. Burrows, 1909 (Min. and Sci. Press, vol. 99, p. 292).

Pluma formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799 and 836–843, with maps). *Pluma fm.*—Alternating beds of finely foliated garnet schist and fine-grained gray-black carbonaceous clay slates, some of which are pyritiferous. Thickness of slates exceeds that of schists. Total thickness 4,000 ft. Uppermost pre-Camb. fm. in Lead dist. Believed to be of Keewatin age.

Named for Pluma, about 1½ mi. E. of Lead, Lawrence Co., where best exposures occur.

Plumas series.

Jurassic (Upper, Middle, and Lower): Northern California.

J. P. Smith, 1910 (Jour. Geol., vol. 18, table opp. p. 217). *Plumas series* includes Hinchman ss. of Plumas Co., Mormon ss., and Hardgrave ss., the *Arietites* beds of Inyo Co., Calif. and Nev. being considered=lower part of Hardgrave ss.

Plum Creek clay.

Silurian: East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 44, 61). *Plum Creek clay.*—Clay, 5 ft. thick, forming part of Indian Fields fm. (of Niagaran age). Overlain by Oldham ls. (top memb. of Indian Fields fm.) and underlain by ls., 1 to 2 ft. thick, which forms basal part of Indian Fields fm. and is regarded as belonging above the line of uncon. which in east-central Ky. is marked by *Whitfieldella subquadrata* and an oolitic iron-ore bed. [In 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 172, 173) Foerste assigned this clay to Medinan. In 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 33, pp. 130–133) Foerste gave further details.]

Named for Plum Creek, Powell Co.

†Plum Creek beds. (In Chester group.)

Mississippian: Southwestern Illinois (Randolph and Monroe Counties).

E. O. Ulrich, 1917 (Ky. Geol. Surv., Miss. fms. of western Ky., pt. 2, pp. 44, 56, 230, pl. D). Most of Glen Dean fossils marked as found in Randolph Co. area in Ill. occur there in the 40 ft. of shaly ls. ("Plum Creek beds") that has been included by Weller—somewhat arbitrarily, I think—in top of Okaw ls.

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41, p. 132). *Upper Okaw ls. (Plum Creek beds)* of Randolph Co. is=Glen Dean ls. of SE. Ill.

Preoccupied. Replaced by *Glen Dean ls.*

Plum Creek shale.

Middle Devonian: Northern Ohio.

A. W. Grabau, 1917 (Jour. Geol., vol. 25, pp. 337–343). *Plum Creek shales.*—If name *Prout ls.* is to be restricted to the ls. memb. of the northern series, then the sh. below it must receive another name. It certainly is not Olentangy, which name belongs to earliest Upper Dev. fm. of central O.

Plummer limestone member (of Pawhuska formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

D. E. Winchester, 1918 (U. S. G. S. Bull. 686C, pp. 11–12). *Plummer ls. memb. of Pawhuska ls.*—Black flinty angular ls., only locally fossiliferous, separated into two benches by 6 to 8 ft. of sh. The outcrop of upper bench beneath the gray ledge-making ls. of Pawhuska fm., is usually marked by long, square-edged blocks, only one edge of which is exposed. The lower bench is of much less value as a key bed. Named for exposures near house on Plummer ranch, T. 26 N., R. 9 E.

Plum Point marl member (of Calvert formation).

Miocene: Eastern Maryland.

G. B. Shattuck, 1904 (Md. Geol. Surv. Miocene vol., p. lxxiv). *Plum Point marls memb.*—A series of sandy clays and marls in which are embedded large numbers of organic remains, including diatoms. Of bluish-green to grayish-brown and buff colors. Top memb. of Calvert fm. Overlies Fairhaven diatomaceous earth memb. Named for Plum Point, Calvert Co.

Pluto shale. (In Hinton formation.)

Mississippian: Southern West Virginia and southwestern Virginia.

D. B. Reger, 1920 (W. Va. Geol. Surv. Rept. Webster Co., pp. 214, 219–220). *Pluto sh.*—Dark, carbonaceous, sometimes cherty; with plant and marine fossils. Thickness 0 to 4 ft. Lies 0 to 5 ft. below Terry ls., the intervening beds consisting of variegated sandy sh. Rests on Pluto coal. Included in Mauch Chunk.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295, 332–335), applied name *Pluto sh.* to 0 to 40 ft. of sh. overlying Pluto coal, and *Lower Pluto sh.* to 50 to 80 ft. of greenish-brown sandy sh., with occasional red beds and streaks of ss., carrying marine fossils and near base a plant zone. The *Lower Pluto sh.* underlies Pluto ls. and rests on Falls Mills ss. (all members of Hinton group [fm.]), and was noted in Mercer and Summers Counties, W. Va., and in Tazewell Co., Va.

Pluto limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295, 334). *Pluto ls.*—Shaly ls., 0 to 2 ft. thick, yellowish green, with marine fossils. Underlies Pluto coal and overlies Lower Pluto sh.; all members of Hinton group [fm.]. Named for association with Pluto coal in Summers Co.

Plymouth interlobate moraine.

Pleistocene (Wisconsin stage): Southeastern Massachusetts (Cape Cod).

N. S. Shaler, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 553). *Plymouth moraine* extends in a general southerly direction from near harbor of that name. Appears at first sight to be the largest, and is perhaps the most continuous, deposit of the kind in New England.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 138). The terminal moraine of lobe that filled Cape Cod Bay (the northern arm of Cape Cod was not then formed) now skirts S. shore of the bay, and at its SW. corner joins Falmouth moraine.

and the two extend N., a little back from present shore, as the *Plymouth interlobate moraine.*

Named for Plymouth Woods, on W. shore of Cape Cod Bay. Extends as far N. as Kingston, Mass. Same as Plymouth moraine of Shaler.

Plymouth ferruginous chert member (of Ironwood formation).

Pre-Cambrian (upper Huronian): Northwestern Michigan and northwestern Wisconsin (Gogebic district).

W. O. Hotchkiss, 1919 (Eng. and Min. Jour., vol. 108, pp. 501, 502). *Plymouth ferruginous chert memb.*—Dominantly wavy-bedded granular and fine-grained ferruginous cherts; some sl.; a thin cherty qtzite sometimes present at base. Basal memb. of Ironwood fm. Underlies (uncon.) Yale memb. and uncon. overlies Palms fm. Named for Plymouth mine, Gogebic range.

Plymouth member.

Carboniferous: Nova Scotia.

W. A. Bell, 1925 (Canadian Inst. Min. and Met. Bull. 158, p. 618).

Plymouth marble.

Lower Cambrian: Southeastern Vermont (Windsor County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288). *Plymouth dol.* of central Vt. is Lower Camb. and Sherman marble of southern Vt. is Lower Camb. and=*Plymouth marble.* [*Plymouth marble* was used as a commercial term as far back as 1861 (Rept. Geol. Vt., vol. 2).]

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 405). *Plymouth marble.*—Chiefly dolomitic marble, gray or darkly mottled. In town of Plymouth ls. cgls. appear in the fm., some of which have been used for ornamental stone known commercially as "*Plymouth breccia.*" The marble is much folded and in places probably faulted, so that true thickness is unknown. Easily soluble, and underlies the deep valley which bisects Green Mtns in this region, hence exposures are few. Correlated with Rutland dol.

Plymouth granite.

Late Paleozoic: Southeastern Vermont (Windsor County).

E. L. Perry, 1929 (16th Rept. Vt. State Geol., pp. 44–46). *Plymouth granite,* intrusive, late Paleozoic. Occurs on S. slope of Morrison Hill in Plymouth [Woodstock quad.], about ½ mi. NW. of Pinney Hollow road and an equal distance due W. of Pinney Hollow schoolhouse E. of road to abandoned Morrison farm at about 1,500-foot contour level.

Plymouth conglomerate.

Lower Cambrian: Southeastern Vermont (Windham County).

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., p. 220). In Windham Twp [Windham Co.] the Lower Camb. terranes consist of following fms.: Sherburne cgl., *Plymouth cgl.,* Plymouth dol., albitic mica schist, Pinney Hollow schist, and Ottauquechee schist. [The *Plymouth cgl.* referred to may be *Plymouth breccia* mentioned by Keith in 1932 entry under *Plymouth marble.*]

†Plymouth breccia.

A trade name applied to ls. cgl. quarried from Plymouth marble in town of Plymouth, SE. Vt. See 1932 entry under *Plymouth marble.*

Pocahontas formation. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26, p. 3). *Pocahontas fm.*—Gray and green argill. ss. and sandy sh. with two or three coal seams in lower part and Pocahontas coal [No. 3 Pocahontas rider coal] at extreme top. Underlies Clark fm. and overlies Bluestone fm. Thickness 360 ft.

Corresponds to lower part of Pocahontas group of I. C. White.

Named for Pocahontas, Tazewell Co., Va.

†Pocahontas group. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A, p. 13). *Pocahontas group* (*Lower Pottsville*).—Includes: (1) Flat Top Mtn ss. at top; (2) Pocahontas coals Nos.

8, 7, 6, 5, 4, 3, 2, and 1, together with intervening sss. and shales; and (3) at base the *Pocahontas sss.* Rests uncon. on Mauch Chunk red sh. Named for Pocahontas, Tazewell Co., Va. [This definition applies *Pocahontas* to a broader unit than Pocahontas fm. as originally defined by M. R. Campbell.]

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. on Wyoming and McDowell Counties). No. 8 Pocahontas coal is basal memb. of New River group, which rests on Flattop Mtn ss., the top memb. of *Pocahontas group.* [This definition is the one now followed by W. Va. Geol. Surv.]

Pocahontas group of I. C. White is basal fm. of Pottsville group.

Pocahontas sandstones. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, pp. 224–232). *Upper Pocahontas ss.*—Massive to heavy-bedded, medium-grained to coarse, bluish gray to buff, 50 to 75 ft. thick; lies 0 to 5 ft. below Pocahontas No. 4 coal and overlies Pocahontas No. 3 rider coal; quarried at Pocahontas, Tazewell Co., Va. *Lower Pocahontas ss.*—Massive to heavy-bedded, medium-grained, buff to bluish gray, micaceous, 0 to 50 ft. thick; lies 0 to 8 ft. above Pocahontas No. 2 coal; when shaly often carries Pocahontas No. 2A coal near middle.

Pochuck gabbro gneiss.

Pre-Cambrian: Northern New Jersey and eastern Pennsylvania.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 439). The gneissic outlier of Pochuck Mtn is represented by two bands of rock. The eastern band, which adjoins the valley and forms E. slope of Pochuck Mtn, we have called the *Pochuck gneiss.* Is about 1 mi. in width and has been traced from near Hamburg to N. edge of area mapped. The prevalent rock type is a finely foliated gneiss, rich in biotite and hornblende and often grading into mica schist. With that type there are often associated bands of amphibolite gneiss.

A. C. Spencer, 1908 (U. S. G. S. Franklin Furnace folio, No. 161). Name *Pochuck gneiss* is here used to include all gneisses in Highlands region that contain hornblende, pyroxene, or mica as principal mineral constituents. Some of these rocks are probably of sed. origin, and others may be altered igneous rocks, but in general they are so completely metamorphosed that their original nature cannot be ascertained. Appear to be older than intrusive Losee and Byram gneisses. Include many varieties, but all characterized by dark lines attributable to presence of hornblende, pyroxene, or mica as important mineral constituents. Usually the only light-colored mineral present is oligoclase, but some facies contain considerable scapolite. Microcline observed occasionally, andesine and labradorite feldspar rarely. Rocks range from medium- to fairly coarse-grained; texture foliated granular. In Franklin Furnace area the gneiss passes beneath Franklin ls. Although Pochuck gneiss and Franklin ls. are regarded as older than Losee and Byram gneisses, the original relations are not determinable.

W. S. Bayley, R. D. Salisbury, and H. B. Kümmel, 1914 (U. S. G. S. Raritan folio, No. 191, p. 8). It seems probable the black gneisses which have been included under term *Pochuck gneiss* should properly be divided into 2 groups of different age and possibly of different origin, the first group comprising gneisses, possibly of sed. origin, older than Byram and Losee gneisses, and the second group comprising dark gneisses of igneous origin contemp. with Byram and Losee gneisses. The latter group would probably include the dark gneisses intrusive in Franklin ls. The 2 groups have not been mapped separately because of impossibility of discriminating them in field.

The name *Pochuck gabbro gneiss* is now restricted by U. S. Geol. Survey to the black gneiss of intrusive igneous origin, and the older dark gneisses of sed. origin that formerly were included under the name *Pochuck gneiss* are now included in Pickering gneiss.

Pochuck diorite.

Pre-Cambrian: Eastern New York.

C. P. Berkey and M. Rice, 1921 (N. Y. State Mus. Bull. 225, 226, p. 51). *Pochuck diorite,* intrusive, West Point quad., pre-Camb.

Pocono formation (also **Pocono group**).

Mississippian: Pennsylvania, eastern Ohio, northern West Virginia, and western Maryland and Virginia.

J. P. Lesley, 1876 (2d Pa. Geol. Surv. Rept. L, App. E, pp. 221, 222, pl. opp. p. 224, p. 227). *Pocono ss. (Vespertine of Rogers; No. X; Upper or Gray Catskill; Mountain ss.)*, underlies Mauch Chunk (Umbral) red sh. and overlies Catskill red rocks. [Lesley did not mention type loc. The pl. opp. p. 224 is of Boyd's hill oil well, Pittsburgh, and on it "Pocono, No. X (or Upper (gray) Catskill) (or Vespertine of Rogers)" is bracketed to include all beds up to base of Mountain ls., including New River Coal Measures in upper part.]

Several county maps of 2d Pa. Geol. Surv. containing the name *Pocono ss.* bear date 1876, but the repts which they accompanied were not published until 1877 and later years. Among these are the maps of Bradford and Tioga Counties (central northern Pa.), which Lesley stated, in his rept for 1875 (A), published in 1876, would be completed that winter.

C. A. Ashburner, 1877 (Am. Phil. Soc. Proc., vol. 16, No. 99, Jan. to May, 1877, pp. 519–560). *Pocono (Vespertine) Gray ss.—Pocono* is new name proposed by present State Geologist [J. P. Lesley]. Underlies Mauch Chunk Red sh. and overlies Catskill fm. Thickness 2,133 ft. Is No. X of repts. Constitutes mass of Pocono Mtns, Pa. The middle memb. (*New River Coal Series*), 313 ft. thick, is original New River series of Lesley. [The latter statement is erroneous, according to D. B. Reger, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 403). Ashburner's paper was read Feb. 16, 1877, and was reviewed in Am. Jour. Sci., 3d, vol. 13, pp. 384–385, May 1877.]

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxiii–xxx). *Pocono (Upper Catskill) ss.*—New name proposed by State Geologist of Pa. [J. P. Lesley] for Rogers' "Vespertine, No. X." Is basal fm. of New River system (No. X, in Greene Co., SW. Pa.), the upper fm. of that system being designated New River Coal Measures. Rests on Catskill Old Red ss. (IX). Forms the mass of the great mtn plateau btw. Delaware and Lehigh Rivers, and attains greatest development in Pocono Mtns [of NE. Pa. (Monroe Co.)].

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, p. 235), applied *Elk Mtn transition group* (also *Transition (Sub-Pocono) measures*) to 375 ft. of beds underlying Pocono ss. and overlying Catskill fm., in Susquehanna and Wayne Counties, NE. Pa., and treated Mount Pleasant cgl. as basal memb. of this transition group.

J. P. Lesley, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. ix to xv), explained how he came to map incorrectly as *Pocono* rocks that are not Pocono. He stated: "To find any Pocono on Pocono Plateau one must go a number of mi. to N. of front edge of the plateau, where ridges of the lowest Pocono rock, the Mount Pleasant cgl., remain uneroded."

J. P. Lesley, 1882 (2d Pa. Geol. Surv. Rept. G_6, p. 78, footnote). The Cherry Ridge cgls. were considered by First Survey as base of No. X. Hence I named whole of No. X the *Pocono fm.*, because entire crest of the escarpment, and face of plateau behind it, are made by these rocks. White prefers to carry top of Catskill fm. 500 ft. higher up the column.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 89–95). Mount Pleasant cgl. is basal memb. of *Pocono fm.* in Pike and Monroe Counties, Pa., and Mount Pleasant red sh. is topmost memb. of Catskill series.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7), applied *Pocono-Catskill group (transition group)* to 300 to 500 ft. of beds underlying Pocono ss. and overlying Catskill series proper in the six counties of NE. Pa., and treated Mount Pleasant cgl. as basal memb. of this transition group.

In some subsequent repts of 2d Pa. Geol. Survey these transition beds of NE. Pa. were treated as distinct from Pocono, and in other repts, covering the same areas, the Pocono was described as resting on the Catskill.

C. S. Prosser, 1894 (U. S. G. S. Bull. 120, p. 78), treated Mount Pleasant cgl. as basal memb. of Pocono.

J. J. Stevenson, 1903 (Geol. Soc. Am. Bull., vol. 14), included in Pocono all beds to base of Mount Pleasant cgl. of NE. Pa. and to top of Riceville sh. of NW. Pa.

J. Barrell, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 429–472). *Pocono ss.* has two phases—marine in western Pa. and Ohio and fluviatile in eastern Pa. Grades into underlying Catskill through beds of passage, the bdy line being arbitrary, and Pa. geologists differing among themselves to extent of several hundred ft.

W. A. VerWiebe, 1917 (Am. Jour. Sci., 4th, vol. 43, pp. 301–307), applied *Pocono* to beds of NW. Pa. extending down to base of Berea ss.

D. B. Reger, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 397–410), doubtfully correlated Berea ss. (which he made basal memb. of Pocono) with Mount Pleasant cgl.

In many repts on NW. Pa. all beds down to top of Catskill and top of Riceville sh. have been included in the Pocono.

The present Pa. Geol. Survey classifies the Pocono as a *series*.

The 1884 geol. map of Monroe Co., Pa. (2d Pa. Geol. Surv.), mapped Pocono ss. at and around Pocono Mtn (Jackson Twp), also in W. part of Pocono Twp. and near Pocono Station. But this is not Pocono, according to G. H. Chadwick (see Feb. 1935, entry), who also quoted I. C. White's Rept G_6, to same effect.

G. H. Chadwick, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 177). The eastern or *type Pocono* has nothing to do with the Miss. strata and faunas called by that name in other parts of the State, but is midway in Upper Dev., as may also be typical Mauch Chunk.

D. White, 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 265–272). The Pocono is a moderately distinct strat. and sedimentary unit, of continental gray cgls., coals, and shales, btw. red Mauch Chunk (above) and red Catskill (below), extending from East Mauch Chunk, on slope of Pocono Mtns, southward along E. side of Appalachian Trough as far as Tenn., and called *Pocono* since that name was proposed to supersede Rogers' Vespertine. On Lehigh River below Mauch Chunk, where it is now well exposed, due to modern road building, it embraces about 1,250 ft. of beds, as measured by Winslow, consisting mainly of gray sss., many of which are coarse sand or very fine gravel, coarse cgls., numerous coal beds, and shales with some greenish flaggy layers. The lower portion presents here and there relatively thin red sh. deposits. The Pocono retains these general characters throughout greater part of its outcrop along E. border of Appalachian Carbf. from East Mauch Chunk to Big Moccasin Gap, 2 to 3 mi. E. of Gate City, Scott Co., Va., and about 2½ mi. N. of Tenn. line. The Pocono forms a continuous well-marked topog. feature throughout eastern zone of Appalachian embayment. Viewed from both diastrophic and paleobotanical standpoints the Pocono of eastern belt is Miss.

G. H. Chadwick, Feb. 1935 (Am. Jour. Sci., 5th, vol. 29, No. 170, pp. 133–143). "What is Pocono?" According to I. C. White's Rept. G_6, 2d Pa. Geol. Surv., 1882, pp. 89–90, there is no Pocono in Pocono Mtn (Pocono Knob) or Pocono Twp, or in fact on whole Pocono Plateau except topping a few isolated peaks far back from the scarp. [Long discussion. See also *Moosic*.]

G. H. Ashley and B. Willard, 1935 (Sci., n. s., vol. 81, No. 2112, June 21, pp. 615–617). Lesley, perhaps at a staff conference, certainly not later than 1876, proposed *Pocono* to replace Vespertine or No. X of Rogers, whose [1858] definition [quoted] is essentially the definition of Pocono as now in use (D. White, Am. Jour. Sci., 5th, vol. 27, pp. 265–272, 1934), and is equiv. to that officially recognized by present Pa. Survey. *Pocono* was intended to be applied throughout the State wherever *Vespertine* had been used, whatever his type loc. may have been. This is sense in which *Pocono* is now accepted and used stratigraphically in Pa. and to S. Its application to plateau btw. Delaware and Lehigh Rivers, whatever Lesley's original intent, may be wrong, and, if so, has been wrongly followed. But it seems reasonable that Lesley's original thought, even though he incorrectly dated the beds of the plateau, was to apply the name to the ss. btw. the "Catskill" and Mauch Chunk. There seems no necessity for discontinuing use of *Pocono fm.* for the gray sss. and cgls., probably of early Miss. age, which overlie highest recognized Dev. beds and help support Allegheny Front, border much of the anthracite fields, produce prominent ridges in central Pa., and appear as more or less flat-lying beds in W. part of State. But in so doing, we must bear in mind the anomalous situation that first published application of term was not to a type loc. of that name. Evidently we are forced either to propose a new term, or, and this is by far the more reasonable and least confusing course, accept a name, which, however dubious its origin, is made acceptable by long usage.

B. Willard 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 597–599). There is no reasonable doubt that Lesley's type loc. for his redefined Pocono is essentially included in Moosic Mtns. Although his definition is clear, and he promised to publish the map of Pike and Monroe Counties to conform thereto, he did nothing of the sort. Instead, the map of those counties was drawn nearly as that part of Rogers' 1858 State map. This error was continued on 1893 and 1931 State maps. Writer's only disagreement with Lesley's redefinition of Pocono [1882] would be that the base should be drawn a little higher (300 to 400 ft.), at Griswolds Gap cgl., not at Mount Pleasant cgl. This very change was adopted by I. C. White in vol. G_7, 1883. No fossils have been described from type region of Pocono, but D. White recognized Lower Miss. age of Pocono flora at Lehigh River near Mauch Chunk. This has been corroborated by W. Darrah from Pocono plants he has studied from that section. That the beds exposed at this locality and in Moosic Mtns are=Pocono cannot now be denied. Lesley realized this. Because Lower Miss. continental strata, known as Pocono fm. as redefined by Lesley, are found on Pocono Plateau along its W. border, writer holds the name should be retained, at least until better reasons for change than can now be marshaled are available. The name should still be applied from type loc. to W. and S. all through central Pa. To substitute *Moosic*, as Chadwick has hinted, would produce confusion concerning a wide area where *Pocono* has had long standing. Possibly such a change may eventually be found advisable, but at present it is writer's conviction that neither he, nor Chadwick, nor anyone else, has given sufficient study to problem to offer such a change. For present *Pocono* should be continued to be interpreted essentially as Lesley finally defined it and as observations dictate. [On p. 603 Willard stated:] There is Pocono of Miss. age on Pocono Plateau. Correlations, based on sections by Winslow and I. C. White and determination of nearby floras by D. White and W. Darrah, establish, with reasonable certainty, the Miss. age of the Pocono in Moosic Mtns.]

Poestenkill fault breccia.

Ordovician: Eastern New York (Albany, Cohoes, Troy, and Schenectady quadrangles).

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285, pp. 113–115). *Poestenkill fault breccia.*—Largely composed of black Normanskill chert, Normanskill grit, and Bald Mtn ls. Composition very different from that of Rysedorph cgl. Named for outcrop in bed of the Poestenkill.

Pogonip limestone.

Lower Ordovician: Eastern and southern Nevada and southeastern California.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, map IV), and 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 187–195, 248). *Pogonip ls.*—Dark ls.; lower ls. beds highly siliceous and steely black, with blue shades, varying a good deal in physical characteristics, passing downward into rather argill. shales; higher in series the rock is dark blue and much banded by zones of aren. ls. and occasional seams of pure chert several inches thick. Thickness 4,000 ft. Conformably underlies Ogden qtzite (Dev.) and conformably overlies Camb. qtzite. Type loc. Pogonip Ridge at White Pine [Hamilton], Nev. [This definition includes all beds btw. Prospect Mtn qtzite (Lower Camb.) and Eureka qtzite (Middle Ord.).]

In 1883 (U. S. G. S. 3d Ann. Rept., pp. 253-263 and map) Arnold Hague, in his rept. on Eureka dist., defined *Pogonip ls.* as comprising 2,700 ft. of highly fossiliferous lss., the upper part consisting of purer fine-grained ls. of bluish-gray color and distinctly bedded, and the lower part consisting of interstratified lss., argillites, and, at base, aren. beds; the fm. being overlain by Eureka qtzite and underlain by Hamburg sh. (later named *Dunderberg sh*). This is commonly accepted definition of Pogonip ls. As thus defined the main mass of fm. has been classified as of Beekmantown age, but at top it carries a Chazy fauna. In 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, pp. 466–467, 475), however, C. D. Walcott proposed restricting Pogonip to upper part of Pogonip ls. of previous usage, and applied *Goodwin fm.* to lower 1,500 ft., which he stated contain a "Lower Ozarkian" fauna. The fm. has been mapped by S. H. Ball (U. S. G. S. Bull. 308, 1907) in Inyo Co., Calif. The U. S. Geol. Survey uses *Pogonip ls.* in broad sense.

†Pogonipan series.

A term introduced by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 53, 80), for a part of Pogonip ls. of Nev., and applied by him to supposedly contemp. deposits in other States, for example, to Bighorn dol. of Wyo.

Pohenagamuk formation.

Ordovician: Quebec.

J. A. Dresser, 1912 (Canada Geol. Surv. Mem. 35, p. 25).

Pohono granodiorite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 123). Grayish-white mixture of quartz and feldspar in which are embedded elongated grains of hornblende and biotite about 1 mm in diam.

Named from occurrence near Pohono Trail.

Poinsettan series.

A name introduced by C. [R.] Keyes to cover the late Tert. gravels of Mo., and later applied by him in Ill. (See Iowa Acad. Sci. Proc., vol. 22, p. 252, 1915.) Derivation of name not stated.

Point a Pierre grits.

Cretaceous: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in Geol., No. 7, p. 39).

Point aux Barques sandstone.

Mississippian: Michigan (Saginaw Bay region).

A. Winchell, 1871 (Am. Phil. Soc. Proc., vol. 11, btw. pp. 60 and 66). *Point aux Barques sss.* belong to Marshall group. [And are so mapped on 1916 geol. map of Mich. Geol. Surv.]

A. C. Lane, 1900 (Mich. Geol. Surv. vol. 7, pt. 2), gave thickness of *Point aux Barques ss.* as 18 ft., and stated that it belongs to lower part of Marshall fm.

Point aux Barques lighthouse.

Mississippian: Michigan (Huron County).

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30, p. 85). *Point aux Barques lighthouse.* [In columnar section of Huron Co. this name is applied to a thin ss. in upper part of Coldwater sh. lying a considerable distance below Point aux Barques ss.]

Point aux Gres limestone.

Mississippian: Eastern Michigan (Arenac County).

C. C. Douglass, 1839? (Mich. Leg. House Doc. 27, btw. pp. 97 and 111). *Point aux Gres ls.*—Light cream-colored aren. ls. containing Septarea. Overlies black bituminous sh., and uncon. underlies Tert.

C. C. Douglass, 1841 (Mich. Leg. Doc., vol. 1, No. 2, 4th Ann. Rept. State Geol., for 1840, btw. pp. 545 and 551). *Point aux Gres ls.*—Light-colored aren. ls. containing Septarea. Overlies black bituminous sh. and underlies Tert.

Only known uses of name. The 1916 geol. map of Mich Geol. Surv. mapped the ls. of Point aux Gres as *Bayport ls.*, a name that has been in use in Mich. since 1899.

Point Edward formation.

Pennsylvanian: Nova Scotia.

J. E. Hyde, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 252).

Pointe Levis group.

Cambrian: Canada.

J. Marcou, 1897 (Am. Geol., vol. 19, pp. 43–45). "Exact syn. Phillipsburg group."

Point Grey formation.

Pleistocene: British Columbia.

E. W. Berry and W. A. Johnston, 1922 (Roy. Soc. Canada Proc. and Trans., 3d ser., vol. 16, sec. 4, p. 134), and W. A. Johnston, 1923 (Canada Geol. Surv. Mem. 135, p. 43).

Point Hey sandstone member (of Redwood formation).

Oligocene: Southeastern Alaska (Katalla district, Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 773+). *Point Hey ss. memb.*—Basal memb. of Redwood fm. Consists of 1,100 ft. of sss. and cgls. with thin sh. beds, and with heavy cgls. at top. Lower part is pebbly ss. and fine-grained thin-bedded shaly ss. with intercalations of dark sandy sh. This passes up into flaggy sss. and sandy shales with thin beds of sandy ls. and with abundant plant fragments. Lenses of cgl. are numerous, and upper part consists of a fairly heavy cgl. with pebbles and cobbles up to 6 or 8 in. diam. Conformably underlies Puffy sh. memb. and conformably overlies Burls Creek sh. memb. of Katalla fm. [restricted]. Assigned to upper Olig. on basis of lithologic correlation with fossiliferous rocks in Yakataga dist. that are assigned to upper Olig. by B. L. Clark.

The U. S. Geol. Survey classifies typical Katalla fm. as Mio. (?).

Point Lookout sandstone. (In Mesaverde group.)

Upper Cretaceous: Southwestern Colorado and northwestern New Mexico.

A. J. Collier, 1919 (U. S. G. S. Bull. 691K). *Point Lookout ss.*—The lower massive ss. of Mesaverde group of SW. Colo. Is 250 to 300 ft. thick. Forms the cliffs which border Menefee and Weber Mtns and make them inaccessible at many places. Seen to best advantage in imposing cliffs at Point Lookout, about 7½ mi. SW. of Mancos, Colo. Is "Lower Escarpment" of W. H. Holmes' subdivisions of the Mesaverde. Underlies Menefee fm.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). [See under *Mesaverde group*, 1924 entry.]

Point Lookout granite.

Pre-Cambrian (?): Southwestern Virginia (Grayson County).

A. I. Jonas, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 49). A biotite granite here named *Point Lookout granite*, from its occurrence in Point Lookout Mtn, Grayson Co., SW. Va. [Not described.]

†Point of Rocks group.

Upper Cretaceous (Montana): Southwestern Wyoming, northwestern Colorado, and northeastern Utah (Uinta County).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 47, 155). *Point of Rocks group.*—Uncon. underlies Bitter Creek group and overlies Salt Wells group. Thickness 1,800 ft. A good section can be obtained at Point of Rocks Station [Sweetwater Co., Wyo.]. Consists of (descending): (1) Massive gray ss. (Upper Hogback ss.); (2) irregularly bedded shales and sss.; (3) massive gray ss. (Middle Hogback ss.); (4) massive and thinly bedded yellowish-buff sss. alternating with massive beds of light-gray or white ss.; and (5) *Golden Wall ss. or group*, consisting of thinly laminated gray and buff ss.

Includes Adaville and Blair fms. (=all of Mesaverde group) of SW. Wyo. The †Goldenwall ss. is present in SW. Wyo. only.

Point Pleasant limestone.

Middle Ordovician: Southwestern Ohio and northern Kentucky.

J. S. Newberry, 1873 (Ohio Geol. Surv. vol. 1, table opp. p. 89, pp. 119–121). *Mount [Point] Pleasant beds.*—Alternating lss. and shales, 350± ft. thick, underlying Eden sh. and overlying Trenton ls. in Ohio.

E. Orton, 1873 (Ohio Geol. Surv. vol. 1, pp. 370, 373, 378, and table opp. p. 399). *Point Pleasant beds.*—Massive blue lss., 50 ft. thick, of lighter color than upper part of Cincinnati group, interbedded with concretionary-bearing sh., beginning at low-water mark at Cincinnati and descending until they include lowest rocks exposed in the State. It is not easy to determine with exactness the upper bdy above mentioned at Point Pleasant, as no facts can be found in either lithological or fossil characters that serve to identify any particular layer as the bottom layer at Cincinnati; but judging from such indications as both lithology and fossils furnish, it is safe to say that Point Pleasant beds have at least the thickness already assigned to them, viz. 50 ft. Overlain by River Quarry beds and underlain, in well borings, by Calciferous sandrock. Lowest fm. of Cincinnati group.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, pp. 53+). *Point Pleasant beds* are same as River Quarry beds. Unquestionably of Trenton age. Thickness 50 ft.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, pp. 8–10), applied name *Point Pleasant ls.* to 25+ ft. of ls. underlying Fulton sh. and overlying Bromley sh. in vicinity of Cincinnati.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 13, 14, 211–212), stated that *Point Pleasant bed* underlies Utica sh. and overlies Greendale bed.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull., vol. 14, pp. 209–228), applied *Nicholas ls.* to 35 ft. of ls. beneath Fulton sh. and above Point Pleasant, and stated: "The term *Point Pleasant* should be restricted to the lower part of the exposures at Point Pleasant, as intended by Prof. Orton. That part of the river quarry beds at Cincinnati which contains *Trinucleus concentricus* does not belong to the Point Pleasant part of Cynthiana fm."

See also under *Cynthiana fm.*

Named for exposures at Point Pleasant, Clermont Co., Ohio.

Point Woodbury formation.

Carboniferous or pre-Carboniferous: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. B, p. 60).

Poison Canyon formation.

Eocene: Southeastern Colorado (Huerfano County).

R. C. Hills, 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, pp. 148–164). *Huerfano beds proper.*—Uncon. overlie the Laramie and Colorado along the shore line and in part rest on Archean, although elsewhere graduating conformably into upper part of Laramie. Are uncon. overlain by coarse cgls. and sss. tentatively assigned to Plio. The most typical exposures of these Eocene beds occur on drainage of Muddy Branch of Huerfano River, while best section is probably to be found in the nearly uninterrupted exposure of inclined beds extending down Poison Canon [W. of Gardner] and across Muddy Creek to Promontory Bluffs. Total thickness here developed can hardly be less than 7,000 to 8,000 ft., distributed as follows (descending): (1) Red and yellow sandy clays and marls, sometimes shaly, alternating with yellowish, white, gray, and greenish sands, 2,000 ft.; (2) light-red, white, brownish, or variegated soft sss, alternating with red and yellow sandy clays and marls, 1,500 ft.; (3) yellowish or light-colored soft sss. and cgls. with occasional beds of yellow clay or marl, 3,500 to 4,500 ft. [Throughout this paper the author refers to these beds in Poison Canyon area as *Poison Canyon series.* He also mentions eruptive pebbles and finer eruptive debris contained in the *Poison Canyon cgls.* As thus originally defined "*Huerfano beds proper*" and "*Poison Canyon series*" applied to all of Eocene in Huerfano Basin.]

R. C. Hills, 1889 (Colo. Sci. Soc. Proc., vol. 3, pt. 2, pp. 218, 222). Recent measurements give total thickness of *Huerfano beds* near mouth of Poison Canyon of 7,100 ft. It appears that the beds will be more clearly defined by *restricting* the designation "middle division" to about 300 ft. of massive pink and white ss. which forms a well-marked horizon btw. upper and lower beds and is recognizable wherever it occurs throughout the basin. With this modification the thickness of the 3 divisions is (descending): (1) marls, clays, soft shales, and sands, of red, gray, yellow, green, and purple colors, red predominating, 3,300 ft.; (2) pink and white massive sss., 300 ft.; (3) soft sss. and fine cgls. of yellowish tint, with occasional bands of yellow clay or marl, 3,500 ft. The total thickness in Poison Canyon is no doubt greater than is now exposed in any other part of field. Evidence thus far accumulated points strongly to Bridger age of upper div. of *Huerfano series*, although it is doubtful if lower div., in which vertebrate remains have not yet been found, can be included in same category.

R. C. Hills, 1890 (Colo. Sci. Soc. Proc., vol. 3, pt. 3, pp. 391, 395). In Huerfano Basin there are certain deposits (*Poison Canyon beds*) referred by myself to Lower Eocene, which consist of massive soft sss., often conglomeratic, alternating with relatively thin beds of yellow clay and some clay sh. Away from old shore border they are apparently conformable with underlying Laramie, with which they might be confounded, but along W. margin of the exposures they show great angular uncon. with all Cret. beds. The existence of eruptive pebbles in Huerfano Eocene, as stated by me in pt. 1 of this vol., is true only of the *upper div. to which the term "Huerfano beds" is now restricted*, the statement that they occurred in *the lower div. of "Poison Canyon beds"* being due to an error in original notes.

R. C. Hills, 1893? (Colo. Sci. Soc. Proc., vol. 4, pp. 7–9; paper read Feb. 2, 1891). Term "Poison Canyon series" was first employed as a convenient designation for the lithological sequence of Eocene beds at locality where they were first studied and where the two lower members especially are characteristically developed. A complete section of the upper one, however, is not shown at Poison Canyon, the inclined strata extending some distance into Muddy Creek Valley beyond. Subsequently "Huerfano series" was used with reference to Huerfano Eocene beds collectively; and since this term necessarily includes all beds exposed in Poison Canyon, it seems appropriate to retain it in sense it was originally employed, as a designation for entire Eocene series of Huerfano lake basin, in preference to former term "Poison Canyon series." The general designation "Huerfano beds" was originally applied to the subdivision of Eocene recognized in Huerfano and Cuchara Basins. As it is now apparent that these several subdivisions cannot all be referred to same stage of sedimentation, it is proposed (1) to restrict *Huerfano beds* to *upper* of the 3 subdivisions described in vol. 3, pt. 2, p. 218, which contains mammalian remains indicating Bridger age; (2) to name the *middle memb. Cuchara beds*, after Cuchara River, where they form the surface exposures N. and S. of La Veta; and (3) to apply the name *Poison Canyon beds* to the *lower memb.*, after the locality on Poison Creek where they are characteristically developed. The relations of the fms. can be expressed as follows:

Huerfano series (Eocene)	Huerfano beds=Bridger group.	
	[Uncon.]	
	Cuchara beds	Lower Eocene.
	[Marked uncon.]	
	Poison Canyon beds	

H. F. Osborn, 1929 (U. S. G. S. Mon. 55). Huerfano fm. correlates with lower part of Bridger fm., upper part of Wasatch fm., and upper part of Fort Union fm. The Cuchara fm. is of middle Wasatch age and the *Poison Canyon fm.* is of lower Wasatch age.

W. T. Lee, 1917 (U. S. G. S. P. P. 101, p. 61). *Poison Canyon fm.* is younger than Raton fm. and has generally been regarded as uncon. with it. It seems possible Poison Canyon and Raton fms. may differ but little in age, and that their physical differences may be due to local variations in conditions of sedimentation.

The U. S. Geol. Survey does not employ the same name in two senses. It therefore has abandoned "Huerfano series" as a local name for the Eocene deposits of Huerfano Basin, but uses *Huerfano fm.* as restricted by Hills.

†Poison Canyon series.

See explanation under *Poison Canyon fm.*

Poison Creek formation.

Pliocene (?): Southwestern Idaho (Snake River valley).

J. P. Buwalda, 1923 (Idaho Bur. Mines and Geol. Pam. 5, p. 3). *Poison Creek fm.* consists of ash, clays, shales, and sss. very similar to Payette fm. (middle or upper Mio.) but containing mammalian fossils indicating lower Plio. or later age. It immediately overlies the 1,000 ft. of rhyolite flows which rest on Payette fm., in Snake River Valley of SW. Idaho. The Idaho fm., which lies in middle and flatter part of the valley, is generally made up of cream-tinted silt and volcanic ash, contains mammalian fossils indicating Pleist. age, and rests uncon. on underlying fms. [On p. 8 he mentions sed. beds extending SE. from E. flanks of Silver City Range at Murphy to Grandview and Bruneau River dist. which "are quite similar to those exposed at N. end of Silver City Range at *Poison Creek grade*." This appears to be type loc. The Payette fm. as first defined and as used in previous repts was said to be of Mio. age and immediately overlain by Idaho fm. (Plio.), from which it was said to be separated with difficulty. The introduction of this new name appears to mean a restriction of Idaho fm.]

Pokegama quartzite.

Pre-Cambrian (middle Huronian): Northeastern Minnesota (Mesabi district).

H. V. Winchell, 1893 (Minn. Geol. Surv. 20th Ann. Rept., p. 123). There seems to be no question that the qtzite of Mesabi iron range which rests uncon. on the schists and granite is same as Pewabic qtzite at Gunflint Lake and *Pokegama qtzite* of Mississippi River.

G. E. Culver, 1894 (Minn. Geol. Nat. Hist. Surv. 22d Ann. Rept., p. 102). *Pokegama qtzite (Pewabic).*—The qtzite at Pokegama Falls, on the Miss., appears at intervals along an irregular line extending from N. end of Pokegama Lake NE. to rapids of Prairie River. At all exposures it appears pinkish, is rather fine grained and very hard. At Pokegama Falls, where it has been quarried, it is seen to have been originally greenish in color. Iron ore is found in it at many places, always apparently in upper portion. The qtzite was not seen in contact with any other rock.

U. S. Grant, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4, p. 181). *Pokegama qtzite.*—Coarse-grained vitreous qtzite, white, gray, reddish, and greenish. Thickness 335 ft. Mapped. Also called at times *Pewabic qtzite.*

C. R. Van Hise and C. K. Leith, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 353, 357–358). *Pokegama fm.*—Fine cgl., qtzite, and quartz sl., 0 to 450 ft. thick. Conformably underlies Biwabik fm. and uncon. overlies Lower Huronian. Basal fm. of Upper Huronian of Mesabi dist.

C. K. Leith, 1903 (U. S. G. S. Mon. 43, p. 90). *Pokegama qtzite.*—Chiefly vitreous qtzites of various colors; some micaceous quartz sl.; at base cgl. Thickness 0 to 500 ft. Underlies Biwabik fm., with slight erosion interval between, and uncon. overlies Lower Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 164), gave thickness as ranging up to 200 ft., and assigned fm. to upper Huronian.

C. K. Leith, 1933 (16th Int. Geol. Cong. Guidebook 27, p. 9), assigned this fm. to middle Huronian, as did C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184).

Polaris Harbour formation.

Silurian: North Greenland.

C. Poulsen, 1934 (Mus. minér et géol. comm. pal. No. 50, pp. 6, 43).

Poleo sandstone.

Triassic (Upper?): Central northern New Mexico.

F. v. Huene, 1911 (Neues Jahrb., Beilage-Bd. 32, pp. 730–739, pl. 32). The soft massive grayish-yellow ss., 12 to 15 m. thick, forming crest of Mesa Poleo, we always called "*Poleo top ss.*"

N. H. Darton, 1922 (U. S. G. S. Bull. 726, p. 183). Shinarump cgl. appears to be represented in Nacimiento-Chama-Cobre region by a massive ss. which Huene has called *Poleo ss.*, from Poleo Mesa, of which it forms the surface. This ss. contains Triassic plants. Above this *Poleo ss.*, as I shall term it in this paper, are red shales supposed to belong to Chinle fm., extending up to base of unmistakable Wingate ss. Underlying the Poleo ss. are red shales and sss. 1,000± ft. thick, which doubtless include representatives of Moenkopi, Chupadera, and Abo fms.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, p. 1428). Upper Triassic vertebrates occur at some places below Poleo ss. (according to E. C. Case, Contr. from Mus. Pal. Univ. Mich., vol. 3, No. 1, 1928), indicating that Poleo ss. and some part of underlying beds are younger than Permian and that Poleo ss. is younger than Shinarump cgl.

†Polk Bayou limestone.

Upper and Middle Ordovician: Northern Arkansas.

H. S. Williams, 1899 (Am. Jour. Sci., 4th, vol. 8, pp. 139–152). *Polk Bayou ls.*—Coarse-grained pinkish or red marble containing Ord. (Trenton) fossils. [Relations to underlying and overlying fms. not clearly defined, but name *St. Clair ls.* seems to be applied to the Sil. ls. and *Izard ls.* to an older (Ord.) ls., the name *Polk Bayou ls.* being applied to all beds containing Trenton fossils.]

H. S. Williams, 1900 (Ark. Geol. Surv. Ann. Rept. 1892, vol. 5, pp. 278–284). *Polk Bayou ls.*, name suggested by J. C. Branner in letter, adopted for Cincinnati memb. of Dr. Penrose's St. Clair ls., or for the ls. underlying the manganese-bearing shales named Cason sh., instead of restricting St. Clair ls. to this memb., as writer did in 1894, since this ls. does not outcrop in region of St. Clair Springs. Uncon. underlies Cason sh. and overlies Izard ls.

At type loc. contains Richmond fossils in upper part and Black River fossils in lower part, with uncon. btw. them representing Lorraine and Trenton time. Is now divided into Fernvale ls. (of Richmond age) and Kimmswick ls. (of Black River age). Underlies Cason sh. uncon. and uncon. overlies Plattin ls. (See H. D. Miser, U. S. G. S. Bull. 715G, 1920.)

Named for Polk Bayou, near Batesville, Independence Co.

†Polk County ash bed. (In Stanley shale.)

Pennsylvanian: Southwestern Arkansas.

J. F. Williams, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 375–376). *Polk County ash bed.*—In SW. Ark. btw. Ind. Ter. [Okla.] border and upper waters of Little Missouri River, a series of outcrops of rock containing much detrital igneous material interbedded with sss. and shales following them in all their folds. Owing to active weathering the rock in most places appears only in form of boulders, from which little or nothing could be learned concerning its mode of occurrence. Writer has not examined the rocks in field, but they were observed and noted by J. P. Smith and afterward by R. A. F. Penrose, Jr. Penrose thinks in some places the beds are 20 or more ft. thick.

Replaced by *Hatton tuff lentil* of Stanley sh., a county name being considered inappropriate for so minor a unit.

Named for exposures in Polk Co.

Polk Creek shale.

Upper Ordovician (Richmond): Southwestern Arkansas and southeastern Oklahoma.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557; also Slates of Ark., Ark. Geol. Surv., pp. 30, 36). *Polk Creek sh.*—Sh. resembling Ouachita sh. in color, hardness, and texture, in presence of large number of quartz veins, and in locally having well-developed slaty cleavage. Differs from Ouachita sh. in containing no sandy or calc. layers and in being only about 100 ft. thick; in places appears to be absent. Overlies Bigfork chert and underlies [uncon.?] Blaylock ss.

Named for Polk Creek, Montgomery Co., Ark.

Pomeroy sandstone. (In Monongahela formation.)

Pennsylvanian: Southeastern Ohio.

E. Lovejoy, 1888 (Ohio Geol. Surv. vol. 6, pp. 630, 631, 635). *Pomeroy ss.*, 10 to 75 ft. thick, overlies Pomeroy coal. Upper part of ss. is in some areas replaced by red clay. In places the ss. replaces the ls. 45 ft. above Pomeroy coal. Included in Upper Coal Measures.

Named for Pomeroy, Meigs Co.

Pomeroy quartz monzonite.

Post-Carboniferous: Central Colorado (Monarch-Tomichi region).

R. D. Crawford, 1913 (Colo. Geol. Surv. Bull. 4, p. 79). Pinkish gray to bluish gray. Carries great numbers of small bluish-gray plagioclase crystals. Named for Pomeroy Mtn., Monarch dist.

Pomfret phyllite.

Carboniferous: Eastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, p. 129). *Pomfret phyllite.*—Skirting E. border of Woodstock quartz schist, and extending S. into Hampton, is a narrow belt of mica sl. or phyllite. A detached area occurs in Bozrah and Franklin. Where typically developed, in NE. part of Pomfret, the phyllite is well foliated, the foliation planes being made of minute flakes of mica, which give the rock a purplish tone and silky luster. This type continued northward seems=Worcester phyllite. In addition to the typical phyllite, this fm.

also exhibits distinctly schistose varieties, containing much muscovite in fairly large plates. This type is traversed in places by calc. seams with which hornblende crystals are associated.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the continuation of this fm. in Mass. as Worcester phyllite, which name has priority.

Pomfret granite.

Devonian: Southeastern Vermont (Windsor County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of eastern Vt., but without definition. Probably named for Pomfret Twp, Windsor Co., or some of villages of that name within that Twp, in Woodstock quad.

Pompey member. (In Skaneateles shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 219, 220, etc.). *Pompey memb. of Skaneateles fm.*—Black sh. that grades gradually upward into aren. mudstone, and, in some localities, into cross-bedded ss. *Leiorhynchus* fossils at base; Hamilton fossils abundant at top. Underlies Berwyn memb. of Skaneateles fm. and overlies Delphi memb. Lies 150 ft. below Centerfield ls. Extends from Skaneateles Lake to Chenango Valley. Type section is at top of Pratt Falls, being the upper 60 ft. of that section, the upper hard beds (*Eunella-Nyassa* zone) forming the supporting ledge of the cascade. Easternmost locality of Pompey is at the cascades above the lower falls in Honts Creek, Sangerfield Valley, to E. of which it cannot be separated from Berwyn memb. Is 60± ft. thick in Chenango Valley, 45 to 50 in Onondaga Valley. [Derivation of name Pompey probably is village in Tully quad.]

Ponca sand.

A subsurface sand, of Penn. age and 40 to 150± ft. thick, in central northern Okla., reported to correlate with Upper Hoover sand and with a part of Elgin ss.

Ponca sandstone.

Upper Cretaceous: Northwestern Iowa and northeastern Nebraska.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 148, 150). *Ponca ss.*—Sss., 25 ft. thick, underlying Woodbury [restricted] shales and overlying Sergeant shales. Composes top fm. of Dakotan series.

Named for Ponca, Dixon Co., Nebr.

Ponce chalky limestones.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 10, 17).

Poncho Rico formation.

Pliocene and Miocene (?): Southern California (Salinas Valley).

R. D. Reed, 1925 (Jour. Geol., vol. 33, pp. 591, 592, 605–607). *Poncho Rico fm.*—Marine strata variously classed as latest Mio. or earliest Plio. Overlies Santa Margarita fm.; where latter is absent rests on Monterey sh. Underlies nonmarine Paso Robles fm. A striking feature of lower part of sandy strata resting on Monterey sh. (Santa Margarita, in strict sense) is large amount of cleanly washed white granitic sand that it contains. One sample proved to contain almost nothing but quartz grains, an extremely unusual condition for a Tert. ss. In higher parts of series diatomite occurs on great scale; also clastic sh., yellowish ss., and cgl. beds in which Monterey sh. pebbles play an increasingly prominent role toward top of series. These are strata here grouped together as Poncho Rico fm.

These beds were identified as Jacalitos and Etchegoin fms. by W. A. English in U. S. G. S. Bull. 691, p. 231, 1919.

Probably named for exposures along or near Poncho Rico Creek, Monterey Co.

Pond limestone.

Mississippian (Chester): Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). [See under *Southward Pond fm.*]

†Ponderosa marl.

Paleontologic name applied in early repts on eastern Tex. to Taylor marl.

Pond Hill granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., Moosilauke map, p. 28). *Pond Hill granite.*—Medium- to fine-grained granite of quartz, potash feldspar, oligoclase, and biotite. Late Dev. or late Carbf. Assigned to New Hampshire magma series. [Mapped on Pond Hill.]

Pondville conglomerate.

Carboniferous: Southeastern Massachusetts and eastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134–141). *Pondville group.*—Consists of "basal arkose beds" (grayish arkoses and quartz pebble and qtzite cgls.) to N., in Norfolk County Basin, and of "suprabasal cgls." to S., in Narragansett Basin, where they usually overlie beds of arkose. The "suprabasal cgls." include *Millers River cgl.*, 300 to 400 ft. thick. The Pondville group underlies Wamsutta group and uncon. overlies pre-Carbf. granitite. The basal arkose beds are well exposed near Pondville Station, on Walpole & Wrentham R. R. [Norfolk Co., Mass.].

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 54). *Pondville cgl.*—Coarse cgl. or arkose made up of material derived from adjacent granite. Underlies Wamsutta fm.

†Ponent series.

Upper Devonian and Carboniferous (?): Appalachian region.

H. D. Rogers, 1844 (Am. Jour. Sci., 1st, vol. 47, pp. 153–158). *Ponent series* "includes all rocks between base of Catskill red ss. and top of overlying cgl. (formation X of Pa. and Va. ann. repts). Usually embraces but 2 formations, the *Ponent red ss.* and the *Ponent cgl.* or Catskill red ss." [As thus defined includes Catskill fm. and probably Cattaraugus, Oswayo, and Knapp fms. of northern Pa.]

†Ponent conglomerate.

See under †*Ponent series.*

†Ponent red sandstone.

See under †*Ponent series.*

Pontchartrain clay.

Pleistocene: Southeastern Louisiana and southwestern Mississippi.

L. C. Johnson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 24–25). There was, indeed, an era during which the Mississippi embouched through Manachac, and during which the action was so much grander and so different in character [from Biloxi sand] as to require different consideration. During this era there was formed what may provisionally and for convenience be called *Pontchartrain clays.* The method of action was essentially similar to that concerned in the building of the coast sand fm. during Biloxi period, and similar to that displayed by the comparative insignificant agency of the Nita crevasse. Hence all the Pontchartrain clays extend farther inland than the Biloxi sands, or to the edge of the rolling lands of St. Tammany and even to foot of the gravelly hills of Miss. and Ala., as well as up the large estuaries of Pearl and Pascagoula Rivers; the bluffs, excavations, and artesian borings reveal a like sequence of sands and brownish or yellowish-blue clays under a thick coat of clay which forms the water-holding pan of the "pine meadows." No fossils found. Assigned to glacial period. Considered older than Biloxi sand.

G. D. Harris and A. C. Veatch, 1899 (La. Geol. Surv., pt. 5, Rept. for 1899). Investigations by L. C. Johnson in 1890, in southern Miss. and in region N. of Lake Pontchartrain, in coastal phase of the Port Hudson, led him to propose for it the name *Pontchartrain clays.* At same time he proposed the name *Biloxi sands* for the more recent coastal fms. The difficulty of distinguishing btw. the two beds, which were formed under very similar conditions, led to extension of meaning of Biloxi sands to include Pontchartrain clays.

G. D. Harris, 1905 (La. Geol. Surv. Bull. 1, pp. 10–20). If anything is to be gained by applying a name to clays that were evidently deposited in brackish-water bays, estuaries, and lakes along the Gulf border, some such term as "Pontchartrain clays" may be used, with understanding the name denotes a particular kind of deposit or phase of deposition having no special time value. So, too, the deposits, mainly alluvial, containing a large amount of vegetable matter, especially stumps and trunks of trees, may, if necessary, be classed as Port Hudson clays, and marine sands, which may be found at various depths, may be referred to as *Biloxi sands*; but in all cases *the terms must be understood as denoting mere phases of deposition, not stratigraphic units.*

L. C. Johnson, 1905 (U. S. G. S. W. S. P. 114, pp. 171–178). Port Hudson group includes *Pontchartrain clay* and Biloxi sand. The former is a greenish clay occurring in a narrow belt in extreme S. part of Miss., and separated from the coast by a very narrow strip of sandy beds known as Biloxi sands. The buckshot sands of the delta have sometimes been referred to Port Hudson group.

See also under *Port Hudson fm.*

Pontiac schist.

Pontiac group.

Pre-Cambrian: Quebec.

M. E. Wilson, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 175). *Pontiac schist.*

M. E. Wilson, 1912 (Canada Geol. Surv. Summ. Rept. 1911, pp. 274, 275). *Pontiac group.*

Pontiac limestone. (In McLeansboro formation.)

Pennsylvanian: Central eastern Illinois (Livingston County).

J. E. Lamar, 1929 (Ill. Geol. Surv. Rept. Invest. No. 17, passim). *Pontiac ls.*—Nodular fine-grained brown, light-gray, or bluish-gray ls., containing numerous cavities lined with crystals of calcite. Irregular masses of hydrated iron oxide are also common in cavities and along joint planes. Where unweathered is in beds 1 to 3 ft. thick, but weathers to slabs 1 to 2 in. thick. General character quite constant, so that bed is recognizable at its various outcrops. Quarried near Pontiac, where it consists of (descending): (1) Gray porous ls., locally spotted brown by iron hydroxide, 11 ft.; (2) ls. similar to above but less porous and bluish gray, 3 ft.; (3) bluish gray ls., clayey, fossiliferous, 1 ft. 2 in. This 3-fold division is common to most outcrops of the stone. Outcrops SE., NE., and NW. of Pontiac, Livingston Co. Although it is probably the Lonsdale or La Salle ls. it is here called *Pontiac ls.* because of uncertainty of its identity. Lies 0 to 36± ft. below top of Penn. Unconsolidated materials overlie the ls. at all outcrops visited. In some places it is overlain by a tough greenish-brown clay; in others by a pebbly gray or brown glacial clay which is usually thin but may be 15 or 20 ft. thick.

Pontotoc group.

Pennsylvanian and Permian (?): Central southern Oklahoma.

G. D. Morgan, 1922 (Okla. Geol. Surv. Circ. No. 11). *Pontotoc series.*—An arkosic series, 1,000 to 1,500 ft. thick, consisting of coarse sss., shales, and impure argill. or aren. lss. In a general way divided into three parts: (1) In upper div. shales predominate, lss. are almost absent, and although there are a few local occurrences of grits and cgls. the sss. become thinner and more fine-grained, with a consequent decrease in size of feldspar particles; (2) middle part carries sss., but shales are thicker and more numerous than in lower part, and a total thickness of about 100 ft. of impure lss. is present; (3) lower part consists of alternating strata of sss., cgls., and shales. Base is drawn where magascopic feldspar is first encountered, and top is drawn where megascopic feldspar disappears. Assigned to late Penn.

G. D. Morgan, 1923 (Okla. Geol. Surv. Circ. No. 12). *Pontotoc series* (arkosic, conglomeratic) is separated from underlying *Seminole fm.* by 4 new fms. to be described in a forthcoming paper, named (descending) Ada, Vamoosa, Belle City, and Francis.

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2). *Pontotoc terrane* is divided into (descending) Konawa fm. and Stratford fm. (both Perm.) and Vanoss fm. (Penn.). Overlies Ada fm. and underlies Asher fm. Is characterized by arkosic materials.

H. D. Miser, 1926 (Okla. geol. map). *Pontotoc group* includes beds below Asher fm. and above Ada fm. Is of Penn. and possibly Perm. age.

Named for development in western part of Pontotoc Co.

Pony series.

Pre-Cambrian (pre-Belt): Southwestern Montana (Madison County).

W. Tansley, P. A. Schafer, and L. H. Hart, 1933 (Mont. Bur. Mines and Geol. Mem. 9, p. 8, map). *Pony series.*—Dark and light-colored gneisses and schists, of sed. and igneous origin and pre-Beltian age, folded and faulted in complex manner, and uncon. underlying Cherry Creek series (pre-Beltian) in Tobacco Root Mtns, Madison Co. More metamorphosed than Belt series. [Thickness not given.] Named for exposures at and in vicinity of town of Pony.

Pony Creek shale. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 74, 81). *Pony Creek sh.*—Top bed of McKissick Grove sh. memb. of Wabaunsee fm. Bluish to reddish argill. sh., brownish sandy sh., some ss. Varies much in color and texture. Thickness 23 ft. Thickens southward. Overlies Dover ls. and underlies Brownville ls. Named for exposures E. of Pony Creek, btw. Kans.-Nebr. line and 2 mi. S. of Falls City, Nebr.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, p. 96). *Pony Creek sh.*, top bed of McKissick Grove sh., underlies Brownville ls. and overlies Jim Creek ls., which is separated from Dover ls. by Table Creek sh.

R. C. Moore and G. E. Condra (Oct. 1932 revised correlation chart). *McKissick Grove sh.* divided into (descending) Pony Creek sh., Nebraska City ls., French sh., Dover ls., Table Creek sh., Maple Hill ls., and Pierson Point sh.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 9–10). *Pony Creek sh. fm.* underlies Brownville ls. fm. and overlies Dover ls. fm., which rests on McKissick sh. fm. [restricted].

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 243–244). *Pony Creek sh.* is here restricted to beds overlying Caneyville ls. and underlying Brownville ls. Thickness 5 to 20 ft. Consists of bluish and bluish gray sh. and locally some red clayey or sandy sh.; locally some ss. in middle; a thin coal bed in upper part. The Pony Creek sh. extends entirely across Kans. and is well developed in Nebr. and northern Okla.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Pony Express beds. (In Morrison formation.)

Upper Jurassic: Southwestern Colorado (Ouray district).

J. D. Irving, 1905 (U. S. G. S. Bull. 260, p. 56). [*Black Girl and Pony Express ls.* is shown as basal bed of McElmo fm. in section of Gold Hill, Ouray dist.]

W. S. Burbank, 1930 (Colo. Sci. Soc., vol. 12, pp. 151–232). *"Pony Express beds."*—An important ore-bearing horizon forming basal part of Wanakah sh. memb. of Morrison fm. in Ouray dist. Consists of sh., ls., and breccia, 1 to 70 ft. thick. Separates "Upper La Plata" of Cross from "Lower La Plata." Commonly known to miners as "Pony Express ls." and "Pony Express contact," from its occurrence in Pony Express mine.

Pony Spring siltstone member (of Maroon formation).

Permian: Central Colorado (Park and Chaffee Counties).

D. B. Gould, 1935 (A. A. P. G. Bull., vol. 19, No. 7, pp. 971–1009). *Pony Spring siltstone memb. of Maroon fm.*—Gray to light-red siltstone with interbedded gray-green ss. and gray sh. Thickness 5,931 ft. Named for Pony Spring, at W. side of Pony Park, near NW. corner sec. 28, T. 12 S., R. 77 W. Lies 644 ft. below top of Maroon fm. in Salt Creek area, Park and Chaffee Counties. Includes at base Bath ss. submemb., 810 ft. thick. Rests conformably on Chubb siltstone memb. Assigned to Perm.

Pools Brook limestone.

Silurian (?): Central New York (Onondaga County).

B. Smith, 1929 (N. Y. State Mus. Bull. 281, pp. 27, 31). *Pools Brook ls.*—Laminated dark-blue ls. that weathers bluish white. Occurs in E. part of Onondaga Co. At Manlius may be 30 ft. thick. Is usually capped by basal quartz ss. of Onondaga, but for short distance E. of Manlius it is uncon. overlain by Bishop Brook ls. Conformably overlies Jamesville ls., which has been included in Helderbergian by some authors, but is here included in Manlius. Named for Pools Brook Valley, along whose southern rim it is exposed. Is next to top fm. of Manlius group.

Poonah sands.

Miocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in Geol., No. 7, p. 68).

Poorman formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793-799, 836-843, with maps). *Poorman fm.*—Most abundant rocks are carbonaceous banded mica schists and slates, of light-gray to dark-gray color, and fine-grained. A few beds of garnetiferous schist are interbedded. All rocks are schistose, tightly folded, and considerably cross-jointed. The fm. is calc., graphitic, and pyritiferous. Thickness 2,500 ft. Basal fm. in Lead dist. Overlain by De Smet fm., into which it grades. Believed to be of Keewatin age.

Named for exposed section at junction of Poorman and Deadwood Gulches, along railroad track, Lead dist.

Poor Mountain limestone series.

Poor Mountain series.

Poor Mountain zone.

Cambrian (?): Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 10). *Poor Mtn zone (Cambr. ?).*—This fm. is exposed along Rich Mtn, Poor Mtn, and Potato Top Mtn, which establishes SE. limit of prominently elevated region of Oconee Co. The soluble character of the ls. has largely caused its disappearance from depressed areas intermediate to successive knobs of ridges; where it has been rapidly drained it has persisted. The exposure of this series from a high point on Poor Mtn to a low point on a dale of Rich Mtn, indicates a moderate dip to SE. Narrow belt of Carolina gneiss series underlies Poor Mtn series, which comprises dark calc. slates, marble, thin hornblende schists, ottrelite (?) schists, sss., itacolumite. The white dolomitic marble of this zone grades to a dark-green pyroxenic mass, in places altered by dynamometamorphic action to hornblende. This series probably pertains to Keith's "Brevard schists," assigned to Camb.

Named for exposures along Poor Mtn, Oconee Co.

Pope Chapel sandstone member (of Atoka formation).

Pennsylvanian: Eastern Oklahoma (Muskogee and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503-520). *Pope Chapel ss. memb. of Atoka fm.*—Massive to irregularly bedded ss., coarse- to medium-grained, saccharoidal, highly colored, usually red, brown, yellow, or white; contains clay blebs. Thickness 50 ft. Separated from Coata ss. (basal memb. of Atoka fm.) by 150 to 220 ft. of sh. and from overlying Georges Fork ss. memb. by 80 to 120 ft. of sh. Named for exposure at Pope Chapel, sec. 24, T. 12 N., R. 19 E.

Pope Creek cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179-193) to a portion of lower part of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated. Probably named for Pope Creek, Mercer Co., NW. Ill. (See also Geol. Soc. Am. Bull., vol. 42, 1931, pp. 801-812.)

†Pope Hollow conglomerate.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

J. F. Carll, 1883 (2d Pa. Geol. Surv. Rept. I_4, pp. 180-181). Wrightsville cgl. of Warren Co., Pa., is probably the SW. continuation of *Pope's Hollow cgl.* of N. Y. [See Wrightsville cgl.]

G. D. Harris, 1891 (Am. Geol., vol. 7, pp. 168, 172-178). *Pope Hollow cgl.*—At Pope Hollow, S. part of Chautauqua Co., N. Y., it is 50 ft. thick, and lies below 100 ft. of Barren series forming top beds of Chemung group and above the Lamellibranch series, also a part of the Chemung. Is probably=Wrightsville cgl.

F. A. Randall, 1894 (N. Y. State Mus. 47th Ann. Rept., pp. 713–719). *Pope Hollow cgl.*—Ss. with flat pebbles, but fewer pebbles than the older Panama cgl. Is 23 ft. thick at Warren, Pa.; 20 ft. at Corydon, Pa.; 20 ft. at Pope Hollow, N. Y. Probably=Salamanca cgl.

L. C. Glenn, 1904 (Geol. Soc. Am. Bull., vol. 14, pp. 522–531). Salamanca, Panama, Pope's Hollow, and Tuna are all same cgl.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 88). Salamanca cgl. has been called "Pope Hollow."

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 87–89). *Pope Hollow cgl. memb.*—Upper memb. of Salamanca formational suite. Is same as Wrightsville cgl. of Warren Co., Pa., Millers ss. of Chadwick, Salamanca cgl. of Butts (Warren folio) and Glenn (N. Y. State Mus. Bull. 69, 1903), and Venango second oil sand (upper stratum) of Carll (1875 and 1883) and of I. C. White (Rept. Q_4).

†Popo Agie beds. (Pronounced pōpō'-zhah.)

Upper Triassic: Western Wyoming (Wind River Mountains).

W. C. Knight, 1901 (Eng. and Min. Jour., vol. 72, p. 359), used *Popo Agie* in a table, for Triassic beds above what he called *Shoshone* and below what he called *Oil Springs*, and also for Perm. beds; but judging from pp. 628–629 of this Jour. he did not intend the names as geologic terms.

S. W. Williston, 1904 (Jour. Geol., vol. 12, p. 688). *Popo Agie beds.*—Univ. Chicago paleontological expedition to Wyo. the past summer secured valuable collection of stegocephalian and reptilian remains from Trias, from 40 to 80 ft. of beds lying about 200 ft. below top of the red-beds and 600± ft. above their base. Their description will be given later in paper by N. H. Brown, their discoverer, and writer. Meanwhile the horizon may be distinguished by name *Popo Agie*, suggested by Brown, from the river along whose branches they are most characteristically shown. Assigned to Upper Triassic.

S. W. Williston, 1905 (Jour. Geol., vol. 13, pp. 338–350). *Popo Agie beds* believed to be of early Keuper age [Upper Triassic].

E. B. Branson, 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 220–229), assigned these beds to Upper Triassic, but later (1929) he assigned them to Middle Triassic and stated he believed them to be older than Jelm fm.

C. L. Camp, 1930 (Calif. Univ. Mem. No. 10, p. 5, quarto), assigned these beds to Middle Triassic.

The U. S. Geol. Survey has adopted *Jelm* for these rocks, as explained under *Jelm fm.*, but Branson and Camp have thrown doubt upon equiv. of the two.

†Poquag quartzite.

Same as †Poughquag qtzite.

Porcupine beds.

Tertiary: Southwestern Alaska (Yukon gold district).

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 197, 253). *Porcupine beds.*—Mio. or Plio. Exposed on Porcupine River, btw. mouth of Driftwood River and head of the Ramparts. Yellowish and whitish sands and sss. interbedded with grayish rather hard cgl. of quartz pebbles, fragments of sh., and scales of silvery micaceous schist. Probably=Twelvemile beds.

Porcupine series.

Cretaceous: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 216).

Porcupine group.

Ordovician and Silurian: Yukon-Alaska boundary between Porcupine and Yukon Rivers.

D. D. Cairnes, 1912 (Canada Geol. Surv. Summ. Rept. 1911, pp. 26–33, in rept. on Yukon-Alaska bdy btw. Porcupine and Yukon Rivers). *Porcupine group.*—Lss., dolomitic lss., and dolomites, white, various shades of gray to almost black, and

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

sionally reddish or pink; massive, crystalline. Fossils are Ord. and early, middle, and late Sil. Named because the rocks correspond to the Ord.-Sil. rocks on Porcupine River described [but not named] by E. M. Kindle, Geol. Soc. Am. Bull., vol. 19, pp. 322–327, 1908. Thickness at least 6,000 ft. Underlies Raquet series (Carbf.) and forms bedrock of northern 20 mi. of dist. mapped.

Porcupine Hill series.

Upper Cretaceous or Eocene: Canada.

G. M. Dawson, 1883 (Canada Geol. Surv. Repts 1880–81–82, p. 4B) and 1885 (Canada Geol. Surv. Repts 1882–83–84, pp. 82C, 96C, 112C–113C). Included in Laramie.

Recent repts of Canada Geol. Survey assign *Porcupine Hills fm.* to Tert.

Porphyrian.

Pre-Cambrian: General.

See under *Pelodian.*

Porphyry Peak rhyolite.

Tertiary: Central southern Colorado (Bonanza district, Saguache County).

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Porphyry Peak rhyolite.*—Rhyolite flows and interbedded tuffs and aggls.; some intrusive rhyolite included. Thickness 0 to 1,000± ft. Overlies Squirrel Gulch latite and underlies Brewer Creek latite. Exposed on slopes of Porphyry Peak.

Porphyry Peaks rhyolite.

Tertiary: Central northern Colorado.

L. E. Spock, Jr., 1928 (N. Y. Acad. Sci. Annals, vol. 30). *Porphyry Peaks rhyolite.*—A rhyolite porphyry, brownish gray, remarkable for its large glassy feldspar phenocrysts and rapid mechanical disintegration. Caps Porphyry Peaks and occurs on mtn tops on either side of Stillwater Creek farther S. [in NE. part of Grand Co.].

Portage group (also **formation** and **shale**).

Upper Devonian: New York, Pennsylvania, Maryland, West Virginia, and western Virginia.

J. Hall, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 391–392, 452–455). *Portage or Upper Fucoidal group.*—Underlies Chemung group and overlies Gardeau or Lower Fucoidal group. Consists of (descending): (1) Slightly argill., compact, and finer-grained ss. than No. 2, 150 to 200 ft.; in places contains some pyrites; (2) shales and sss.; (3) coarse-grained ss. forming platform or table rock of lower falls of Genesee River. The sss. do not have the glazing of sh., as do those of underlying Gardeau or Lower Fucoidal group.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 171, 172). *Portage or Nunda group.*—Includes Cashaqua sh., Gardeau and Portage groups, and Sherburne flagstone and sh. of the repts. Underlies Ithaca group and overlies Genesee sl.

J. Hall 1843 (Geol. N. Y., 4th dist., pp. 224–249). *Portage or Nunda group.*—Includes Sherburne flagstones and sh., Cashaqua sh., Gardeau and Portage groups of ann. repts. Named for superior development along banks of Genesee River in dist. formerly included in town of Nunda, now Portage. Overlies Genesee sl. and underlies Chemung group (in which Ithaca sh. is included, because of its fossils). Thickness not less than 1,000 ft. Divided into (descending) Portage sss. (the thick-bedded sss. at Portage), Gardeau sh. and flagstones, and Cashaqua sh.

In subsequent repts *Portage* continued for many years to be applied to the sss. and shales below the Chemung and above Genesee sh.

In 1885 (N. Y. State Geol. Rept. for 1884, pp. 9–22, and U. S. G. S. Bull. 16) J. M. Clarke included "Portage sss." in Chemung group, because of their contained fauna. He also described Portage or Nunda group of Hall as containing, in Ontario Co., in lower part, an "Upper Black Band" 5 to 10 ft. thick and a "Lower Black Band" 40 ft. thick, the two separated by 150 ft. of greenish and drab soft shales, the "Lower Black Band" being underlain by 10 to 15 ft. of soft olive-green and grayish shales resting on Genesee beds. The "Lower Black Band" was later named *Middlesex sh.* According to D. D. Luther, 1899 (N. Y. State Geol. 16th Ann. Rept., for 1896), the black sh., 30 to 40 ft. thick, that "has sometimes been called the Lower Black Band of the Portage Group" belongs in Genesee sh. (In 1904, however, Luther and Clarke included this bed in the Portage.) In 1888 C. S. Prosser and H. S. Williams classified the Portage rocks as consisting of Upper Portage sss. and shales, 600 ft.; Middle Portage or Ithaca, 450 ft.; and Lower Portage sss. and shales, 250 ft. In 1893 Prosser (Geol. Soc. Am. Bull., vol. 4, pp. 116–117) applied *Portage* to rocks btw. the Chemung and Genesee, and assigned to them thicknesses of 900 to 1,000 ft. in western N. Y., 1,300 to 1,780 ft. in western-central N. Y., and 1,315 ft. in eastern N. Y. In 1894 James Hall applied *Portage* to the rocks btw. Genesee and Chemung. The same year J. M. Clarke described Upper Portage as=the [so-called] Portage sss., the Middle Portage as=the Ithaca, and the Lower Portage as resting on the Genesee. In 1897 James Hall continued to include in top of Portage group the "mass of heavy bedded sss. which were originally termed 'Portage sss.'" The same year (also in 1899) J. M. Clarke included in top of the Portage not only the †Portage ss. but the overlying Wiscoy shales and flags, and defined the Portage base as top of Genesee sh. In 1898 and 1899 F. J. H. Merrill divided Portage group into Portage ss., Naples beds, Gardeau sh. and ss., and Cashaqua sh.; and D. D. Luther also used Portage in two senses, i. e., for the group and for top fm. of the group. In 1901 and 1902 Luther called the group *Portage or Nunda*, included in it the Wiscoy shales at top, and applied *Portage sss.* to the sss. underlying the Wiscoy. J. M. Clarke's 1903 Hdb. included in Portage group the Wiscoy sh., "Portage sss.," and underlying beds to base of Middlesex sh. In 1903 H. F. Cleland (U. S. G. S. Bull. 206), also J. M. Clarke and D. D. Luther (N. Y. State Mus. Bulls. 63 and 82), applied *Portage* to the beds btw. the Ithaca and the Genesee. In 1906 and 1907 (Jour. Geol., vols. 14 and 15) H. S. Williams used *Nunda fm.* to include the beds btw. Chemung and Genesee, the name Portage "having been dropped because it was already specifically applied to the upper ss. memb. of Nunda fm. of Genesee Valley." In 1908 (N. Y. State Mus. Bull. 118) J. M. Clarke and D. D. Luther introduced *Nunda ss.* for the sss. that had previously been called *Portage sss.*, and stated that paleontologically the Wiscoy shales and sands belong to Portage group, although they were not included in original (1840) definition of Portage group. In 1909 (U. S. G. S. Watkins Glen-Catatonk folio, No. 169) H. S. Williams defined *Portage fm.* of typical Chemung area as underlying Cayuta memb. of the Chemung, overlying Genesee sh., and as divided into (descending) Enfield memb., Ithaca memb., and Sherburne memb. In 1912 C. A. Hartnagel (N. Y. State Mus. Hdb. 19, p. 74) defined Portage fm. of western N. Y. as consisting of beds carrying the Naples fauna; in central N. Y. of the Sherburne and Ithaca beds partially intercalated with the Naples fauna; in eastern N. Y. of the Sherburne and Ithaca beds (marine) overlain by the Oneonta beds (brackish). And he included in the Portage all beds btw. top of Wiscoy sh. and base of Middlesex sh. In 1913 H. S. Williams (U. S. G. S. P. P. 79) defined *Portage fm.* of central N. Y. as underlying Cayuta sh. memb. of Chemung fm., as resting on Genesee sh., and as divided into Enfield sh. memb. (top), Ithaca sh. memb., and Sherburne flagstone memb. (base); and described Oneonta ss. of eastern N. Y. as=upper part of Ithaca sh. memb. He also stated that to E. the Chemung type of sediments began earlier and occupy the time interval of Enfield sh. and upper part of Ithaca sh. In 1920 (Geol. Soc. Am. Bull., vol. 31, p. 118) G. H. Chadwick included in the Portage all beds btw. base of Middlesex sh. and top of Nunda ss. In 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69) and 1924 (N. Y. State Mus. Bull. 251, pp. 149–157) he transferred to the Chemung of western N. Y. certain beds (Dunkirk sh., Gowanda sh., Laona ss., Westfield sh., Shumla ss., and Northeast sh.) that had previously been included in the Portage, and drew base of Chemung at top of Hanover sh. of western N. Y. and at top of Wiscoy sh. of west-central N. Y. (See his correlations under *Chemung fm.*, 1924 entry.)

E. W. Hard, 1931 (A. A. P. G. Bull., vol. 15, pp. 165–180) and I. W. Fox, 1932 (A. A. P. G. Bull., vol. 16, No. 7, pp. 676–690), expanded Portage group by including in it, at base, West River fm. and Genundewa ls., both formerly included in the Genesee, which they restricted to the basal part of the Genesee of common usage, or to the beds named *Geneseo sh.* by Chadwick in 1920.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), divided *Portage group* of western N. Y. into (descending) Wiscoy sh., *Nunda ss.*, Gardeau sh., Grimes ss., Hatch sh., Rhinestreet sh., Cashaqua sh., Middlesex sh., Standish sh., West River sh., and Genundewa ls., and restricted the *Genesee* to the basal memb. (the Geneseo sh. of Chadwick).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 96–100), adopted *Portage* for the bluestone and *Nunda* for the group.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 319). All the upper and major part of what has long passed as "Portage group" (correctly *Nunda*) is=type Chemung, although wholly different in facies. [On p. 345 he stated:] Along Genesee River, at and below Portageville, is type section of what has currently passed as *Portage*, i. e., all beds from Genesee group up to include Portage sss. (bluestone), to which it seems historically necessary to limit the name, and above these the Wiscoy shales. A century of painstaking collecting has failed to disclose throughout this entire "Portage" sequence (along Genesee River) a single fossil of Chemung aspect. In topmost beds (Wiscoy memb.) one is startled, however, to find a large cup coral, "out of its depth." [On p. 346:] No one in those days [Hall's time] would have been countenanced in supposition Chemung at E. and Portage at W. are identical. [On p. 352:] The former "Portage" (correctly the *Nunda*) group, because it bestrides both Naples and Chemung, lacks application beyond its type section along Genesee River. Historically, Portage either applied to the bluestones or is replaced by the uncontroversial synonym *High Point*, for *Nunda*, having been used first in group sense, has no rights of restricted applications to these bluestones in way Clarke employed it over protests of H. S. Williams. [On this p. 352 Chadwick correlated Wellsburg ss. memb. of type Chemung with (descending) Hanover sh., Pipe Creek black sh., and *Portage bluestones*, and correlated the underlying Cayuta memb. of type Chemung with (descending) Letchworth sh. (new), Gardeau sh., and Grimes ss.]

The U. S. Geol. Survey in 1908 (after correspondence with interested American geologists) discarded *Portage ss.* and adopted *Portage group*, to include the rocks below Cayuta sh. memb. of Chemung and above Genesee sh., or the same definition then employed by N. Y. State Survey. In central Pa. the Portage group has been divided into Brallier sh. above and Harrell sh. below and includes at top beds equiv. to Wiscoy sh. of N. Y. The Middlesex sh. is recognized as basal bed of the Portage of N. Y. B. Willard, 1935 (Pa. Acad. Sci. Proc., vol. 9, p. 40), divided *Portage group* of Pa. into (descending) Trimmers Rock ("Ithaca") ss., Braillier greenish sh., Harrell dark gray sh., Burket ("Genesee") black sh., and Tully ls.

†Portage sandstone.

Upper Devonian: New York.

J. Hall, 1843 (Geol. N. Y., div. 4, 4th dist., pp. 226, 228–229, 248). *Portage sss.*—The thick-bedded sss. at Portage, which form terminal rocks of Portage group. Well exposed in deep gorge below Portageville. Upper part consists of thick-bedded ss. with little sh.; while below the sandy layers become thinner, with more frequent alternations of sh. The thick-bedded character of the sss. and presence of fucoids passing vertically through the strata induced separation from the rocks below, where the characteristic species of same genus lies horizontally upon surface of the strata. Rests on Gardeau sh. and flagstones and is overlain by Chemung group.

In some repts this ss. has been included in Chemung group. See further explanation under *Portage group*.

In 1908 J. M. Clarke and D. D. Luther replaced this name with *Nunda ss.*, which they included in Portage fm. C. A. Hartnagel (1912 Hdb.) and G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69) also included this ss. in the Portage. Chadwick later (see 1935 entry under *Portage group*) recommended abandonment of Portage group and limitation of *Portage* to this ss.

Portage moraine.

Name that has been applied to a Pleist. moraine deposited at Portage, N. Y. (See H. L. Fairchild, N. Y. State Mus. Bull. 118, 1908, pp. 76, 79.)

Port au Port shale and gritstone.

Age (?) : Newfoundland.

J. B. Jukes, 1839 (Rept. on geol. of Newfoundland, p. 4).

Port Austin sandstone.

Mississippian: Michigan (Huron County).

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30, p. 85). *Port Austin ss.*—Younger than Point aux Barques ss., both of which belong to Lower Marshall.

A. C. Lane, 1910 (Jour. Geol., vol. 18, p. 422). *Point* [Port] *Austin ss.*, 23 ft. thick, is separated from underlying Point aux Barques ss. by 68 ft. of sandy sh.

Named for exposures at Port Austin, Huron Co.

Port Byron limestone.

Silurian (Niagaran) : Northwestern Illinois.

T. E. Savage, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 525-526, 531-533). *Port Byron ls.*—In new limekiln quarry at town of Port Byron [Rock Island Co.] a thickness of 35 to 40 ft. of yellowish dol. is exposed. It occurs in thin irregular layers, which, in occasional pockets and along thin bands, are crowded with fossils [listed], which also occur in upper ls. of Thornton quarry, near Chicago, and which are thought to indicate Guelph age. The strata, which dip SE. at angle of nearly 35°, are considered = to those in upper part of quarry at Thornton, Ill. [which are 54 ft. thick], and the name *Port Byron* is given to this ls. It overlies Racine ls. (restricted to beds of pre-Guelph age) without distinct break.

Is uppermost fm. of Niagaran age in Ill., according to later repts. See under *LeClaire dol.*, 1935 entry, for additional information.

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 270-274). *Port Byron ls.* occurs in NW. Ill. only. Savage has decided these beds are same as Leclaire of Iowa (type loc. of which is just across Miss. River from Port Byron, Ill.) and has suggested that Port Byron be abandoned. But, since the Port Byron of Ill. includes all Sil. beds above Racine ls., it is more nearly identical with the Gower than with the LeClaire. It seems best to retain LeClaire, and to restrict it to the "reef" phase of the Greer of Iowa. Rocks of this age are restricted to NW. Ill. and Iowa. Although Savage originally believed the Port Byron occurs in NE. Ill., he is now of opinion (personal communication) the NE. Ill. section does not contain any strata of Port Byron age.

Port Clarence limestone.

Lower and Upper Ordovician, Silurian, and Devonian: Northwestern Alaska (Seward Peninsula).

A. J. Collier, 1902 (U. S. G. S. P. P. 2, p. 18, map). *Port Clarence ls.*—Blue or gray ls., almost unaltered; basal beds flaggy and slightly schistose. Thickness 2,000± ft. Fossils identified by Schuchert as belonging to Lower Sil. system [Ord.]. Is basal part of Nome series. Conformably underlies Kugruk group (Upper Sil.). Rests, probably uncon., on Kuzitrin series.

Later work proved that the lss. included in overlying †Kugruk (Kougarok) group are Port Clarence ls., and Kugruk (Kougarok) was discarded. (See Collier, U. S. G. S. Bull. 328, 1908, pp. 61–65.) Further work also yielded fossils from Port Clarence ls. that were identified by E. Kirk as including Lower Ord., Upper Ord., and middle and late Sil. faunas. P. S. Smith (U. S. G. S. P. P. 192, in process of publication) also shows that Port Clarence ls. includes Dev. But sufficient work has not been done to differentiate the rocks of these different ages, so that the blanket term *Port Clarence ls.* is still continued. The type loc. is in York Mtns, N. of Port Clarence.

Port Deposit gneiss.

Pre-Cambrian: Northeastern Maryland (Cecil, Harford, and Baltimore Counties) and southeastern Pennsylvania.

G. P. Grimsley, 1894 (Cincinnati Soc. Nat. Hist. Jour., vol. 17, p. 112). *Port Deposit granite gneiss.*—Has been called *syenite, granite,* and *gneiss.* Probably of igneous eruptive origin. Occurs at Port Deposit, Cecil Co.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799). *Port Deposit gneiss* assigned to Algonkian, but later than Glenarm series.

E. B. Knopf and A. I. Jonas, 1929 (Md. Geol. Surv. Baltimore Co. Rept., pp. 104, 127). *Port Deposit granite (granodiorite).*—There are several outcrops in Baltimore Co. of rock that has been correlated with Port Deposit gneiss of Cecil and Harford Counties, on account of general geol. relations and lithologic similarity. NE. of Baltimore the rock is gray porphyritic gneiss; the rock of Melvale area and Rognel Heights quarry is a porphyritic biotite gneiss; the granite at Oakland is a potassic muscovite granite. Assigned to late pre-Camb. Intrudes Glenarm series (late pre-Camb.).

This fm. was formerly classified by U. S. Geol. Survey as of Algonkian age, but that term having now been discarded as a time term it is classified as pre-Camb.

Porter shale.

Oligocene: Southwestern Washington (Thurston County) and Puget Sound region.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). [See 1912 entry under *Lincoln fm.*]

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). *Porter horizon* is characterized by *Turritella porterensis* zone, Olig. Fossils listed. Outcrops at Porter and along Porter Creek. Older than Blakeley horizon and younger than Lincoln horizon.

K. E. H. Van Winkle, 1918 (Geol. Soc. Am. Bull., vol. 29, p. 166). *Porter fm.*—Strat. and faunal studies of this fm. at type loc. on Porter Creek show that it consists of 1,200 ft. of predominantly shaly sss. and sandy shales, resting uncon. on Tejon basalts. Fauna at Porter has closer similarity to that at Lincoln Creek than it has to Blakeley fauna at Restoration Point, and it is possible the beds can be correlated with those exposed at Lincoln Creek [Lincoln fm. of Weaver].

Porter sand.

A subsurface sand, of Upper Dev. (Portage?) age, in western Pa., southern N. Y., and W. Va. Considered same as Elk sand.

†Porter terrane.

An abbreviated form of *Porters Creek clay*, employed by C. [R.] Keyes.

Porters Creek clay. (In Midway group.)

Eocene (lower): Western Tennessee and Kentucky, southwestern Illinois, southeastern Missouri, eastern Mississippi, and southwestern Alabama.

J. M. Safford, 1864 (Am. Jour. Sci., 2d, vol. 37, pp. 361, 368). *Porter's Creek group.*—No marked distinction btw. this and adjacent groups (Ripley and La-Grange), except that it contains proportionally much more laminated or slaty clay, several beds of which are from 5 to 60 ft. thick. In Hardeman Co., on Porter's Creek—the first creek on map W. of Middleton—is a heavy bed said to be 100 ft. thick. The clay has the usual characters, contains mica scales, is dark when wet and whitish gray when dry. Thickness 200 to 300 ft. Underlies Orange sand or La Grange group and overlies Ripley group (Cret.). Heretofore included in Orange sand.

J. M. Safford, 1892 (Geol. Soc. Am. Bull. vol. 3, pp. 511–512; Am. Geol. vol. 9, pp. 63–64), separated from Ripley fm. of Tenn. certain beds which he named "Middleton fm." and assigned to basal Eo. These beds are now known as *Clayton fm.*

G. D. Harris, 1896 (Am. Pal. Bull., vol. 1, pp. 18–22), established the Midway age of Porters Creek clay and †Middleton fm. (Clayton fm.), and *Midway group* is now used to include Porters Creek clay above and Clayton fm. below.

Named for exposures on Porters Creek, Hardeman Co., Tenn. This clay in Ala. is usually known as *Sucarnoochee clay.*

Portersville fossilferous horizon (or limestone). (In Conemaugh formation.)

Pennsylvanian: Southeastern Ohio.

D. D. Condit, 1912 (Ohio Geol. Surv., 4th ser., Bull. 17, pp. 20, 41). *Portersville ls.*—Dark-colored fossiliferous calc. or pyritous sh., 0 to 3 ft. thick; overlies Anderson coal, underlies Cowrun ss., and carries marine fossils. Included in Conemaugh fm.

Named for village near E. edge of Perry Co.

Port Ewen limestone. (In Oriskany group.)

Lower Devonian: Eastern New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 21). *Port Ewen ls.*—The somewhat shaly lss. which are typically exposed and attain thickness of 100 to 200 ft. in vicinity of Port Ewen. Included in Helderbergian group. In Orange Co. sections the fauna seems to graduate into that of the overlying Oriskany. Underlies Oriskany beds and overlies Becraft ls.

Replaces *Kingston beds,* found to be preoccupied. In 1903 (Am. Geol.) C. Schuchert transferred these beds to base of Oriskany group.

In 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 468–470) A. W. Grabau separated from base of Port Ewen ls. 20 to 50 ft. of cherty lss. "containing a modified Becraft fauna," to which he applied the name *Alsen cherty ls.,* and stated that they are separated from rest of the Port Ewen by a big hiatus and discon.

In early repts called "Upper Shaly ls."

The N. Y. State Geol. Survey now includes this ls. in Helderberg group. (See W. Goldring, 1931, N. Y. State Mus. Hdb. 10). But U. S. Geol. Survey at present assigns it to Oriskany group, in which it has been included for many years.

Port Hood coal measures.

Pennsylvanian: Nova Scotia.

P. D. Trask and K. F. Mather, 1927 (Wash. Acad. Sci. Jour., vol. 17, p. 323).

Port Hudson formation.

Pleistocene: Louisiana, southern Mississippi, and eastern Texas.

E. W. Hilgard, 1869 (Am. Jour. Sci., 2d, vol. 47, pp. 77–88; vol. 48, p. 332; also Prel. rept. geol. reconn. La., 1869). *Port Hudson group,* a swamp, lagoon, and estuary fm.=most if not all of my Coast Pliocene. Blue, yellow, and greenish clay, with some orange and yellow sand strata. Thickness 160–630 ft. Older than Loess or Bluff fm. [which is absent at Port Hudson] and younger than Orange sand group [Citronelle fm.]. Assigned to Quat.

L. C. Johnson, 1905 (U. S. G. S. W. S. P. 114, pp. 171–178). *Port Hudson group* includes Pontchartrain clay and Biloxi sand. The former is a greenish clay occurring in a narrow belt in extreme S. part of Miss., and separated from the coast by a very narrow strip of sandy beds known as Biloxi sands. The buckshot sands of the delta have sometimes been referred to Port Hudson group.

A. F. Crider and L. C. Johnson, 1906 (U. S. G. S. W. S. P. 159, pp. 6–13). *Port Hudson fm.*—Clays, silts, and unconsolidated sands, containing old cypress stumps representing different generations superimposed one on another. Possibly the so-called Port Hudson of Yazoo Delta belongs to much younger age than Port Hudson farther south, but for present it is all mapped as one fm. Thickness 100 to 125 ft.

E. N. Lowe, 1925 (Miss. Geol. Surv. Bull. 20). *Port Hudson fm.* is oldest memb. of Pleist. Overlies the Plio. sands and gravels and underlies the loess of river bluffs. At type loc. consists of massive greenish, bluish, or gray clays containing driftwood, pebbles, and mastodon bones. In places interstratified with this clay is white indurate silt or hardpan, and often near the top of the clays are porous calc. concretions, and ferruginous concretions at a lower level. The deposits are river and swamp accumulations. Near Port Hudson below these deposits were found 3 to 4 ft. of brown peaty matter with cypress stumps, showing that the accumulations had been made upon site of an old cypress pond. At that time all lands bordering Lake Pontchartrain and adjacent parts of southern La. were either shallow margins of the Gulf or salt marshes. The mouths of the Miss. opening N. of Lake Pontchartrain spread Port Hudson clays across that part of La. and along the region of "Pine Meadows" on Miss. coast. In this region the river clays were deposited in shallow salt water and contain marine fossils. This marine phase of these deposits, which consist of alternate beds of blue clay and sand to a thickness of at least 200 ft., has been called *Biloxi beds*, because definitely established at Biloxi in boring the city well. Mastodon remains have been found both in the Port Hudson and the loess bordering the Miss.

L. W. Stephenson, W. N. Logan, and G. A. Waring, 1928 (U. S. G. S. W. S. P. 576, p. 63). As described by E. W. Shaw in an unpublished ms. the *Port Hudson fm.* consists chiefly of clay and sand of late Pleist. age and is apparently largely a brackish-water deposit, though a part was laid down by fresh waters at lower end, near mouths of rivers, and a part is a marine deposit offshore. Its areal distribution indicates that a large part was laid down in estuaries, the principal one of which extended up Miss. River to southern Miss. and perhaps farther north. Where best developed the Port Hudson bears only a scant deposit of loess, and this loess is probably of later age than main body of loess, which is regarded as of Iowan or early Peorian age.

Named for prominent development at Port Hudson, East Baton Rouge Co., La.

Port Huron morainic system.

Pleistocene (Wisconsin stage): Eastern and northern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53; also on moraine map in P. P. 106. Named for Port Huron, Mich. In some earlier repts called *Port Huron moraine*. Includes Main moraine, Bay City, Tawas, Whitehall, Manistee, and Cheboygan moraines.

Port Jervis limestone. (In Oriskany group.)

Lower Devonian: Southeastern New York.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). Southwestward, as at Cottekill [Ulster Co.], Connelly cgl. appears to give way to shaly lss. exactly resembling those of underlying Port Ewen, but having a strongly Oriskany fauna, and it is suspected these are = Barrett's *Dalmanites dentatus* zone, herein designated provisionally by the name *Port Jervis*.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 62 and chart). *Port Jervis ls.*—For Ulster Co. the term *Connelly* (1908 Chadwick) has been used to indicate the basal cgl. [of Oriskany ss.] and *Glenerie* (1908 Chadwick) the overlying ls. For Orange Co. *Port Jervis ls.* (1908 Chadwick) has been suggested for the lower div., with *Dalmanites dentatus*, while the upper div., specially characterized by *Spirifer murchisoni*, is as yet without name.

Named for occurrence at Port Jervis, Orange Co.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 381). *Port Jervis ls.* (*Dalmanites dentatus* zone) contains a mingled Helderbergian and Oriskanian fauna. [But she includes it in Oriskany, where it has been included for many years.]

Port Lambton beds.

Devonian: Ontario.

C. R. Stauffer, 1915 (Canada Geol. Surv. Mem. 34, p. 13), and W. Malcolm, 1915 (Canada Geol. Surv. Mem. 81, p. 44).

Portland clays.

C. H. Hitchcock, 1861 (Rept. geol. Maine, pp. 275–282), referred to clays at and around Portland, Maine, as *Portland clays.*

Portland series.

Pre-Carboniferous: New Brunswick.

G. F. Matthew, 1863 (Canadian Nat., vol. 8, pp. 244, 246).

†Portland quartzite.

Pre-Cambrian (middle? Huronian): Central southern Wisconsin (Dodge County).

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, pp. 252–256). *Portland qtzite.*—Outcrops in several places in town of Portland, Dodge Co.

Same as Waterloo qtzite.

Portland group.

Pre-Cambrian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 189).

†Portland shale.

Upper Devonian: Western New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 24 and chart). The Dunkirk sh. of the Portage of Lake Erie section is underlain by Angola sh. and overlain by *Portland sh.*

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1019–1029). Lake Erie section of Portage group is divided into (descending): Laona ss.; *Portland gray shales* with concretions and few flags and frequent layers of black sh.; Dunkirk black sh.; Silver Creek light soft shales; Angola soft shales with concretions.

J. M. Clarke, 1904 (N. Y. State Mus. Mem. 6, pp. 199–214). Portage of Erie and Chautauqua Counties divided into (descending): Laona ss.; Portland light-colored shales and thin flags, 282 ft.; Dunkirk black band, 58 ft.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 78). The Gardeau fm. is recognized as far W. as Lake Erie, where it includes at base the Dunkirk sh. The term "Portland" has been used locally to designate certain sh. and flags lying above the Dunkirk sh. As this term is preoccupied and it is now evident that these beds are embraced in the upper Gardeau, the name *Gardeau* will be used to include these beds. [Hartnagel's 1912 chart, however, shows *Gardeau flags* of western N. Y. as overlying Dunkirk sh.] Assigned to Portage group.

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157). In Lake Erie section *Gowanda beds* replaces Portland beds, which is "preoccupied and withdrawn." Overlie Dunkirk black sh. and uncon. underlie Laona ss. Assigned to Chemung. [See under *Gowanda sh.*]

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, pp. 149–157). [See 1924 quotation under *Dunkirk sh.*]

Probably named for exposures at Portland, Chautauqua Co.

†Portland division (of Selma chalk).

Upper Cretaceous: Alabama.

E. A. Smith, 1903 (58th Cong., 1st sess., S. Ex. Doc. 19, pp. 12–20 and map). *Upper or Portland div. (of Selma chalk).*—Highly argill., from 25 percent upward of clayey matter, some strata being calc. clays or marls containing many fossils, mainly oysters. Along Tombigbee River from Pace's Landing nearly to Moscow, and along Alabama River from Elm Bluff to Old Lexington Landing. It consists of dark-colored fossiliferous clays alternating with lighter-colored and somewhat more indurated ledges of purer, less argill. rock. Top part of Selma chalk. Overlies Demopolis div. of Selma and underlies Ripley fm.

Later workers did not find it feasible to make the 3 subdivisions of the Selma indicated in above rept, and the names have been discarded. (See Ala. Geol. Surv. Rept. No. 14, 1926, p. 239.)

Named for exposures at Portland, Dallas Co.

Portland stone.

Carboniferous: Indiana.

T. C. Hopkins, 1895 (Ind. Dept. Geol. 20th Ann. Rept., p. 306). The Carbf. ss. quarried at Worthy, Vermilion Co., Ind., is known on market as *Portland stone*. Is quarried by Portland Stone Co. Belongs to Coal Measures at a horizon above that of Mansfield stone.

Portland moraine.

Pleistocene (Wisconsin stage): Central Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Portland, Ionia Co.

Portland delta gravels.

Name applied to the Pleist. gravels filling lower Willamette Valley around Portland, Oreg. (See J. P. Buwalda and B. N. Moore, Carnegie Inst. Wash. Pub. 404, 1930, pp. 21–22.)

See also under *Satsop fm.*

Portland Point member. (In Moscow shale.)

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 218, 229, etc.). *Portland Point ls. memb. of Moscow fm.*—Basal beds of Moscow fm. in Cayuga Lake region. Is Second Terebratula zone of Cleland (1903), who published an extensive fauna from it. It has a 1-ft. bed of crinoidal ls. at base, which is followed by alternations of calc. sh. and ls. for about 8½ ft. Traced to E. the basal crinoidal ls. bed becomes a shell breccia, which is seen last at Lebanon, Morrisville quad., where it is only a few in. thick. Upper beds become sandier and homogeneous to E. and can be traced with certainty as far as Sherburne and less certainly into Unadilla Valley. West of Cayuga Lake on Kashong Creek at Seneca Lake the Portland Point consists of a hard light-gray basal ls. followed by 8 ft. of sh., capped by 1 ft. of shaly ls. containing *Centronella impressa* and *Rhipidomella vanuxemi* in some abundance. At Menteth Point, on Canandaigua Lake, the basal ls. is separated from thin ls. beds containing *Centronella impressa* by 15 ft. of sh. West of Canandaigua Lake this association could not be continued because the *Centronella* beds disappear in this direction. The basal ls., however, is *Menteth ls.* of Clarke and Luther (1904), which can be followed W. to Darien and Bullis Bridge. The Menteth and associated beds are correlated with Portland Point memb., although there may be some doubt as to whether the Menteth or the upper *Centronella* beds correlate with basal crinoidal ls. in Cayuga Lake region. The Menteth ls. can be traced W. into Genesee Valley and beyond, where it forms base of the Moscow. In its extent westward this ls. approximates stratigraphically the Tichenor ls. horizon. At Canandaigua Lake it is 55 ft. above Tichenor ls., at Jacox Run (in Genesee Valley) it is only 9 ft. above, and at Hill's Gulch, 5 mi. S. of LeRoy, it is 3 ft. above the Tichenor; at Darien and Bullis Bridge it is uppermost thin noncrinoidal ls. capping the Tichenor. The Menteth was not identified definitely at Spring Brook and Windom. In Livonia salt shaft it appears 416 ft. below surface. Named for excellent exposures at Portland Point (formerly Shurger Point), Cayuga Lake. The name *Deep Run memb.* is proposed for the brittle bluish sh. that lies btw. the underlying Tichenor ls. and the Menteth ls. of Portland Point memb. in Deep Run Ravine, near Cottage City, Canandaigua Lake.

Port Nelson limestone.

Silurian: Manitoba (Hudson Bay).

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 342, 345, 355, 367).

Portneuf limestone. (Of Thaynes group.)

Lower Triassic: Southeastern Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492). *Portneuf ls.*—Top fm. of Thaynes group in Fort Hall Ind. Res. Thickness 1,500± ft. Overlies Fort Hall fm.

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 32, 38). *Portneuf ls.*—Siliceous cherty gray to yellowish ls. in massive beds; rounded elongated nodules and streaks of chert; fossiliferous. Thickness 1,500± ft. Top fm. of Thaynes group in Fort Hall Ind. Res. Underlies Ankareh [now called Timothy] ss. and overlies Fort Hall fm. Named for Portneuf River, at head of which it is well exposed.

Port Renfrew series.

Age (?): Vancouver Island.

C. W. Hall, 1906 (Postelsia, p. 324).

Portsmouth conglomerate.

Carboniferous: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 328–329). *Portsmouth cgls.*—Coarse cgls. exposed near Portsmouth Grove Station, also in Portsmouth camp-meeting grounds and elsewhere in that region.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped Purgatory cgl. over area described.

Portsmouth member. (In Black Hand formation.)

Mississippian: Southern Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 758). *Portsmouth memb.*—Upper sh. memb. of Cuyahoga fm. in central Ross, Pike, and Scioto Counties. Thickness 253 ft. Equivalent to Churn Creek, Vanceburg, and Barden members of SW. part of Scioto Co. Overlies Buena Vista ss. memb. ("City Ledge") and underlies Logan fm. Upper 50 ft. or more of Portsmouth shales at Portsmouth are stratigraphically=lower part of Byer memb. of Logan fm.

J. E. Hyde, 1921 (Ohio Geol. Surv., 4th ser., Bull. 23). *Portsmouth memb. of Logan ss.*, 170 ft. of soft gray clay sh. Is=Byer, Allensville, and probably part of Vinton ss. to E.

Named for Portsmouth, Scioto Co.

Portuguese tuff bed. (In Monterey shale.)

Miocene (middle): Southern California (Palos Verdes Hills).

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 131). The thick bentonitic tuff at top of lower div. of Altamira sh. memb. (basal div. of Monterey sh.) is here named *Portuguese tuff bed*, from Portuguese Bend, on S. coast. Type region is along Portuguese Canyon, where the tuff is 55 ft. thick.

†Portville conglomerate.

Devonian or Carboniferous: Southwestern New York.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 83). The *Portville cgl.* on the hills about Portville, N. Y., was mentioned and named by James Hall (Surv. of 4th geol. dist., Nat. hist. of N. Y., vol. 4, 1843 [page not cited]) and later described by Williams 4 pages after he described Wolf Creek cgl. The *Portville cgl.* is a synonyn of the Wolf Creek because of inadequacy of Hall's definition, page priority of name Wolf Creek in H. S. Williams' paper (U. S. G. S. Bull. 41, 1887, p. 86 vs. p. 90).

The compiler has been unable to find the page in vol. 4, 1843, where Hall used the name "Portville cgl.," but finds that Williams did not use the name. He simply described, under the heading "Portville, Cattaraugus Co., N. Y., 486," the cgl. at that place, which he stated was without doubt the Wolf Creek cgl., described on p. 86. The first use of the name *Portville cgl.* therefore appears to be that of Caster, 1934. On p. 79 of book cited above, Caster stated Wolf Creek cgl. is well shown in vicinity of Portville village and on Wolf Run, near Portville, in Olean quad.

K. E. Caster, 1936 (letter dated Oct. 29). I cannot now find that Hall used *Portville cgl.*, and on rereading Williams' 1887 paper I do not think I would now credit him with applying the name in a strat. manner, although the name is implied throughout his discussion of Portville, Cattaraugus, Co., N. Y. It appears that item "K" on p. 83 of my 1934 paper is incorrect.

Port Washington stage.

Pleistocene: Southeastern New York (Long Island).

J. B. Woodworth, 1901 (N. Y. State Mus. Bull. 48, pp. 621–663 and map, pl. 1). The first definite trace of a halt in ice front after retreat from the main moraine [in Nassau Co. and Borough of Queens, Long Island] is found on northern and western extremity of Manhasset Neck, near Port Washington; hence the ice-laid and the water-laid drift of this episode are here assembled under the name *Port Washington stage of ice retreat*. Some of deposits lying S. of this line and yet N. of the moraine, as in plain N. of Greenvale Station, may constitute an intermediate series of deposits. Included in Wisconsin epoch.

Porus formation.

Pleistocene or Pliocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 85).

Posideon shale member. (In Graford formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 48–50, map). *Posideon sh.*, basal memb. of Graford fm. in Palo Pinto Co. Consists of 50± ft. of dark-gray soft sandy to calc. fossiliferous sh. containing thin layers of ls. Underlies Wiles ls. memb. and overlies Palo Pinto ls. Typically exposed above the Palo Pinto ls. in vicinity of Posideon, Palo Pinto Co.

Poso Creek sand.

Miocene: Southern California (Kern County).

A. Diepenbrock, 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, p. 14 and pl. 2). The upper bed of so-called Santa Margarita fm. in Mount Poso oil field, NE. of Bakersfield, Kern Co., consists of fine, silty, fairly well sorted to well-sorted gray sand of marine origin, which has been locally called *Poso Creek sand*. It rests on a bed of brownish-gray and brown micaceous sandy siltstone containing fish remains, etc.

Possum sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

M. I. Goldman, 1920 (U. S. G. S. Bull. 686W, pp. 330, 332). *Possum ss.*—The first ss. of prominence below Cheshewalla ss. in T. 29 N., R. 11 E., being separated from the Cheshewalla by 75 to 100 ft. of sh. containing several lenticular sss. which together occupy 50± ft. of the interval. The Possum ss. is therefore=part of Revard ss., probably lying at or near top of that ss. In W. part of its area it is a soft massive bed, the freshly broken surface of which shows some discontinuous bedding lines, and is generally covered with rusty or blackish specks as much as ⅛ in. diam. To E., in sec. 32, T. 29 N., R. 12 E., the bed thins abruptly, changes to a hard, platy greenish limy or sideritic ss. a few inches thick, and within a few ft. disappears entirely. Named for occurrence as a prominent ledge along sides of Opossum Creek, in SE. cor. of T. 29 N., R. 11 E.

Possumtrot shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 414). *Possumtrot sh.*—Dark sandy deposit, with streaks of ss. and with plant fossils. Thickness 4 to 25 ft. Underlies Raines Corner coal and overlies Droop ss.; all members of Bluefield group [fm.]. Type loc. on W. side of Indian Creek 1.6 mi. NE. of Raines Corner and slightly N. of Possumtrot Branch, in Monroe Co. Observed in Mercer and Summers Counties, W. Va., and in Giles Co., Va.

†Posterior trap.

†Posterior sandstones and shales.

Descriptive terms applied in early repts to an upper part of Newark group in Conn.

†Postmedidial series.

Nongeographic name applied by H. D. Rogers (Am. Jour. Sci., 1st, vol. 47, pp. 153–158, 1844) to include Chemung group to Marcellus sh., both inclusive.

of Appalachian region. Abandoned by Rogers in his 1858 classification (Geol. Pa., vol. 1, pp. 59, 104–109; vol. 2, pt. 2, pp. 751–775).

Named to indicate "sunset period of the great Appalachian Palaeozoic day," according to Rogers, 1844 citation above.

†Post-Meridian series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 107, 273+, and vol. 2, p. 755). Divided into *Post-Meridian ls.* (Upper Helderberg or Corniferous ls. of N. Y.), 80 ft. thick in NE. Pa.; and *Post-Meridian grits* (*Cauda-Galli and Schoharie grits of N. Y.*), 300 ft. thick NE. of Delaware Water Gap.

Potapaco clay member (of Nanjemoy formation).

Eocene: Eastern Maryland and Virginia.

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Potapaco memb. or substage.*—Greensand, often very argill. and at times gypseous, forming basal memb. of Nanjemoy fm. Underlies Woodstock memb. or substage of Nanjemoy fm. and overlies Aquia fm. Thickness 60 to 65 ft. Potapaco is early name of Port Tobacco Creek, a corruption of word Potapaco, found on Smith and other early maps.

W. B. Clark and B. L. Miller, 1912 (Va. Geol. Surv. Bull. 4, p. 104). *Potapaco clay memb.*—Basal memb. of Nanjemoy fm. Underlies Woodstock greensand marl memb. and overlies Aquia fm.

Potato sandstone.

Miocene probably: Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 374–375, and map). *Potato ss.*—Very hard ss., entirely different from any other rock in dist. For most part is a well-bedded coarse angular arkose with angular boulders of schist and granite. A yellowish variety predominates, but there are also finer greenish and some red varieties. A few thin beds of sh. are found btw. the ss. strata. Bedding varies in thickness from a few in. to more than 30 ft. Age not definitely determined. The intense shearing and induration indicate it is older than Hathaway fm. and Santa Ana ss. Believed to be younger than Saragossa qtzite, but relations are obscure. Tentatively considered Mio. Resembles Puente ss., of Mio. age.

Named for Potato Canyon, San Bernardino Co. Forms the part of the ridge btw. Potato Canyon and Mill Creek E. of Wilson Creek.

†Poteau stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51), and H. M. Chance (idem, p. 52). *Poteau stage* as defined by Winslow is top div. of Coal Measures of Ark. and consists chiefly of sh., 3,300 to 3,900 ft. thick, containing several coal beds, that mined at Huntington and neighboring localities in NW. Ark. being most important and near the base. Overlies Sebastian stage, top memb. of which is Greenwood ss. As described by Stevenson the Poteau stage is top div. of Coal Measures along Choctaw, Oklahoma & Gulf Ry in Ind. Ter.; consists of sss., shales, and coals, over 5,000 ft. thick; overlies Tomlinson stage (top memb. of which is a ss. 50 ft. thick [Greenwood ss. of Winslow]); and it includes Secor coal bed 30 ft. above base.

Probably named for Poteau Mtns, Le Flore Co., Okla., and Sebastian Co., Ark.

Potem formation.

Middle and Lower Jurassic: Northern California (Redding quadrangle).

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Potem fm.*—Sss., shales, and tuffs. Thin-bedded sss. and gray, sometimes slaty shales predominate in lower part and make up greater portion of fm. They are more or less calc. and contain a few small lentils of ls. Tuffaceous cgls. occur sparingly in lower half of fm., but in upper part are most abundant—in fact, nearly all sediments of this part are of igneous material, some of which may have been furnished by contemp. volcanic activity, but most of it was derived by ordinary processes of erosion from a wide expanse of volcanic rocks. Must be at least several thousand ft. thick [2,000± in columnar section]. Regarded as=Hardgrave ss. and most likely the Mormon ss. also. Underlies Chico fm. and overlies in places Bagley andesite and in other places rests, probably conformably, on Modin fm. [See also under *Bagley andesite*.] Named for development on Potem Creek, Shasta Co.

Potlatch anhydrite formation.

Devonian (Upper or Middle): Central northern Montana (Sweetgrass arch, north of Great Falls region).

E. S. Perry, 1928 (Mont. State Bur. Mines and Geol. Mem. 1, pp. 4–6). *Potlatch anhydrite fm.*—Alternating and interbedded sh., anhydrite, gyp., dol., ls., with 20 ft. of rich oil sh. at top; is mainly anhydrite. Thickness 940 ft. The anhydrite and gyp. are compact massive pearl-gray, sometimes cleavable, also irregularly associated with dol. giving mottled appearance. Assigned to Dev. Is probably about=Jefferson fm. Underlies Madison ls. Overlies 300 ft. of light-gray ls. of undet. age. Lies at about 2,500 ft. depth on top of Sunburst dome. Name derived from fact complete section of the fm. is shown by cuttings of Potlatch-Adams No. 1 deep well on sec. 21, T. 34 N., R. 1 W.

P. D. Moore, 1931 (A. A. P. G. Bull., vol. 15, No. 10, pp. 1151–1152). Perry suggests it seems best to classify this as about=Jefferson fm., but Romine and Lebkicher place it definitely in the Threeforks. Writer favors latter opinion.

Potomac group.

Lower Cretaceous: Maryland, Delaware, and Virginia.

W J McGee, 1886 (Rept. Health Office D. C., 1885, pp. 19–21; also Am. Jour. Sci., 3d, vol. 31, pp. 473–474). *Potomac fm.*—Fine homogeneous plastic clay, sand, coarse and fine gravel, with occasional boulder beds. Forms surface E. of a line crossing Potomac River near Chain Bridge and passing a little E. of Brightwood, except where cut through by gneiss. Is known to extend from Baltimore to Washington, thence southward through Fredericksburg and Richmond to Petersburg, Va. Underlies Columbia fm. and uncon. overlies the gneiss.

W J McGee, 1888 (Am. Jour. Sci., 3d, vol. 35, pp. 120–143). *Potomac fm.* is of Mid-Cret. to earliest dawn of Cret. or closing episodes of Jurassic. The upper memb. is 350 ft. thick, and probably corresponds to Raritan clays of N. J. It rests uncon. on lower memb., which is 250 ft. thick. The Potomac is uncon. overlain by upper Cret. N. of the Patapsco, and in other areas is overlain by different fms. to and including Columbia fm. Usually rests on crystalline rocks.

Subsequently the Potomac (nonmarine) was raised to rank of a group, separated into 4 fms., named (descending) Raritan, Patapsco, Arundel, and Patuxent. Further study by W. B. Clark proved Raritan fm. to be Upper Cret. and the other 3 fms. to be Lower Cret., and Raritan fm. was excluded from Potomac group. This is present commonly accepted definition of Potomac group.

†Potomac marble.

A ls.-cgl. lentil in Newark group (Upper Triassic) has for many years been quarried for ornamental stone, especially near Point of Rocks, Md., under trade name of "Potomac marble." W. B. Rogers referred to it in 1840 (Rept. Prog. Geol. Surv. Va. for 1839, p. 72) as "the well-known *Potomac marble*." In southern Pa. it grades laterally into Arendtsville fangl. lentil of Gettysburg sh.

Potosi dolomite.

Upper Cambrian: Eastern and central Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 351, 355). *Potosi ls.*—Ls. containing chert and drusy quartz, constituting country rock about Potosi, Mo. Underlies Crystal City [St. Peter] ss. and overlies St. Joseph ls. Is upper part of St. Francois ls. [This definition was followed by Winslow, 1895 (Am. Geol., vol. 15, pp. 81–89). In 1896 (U. S. G. S. Bull. 132) he gave thickness of his *Potosi ls.* as 270 ft. This is a broad use of Potosi, corresponding to Potosi group of Bain and Ulrich, 1905.]

F. L. Nason, 1901 (Am. Jour. Sci., 4th, vol. 12, p. 358), divided the rocks uncon. above Bonneterre ls. in St. Francois Co., Mo., as follows (descending): (1) Potosi Residuary, 100 ft.; (2) *Potosi lss.*, 350 ft., consisting of cherty ls. at top, drusy quartz in middle, and shaly ls. at base; (3) Potosi slates and cgls., 106 ft.

H. A. Buehler, 1907 (Mo. Bur. Geol. and Mines vol. 6, 2d ser.). *Potosi* underlies Proctor and overlies Doe Run.

E. R. Buckley, 1908 (Am. Min. Cong. Rept. Proc. 10th Ann. Sess., p. 286). *Potosi* underlies Eminence and uncon. overlies Doe Run (top div. of Elvins).

E. R. Buckley, 1909 (Mo. Bur. Geol. and Mines vol. 9, pt. 1). *Potosi fm.* restricted to the siliceous cherty and drusy dol., 300 ft. thick, underlying Eminence fm. and uncon. (?) overlying Doerun fm. (upper part of Elvins fm. of Ulrich). Consists of massive dol. and thick chert alternating. [This is accepted definition of *Potosi ls.* in subsequent repts of Mo. geologists, and is the one followed by U. S. Geol. Survey, which now classifies the fm. as Upper Camb.]

Named for Potosi, Washington Co.

†Potosi group.

Upper Cambrian and Lower Ordovician: Southeastern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 351, 355), used *Potosi ls.* [See 1894 entry under *Potosi dol.*]

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bulls. 260, 267). *Potosi or Yellville group.*—Includes all rocks btw. base of St. Peter ss. above and top of Elvins fm. below. Is characterized by large quantities of chert and drusy quartz.

Discarded in favor of more restricted and useful name *Potosi dol.* Includes fms. of Upper Camb. and Lower Ord. age.

Potosi volcanic series.

Miocene: Southwestern Colorado.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). *Potosi rhyolitic series*—Alternation of rhyolite flows and tuffs, former predominating near base; some of thin upper flows are glassy; a thin augite andesite sheet occurs btw. rhyolite flows in lower part; at base few to 100+ ft. of coarse-grained tuff or flow breccia, gray or light red. Thickness 1,300+ ft. Overlies Intermediate series [later named Silverton volcanic series].

W. Cross and E. Howe in 1905 (U. S. G. S. Silverton folio, No. 120) changed name to *Potosi volcanic series*. In Creede dist. the series is now divided into Piedra group above and Alboroto group below.

W. Cross and E. Howe, 1907 (U. S. G. S. Ouray folio, No. 153), introduced *Henson tuff* for uppermost fm. of Silverton volcanic series, and stated that in Silverton folio the upper part of Henson tuff was included in overlying Potosi volcanic series and lower part in underlying pyroxene andesite, which was then called uppermost fm. of Silverton volcanic series.

Named for Potosi Peak, Silverton quad., where upper several hundred ft. is present.

†Potosi Residuary.

Upper Cambrian: Eastern Missouri.

F. L. Nason, 1901 (Am. Jour. Sci., 4th, vol. 12, pp. 358–361). *Potosi Residuary.*—Residuary Potosi clay with drusy quartz, 100 ft. thick, overlying Potosi ls. (cherty ls. at top, drusy quartz in middle, and shaly ls. at base) in St. Francois Co.

J. Bridge, 1930 (personal communication). Corresponds to part of Eminence and part of Potosi of present nomenclature.

†Potosi slates and conglomerates.

Upper Cambrian: Eastern Missouri.

F. L. Nason, 1901 (Am. Jour. Sci., 4th, vol. 12, pp. 358–361). *Potosi slates and cgls.*—Fossiliferous slates, interbedded with cgls., 100 ft. thick, with basal ls. cgl., 6½ to 10 ft. thick, the disks of ls. in which lie edgewise. Typically exposed near Elvins. Uncon. overlies Bonne Terre or St. Joseph ls. and underlies Potosi lss. (cherty ls. at top, drusy quartz in middle, and shaly ls. at base) in St. Francois Co.

Same as Elvins fm. of present nomenclature.

Potsdam sandstone.

Upper Cambrian: Central and eastern New York.

E. Emmons, 1838 (N. Y. Geol. Surv. 2d Rept., pp. 214–217, 230), described the rocks of St. Lawrence Co., NW. N. Y., as consisting of (descending) calciferous sand rock, transition ls., *ss. of Potsdam* [heading], and primary strata. The *ss. of Potsdam* (in St. Lawrence Co.) he described as a true ss., of red, yellowish-red, gray, and grayish-white colors, made up of grains of sand and held together without a cement; "intermixed with the siliceous grains are finer particles of yellowish feldspar." In one place on p. 217 he called it *Potsdam ss.* On p. 230, under heading "sandstone of Essex," he said: This I consider the same fm. I have described under the name of *Potsdam ss.*

In 1842 (Geol. N. Y., pt. 2) Emmons stated: "In consequence of Potsdam ss. presenting two quite distinct varieties, one well developed at Potsdam and the other at Keeseville [St. Lawrence Co., NW. N. Y.], I have sometimes given it a compound name—the *Potsdam and Keeseville ss.*; for reason that at former place a beautiful granular variety exists, and at latter place a harder and more crystalline mass predominates which resembles the granular quartz of the Taconic system." He also called attention to granitic cgl. forming basal bed of Potsdam ss., and stated that at Potsdam the fm. is 60 to 70 ft. thick. In 1846 Emmons stated thickness of Potsdam ss. as 0 to 300 ft.

For many years the name *Potsdam ss.* continued to be applied to the rocks btw. †Calciferous ss. [Beekmantown] and †Primary strata, and the use of this N. Y. name was extended over a large part of the country. In 1859 (Pal. N. Y., vol. 3, pt. 1) James Hall stated that "it presents a uniform, even monotonous, physical character over the wide areas in which it has been investigated in N. Y., Canada, Pa., Va., Iowa, Wis., and Minn." In 1863 he stated: In final nomenclature of N. Y. geologists *Potsdam ss.* was adopted for lowest stratified rock of the series known to contain fossils. In 1883 (Am. Ass. Adv. Sci. Proc., vol. 31, pp. 40–63) he called attention to wide distribution of Potsdam ss. and said that it is everywhere marked by ripple marks. In 1890 (Geol. Soc. Am. Bull., vol. 1) Brainerd and Seely stated that Potsdam ss. of Champlain Valley consists of mag. ls. and ss., 170 to 200 ft. thick, carrying a peculiar fauna. In 1894 (N. Y. State Mus. 47th Ann. Rept., pp. 669–683) H. P. Cushing stated that 400 ft. of Upper Camb. Potsdam ss. is exposed in Champlain and Beekmantown Twps, N. Y. In 1895 (Geol. Soc. Am. Bull., vol. 6, pp. 285–296) Cushing stated that Potsdam ss. of Chazy Twp, Clinton Co., N. Y., consists of more than 350 ft. of massive beds of ss., of red, white, or yellow-brown color and varying degree of induration, with cgl. and arkose at base, and at top *passage beds* lithologically distinct from †Calciferous above and from Potsdam beds below. In 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1, pp. 503–574) Cushing gave thickness of Potsdam ss. as 350 to 2,000+ ft., and stated that while upper part is Upper Camb. it is far from certain the whole of it is Upper Camb.; that main mass of fm. is quite pure quartz sand, with large feldspathic content in basal layers, with basal cgl., and toward summit interbedded with dolomitic layers or beds of pure sandy dol., forming passage beds to †Calciferous. In N. Y. State Mus. 51st Rept., pt. 1, pp. 137–180, 1899, F. J. H. Merrill stated that the *Potsdam* is 70–333 ft. thick, consists of ss. around the Adirondacks and of correlated lss. in Dutchess, Washington, and Saratoga Counties, with a coarse cgl. at base at a few places. The same year (Sci., n. s., vol. 10, pp. 874–878) J. M. Clarke and C. Schuchert stated that the Potsdam consists of ss. and ls.

In 1901 (N. Y. State Mus. 53d Ann. Rept., pt. 1, pp. r39 to r69) H. P. Cushing removed from top of Potsdam ss. of Clinton Co., N. Y., the "passage beds" (consisting of btw. 500 and 600 ft. of alternating layers of dol. and ss.), and restricted *Potsdam ss.* to 800 or 900 ft. of beds of very uniform character, mostly coarse grit, white or buff, in massive beds, much of it cross-bedded and ripple-marked, with very coarse cgls. at base.

In 1902 (N. Y. State Mus. Bull. 52) G. Van Ingen stated thickness of *Potsdam ss.* in Lake Champlain Basin (SE. Clinton Co. and NE. Essex Co., N. Y.) to be 455 to 1,150 ft., the "transition beds" at top not being present. Upper Camb. fauna in upper part.

In 1903 (N. Y. State Mus. Hdb. 19, p. 12) J. M. Clarke stated: On E. slope of Adirondacks the sand deposits of the Potsdam pass upward without break into the dolomites of Beekmantown fm., and Schaghticoke shales with *Dictyonema flabelliforme* are conformable with shales of both earlier and later date, but mark the top of the Cambric in the sh. facies. In Saratoga Co. the shore deposits of Potsdam ss. are overlain by heavy beds of ls. (*Greenfield ls.*). The Cambric or Neelytown lss. [shown on chart as underlying Schaghticoke sh.] of Orange Co., which constitute a part of Kittatinny ls. series of N. J., are deeper-water deposits of similar character.

According to H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95), the upper 350 ft. of Potsdam ss. (beneath the passage beds) has been shown by Walcott and Van Ingen to carry a sparse Upper Camb. marine fauna, while lower part contains no fossils and may possibly be older than Upper Camb.

In 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 155+) H. P. Cushing introduced *Theresa fm.* for the "passage beds" at top of Potsdam ss., which he defined as consisting of 20 to 70 ft. of somewhat calc. sandy dolomites, with interbedded weak sss., especially near base, and drew line btw. Potsdam ss. as thus restricted and Theresa fm. at base of first dol. layer. The *Theresa fm.* (named for Theresa Twp. Jefferson Co., N. Y., "in which it is exposed in its entirety") he stated is uncon. overlain by Pamelia ls., of Chazy age. (See also J. M. Clarke, N. Y. State Mus. Bull. 121, pp. 11–13, 1908.) In 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 780–781) E. O. Ulrich and H. P. Cushing excluded the passage beds from Potsdam ss. but did not apply any name to them in Mohawk Valley, N. Y., where they are overlain by Little Falls dol. The same year J. M. Clarke (N. Y. State Mus. Bull. 140, pp. 11–12) mapped (in Broadalbin quad., Fulton and Saratoga Counties, N. Y.), under the name *Galway fm.*, a series of distinctly transitional beds btw. Potsdam ss. and Little Falls dol. On p. 99 of same bulletin E. O. Ulrich and H. P. Cushing replaced *Greenfield ls.* (preoccupied) with *Hoyt ls.*, which they treated as a local basal memb. of Little Falls dol. and as overlying *Theresa fm.* or "passage beds" in Mohawk Valley, the name *Theresa fm.* being applied to apparently the same beds that Clarke named *Galway fm.* In N. Y. State Mus. Bull. 145, 1910, Cushing described Potsdam ss. of Thousand Islands region as 100 ft. thick, consisting of red, white, and buff quartz ss., with 0 to 20 ft. of coarse cgl. at base, and overlain by Theresa dol. (consisting of 35 ft. of blue-gray sandy mag. ls. with beds of weak ss., "constituting division A of Brainerd and Seely's Beekmantown, but not Beekmantown").

In 1911 (Geol. Soc. Am. Bull., vol. 22) E. O. Ulrich assigned Little Falls, Hoyt, Theresa, and Potsdam fms. to Saratogan epoch of his Ozarkian system. But all N. Y. State Geol. Surv. and Canada Geol. Surv. publications up to 1926, inclusive, continued to classify Potsdam ss. as Camb. In 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, p. 469) C. D. Walcott recognized Ulrich's Ozarkian as a distinct system, and assigned to it the same N. Y. fms. that Ulrich assigned to it, but he stated (p. 469) that fauna of Hoyt ls. and upper part of Potsdam ss. is comparable with that of lower Mons of Alberta, and (p. 470) that fauna of lower Mons is "predominantly Upper Cambrian."

In 1915 (Geol. Soc. Am. Bull., vol. 26, pp. 289-291) G. H. Chadwick described "*Upper Potsdam*" (*Keeseville?*) as white ss., and the underlying *typical Potsdam sss.* as mostly red, the former being overlain by *Theresa mixed beds or fm.* In 1916 (N. Y. State Mus. Bull. 191) H. P. Cushing included the white ss. in Potsdam ss. of Ogdensburg and adjacent quads. In 1919 (N. Y. State Mus. Bull. 213, 214) W. J. Miller stated that Potsdam ss. (underlying Theresa fm.) is well represented in St. Lawrence, Champlain, and Mohawk Valleys; that in SE. Adirondacks it extends, as outliers, as far as Wells (Hamilton Co.), North River (Warren Co.), and Schroon Lake (Essex Co.), and that it is oldest Camb. fm. in northern N. Y., where Middle and Lower Camb. are unknown. The same year H. I. Alling stated (N. Y. State Mus. Bull. 207, 208) that "white Potsdam" ss. is *Keeseville ss.* of many geologists. In 1920 G. H. Chadwick doubtfully identified "white Potsdam" ss. as *Keeseville ss.*, and stated that possibly there is an uncon. btw. it and the underlying *typical red Potsdam ss. and cgls.*

In 1925 (N. Y. State Mus. Bull. 259, pp. 49-50) H. P. Cushing and D. H. Newland stated: From Potsdam W. to Clayton the Potsdam ss. is rather thin, and in places where the Precambrian floor was highest on the granites and garnet gneisses, for example, it may entirely fail, and Theresa fm. lie on Precambrian. East of Potsdam the fm. rapidly thickens by the successive addition of beds at base. In other words, the thin fm. present from Potsdam to Clayton represents only summit of the fm. as it occurs more to eastward. This upper part consists largely of somewhat calc., not extra-resistant ss., of brown or white color, carries marine fossils sparingly, and seems an unquestionably marine fm. The ss. found in these residual patches in Gouverneur quad. differs from above in color and in being very vitreous and hard and noncalc. except locally when in immediate contact with ls. Angular blocks of hard red ss. are also found as pebbles in the basal cgls. The phenomena are quite as they are in Thousand Islands region and, as shown in rept on that dist., suggest that this lower, hard ss. is materially older than the ordinary Potsdam of the region, although it is not thought to be older than basal part of Potsdam ss. of Clinton Co. It also seems to be a nonmarine fm. The evidence is not yet clear, however, as to precise significance to be attached to observed phenomena. It is quite certain that the deposit of the sand in these hollows of the old surface was not immediately followed by the sands which form the general Potsdam of the region, but that a time interval lay between. Whether this was a long interval, or a comparatively short one, is at present not known. Writer is of opinion the older sand here is approx.=basal part of fm. as it appears in Clinton Co., and that the other, in like manner, is=the summit, and that there is nothing here equiv. to middle div. of fm. in Clinton Co. It is quite possible, however, that there is a break btw. the lower and middle divisions of fm. there, and the whole fm. is very thick, at least 1,290 to 1,500 ft. There is at hand today very little direct evidence in substantiation of the above opinion. The general Potsdam of this NW. area is very thin and is unquestionable equiv. of extreme summit of the fm. in Clinton Co. The precise age of the basal sands of these hollows is an entirely open question.

The early practice of applying the name *Potsdam ss.* to any ss. or sss. occupying a somewhat similar strat. position in the Middle States has in recent years been questioned, and present tendency of geologists is to treat Potsdam ss. as a local (N. Y. and southern Canada) fm. The U. S. Geol. Survey now classifies the Potsdam ss. as *Upper Camb.*

†Potsdam period.

A term applied in some early repts to †Calciferous sandrock (Beekmantown) and underlying Potsdam ss.; also to Upper Cambrian epoch of America.

†Potsdam group.

A term applied in some early repts to Potsdam ss., and also to Upper Cambrian series.

†Potsdam limestone.

A term applied in some early repts to dolomitic beds formerly included in top of Potsdam ss. but later separated and named *Theresa fm.* (See under *Potsdam ss.*) In 1886 (Am. Jour. Sci., 3d, vol. 31, pp. 125–133) W. B. Dwight applied *Potsdam ls.* to 300 ft. of aren. ls. and dol. in Dutchess Co., N. Y., later (1927) identified by E. B. Knopf (from contained fossils) as Hoyt dol. and described as overlain by Rochdale ls. (of Beekmantown age) and underlain by Stissing ls. (of Middle? and Lower Camb. age).

†Potsdamian.

†Potsdamic.

Names applied in some early geologic repts to Upper Cambrian series. See U. S. G. S. Bull. 769, pp. 94–97.

†Pottawatomie formation.

Pennsylvanian: Eastern Kansas.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 92–94). *Pottawatomie fm.*—Group of strata well limited stratigraphically by [top of] Pleasanton shales below and [base of] Lawrence shales above.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), divided *Pottawatomie fm.* into Kansas City, Lansing, and lower part of Douglas fms., and the name has now been abandoned by Kans. Geol. Surv. R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 76), stated that Pottawatomie fm. of Haworth, 1898, extended from base of his (Moore's) 1936 Bronson group to top of his 1936 Lansing group.

Named for Pottawatomie River, SE. Kans., "which rises near the Stanton ls., the uppermost one of the complex, and flows over the gently upturned edges of a number of the fms. here included."

†Pottawatomie series.

Pennsylvanian: Kansas, Missouri, Iowa, Nebraska, and Oklahoma.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Pottawatomie series* extends from uncon. at top of sh. overlying Iatan ls. down to top of Pleasanton sh. Underlies Virgil series and overlies Des Moines series.

R. C. Moore, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, pp. 279–280). [See this reference under *Virgil series.*]

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 88, 96), discarded *Pottawatomie series* and revived *Missouri series,* for the rocks btw. his Virgil series and Des Moines series.

Potter formation.

Tertiary (Pliocene): Panhandle of Texas.

L. T. Patton, 1923 (Univ. Tex. Bull. 2330, pp.78–80). *Potter fm.*—Coarsely stratified sand and gravel somewhat firmly cemented by calcium carbonate. Color slightly darker than overlying Coetas fm., being of reddish cast. Is strongly cross-bedded at many localities. These beds have been called "mortar beds," but it is not proposed to class all "mortar beds" as Potter fm., but only those beds that have a definite relation to overlying Pliocene Coetas fm. Thickness 78 to 100 ft. Characterized by large numbers of water-worn fossils, mainly *Gryphaea,* which have been weathered out of earlier fms. These fossils are not found in Coetas fm. Rests uncon. on Triassic and on Perm. rocks. Is either Plio. or pre-Plio. Tert.

It seems to be present opinion of most if not all workers that there is no Mio. in this part of Tex., and that the deposits of Llano Estacado are all Plio. They are mapped as *Ogallala fm.* (*Plio.*) on 1937 map of Tex.

Potter parvafacies.

Devonian or Carboniferous: Northern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 31). The red parvafacies of Catskill magnafacies may well be called *Potter parvafacies,* from red development of Venango stage in Potter Co., Pa. The next eastern facies development of Venango stage, which is within Tioga magnafacies, might appropriately be called *Elkland parvafacies,* from area about Elkland, Pa. This parvafacies was originally mistaken for eastern extension of Oswayo sh.

Potter Farm formation.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526). *Potter Farm fm.*—Blue to gray sh. alternating with crinoidal sublithographic or argill. lss. of small lateral extent, containing fauna characterized by *Cylindrophyllum.* Greatest measured thickness, 36 ft. Is middle fm. of Thunder Bay stage. Separated from overlying Partridge Point fm. by covered interval of 70 ft. Lies on Norway Point fm. Type loc., Fred Potter farm, E. half of secs. 18 and 19, and sec. 20, T. 31 N., R. 8 E., Alpena Co.

†Pottsboro subgroup.

Lower Cretaceous (Comanche series): Northeastern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 121, 247, 270, 280–288). *Pottsboro subgroup.*—Uppermost subgroup of Denison beds. Includes Grayson marls above (15 ft. thick) and Main Street ls. below (10 ft. thick). Overlies Pawpaw fm. and underlies Woodbine sand.

Named for Pottsboro, Grayson Co.

Pottstown shale. (In Newark group.)

Upper Triassic: Southeastern Pennsylvania (Bucks and Montgomery Counties).

B. S. Lyman, 1893 (Pa. Geol. Surv. geol. and topog. map of Bucks and Montgomery Counties) and 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, pp. 2589–2638). *Pottstown shales.*—Red shales with a few scattered green layers; 10,700 ft. thick. Overlie Perkasie shales and uncon. underlie Potomac sands. Exposed at Pottstown.

Corresponds to upper part of Brunswick sh. of Newark group.

Pottsville formation (also **Pottsville group**).

Pennsylvanian: Pennsylvania; southern Ohio, Indiana, and Illinois; Kentucky, Tennessee, northeastern Mississippi, Alabama, West Virginia, Virginia, and Maryland.

J. P. Lesley, 1876 (2d Pa. Geol. Surv. Rept. L, App. E, pp. 221–227). *Pottsville Seral cgl.* (*Millstone Grit, No. XII*), 59 ft. thick in Boyd's Hill gas well at Pittsburgh, Pa. Overlies Mauch Chunk Umbral Red sh. and underlies Lower Productive Coal Measures. [Type loc. not stated.]

C. A. Ashburner, 1877 (Am. Phil. Soc. Proc., vol. 16, pp. 520, 535). *Pottsville* (*Seral*) *cgl.* (*Millstone Grit, No. XII*).—*Pottsville* is new name proposed by present [Pa.] State Geologist [J. P. Lesley]. Underlies Allegheny River Coal

Measures and overlies Mauch Chunk red sh. Divided into Piedmont ss. (160 ft. thick) at top, Kanawha River Coal Series, and, at base, the Conglomerate proper (80 ft. thick).

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_2, p. xxiii). *Pottsville cgl. (Seral).*— Extends from base of Lower Productive Coal Measures to top of Mauch Chunk sh. Is No. XII of Rogers.

The U. S. Geol. Survey classifies the Pottsville in most areas as a *fm.* Where divided into two or more named and mapped major units, it classifies it as a *group* and the named subdivisions as *fms.* The present Pa. Geol. Survey classifies the Pottsville as a *series*. In anthracite coal field of NE. Pa. (the typical Pottsville region) the Pottsville fm. is 1,200 ft. thick, and three paleobotanic subdivisions of it have been recognized by David White and other geologists. For convenience these are called *upper Pottsville*, *middle Pottsville*, and *lower Pottsville*. The upper Pottsville extends from base of Buck Mtn. (or Twin) coal down to base of sss. considered to=Sharon cgl. memb. of western Pa., and includes, toward middle, Lykens No. 1 coal. The middle Pottsville extends downward from base of the sss. which are correlated with Sharon cgl., and includes Lykens Nos. 2 and 3 coals and underlying rocks. The lower Pottsville includes in upper part Lykens Nos. 4, 5, and 6 coals and toward middle the Lykens Valley coal bed. The fm. thins to NE., and is only about 200 ft. thick in Wilkes-Barre region.

†Poughquag quartzite.

Lower Cambrian: Southeastern New York and western Connecticut.

J. D. Dana, 1872 (Am. Jour. Sci., 3d, vol. 3, pp. 179–186, 250–256). [Describes "the quartzite" of Green Mtn region of Conn., Mass., Vt., and adjacent parts of N. Y. Casually alludes to it on p. 181 as *Green Mtn qtzite*. On pp. 250–256 the qtzite in SE. N. Y. is described under heading "Quartzite of Poughquag, Dutchess Co., N. Y." In one place on p. 250 it is casually alluded to as *Poughquag qtzite*. Throughout rest of articles cited the fm. is simply called "the qtzite." The qtzite at Poughquag "is in general evenly bedded. While there are hard compact layers, many are very thin and friable, looking sometimes as if argill., though really consisting of fine quartz sand. This finer kind is often a little silvery, with micaceous or talcoid scales, and sometimes contains traces of chlorite." Stratification varies little from horizontality. Rests uncon. on Archean. The "overlying" Stockbridge ls. ("the great metamorphic ls. of Green Mtn range") is frequently mentioned in articles cited above, and it is also referred to as "Pawling ls.," "Poughquag ls.," and "Stissing and Barnegat ls." The qtzite is regarded as older than the ls. and uncon. with it.]

F. J. H. Merrill, 1902 (U. S. G. S. New York City folio, No. 83, distributed in August 1902). *Poughquag qtzite* is so named from its probable strat. equivalence to the qtzite of Dutchess Co., which bears same relation to the dol. above and the gneiss below as the qtzite within Harlem quad. The Dutchess Co. qtzite contains Lower Camb. fossils at Stissing. The qtzite varies from almost white to brown in color, is characteristically thin-bedded, occasionally massive, often with muscovite or tourmaline developed along bedding and cleavage planes. Thickness in Harlem quad. 1 to 30 ft., but at type loc. (railroad cut at Poughquag, N. Y.) over 100 ft. is exposed. Rests, with sharp contact, on pre-Camb., and is overlain by Stockbridge ls., the basal beds of which integrate with top beds of the qtzite. [The qtzite of Harlem quad. has since been proved to be of pre-Camb. age, and is now called *Lowerre qtzite*.]

E. C. Eckel, 1902 (N. Y. State Mus. 54th Ann. Rept., pt. 1, pp. r145–r146, r167; received in library of U. S. Geol. Survey about January 2, 1903). In Dutchess, Orange, Putnam, and Westchester Counties a relatively thin qtzite usually underlies the Cambro-Sil. lss. [Described under heading "Stockbridge and Barnegat lss.," the blue ls. of Orange and SW. Dutchess Co. being called *Barnegat*, and the ls. of "the other southeastern counties and western New England" being called *Stockbridge*.] In Stissing Mtn and at other points this qtzite has been found to contain Lower Camb. (Georgian) fossils. It is essentially continuous, stratigraphically, throughout the counties above named, few contacts of Stockbridge ls. with pre-Camb. gneisses failing to show this intervening qtzite. In its lithologic character it is very uniform. Dr. [F. J. H.] Merrill described it in 1896 as *Lowerre qtzite*, while the names *Vermont* and *Cheshire* have been given it by New England geologists. The name recently adopted for it is *Poughquag qtzite* (Dana 1872) in recognition of fact that its thickness, lithologic character, and strat. position are well shown at Poughquag, Dutchess Co., N. Y.

The U. S. Geol. Survey has since 1914 used the older name *Cheshire qtzite* for the Lower Camb. qtzite of SE. N. Y. to which local name "Poughquag" has been applied. The N. Y. State Survey, however, continues to use the local name. (See also †*Stissing qtzite*.)

†Poughquag limestone.

Ordovician and Cambrian: Southeastern New York (Dutchess County).

J. D. Dana, 1872 (Am. Jour. Sci., 3d, vol. 3, pp. 179–186, 250–256), frequently mentioned *Stockbridge ls.*, "the great metamorphic ls. of Green Mountain range," and also called it "Pawling ls.," "Poughquag ls.," "Stissing and Barnegat ls.," because exposed at or near those localities in Dutchess Co., N. Y. "The qtzite of region is considered to be older than the ls. and uncon. with it." In places he used *Pawling (Stockbridge) ls.* He also stated that the Stockbridge ls. extends from Canaan, W. of S., through Dover to Pawling; that it continues beyond latter place southward along the valley for 7 or 8 mi., where both valley and ls. narrow out; and that the Poughquag and Pawling lss. appear to be identical.

The U. S. Geol. Survey uses *Stockbridge* for this ls. The N. Y. State Survey repts use local names *Wappinger ls.* and *Barnegat ls.*

Poul Creek formation.

Oligocene: Southeastern Alaska (Yakataga district, Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 753+). *Poul Creek fm.*—Dark hard platy blue-gray shales (in part calc. and in part sandy), thin-bedded sss., cgls. (of stream, beach, and glacial origin), occasional thin argill., blue-gray lss., and a few beds of glauconitic ss. The shales greatly predominate, especially in lower part, and make up fully 75 percent of fm. Glauconitic sss. are also present, but not so numerous as in the conformably overlying Yakataga fm.; they are usually thin, but one with thickness of 25 ft. was noted. Thickness 3,000+ ft. Named for exposures along Poul Creek, Yakataga dist. A fairly large fauna was obtained from various parts of both Yakataga and Poul Creek fms. According to B. L. Clark both are of upper Olig. age, and=Blakely horizon of Wash. and San Ramon horizon of Calif.

B. L. Clark, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 797–846). [Described the fossils collected by Taliaferro, and said (p. 799):] All determinable species from Yakataga fm. occur also in Poul Creek fm.; the change in lithology is not accompanied by a change in fauna—it belongs to one zone, the Blakely horizon as recognized in Wash., which is considered by writer to be upper Olig.; it is correlated with that of San Ramon fm. of Calif.

Poultney slate.

Lower Ordovician (Beekmantown): Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 403). *Poultney sl.*—Mainly gray sl., which becomes lighter, or even white, on exposure. Most prominent feature is white or light-gray chert which appears in very thin seams or in massive beds 1 ft. or more thick. Resists erosion and outcrops abundantly. Named for good exposures in town of Poultney at bdy of N. Y., 7 mi. SW. of Castleton [in Castleton quad.]. Underlies Indian River sl. (red) and rests uncon. on Hooker sl. (Lower Camb.).

Poundridge granite.

Age (?): Southeastern New York (Westchester County).

G. K. Bell, Jr., 1936 (Geol. Soc. Am. Proc. 1935, p. 65). *Poundridge granite* occupies most of Poundridge (New York State Park) Reservation in NE. Westchester Co. N. Y. Massive pink gneissoid biotite granite, rich in soda, and with abundant pegmatite facies. Writer is inclined to correlate it with Yonkers granite.

Poverty Run limestone. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio (Muskingum County).

W. Stout, 1918 (Ohio Geol. Surv., 4th ser., Bull. 21, p. 65). *Poverty Run memb.*—Consists of (descending): Ore, 4 in.; calc. sh., 1 ft.; gray fossiliferous ls. of marine origin, 5 in. Lies 26 ft. 4 in. below Lower Mercer or No. 3 coal, and 5 ft. above Vandusen coal. Fully exposed on Poverty Run, Muskingum Co.

H. Morningstar, 1922 (Ohio Geol. Surv., 4th ser., Bull. 25, p. 28). *Poverty Run ls.* of Stout (1918) is same as Lowellville ls. of Lamb. (1910).

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, p. 97). *Lowellville or Poverty Run ls.* is oldest known marine ls. of Pottsville fm. of Ohio. Lies in interval btw. Vandusen coal and Lower Mercer clay.

Poway conglomerate.

Tertiary (Eocene): Southern California (San Diego County).

A. J. Ellis, 1919 (U. S. G. S. W. S. P. 446). *Poway cgl.*—Chiefly cgls., but lenses of cross-bedded sand and thin layers of marly clay are exposed in some canyon walls. Forms Poway Mesa and occurs in narrow belt extending from that mesa E. to Witch Creek. Also well exposed near town of Poway, and forms S. wall of Poway Valley. Max. thickness W. of Foster about 1,000 ft. No fossils found and relations to marine San Diego fm. not determined, but probably is somewhat older than upper part of the San Diego. Rests on pre-Tert. crystalline rocks.

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7), said fauna is Eo., and tentatively correlated the fm. with Tejon fm.

W. J. Miller, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 10, p. 1555). Writer is unable to answer the following pertinent questions regarding *Poway cgl.*: Did it ever extend across central and southern parts of Ei Cajon Valley? If so, how was it removed? Is it stream-cut? If so, by what stream? Is it wave-cut, as suggested by Ellis? Are the so-called marine terraces of Ellis in reality stream terraces?

See also under *Ballena gravel.*

Powderhorn granite.

Pre-Cambrian: Central western Colorado (Gunnison River region).

J. F. Hunter, 1925 (U. S. G. S. Bull. 777). *Powderhorn granite group.*—Comprises a large number of genetically related and locally metamorphosed intrusive masses, forming an intricate complex of granite types, whose composition is believed to be nearly uniform but whose texture is strikingly diversified. The rocks range from granite porphyry (near a rhyolite porphyry) to coarsely porphyritic granite. Three types—granite porphyry, porphyritic biotite granite, and gray biotite granite—have been distinguished on map. The granites of Powderhorn group everywhere cut and are younger than Dubois greenstone. To N. of Powderhorn most of divide btw. Cebolla and Goose Creeks consists of these granites.

For 1935 geol. map of Colo. this name was changed to *Powderhorn granite* and the fm. was included in Front Range granite group.

Powell limestone (also **Powell dolomite**).

Lower Ordovician (Beekmantown): Northern Arkansas and southeastern Missouri.

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Powell ls.*—Light-gray to greenish-gray mag. ls. with some sh. and locally a bed of ls. cgl. at base. Thickness 0 to 200 ft. Uncon. underlies Everton ls. and uncon. overlies Cotter dol. The fm. was named by E. O. Ulrich [unpublished] from exposures at Powell Station, on White River branch of St. Louis, Iron Mtn & Southern Ry.

E. T. McKnight, 1935 (U. S. G. S. Bull. 853). Believed by E. O. Ulrich to underlie, uncon., Smithville fm. [See under *Smithville fm.*]

Powell sand.

A subsurface unit, forming lower 100 ft. of Nacatoch sand, of Powell oil field, eastern Tex.

Powell moraine.

Pleistocene (Wisconsin stage): Central Ohio. Shown on moraine map (fig. 8) in U. S. G. S. Columbus folio (No. 197), p. 12. Named for Powell, Delaware Co.

Powelton shale. (In Allegheny formation.)

Pennsylvanian: Central southern Pennsylvania (Huntingdon County).

I. C. White, 1885 (2d Pa. Geol. Surv. Rept. T_3, pp. 61–62). *Powelton shales.*—Chiefly shales, but in places gray ss. replaces the sh. to considerable extent. Thickness 50 ft. Underlie Barnett coal and overlie Cook (Fulton) coal. Named for village in Huntingdon Co.

Powers Bluff quartzite.

Pre-Cambrian (middle Huronian): Central northern Wisconsin (Wood County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 82). *Powers Bluff qtzite.*—Medium- to very fine-grained, mainly pinkish qtzite. Thickness surmised to be perhaps 1,000 ft. Forms main portion of Powers Bluff, near Arpin, Wood Co. In isolated exposures S. of Powers Bluff the qtzite is generally coarser and whiter than that of the bluff. On SE. side of Powers Bluff it is overlain by cgl. containing detritus of Powers Bluff fm. and grading upward into medium- to coarse-grained qtzite. May be Rib Hill qtzite. Assigned to lower Huronian (?).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this qtzite to *middle Huronian.*

Powwow conglomerate member (of Hueco limestone restricted).

Permian (?): Western Texas (Hueco Mountains).

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, pp. 909, 911). Above the beds of Strawn age are lss. containing Canyon and Cisco fossils. *Chaetetes* is absent, and a zone of *Fusulinella mecki* occurs at base. Uppermost beds contain Cisco fusulinids (identifications of C. O. Dunbar). Near top is a memb. of cgl. and red beds, which is folded with the rest of the Carbf. The red beds are well exposed from 2 to 5 mi. S. of Hueco Canyon along main escarpment of Hueco Mtns, and for them the name *Powwow* is proposed, from Powwow Canyon 3½ mi. S. of Hueco Canyon, which is followed by the new El Paso-Carlsbad highway.

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 743). *Powwow cgl. memb. of Hueco ls.*, unnamed then, was correctly placed above the uncon. by J. W. Beede (Univ. Tex. Bull. 1852, p. 14, 1920), but was erroneously grouped with the strata below the uncon. by P. B. and R. E. King in publication cited above.

Poxino Island limestone. (In Wills Creek shale.)

Silurian: Northeastern Pennsylvania (Monroe County).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 146–147, 223–224). *Poxino Island ls.*—Very hard bluish-gray fossiliferous crystalline ls., in thin layers. Thickness 5 ft. Underlies Poxino Island shales and rests on 5 ft. of greenish shales which lie on Clinton red sh. Exposed only in steep bluff on Delaware River opposite Poxino Island. Lowest memb. of Lower Helderberg series.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, p. 94). The Poxino Island sh. and underlying *Poxino Island ls.* are not Lower Helderberg, but belong to Salina group.

Is a ls. in basal part of Wills Creek sh.

†Poxino Island shale.

Silurian (Cayugan): Northeastern Pennsylvania (Monroe and Carbon Counties).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 77, 145–146). *Poxino Island sh.*—A series of buff, greenish, and variegated, limy shales, unfossiliferous, underlying Bossardville ls. and overlying Poxino Island ls. Thickness 200 ft. Exposed in bluff of Delaware River in Middle Smithfield Twp, opposite Poxino Island. Included in Lower Helderberg fm. [Helderberg].

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, p. 94). *Poxino Island sh.* and underlying Poxino Island ls. belong to Salina group, and not to Lower Helderberg.

Essentially same as Wills Creek sh., better-established name.

Pozo formation.

Tertiary (Pliocene?): Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 70, etc.). *Pozo fm.*—Roughly bedded, imperfectly assorted cgls. associated with some soft ss. Mainly of volcanic derivation, andesitic, basaltic, and pumiceous fragments being abundant. Fluviatile. Thickness 0 to 100 (?) ft. Conformably underlies Spearhead rhyolite and uncon. overlies Siebert [Esmeralda] fm. Named for exposures in Pozo Canyon.

†Prairie diluvium.

Descriptive term used in early La. repts to include the Quat. alluvium, yellow loam, and loess.

†Prairie formation.

A term applied in early Ill. and other repts to the Pleist. loess.

Prairie Bluff chalk.

Upper Cretaceous: Southwestern Alabama.

A. Winchell, 1857 (Am. Ass. Adv. Sci. Proc., vol. 2, pp. 83, 84, 90). *Prairie Bluff ls.*—White ls., 6 ft. thick, exposed at top of section at Prairie Bluff. Embraces in upper part a bed of dark-colored disintegrated ls. 4 ft. thick, containing obscure casts of fossils; lower portion abounds in them, and base is almost entirely made up of *Exogyra costata* and *Gryphaea mutabilis*, in very fine state of preservation. I have not seen Tert. beds in immediate superposition above this, but I presume the Prairie Bluff ls. is=Black's Bluff ls. and is uppermost memb. of Cret. series of Ala.

L. W. Stephenson, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 250). *Prairie Bluff tongue of Selma chalk* is revival of Winchell's name *Prairie Bluff ls.*, for the chalk or "ls." exposed in Prairie Bluff, Wilcox Co. Is contemp. with Oktibbeha tongue of Miss., and extends E. from main body of Selma chalk in Marengo Co. nearly through Wilcox Co. It appears to be [is now known to be] separated from underlying Ripley sand by an uncon.

L. W. Stephenson and W. H. Monroe in April 1937 proposed that the Prairie Bluff deposits be raised to rank of a fm., designated *Prairie Bluff chalk*, uncon. overlying the Selma chalk restricted in a limited area in Miss. and Ala., and elsewhere uncon. overlying the Ripley; and that the definition of Prairie Bluff be expanded so as to include the deposits heretofore designated "Oktibbeha tongue of Selma chalk," which was discarded. This is present approved name and definition of U. S. Geol. Survey. (See A. A. P. G. Bull., 1937.)

Prairie Bluff limestone.

See 1st entry under *Prairie Bluff chalk*.

Prairie d'Ane clay.

Pleistocene: Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 32–33, 46–47, 188). *Prairie d'Ane clay.*—Unstratified white or yellow clays, of not very great thickness, sometimes mixed with siliceous gravel, sparsely embedded in places and in other places constituting well-defined hummocks, some 15 ft. in diam. Forms Prairie d'Ane at Prescott, Prairie de Roan at Hope, and Bois d'Arc Prairie 10 mi. S. of Washington. Overlies Arkadelphia shales, or high bluff sands, or chalky Cret. marls. [On p. 29 of book cited these clays and gravel are called *Prairie de Roan div.* On p. 32 author used (in heading) "Prairie d'Ane or White clay till;" on p. 33 he used (in heading) "White Prairie d'Ane clay."]

Named for exposures in Prairie d'Ane at Prescott, Nevada Co.

Prairie de Roan division.

Pleistocene: Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 29, 33). [White clay and gravel till, called *Prairie de Roan div.* on p. 29, but on p. 33 described under heading *Prairie d'Ane or White clay till*, q. v.]

Named for Prairie de Roan at Hope, Hempstead Co.

Prairie du Chien group.

Lower Ordovician (Beekmantown): Southwestern Wisconsin, southern Minnesota, Iowa, and western Illinois.

H. F. Bain, 1906 (U. S. G. S. Bull. 294, p. 18). *Prairie du Chien fm.*—Geographic name to replace "Lower Magnesian" of early repts. Includes (descending): Shakopee or Willow River dol. (approx. 40 ft. thick); New Richmond ss. (15 to 130 ft. thick); and Oneota dol. (200 to 225 ft. thick). Rests on Camb. and is uncon. overlain by St. Peter ss.

For many years the Prairie du Chien has been treated as a *group* and the Shakopee, New Richmond, and Oneota as fms. The Shakopee and New Richmond were for a time classified by U. S. Geol. Survey as Lower Ord. (Beekmantown) and Oneota dol. (formerly classified as Lower Ord.) was classified as Camb. or Ord., it being assigned by E. O. Ulrich to his Ozarkian system. A. C. Trowbridge and G. I. Atwater (Geol. Soc. Am. Bull., vol. 45, pp. 78–79, 1934) would include all of Prairie du Chien group in Lower Ord., and it is so classified in Rept. 9th Ann. Field Conf. Kans. Geol. Soc. (1935) and by U. S. Geol. Survey.

See also under *Oneota dol.*, *New Richmond ss.*, and *Shakopee dol.*

Named for exposures in vicinity of Prairie du Chien, Wis.

Prairie River granite.

Pre-Cambrian: Northeastern Minnesota (Itasca County).

G. E. Culver, 1894 (Minn. Geol. Nat. Hist. Surv. 22d Ann. Rept., btw. pp. 102 and 114). *Prairie River granite* exposed in SE¼ SE¼ sec. 32, also sec. 33, and abundantly in sec. 34, T. 56, R. 25, in Itasca Co. Is a fine-grained gray rock with some gneissic phases and contains some bodies of schist, which were taken to indicate the granite is eruptive.

Prairie Rock limestone.

Upper Cretaceous: Mississippi.

E. C. Eckel, 1905 (U. S. G. S. Bull. 243, pp. 206–219), and A. F. Crider, 1905 (U. S. G. S. Bull. 260, pp. 510–521). [Both of these repts refer to ls. in Selma chalk at *Prairie Rock* as *Prairie Rock ls.* Crider states (p. 515) that the ls. is quarried on SW. side of Bogue Chitto Creek, ½ mi. E. of Prairie Rock. Bogue Chitto Creek is in Neshoba and Kemper Counties, NE. Miss.]

Pratt coal group.

Pennsylvanian: Central Alabama.

A group of coal beds in Pottsville fm. of Warrior coal field, the top coal lying 210 to 260 ft. below Camp Branch ss. memb., and the coals occurring within a vertical section of 150± ft. Includes Pratt coal (at top), Nickel Plate (Cardiff), American (Double), Curry, and Gillespie coals.

Prattsburg sandstone and shale.

Upper Devonian: West-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 25 and chart). *Prattsburg ss.* carries an early Chemung fauna, but is stratigraphically continuous with Wiscoy sh., which carries a Portage fauna.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63). *Prattsburg ss. and sh.*—Top div. of Chemung beds in Canandaigua and Naples quads. Overlies High Point ss. Thickness 500 to 625 ft. Upper 300 to 400 ft. consists of light bluish-gray sss., usually in lentils and compact or uneven layers, with interstratified shales (mostly blue and hard, but black and slaty layers occur frequently). Lower 200 to 225 ft. consists of sss. (mostly olive gray, rather soft and schistose or in thin even layers) and shales (in part soft and blocky, but blue, olive, and black layers also occur), which lie in horizon of Wiscoy shales, but the Wiscoy carries a Portage fauna. [For Clarke and Luther 1905 see 1905 item under *Wiscoy sh.*]

D. D. Luther, 1906 (N. Y. State Mus. Bull. 101). *Wiscoy (Prattsburg) shales.*—In Penn Yan-Hammondsport quads. the *Prattsburg shales and flags* are mostly shales or thin blocky or shaly sss. 250 ft. thick, and contain many Chemung and few Portage fossils; but in Genesee River section at Wiscoy the beds are soft, shaly, and somewhat calc. and contain only Portage fossils.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [Table shows upper part of *Prattsburg sss.* as=basal Chemung and lower part as=Wiscoy sh. (pre-Chemung). Underlying fm. is called *Highpoint ss.* and overlying fm. is called *Gowanda*.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *Prattsburg ss.* is included in Portage group.

Named for occurrence at Prattsburg, Steuben Co.

Praysville porphyry.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 81, 176, 177). *Suffolk or Praysville porphyry.* Occurs on Old Suffolk mining location, Praysville, Keweenaw Point.

Belongs to Bohemian Range group.

pre-Kansan drift (Pleistocene).

A name that has sometimes been applied to the oldest or Nebraskan glacial drift, because it is older than the Kansan drift.

†Premedidial series.

Nongeographic name applied by H. D. Rogers (Am. Jour. Sci., 1st, vol. 47, pp. 153–158, 1844) to the rocks of Appalachian region including Oriskany ss. at top and "Pentamerus and Catskill shaly lss." of N. Y. at base. Rogers abandoned the name in his 1858 classification (Geol. Pa., vol. 1, pp. 59, 104–109; vol. 2, pt. 2, pp. 751–775).

Named to indicate "forenoon period of the great Appalachian Palaeozoic day," according to Rogers, 1844 citation above.

†Pre-Meridian series.

†Pre-Meridian limestone.

Nongeographic names introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 107, 136–137, 272+, and vol. 2, p. 754) for beds stated to be same as Lower Helderberg ls. of N. Y. [Helderberg group of present nomenclature].

Prescott diorite.

Late Carboniferous or post-Carboniferous: Western central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, pl. 34). *Prescott diorite.*—A great stock of coarse plagioclase-hornblende rock.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 215 and map). *Prescott diorite* comprises Packard Mtn in Prescott, Mass.

Presidio formation. (Of Trinity group.)

Lower Cretaceous (Comanche series): Western Texas (Presidio County).

J. A. Udden, 1904 (Univ. Tex. Min. Surv. Bull. 8, pp. 10, 11, 25–30). *Presidio beds.*—Fossiliferous beds of cgl., clay, ls., and ss., 400 ft. thick, constituting lithologic unit in sense they have one character in common in which they differ from other Lower Cret. divisions, i. e., they are all mixtures of mechanical sediments, such as gravel, sand, and clay, with precipitated carbonate of lime as an original ingredient, the lss. being never free from sand and the sss. rarely free from calc. material. Basal fm. of Lower Cret. Uncon. overlies Carbf. and underlies Shafter beds. Lithologically and stratigraphically resemble Travis Peak beds, but differ faunally.

C. P. Ross and W. E. Cartwright, 1935 (Univ. Tex. Bull. 3401, pt. 3, pp. 585–586). *Presidio fm.*—Uncon. underlies Shafter ls. Appears to be identical with Travis Peak fm. and may eventually be abandoned.

Named for exposures W. of new shaft of Presidio Mining Co., Presidio Co.

Presque Isle granite.

Pre-Cambrian (post-Keweenawan): Northwestern Michigan (Gogebic range).

R. C. Allen and L. P. Barrett, 1915 (Jour. Geol., vol. 23, p. 697). *Presque Isle granite.*—Acid type. Varies through gradational phases into syenite and diorite. Mainly massive, but marked gneissosity is not uncommon. Uncon. underlies Copps group in E. part of Gogebic range.

R. C. Allen, 1915 (Mich. Geol. and Biol. Surv. Pub. 18, geol. ser. 15, pp. 23, 30, 50). *Presque Isle granite* intrudes Palms and Ironwood fms. Named for Presque Isle River. [In table is placed above Tyler sl.] As mapped may include some Laurentian rocks, but greater part is of late Animikie age.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned *Presque Isle granite* to Killarney revolution (post-Keweenawan pre-Cambrian).

Presque Isle series.

Middle Devonian: Northeastern Michigan (Presque Isle and Alpena Counties).

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14, pp. 4, 25+). *Presque Isle series.*—Name newly proposed by A. W. Grabau, on pp. 290–308 of unpublished ms. dated in 1915. The fourfold subdivision previously adopted for Traverse group in Presque Isle and Alpena Counties has more recently been restricted by Grabau, the Bell shales now forming lowest memb. of Presque Isle series. Grabau's downward succession as now understood is [as listed under 1930 entry under *Traverse fm.*]. Fossils listed. Derivation of name not stated.

Presqu' île dolomite.

Devonian: Northwest Territories, Canada.

A. E. Cameron, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 26).

†Preston formation. (In Washita group.)

Lower Cretaceous (Comanche series): Northeastern Texas.

R. T. Hill, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 302, 303, 326). The Kiamitia and Duck Creek beds collectively can appropriately be called *Preston beds*, in honor of Professor Marcou's type loc., where the beds are best exposed. Underlie Fort Worth beds and overlie Fredericksburg div. Are paleontologically a single fauna.

Considered an unnecessary name, as Kiamichi clay and Duck Creek fm. are easily separable.

Named for Preston, Grayson Co.

Preston gabbro.

Carboniferous or post-Carboniferous: Eastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 74, 115, 153, and map). *Preston gabbro diorite.*—Dark-colored rock which shows a number of variations and follows a definite gradation from center of mass towards the periphery. Includes coarse porphyritic gabbro, diorite, and quartz diorite. Intruded before the metamorphism that reconstructed the rocks of the entire State. Covers part of Preston Twp.

G. F. Loughlin, 1912 (U. S. G. S. Bull. 492), mapped and described two facies of Preston gabbro—a coarse porphyritic gabbro with large poikilitic phenocrysts of diallage, and a quartz-hornblende gabbro. The Preston gabbro is older than Sterling granite gneiss. It intrudes sed. rocks of Camb. and Carbf. age.

Preston limestone. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 16, 26, 28). In Missouri River section btw. La Platte, Nebr., and Charleston Creek, Kans., *Preston ls.* is hard, massive, bluish, breaks into boxlike blocks, and is 2½ to 3 ft. thick. In Big Nemaha Valley section, Nebr., it consists of several lss. separated by sh.; is light-colored, also bluish, brownish; includes hard and massive beds; thickness 4 to 11 ft. Separated from overlying Tarkio ls. by 40 to 50 ft. of sh. with thin lss., and from underlying Fargo ls. [Wakarusa ls.] by 14 to 34 ft. of sh. Type loc. near level of railroad at bridge W. of Preston, Richardson Co., Nebr.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 60, 63). "Preston" ls. is now known to be Emporia ls.; latter name has priority.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, p. 96) used *Emporia ls.*, as did Condra and Moore in their Oct. 1932 revised chart of Perm. and Penn. rocks of Kans. and Nebr. But Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10), discarded *Emporia* for *Preston*.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 224–226), discarded both Emporia and Preston and treated their named subdivisions (Reading ls., Harveyville sh., and Elmont ls.) as fms.

Preston hornblende diorite.

Paleozoic (?): Northwestern California (Siskiyou and Del Norte Counties).

J. H. Maxson, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, p. 128 and map). *Preston hornblende diorite.*—Commonly a fine-grained gray rock closely cut by quartz veinlets. Green hornblende is more characteristic than brown, though both occur. Intrudes Grayback fm. (Dev.) and is intruded by serpentine and by Siskiyou granodiorite. May come anywhere in great interval btw. Dev. and late Jurassic; is likely to prove to be late Paleozoic. Named for occurrence in Preston Peak, Siskiyou Co.

Preston sand.

A subsurface sand or sands, of early Penn. (Cherokee) age, in central eastern Okla., said to correspond to Dutcher sand series. In its type area (Preston pool, Okmulgee Co.) the sand beneath the Booch sand is called Dutcher sand.

Preuss sandstone.

Upper Jurassic: Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98, pp. 76, 81). *Preuss ss.*—Very fine, even-grained sss., pale reddish gray to deep dull red, usually calc. and more or less argill., becoming very shaly in places; the beds generally less than 6 in. thick. Weathers to dull-red soil. Thickness 1,300 ft. Underlies Stump ss. and overlies, with minor uncon., Twin Creek ls. Named for Preuss Creek, in NE. part of Montpelier quad., about 12 mi. NE. of Montpelier.

Price sandstone.

Mississippian (Osage): Southwestern Virginia.

M. R. Campbell, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 171, 177, pl. 4). *Price (Pocono) ss.*—Alternating coarse yellow or green sss., beds of sh., and coal. Overlies Kimberling sh. and underlies Pulaski sh. [Maccrady fm.]. [In later repts thickness is given as 200 to 420 ft. or more.]

Named for Price Mtn, Montgomery Co.

Price River formation. (Of Mesaverde group.)

Upper Cretaceous: Central eastern Utah (Wasatch Plateau and Book Cliffs).

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 445+). *Price River fm.*—A succession of sss., grits, and cgls. with a minor amount of sh. Thickness 900 to 1,000 ft. Includes Castlegate ss. memb. (150 to 400 ft. thick) at base. Is top fm. of Mesaverde group in Wasatch Plateau. Uncon. underlies Wasatch fm. and overlies (uncon.?) Blackhawk fm., of Mesaverde group.

Named for exposures in Price River Canyon, NW. of town of Castlegate.

Prichard slate (also **Prichard formation**).

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and northwestern Montana.

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, pp. 277–285). *Prichard sl.*—Mostly blue-black, blue-gray to light-gray sl., generally distinctly banded; considerable interbedded gray ss.; upper part characterized by rapid alternations of argill. and aren. layers and by shallow-water features. Thickness 8,000+ ft. Base not exposed. Underlies Burke fm. Occupies almost entire drainage basin of Prichard Creek, Coeur d'Alene dist., Idaho. Description of general geology of region is based almost wholly on work of F. C. Calkins.

Priddy sand.

A subsurface sand, of Penn. age and 20 to 30 ft. thick, in Cotton Co., Okla. Lies higher than Keys sand.

Pride shale. (In Bluestone formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 294, 325). *Pride sh.*—Greenish-brown fissile sandy sh., often weathering into pencil-like forms. Thickness 70 to 150 ft. Underlies Pipestem coal and overlies Princeton cgl. or ss. Is basal memb. of Bluestone group [fm.]. Type loc., at base of Bent Mtn, just S. of Pride, Mercer Co., W. Va.

Priest Hill granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Franconia quadrangle).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., pp. 9, etc.). *Priest Hill granite* is proposed for a somewhat gneissic granite exposed only on Priest Hill. Light-gray granular rock, chiefly quartz, feldspar, and some biotite, with very small amount of muscovite. Is late Dev. or late Carbf. Assigned to New Hampshire magma series.

Priest River terrane.

Pre-Cambrian: Southern British Columbia and northwestern Idaho.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 6, 7, 116° 30' to 117° 30'). *Priest River terrane*, pre-Beltian. [Maps the following subdivisions, descending order:] Mica schists, qtzites, and dolomites; dolomites, qtzite, phyllite; phyllites and sericite-quartz schist; sheared massive qtzite, with sericite and chlorite schist; sericite schist spangled with large biotite crystals; schistose qtzite and mica schist.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 178, 194, 258). *Priest River terrane* uncon. underlies Irene cgl. Correlates with Cherry Creek beds of Mont. Outcrops at and to E. of headwaters of Priest River.

In 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 61) Drysdale assigned these rocks to Belt series, or "Beltian," as he called it.

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, pp. 47–49). *Priest River terrane* believed to be at least 18,000 ft. thick.

†Prieta sandstone.

Upper Cretaceous: Central northern New Mexico.

C. L. Herrick and D. W. Johnson, 1900 (N. Mex. Univ. Bull., vol. 2, pt. 1, pp. 3–63). *Prieta sss.* (also *Prieta series*).—Loose yellow ss., with shaly phases. Thickness 1,000 ft. Overlies massive Punta de la Mesa ss. in Albuquerque quad., and is overlain by lignitic div. of Cret., consisting of sand, ss., and lignite beds. [Derivation of name not stated.]

†Prieta series.

See †*Prieta ss.*

†Primal series.

Nongeographic name introduced by H. D. Rogers (Am. Jour. Sci., 1st, vol. 47, pp. 153–158, 1844) to embrace the rocks btw. base of "Calciferous ss." of N. Y. [Beekmantown] at top and base of Paleozoic. In 1858 (Geol. Pa., vol. 1, pp. 104, 122–123, 150–207+, and vol. 2, p. 751) Rogers divided his "Primal series" into (descending): "Primal upper slate," 700 ft.; "Primal white ss. (Potsdam ss. of N. Y.)," 300± ft.; "Primal older slate," 1,200 ft. in Va., but too folded to measure in Pa.; and "Primal cgl.," absent in Pa., but 150 ft. thick in Va. and Tenn.

Named to indicate "dawn period of the great Appalachian Palaeozoic day," according to Rogers, 1844 citation above.

†Primal crystalline schists.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 59, 104–109) for the rocks now classified as pre-Camb. and known as *Glenarm series*. Rogers defined the unit as underlain by "Gneissic or Hypozoic rocks" and overlain by †Primal cgl.

†Primary system.

A term applied in early N. Y. repts to all pre-Potsdam rocks; also to pre-†Taconic rocks, the †Taconic being defined as intermediate btw. Potsdam ss. and †Primary system.

†Primitive.

Paleozoic and Proterozoic.

Giovanni Arduino, an eminent Italian scientist, in 1760 published (Nuova raccolta di Opuscoli Filologici ec del P. Abb. Calogera, T. VI, Venice, p. 159) the first geologic time classification. His subdivisions consisted of Primitive (the oldest), Secondary, and Tertiary (the youngest). In this classification the more recent surficial deposits of the earth, to which the name Quaternary is now applied, were ignored. His "Primitive" included the Paleozoic and pre-Paleozoic rocks; his "Secondary" included the Mesozoic rocks; and his Tertiary included the post-Mesozoic and pre-Quaternary deposits, or those to which the name Tertiary is still applied. The book cited above is very rare. A copy of it is in the Royal Library Vittorio Emanuele, at Rome, Italy, shelf number 79, A 15. The only copy known in this country is in the Library of the Army Medical Mus., Washington, D. C.

Primm sand.

See 1925 entry under *Meakin sand*.

†Primordial.

A term applied in early geologic repts, especially those of Europe, to the rocks now called *Cambrian system*.

Primrose sandstone member (of Springer formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

R. Roth, 1928 (Econ. Geol., vol. 23, p. 45). [See under *Overbrook ss. memb.*]

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 13). *Primrose memb. of Springer fm.* is a zone of shaly to thin-bedded semi-crystalline calc. ss. 150 to 250 ft. thick, locally carrying 1 or 2 ft. of impure fossiliferous ls. Lies 100 to 300 ft. above Lake Ardmore memb. of Springer fm.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 19). *Primrose memb.* lies 250 to 500 ft. above Lake Ardmore memb. Named for Primrose Ridge, in sec. 7, T. 4 S., R. 2 E., on which stand the buildings of Primrose dairy farm.

Prince Rupert formation.

Carboniferous or Triassic: British Columbia.

R. G. McConnell, 1913 (12th Int. Geol. Cong. Guidebook 10, p. 17). Upper Paleozoic (?).

V. Dolmage, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. A, p. 12), and G. Hanson, 1925 (Summ. Rept. 1924, pt. A, p. 40), assigned this fm. to Carbf. or Triassic.

Princess formation.

Carboniferous or pre-Carboniferous: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. B, p. 60).

Princess Anne formation. (In Columbia group.)

Pleistocene: Coastal Plain of Maryland and Virginia.

C. K. Wentworth, 1930 (Va. Geol. Surv. Bull. 32, pp. 81+). L. W. Stephenson (N. C. Geol. Surv. Bull. 3, 1912) included in Pamlico terrace the whole area of Coastal Plain in N. C. east of Chowan-Dismal Swamp scarp and below 25 ft. elev. From recent topog. maps of Coastal Plain of Va. it is clear there is a distinct terrace about 12 ft. above sea level, which is separated from the 25-ft. terrace by a well-marked scarp, which is prominent in Cape Henry quad. E. of Norfolk. It appears from maps to be well developed on seaward side of Eastern Shore. This low terrace and fm. are here designated *Princess Anne terrace and fm.* because of their typical occurrence at village of Princess Anne, in Princess Anne Co., Va. Here the terrace forms a rounded reentrant extending into type area of Dismal Swamp terrace. The scarp that separates Princess Anne and Dismal Swamp terraces is well developed E. and SE. of Barney's Corner, Princess Anne Co. Thickness 15 to 20 ft. Is of marine origin. [On p. 105 he says largely marine.]

C. W. Cooke, 1931 (Wash. Acad. Sci. Proc., vol. 21, p. 513). Wentworth separated "Princess Anne" terrace from "Dismal Swamp" terrace because of presence of a low scarp above 12 ft. in neighborhood of Norfolk and elsewhere in Va. Although no one can dispute the existence of this scarp (which is plainly shown on Cape Henry quad.) opinions may differ as to whether it is really a sea cliff formed at a stage of sea about 12 ft. above present sea level. Evidence at present appears inconclusive.

L. W. Stephenson, C. W. Cooke, and W. C. Mansfield, 1932 (16th Int. Geol. Cong., Guidebooks 5 and 12). Shore line of Pamlico terrace (which is regarded by Cooke as identical with "Dismal Swamp" terrace) lies about 25 ft. above sea level, that of Princess Anne terrace about 12 ft.

The terrace fms. of Columbia group now recognized by Cooke from Del. to southern Ga. and probably into Fla., are enumerated herein under *Columbia group*.

Princes Town marl.

Miocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in Geol., No. 7, p. 54).

†Princeton limestone.

Mississippian: Western Kentucky.

The original use of this name is said to be by Ulrich in Crittenden Press, Dec. 1890. This publication is not in U. S. Geol. Survey Library nor in Library of Congress.

E. O. Ulrich, 1903 (U. S. G. S. Bull. 213, pp. 207–208). *Princeton ls.*—Upper third, light-gray compact ls. with more or less sh.; in middle, calc. ss. 1 to 12 ft. thick; lower two-thirds, massive, oolitic, light-gray or nearly white ls. Thickness of fm. 200 to 250 ft. Underlies Chester group and overlies St. Louis ls. in Crittenden, Livingston, Caldwell, and adjacent counties of western Ky.

E. O. Ulrich and W. S. T. Smith, 1905 (U. S. G. S. P. P. 36, pp. 39, 52). *Princeton ls.* is same as Ste. Genevieve ls. [Also see U. S. G. S. Bull. 225, p. 507, 1904, in which Ulrich discarded *Princeton ls.* for *Ste. Genevieve ls.*]

Probably named for Princeton, Caldwell Co. In repts on Ky. prior to 1903 these beds were included in St. Louis ls. or "group."

Princeton sandstone.

Mississippian: Southern West Virginia and southwestern Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, pp. 487, 489). *Princeton cgl.*—One of most variable beds of a variable series. First appears in section 1,100 ft. above railroad grade at Hinton, where it consists of 15 to 20 ft. of loosely cemented sand containing many well-rounded quartz pebbles. On crest of hill below Sandstone, 1,050 ft. above railroad, is represented by 30 ft. of ss., very hard when unweathered but yielding quickly to disintegrating agencies, and so far as seen contains no pebbles. At Meadow Creek this ss. is 60 ft. thick, is conglomeratic, and is 820 ft. above railroad track. Two and one-half mi. below it is 600 ft. above grade and is 80 ft. thick.

which is max. thickness in New River. Opposite mouth of Mill Creek it is 180 ft. above grade; at Quinnimont it is 200 ft. above grade and is a cgl., 20 ft. thick, lying uncon. upon shales. Is absent in section up Laurel Creek, but comes in again and is present along road from Quinnimont to Prince. Overlies Hinton fm. and underlies Royal fm.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26, p. 3), named the fm. overlying the Princeton the *Bluestone fm.*

Named for Princeton, Mercer Co., W. Va.

Princeton quartz monzonite.

Post-Carboniferous: Central Colorado (Monarch-Tomichi region).

R. D. Crawford, 1913 (Colo. Geol. Surv. Bull. 4, p. 78). Named for Mount Princeton, N. of Monarch-Tomichi dist.

Princeton series.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Marquette County).

R. C. Allen, 1914 (Jour. Geol., vol. 22, p. 571). *Princeton series.*—Interbedded slates, ferruginous slates, cherts, qtzites, ferruginous qtzites, and graywacke, with, at base, cgl. 30 to 100 ft. thick. Thickness 400 to 500 ft. Uncon. overlies Gwinn series.

Named for Princeton mine, Gwinn dist.

Princeton moraine.

Pleistocene (Wisconsin stage): Northwestern Illinois (Bureau County). See C. O. Sauer, 1916 (Ill. Geol. Surv. Bull. 27, p. 75, fig. 23).

Principe formation.

Eocene: Cuba.

R. H. Palmer, 1934 (Jour. Geol., vol. 42, No. 2, p. 132).

Pringle andesite.

Tertiary: Central southern Colorado (Silver Cliff-Rosita region).

W. Cross, 1890 (Colo. Sci. Soc. Proc., vol. 3, pt. 3, p. 276). *Pringle andesite,* a mica-argite andesite, forms upper part of Pringle Hill, W. of Rosita.

Procamelus beds.

A paleontologic name applied by E. D. Cope to upper Mio. strata of the West containing fossil remains of *Procamelus.*

Proctor sandstone. (In Greene formation.)

Permian: Northern West Virginia.

I. C. White, 1883 (The Virginias, vol. 4, p. 124). Along Ohio River below mouth of Proctor Creek, just S. of Marshall-Wetzel Co. line, occur 3 sss., called *Upper Proctor ss., Middle Proctor ss.,* and *Lower Proctor ss.* The Upper Proctor is very massive yellowish gray, rather micaceous, and 30 ft. thick; the Lower Proctor is massive and 10 ft. thick; the Middle Proctor is massive and lies about midway btw. Upper and Lower Proctor sss., which are separated by 183 ft. of sh. with some ss. and 2 coal beds.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel, and Tyler Counties). *Proctor sss.*—Great massive sss., which form 2 or 3 ledges, separated by red and sandy sh. Thickness 70 ft. Younger than Windy Gap ls. Named for Proctor magisterial dist., Wetzel Co.

R. V. Hennen, 1912 (W. Va. Geol. Surv. Rept. Doddridge and Harrison Counties). *Proctor sss.*—Topmost beds of Dunkard series so far as known. Confined to summits of high knobs. [In general section for W. Va. the thickness of Proctor sss. is given as 150 ft.]

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties). *Upper Proctor ss.* is flaggy, 40 ft. thick, and lies 15 ft. above *Middle Proctor ss.,* which is 25 ft. thick and lies 10 ft. above *Lower Proctor ss.,* which is massive, green, micaceous, 25 ft. thick, and lies 35 ft. above Windy Gap ls.

Proctor dolomite.

Cambrian (Upper): Central and eastern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 366). *Proctor ls.*—Mag. lss., in massive layers 5 to 10 ft. thick, not specially distinguishable from overlying Osage ls., though perhaps less cherty. Overlain by Cole Camp ss. [Oldest fm. listed in central Mo.]

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser.). *Proctor ls.*—Bluish usually, but also grayish, pinkish, greenish or yellowish dol., uncon. underlying Gunter ss. in Miller Co. Thickness 57+ ft. Is Fourth Mag. ls. of Swallow. [Oldest fm. listed in Miller Co.]

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, p. 42). Decaturville ls.=Proctor ls. and is younger than Lesueur ls.

E. R. Buckley, 1905 (Mo. Bur. Geol. and Mines vol. 3, 2d ser., pp. 3–9). *Proctor ls.* (dol.) uncon. underlies Gunter ss.; is younger than LaMotte ss. and=Bonne Terre ls.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bulls. 260 and 267). *Proctor ls.*= Fourth Mag. ls. Is younger than Elvins fm.

H. A. Buehler, 1907 (Mo. Bur. Geol. and Mines vol. 6, 2d ser., pp. 217–232). *Proctor* lies btw. Potosi below and Gunter above.

C. F. Marbut, 1908 (Mo. Bur. Geol. and Mines vol. 7, 2d ser.). *Proctor ls.* in Morgan Co. consists of 150+ ft. of massive mag. gray ls. with no chert, uncon. underlying Gunter ss. memb. of Gasconade fm.

E. R. Buckley, 1908 (Am. Min. Cong. Rept. Proc. 10th Ann. Sess., p. 286), gave following downward succession: Roubidoux; Gasconade; uncon.; Proctor; Eminence; Potosi; uncon.; Elvins (with Doe Run at top). [This definition of Proctor was followed by R. S. Bassler, 1911 (U. S. Nat. Mus. Bull. 77, p. 39).]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27, pp. 629–633). *Proctor dol.*—Nonsiliceous massive dol., with no chert; uncon. underlying Gunter ss. and resting on Eminence chert. Best developed in Morgan and Miller Counties, where it attains thickness of about 60 ft. Much thinner in Shannon and Carter Counties, and seems to be locally absent.

Wallace Lee, 1914 (Mo. Bur. Geol. and Mines vol. 12, 2d ser.). *Proctor fm.* of Miller Co. and to W. underlies Gunter ss. memb. of Gasconade fm. and probably is included in upper Eminence. The exposures of Proctor fm. in basin of Osage River occur chiefly in bluffs. They are noncherty, entirely without fossils, and resemble the bluff exposures near top of Eminence fm. at type loc., which also underlies, probably uncon., 4 or 5 ft. of ss. forming basal bed of Gasconade fm.

H. A. Buehler, 1917 (Am. Inst. Min. Engrs. Bull. 130, pp. 1699–1718). *Proctor*, 100 ft. thick, underlies Gasconade and overlies Eminence. [Same definition was given by C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser.).]

E. B. Branson, 1918 (Univ. Mo. Bull., vol. 19, No. 15). *Proctor fm.*, 0 to 60 ft. thick, occurs on W. flank of Ozarks. Consists of thick beds of medium- to coarse-grained crystalline to granular gray dol., deeply pitted on weathered surface; chert entirely absent in many regions but occurs here and there in some outcrops. Further investigation may show that Eminence and Proctor are same fm. The Eminence of E. flanks of Ozarks uncon. underlies Gasconade fm.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.). *Proctor fm.* is about 60 ft. thick at type loc., in Miller, Morgan, and Camden Counties, and thinner in Carter, Shannon, and Washington Counties. Does not appear to have been recognized elsewhere. Uncon. underlies Gunter ss. and uncon. overlies Eminence fm., which is typically exposed in Shannon, Carter, Washington, and other Counties, and is doubtfully present in Camden and Morgan Counties.

Named for exposures on Proctor Creek, Morgan Co.

Proctor's Lake limestone.

A name applied by W. E. Logan, 1863 (Canada Geol. Surv. 15th Rept. Prog., pp. 43–45), to a 20-ft. bed of ls. in middle part of Grenville series of Grenville region, Ontario.

†Productive Measures.

See under †*Barren Measures*.

†Progonic (also †Progonozoic).

Names proposed by J. J. Sederholm in 1914 to cover all pre-Camb. time and rocks. Correspond to Proterozoic era of U. S. Geol. Survey. For definition see U. S. G. S. Bull. 769, pp. 30-31.

Proserpine quartz porphyry.

Age (?): British Columbia.

W. L. Uglow, 1922 (Canadian Inst. Min. and Met. Mon. Bull. No. 127).

Proserpine intrusives.

Pre-Mississippian: Canada.

W. A. Johnston and W. L. Uglow, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. A1, No. 2331, p. 5A).

Prospect porphyritic gneiss.

Ordovician (?): Western and western central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 59, 102-104, and map). *Prospect porphyritic gneiss.*—Light-gray porphyritic gneiss, including small areas of porphyritic granite with inconspicuous gneissoid development and narrow bands of mica schist distributed unevenly. At its extreme N. limit it is prevailingly less porphyritic and more quartzose and contains areas of intrusive basic rocks. Is believed to have been originally a mass of porphyritic granite intruded into Hartland (Hoosac) schist. Covers E. part of Prospect Twp.

†Prospectan series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 51, 53, 80), to Prospect Mtn qtzite and overlying Pioche sh. of Nev.

Prospect Hill sandstone member (of Hannibal shale). (In Kinderhook group.)

Mississippian: Southeastern Iowa (Des Moines County).

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 22, 23-24). *Prospect Hill ss. memb. of Hannibal fm.*—Soft fine-grained drab-weathering buff ss., shaly in upper part; some seams filled with casts of fossil shells; occasional plant remains. Thickness at Prospect Hill, Burlington, Iowa, 6 ft. Top memb. of Hannibal fm. Underlies Chouteau ls. and overlies McKerney ls. memb. of Hannibal. Is of slightly lighter color and denser texture than English River ss. memb., and fossils are different. Contains a large Chouteau element in its fauna, but it is lithologically and faunally more closely allied to Hannibal fm. at Burlington.

Prospect Mountain quartzite.

Lower Cambrian: Eastern Nevada and western Utah (House Range and Gold Hill district).

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 254). *Prospect Mtn qtzite.*—Bedded brownish-white qtzites weathering dark brown; ferruginous near base; intercalated with thin layers of aren. sh.; beds whiter near summit. Thickness 1,500 ft. Oldest sed. rock exposed in Eureka dist. Directly overlain by Prospect Mtn ls. [now replaced by Eldorado ls.]. Named for occurrence in Prospect Peak, Eureka dist., Nev.

This fm. has been mapped by S. H. Ball (U. S. G. S. Bull. 308, 1907) in Inyo Co., Calif., and has been identified by C. D. Walcott in House Range, western Utah (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 12, 1908), with a thickness of 1,200+ ft.

†Prospect Mountain limestone.

Middle Cambrian: Eastern Nevada.

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept. pp. 253, 254-259). *Prospect Mtn ls.*—Gray compact ls., crystalline and granular, lighter in color than Hamburg ls., traversed with thin seams of calcite; bedding planes very imperfect. Interstratified are lenticular or wedge-shaped bodies of sh. varying greatly in width. Thickness 3,050 ft. Rests on Prospect Mtn qtzite and grades into overlying Secret Canyon sh. Named for exposures on Prospect Mtn, Eureka dist.

Replaced by Eldorado ls., the name *Prospect Mtn* being retained for the qtzite.

Prospect Peak basalts.

See under *West Prospect basalt.*

Prospect Point eruptives.

Post-Eocene: British Columbia.

W. A. Johnston, 1923 (Canada Geol. Surv. Mem. 135, p. 33).

Prosperity limestone member (of Greene formation).

Permian: Southwestern Pennsylvania (Washington County) and southeastern Ohio.

F. G. Clapp, 1907 (U. S. G. S. Bull. 300, pp. 13, 128; and U. S. G. S. Amity folio, No. 144; name suggested by M. J. Munn; see also U. S. G. S. Bull. 318, p. 77). *Prosperity ls. memb. of Greene fm.*—Hard dark blue-gray to nearly black compact ls.; in appearance almost exactly like Upper Washington ls. Supposed to reach max. thickness of 20 ft. Lies 100 to 180 ft. above Upper Washington ls. Named for village of Prosperity, Washington Co., Pa.

Prosperity sand.

Name applied to a subsurface sand of Perm. age in Cement oil field, Caddo Co., Okla., lying at 2,400 ft. depth, and about 100 ft. lower than Fortuna sand.

Prosser limestone.

Middle Ordovician: Southeastern Minnesota, northeastern Iowa, and northwestern Illinois.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27, pp. 368, 369, 524, 525). *Prosser ls.*—Name proposed for a fm. comprising the *Clitambonites, Nematopora,* and *Fusispira* beds of Minn. repts. Upper part corresponds to lower part of Galena dol., and lower part is older than Galena, but of basal Trenton age. Uncon. underlies Stewartville dol. and uncon. overlies Decorah sh.

R. S. Bassler, 1911 (U. S. Nat. Mus. Bull. 77, pp. 25–27). *Prosser ls.*—Cherty nonmag. light-blue fine-grained ls. 10 to 20 ft. thick; underlain by 20 to 35 ft. of thin-bedded, occasionally shaly fine-grained bluish ls. containing *Fusispira* bed fauna and locally the *Nematopora* fauna in basal strata; underlain by 20 to 45 ft. of thin-bedded shaly ls. containing large examples of *Receptaculites oweni* at top and *Clitambonites* fauna at base. Underlies Stewartville dol. and overlies Decorah sh. Is basal fm. of Trenton group.

C. R. Stauffer, 1933 (Minn. Geol. Surv. Bull. 23, p. 21). *Prosser ls.* is typically developed in Fillmore Co., where it attains thickness of about 60 ft. and is uniformly a high-grade ls. It receives its name from a small gulch [Prosser Ravine] near [west of] Wykoff [Fillmore Co., Minn.], where it is fully developed. Outcrops along all larger streams in Olmsted and Fillmore Counties, often with very little overburden. Underlies Stewartville dol. and grades into underlying Decorah sh. Basal part is often shaly. Necessary to depend on fauna to distinguish it from Decorah, and even that is not a sure guide.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 27). *Prosser div.* of Galena dol. can be seen in Jo Daviess Co., Ill. [Fig. 1 of this rept. shows it as overlying Decorah and underlying Stewartville.]

G. M. Kay, 1935 (pp. 290–292 of Conf. Rept. cited above). In SE. area the Prosser is discon. on Decorah fm. and underlying Platteville. In southern Minn. it is 135 ft. thick, and reaches max. of 170 to 180 ft. in eastern Iowa. Outcrops in Miss. River bluffs from NW. Ill. to opposite mouth of Wisconsin River. There is possibly a discon. btw. the Prosser and overlying Stewartville.

†Protean group.

A term applied by L. Vanuxem in early N. Y. repts (1838, 1839, etc.) to the rocks now designated as *Niagara group.* The term as used by James Hall in early N. Y. repts (1842 et seq.), however, applied to Clinton fm. only, because of its diverse lithology, the meaning of *protean* being "changeable in form."

Protection formation.

Upper Cretaceous: British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 99).

Proterozoic era.

As used for many years by U. S. Geol. Survey and other geologists this term includes all pre-Cambrian time represented by rocks visible for study. It has, however, been restricted by some geologists to what for many years was known as "Algonkian period," and by other geologists to "late Algonkian" time. As originally defined it applied to †Algonkian period only. (For definition see U. S. G. S. Bull. 769, 1925, pp. 14, 31–42.) The U. S. Geol. Survey has discarded "Algonkian system" and "Archean system," and classifies all pre-Paleozoic rocks as *pre-Camb.*, the time covered by these rocks being called *Proterozoic era.*

Protoceras beds (also Protoceras sandstones).

A paleontologic name that has been applied to part of Brule clay (Olig.) of western Nebr., Wyo., and S. Dak.

†Protozoic era.

A name suggested by Rev. A. Sedgwick in 1838 (Geol. Soc. London Proc., vol. 2, No. 58, p. 684) for the pre-Cambrian rocks in case they should be found to contain organic remains. See U. S. G. S. Bull. 769, 1925, pp. 42–43.

Prout limestone.

Middle Devonian: Northern Ohio.

C. R. Stauffer, 1907 (Jour. Geol., vol. 15, p. 592). *Prout ls.*—A thin fossiliferous layer immediately below Huron sh. in northern Ohio. Certainly of Hamilton age. Generally supposed to be northern equiv. of Olentangy sh.

C. R. Stauffer, 1909 (Ohio Geol. Surv. Bull. 10, pp. 27, 90, 115, 117, 119, 120). *Prout ls. memb.*—Top memb. of Olentangy sh. Thickness 10 ft. in Sandusky region. Fauna not abundant nor well preserved, but it carries among its more plentiful species forms common to Delaware ls.

C. R. Stauffer, G. D. Hubbard, J. A. Bownocker, 1911 (Ohio Geol. Surv., 4th ser., Bull. 14). That *Prout ls.* is northern equiv. of Olentangy sh. is reasonably certain.

C. S. Prosser, 1913 (Jour. Geol., vol. 21, p. 326). *Prout ls.*, 10 ft. thick, known only in northern Ohio, and it is probably well to consider it as a lentil or memb. of Olentangy fm., as Stauffer has done. Type loc. is deep cut on B. & O. R. R. 6 mi. S. of Sandusky and 1 mi. N. of Prout [Erie Co.], in which 5 ft. of ls. is now shown.

A. W. Grabau, 1917 (Jour. Geol., vol. 25, pp. 337–343), assigned Olentangy sh. to Upper Dev. (and=in part Huron sh.), applied name *Plum Creek shales* to shales (of Hamilton age) beneath *Prout ls.* and above Delaware ls., and included both Prout ls. and Plum Creek shales in *Prout fm.*

Prout series.

Middle Devonian: Northern Ohio.

A. W. Grabau, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 112). *Prout series* proposed for northern Ohio lss. and shales of early Hamilton age, which are considerably older than Olentangy sh., which is Upper Dev.

A. W. Grabau, 1917 (Jour. Geol., vol. 25, pp. 337–343). *Prout fm.* includes Prout ls. above and Plum Creek shales below.

Providence sand member (of Ripley formation).

Upper Cretaceous: Western Georgia and southeastern Alabama.

Otto Veatch, 1909 (Ga. Geol. Surv. Bull. 18, p. 86). *Providence sand.*—Unconsolidated yellow, white, red, and purplish cross-bedded sand, 150 ft. thick, forming top subdivision of Ripley fm. in Chattahoochee, Stewart, Marion, and Quitman Counties. Overlies Renfroes marl, through gradual transition. Underlies bright-red sand, in which, at a few localities, boulders of fossiliferous siliceous ls. are found, and which are probably Eocene.

Is top memb. of Ripley fm.

Named for exposures in the deep gullies at Providence, 8 mi. W. of Lumpkin, Stewart Co., Ga.

Providence limestone. (In McLeansboro formation.)

Pennsylvanian: Western Kentucky (Webster and McLean Counties).

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 98). *Providence ls.*—Blue argill. ls., usually quite impure and variable in composition and irregular in bedding. In places split into 2 members by a few inches or ft. of gray argill. sh. Thickness 0 to 12 ft. Lies 0 to 4 ft. above coal No. 11 and lower than coal No. 12. Marine fossils. Well exposed in and about Providence.

L. C. Robinson, 1931 (Ky. Geol. Surv., ser. 6, vol. 37, p. 314). *Providence ls.* (the *Jolly ls. of F. M. Hutchinson*) is an important memb. of Carbondale fm. It is only well-marked ls. horizon in the Carbondale, and is rather persistent wherever the Carbondale is exposed. It occurs a few ft. higher than No. 11 coal, and ranges in thickness from 1 to 4 ft. Is a shaly ls. of bluish color and weathers light brown. [Derivation of name not stated and reason for discarding Jolly ls. of Hutchinson not given. Coal No. 11 of Ky. is coal No. 6 of Ill., which is top bed of Carbondale fm. This ls. therefore belongs in McLeansboro fm.]

Providence Cove beds.

Age (?): Vancouver Island.

C. W. Hall, 1906 (Postelsia, p. 324).

Provo epoch.

Provo stage.

Provo epoch is name applied to the time during which Lake Bonneville of Utah stood at the *Provo stage*.

†Prozoic era.

A name proposed by J. Phillips in 1855 for pre-Paleozoic time, and thus synonymous with Proterozoic era of U. S. Geol. Survey. For definition see U. S. G. S. Bull. 769, p. 43.

Prue sand.

A subsurface sand, of Penn. age and 0 to 110 ft. thick, in northern Okla. Is older than Bixler sand and younger than Markham sand. Lies not far below Oswego lime in Prue pool, Osage Co.

Pryor conglomerate member (of Cloverly formation).

Lower Cretaceous: Central southern Montana (Carbon County) and central northern Wyoming (Bighorn Basin).

C. J. Hares, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 429). Gastroliths were found in summer of 1916 in Cloverly fm. in NE. part of Bighorn Basin, Wyo., at about base of Pryor Mtns in [Carbon Co.,] Mont. These gastroliths occur in sh. portion of the Cloverly, btw. *Pryor cgl. memb.* at base and Greybull ss. memb.

C. F. Bowen, 1918 (U. S. G. S. Bull. 691F, section A of pl. 25), published the Elk Basin section from C. J. Hares' unpublished rept., and showed *Pryor cgl. memb.* as basal 40± ft. of Cloverly fm.

Pryor Creek shale. (In Cherokee shale.)

Pennsylvanian: Northeastern Oklahoma (Nowata and Vinita region).

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. No. 4, p. 13). Basal part of Vinita fm. [Cherokee sh.] in NE. Okla. consists of 550 ft. of bluish sh. that weathers light yellow and a few sss. This unit is well exposed in vicinity of town of Pryor Creek, and may be called *Pryor Creek sh.* It is probably=Drake's Lower Coal Measures.

†Psychozoic era.

Name proposed by J. Le Conte (Am. Jour. Sci., 3d, vol. 14, p. 114, 1877) for the epoch beginning "with the completed supremacy of man, i. e., the Present epoch." (See U. S. G. S. Bull. 769, p. 9.)

Ptarmigan limestone.

Middle Cambrian: Alberta and British Columbia.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 1, Pub. 2444, pp. 1-5). *Ptarmigan fm.* is proposed for series of aren. gray lss. interbedded with bands of thinner-bedded dark bluish-black lss. and some sh. bands, that occur above Mount Whyte (Lower Camb.) and beneath Cathedral fm. (Middle Camb.) in Alberta and B. C. Thickness 516 ft. at Ptarmigan Peak and 664 ft. at Ross Lake, 8½ mi. W.-SW. of Ptarmigan Lake. Contains Middle Camb. fossils, including the *Albertella* fauna of Alberta and B. C. Type loc. is SE. slope of Ptarmigan Peak, above Ptarmigan Lake, 4¾ mi. NE. of Lake Louise Station on Canadian Pacific R. R., Alberta. [Detailed section given and fossils listed.] The *Albertella* zone, 7 to 11 ft. thick, is here named *Ross Lake sh. memb. of Ptarmigan fm.* It lies about 100 ft. below top of Ptarmigan fm. It may be an error to include the Ross Lake sh., with its *Albertella* fauna, in Ptarmigan fm. That is one of problems for future worker in field to determine.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 2, Pub. 2445). At Mount Bosworth the Cathedral lss. are 1,086 ft. thick, exclusive of a lower div. of 509 ft., which I have now included in a recently recognized fm. named *Ptarmigan*.

†Pteranodon beds.

Paleontologic name formerly applied to Smoky Hill chalk (Upper Cret.) of Kans.

Puckett sandstone member (of Mingo formation, in Pottsville group).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 40). *Puckett ss. memb.*—Cliff-making ss., 0 to 100 ft. thick, in Mingo fm., lying 160 ft. below top of Mingo.

Named for Puckett Creek, Bell Co., Ky.

Puckmummie schist.

Post-Ordovician(?): Northwestern Alaska (Seward Peninsula).

P. S. Smith, 1910 (U. S. G. S. Bull. 433, pp. 50, 62+, maps). *Puckmummie schist.*—Dark slates and schists, little metamorphosed, noncalcareous, of sed. origin. Best exposed on lower part of Puckmummie Creek and on rocky knob to E., in low hill NW. of Post Creek, and in a few scattered outcrops. Is probably = Hurrah sl. (post-Ord.?), from which it differs only in being somewhat more schistose. Is younger than Solomon schist and probably younger than Sowik ls. Assigned to post-Ord.

Puckwunge conglomerate.

Pre-Cambrian (lower Keweenawan): Northeastern Minnesota (Cook County).

N. H. Winchell, 1897 (Am. Geol., vol. 20, pp. 50–51). *Puckwunge cgl.*—Basal cgl. of Keweenawan. Chiefly qtzite pebbles, white to pink and red. Named for stream that enters Pigeon River from W. to N. of Grand Portage village, Cook Co. What it lies upon we could not find out, but in a lower level in same hills is a singular-looking and somewhat slaty soft greenish rock of late Animikie age which we named *Puckwunge sl.* This sl. extends across Puckwunge Valley and to the E. and is probably an upper memb. of the Animikie.

N. H. Winchell, 1900 (Geol. Minn. Final Rept., vol. 5, pt. 1). *Puckwunge cgl.*, the fragmental base of the Keweenawan; 144 ft. exposed; unexposed part probably as much more. Contains much debris from Animikie slates.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 370, 371, 394). *Puckwunge cgl.* lies at base of Keweenawan series. It grades up into ss. and rests uncon. on Animikie.

†Puckwunge slate.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Cook County). See under *Puckwunge cgl.*

Pueblo formation. (In Cisco group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Pueblo fm.*—Is bounded at top by *Pueblo ls.* [Camp Colorado ls.], which is yellow, fossiliferous, and impure. Near Red Bed line in Stephens Co. it changes to sand and loses its identity, but just below its horizon is a thin ls. abundant in *Myalina* fossils, which characterize this bed. The members of this fm. are so variable that no one section is typical. Underlies Moran fm. and overlies Waldrip fm. [now replaced by Harpersville fm.].

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 40). *Pueblo fm.*—Largely gray, buff, or reddish sh., with Camp Colorado ls. (3 to 6 ft. thick) at top and Camp Creek sh. memb. at base. Thickness of fm. 150 to 200 ft. Underlies Watts Creek sh. memb. of Moran fm. and overlies Harpersville fm., top memb. of which is Saddle Creek ls. [This is present definition of U. S. Geol. Survey.]

Named for exposures along valley of Battle Creek at Pueblo, Callahan Co.

†Pueblo limestone member (of Pueblo formation).

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). [See under *Pueblo fm.*]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 40), replaced this name with *Camp Colorado ls. memb.*

†Pueblo quartzite.

Pre-Cambrian: Central northern New Mexico (Taos County).

J. W. Gruner, 1920 (Jour. Geol., vol. 28, pp. 731–742). *Pueblo qtzite.*—As a whole is yellow, but southern end becomes reddish and purplish gray. Exposed at head of Pueblo Creek [Twps 26 and 27 N., Rs. 14 and 15 E.], Taos Co.

Pueblo formation.

Mesozoic or older: Southeastern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Pueblo fm.*—Crystalline rocks, porphyries, schists, etc., massive and irregular, of undet. thickness. Type loc. Pueblo Mtns, S. part of Harney Co.

Pueblo Mountain series.

Tertiary (late): Southeastern Oregon and northwestern Nevada.

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, pp. 14, etc.). The acidic flow capping the *Pueblo Mtn series* (the great volcanic series of Pueblo Mtn) is definitely older than Thousand Creek beds, which are late Plio.

Evidently refers to *Pueblo Range series* of Merriam.

Pueblo Range series.

Miocene (early): Northwestern Nevada.

J. C. Merriam, 1910 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 6, No. 2, pp. 26–52, pl. 2). *Pueblo Range series.*—More than 1,000 ft. of eruptives, consisting of basalt, tuff, and rhyolite, the rhyolite following the basalt. Older than Virgin Valley beds, an epoch of erosion intervening. Whether the sed. beds in upper part of Pueblo Range section actually belong with the underlying lavas and tuffs is uncertain, but they appear to represent one general period of deposition. For practical purposes it is desirable to refer to the rhyolites and basalts on W. side of Pueblo Range, with whatever eruptives or other beds may be shown to belong in the same series, as the *Pueblo Range series*, a geographic designation indicating the section first described by J. Blake (Proc. Calif. Acad. Sci., vol. 5, pp. 210–214, 1875), who assigned the beds to early Mio.

Puente formation.

Miocene (upper and middle): Southern California (Puente Hills and Los Angeles district).

G. H. Eldridge and R. Arnold, 1907 (U. S. G. S. Bull. 309). *Puente fm.*—Miocene deposits uncon. underlying Fernando fm. in Puente Hills [S. part of Los Angeles Co.] and Los Angeles dist. Consists of (descending):

Upper Puente sh., 300–2,000 ft. (Earthy chalk-like sh. with a few beds of fine yellow ferruginous ss. and quartzose calc. concretions.) Resembles Monterey sh.

Puente ss., 300–2,000 ft. (Moderately coarse gray and yellow heavy-bedded ss. separated by minor bands of organic siliceous sh.)

Lower Puente sh., 2,000 ft. (Chiefly earthy sh., but with minor members of siliceous nature, the whole gray or brown, from presence of iron and bitumen. Thin fine-grained sss. interbedded from top to base, and lentils of gray ls. This is lowest rock exposed in Puente Hills.)

Is uncon. overlain by Fernando fm., and overlies, uncon., pre-Cret. granite and schist.

According to W. S. W. Kew (U. S. G. S. Bull. 753, pl. 3, 1924) the Puente fm. of Puente Hills corresponds to Modelo fm. of Bull. 753, and Puente fm. of Los Angeles dist. corresponds to Modelo and underlying Topanga fm. of Bull. 753.

†Puente sandstone.

See under *Puente fm.*

†Puente shale.

See under *Puente fm.*

Puercan series.

A name introduced by C. [R.] Keyes to include Torrejon and Puerco fms. of current terminology, but he substitutes *Jemez* for *Puerco* in his classification. (See Pan-Am. Geol., vol. 58, No. 4, p. 289, 1932.)

Puerco formation. (In Nacimiento group.)

Eocene: Northwestern New Mexico.

E. D. Cope, 1875 (Ann. Rept. Chief Engrs U. S. A., Rept. Secy War to 44th Cong., vol. 2, pt. 2, pp. 1008–1017). *Puerco marls.*—Soft soapy marls, black and green; no lignite nor coal. Lowest beds of Eocene in Rio Puerco region. Important near Nacimiento. Outcrop over 40 mi. Valley of Upper Puerco excavated in them. No fossils except petrified wood, which gives weight to probability they are lacustrine. In places rest on Eocene sss.; in other places on Cret. No. 4. Are conformably overlain by light-reddish or yellowish sss. of Green River group (Eo.) [now known to belong to Wasatch fm. instead]. [On p. 1016 he calls the beds *Puerco group* and gives thickness of 500 ft.]

E. D. Cope, 1877 (U. S. Geog. Surv. W. 100th Mer., vol. 4, pt. 2, pp. 14–18). *Puerco group.*—Green and black marls, believed to be lacustrine. Thickness 500 ft. Overlies Cret. No. 4.

E. D. Cope, 1884 (U. S. Geog. and Geol. Surv. Terr., vol. 3, pp. 4–20). Most southern locality at which I have observed *Puerco fm.* is the one for which I named it, and where its characters are distinctly displayed, as W. of Jemez and Nacimiento Mtns, N. Mex., at sources of Puerco River, where its outcrop is about 500 ft. thick. On E. side of Animas River thickness is 1,000 to 1,200 ft.

E. D. Cope, 1888 (Am. Geol., vol. 2, pp. 266–267). *Puerco fm.* of NW. N. Mex. and SW. Colo. is 850 ft. thick and consists of sss. and soapy marls. It overlies Laramie fm. and underlies Wasatch. Contains rich vertebrate fauna (listed).

E. D. Cope, 1888 (Am. Phil. Soc. Trans., n. s., vol. 16, pt. 2, pp. 298+), divided his *Puerco series* into *Upper Puerco* and *Lower Puerco* and described the fossils, but did not define the subdivisions.

J. L. Wortman, 1897 (Sci., n. s., vol. 6, p. 852), proposed restricting Puerco to the lower Puerco and adopting name Torregon [Torrejon] fm. for the upper Puerco. (See under *Torrejon fm.*)

W. D. Matthew, 1900 (Am. Mus. Nat. Hist. Bull., vol. 12, p. 20). *Puerco fm.* is 500 ft. thick and overlying Torrejon fm. 300 ft. thick.

J. H. Gardner, 1910 (Jour. Geol., vol. 18, No. 8, p. 713). *Puerco fm.*, lower fm. of Nacimiento group, consists of variegated clay, sh., and soft coarse-grained ss. of white, gray, and tan colors. Thickness 560 ft. Underlies Torrejon fm., but the two cannot everywhere be readily separated without fossils.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, pp. 35+). The name *Puerco* was applied by Cope in 1875 to entire series of beds on Puerco River, now supposed to include both Puerco and Torrejon fms. No fossils have been found in the beds on Puerco River, but later numerous fossils were found W. of Puerco River, which were believed by Cope to have come from the equiv. of his Puerco beds, and were described by him as "Puerco fauna." These fossils were later separated by Wortman (1897) into two quite distinct faunas. For the beds yielding the younger fauna he proposed the name *Torrejon*, from exposures on Arroyo Torrejon, Sandoval Co., retaining Cope's name Puerco for the beds yielding the older fauna. In these senses the names have been generally accepted since that time. The Torrejon fauna is interpreted by most students of vertebrate paleontology to be a direct descendent of Puerco fauna, but is sufficiently different to demand the lapse of a long interval of time. As, in addition, the two faunal zones appear to be relatively close together stratigraphically at some localities and widely separated at others, and as the area yielding Torrejon fauna is much greater in extent than that yielding Puerco fauna, it would seem necessary to assume a hiatus. But owing to great similarity in lithology and restriction of fossils to relatively narrow zones with a barren interval between, no break has been recognized in the field in the series of beds, even at localities where both fms. are known to be present. *Nacimiento group* is a convenient term where the two fms. are not distinguished on maps and in discussions. The Puerco fm. as defined by its fauna is now known only in a small area extending from Escavada Wash to head of W. fork of Gallego Arroyo, SE. part of San Juan Co., N. Mex. The distance along the outcrop is 35± mi. No fossils are known from section on Puerco River near Cuba, whence the name was derived, and only Torrejon fossils from beds on Arroyo Torrejon. In fact, as Puerco fm. is characterized only by its fossils, it is very doubtful whether the fm. is present at either of these localities. It is purely an assumption to apply either *Puerco* or *Torrejon* to the barren interval btw. the fossiliferous zones of the Puerco and Torrejon or to the lateral extension of the beds in this interval into localities where Puerco fossils are not known. The barren interval is rather thin on both Arroyo Torrejon and Puerco River, and may be later than fossiliferous Puerco. It is possible Torrejon fm. overlaps and conceals Puerco fm. over most of San Juan Basin, and writer prefers this hypothesis. The Puerco uncon. overlies Ojo Alamo ss. [Fossils listed.]

C. H. Dane, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 14, pp. 406–411, 1932), presented evidence to show that "the *Puerco fm.* may be present along Rio Puerco, although the distinctive vertebrate fauna by which alone it is recognized has not yet been found there."

Puertecito formation.

Lower Cretaceous (?) to base of Triassic: Northwestern New Mexico (Socorro and Valencia Counties).

E. H. Wells, 1919 [1920] (N. Mex. State School Mines Bull. 3). *Puertecito fm.*—The sed. beds btw. Perm. and Cret. rocks. Consist of purplish-red shales, purplish-red and purplish-gray sss., and a few thin cgl. beds. Colors maroon, purplish red, purplish gray, subordinate white, grayish drab, and purplish blue. Thickness 1,150 to 1,250 ft. in Puertecito dist., Socorro and Valencia Counties. Possibly upper part includes Jurassic and Lower Cret. Darton considers the fm. largely Triassic.

Puertecitos limestone.

Upper Cambrian (?): Mexico (Sonora).

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 320). [Named for town. No age assigned.]

M. L. Lee, 1912 (Econ. Geol., vol. 7, p. 327). Puertecitos ls. of Mexico is of same age as Abrigo ls. of Ariz. [which is Upper Camb.].

Puerto Colorado sandstone member (of Indio formation).

Eocene (lower): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1368, 1371, 1380). *Puerto Colorado ss.*, basal memb. of Indio fm. Crops out in Puerto Colorado scarp at kilometer 1188 on Laredo-Monterrey highway. Can be traced from Rio Grande to Rio San Juan, Tamaulipas.

Puerto Ferro limestone.

Miocene: Puerto Rico.

H. A. Meyerhoff, 1933 (Geol. of Puerto Rico, p. 74).

Puffy shale member (of Redwood formation).

Oligocene: Southeastern Alaska (Katalla district, Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 773+). *Puffy sh. memb.*—Upper memb. of Redwood fm. Predominantly dark clay sh., with many thin layers of fine flaggy sss. and many sh.-matrix cgls., in part of glacial origin. Thickness 4,000+ ft.; top not seen. Conformably overlies Point Hey ss. memb. Lower 200 to 300 ft. consists of massive calc. sh. with thin beds of hard fine-grained ss., which stands out as cliffs in upper part of Puffy Creek Basin. Assigned to upper Olig. on basis of correlation with fossiliferous rocks in Yakataga dist. that are assigned to upper Olig. by B. L. Clark.

The U. S. Geol. Survey classifies typical Katalla fm. as Mio. (?). Taliaferro correlated his Redwood fm. with Katalla.

Puget group.

Eocene: Western Washington (Puget Sound Basin).

C. A. White, 1888 (Am. Jour. Sci., 3d, vol. 36, pp. 443–450). *Puget group.*—Deposited in estuary. Brackish-water fauna. Occupies large part of Puget Sound Basin and extends upon W. flank of Cascade Range. Similar deposits on E. side of Cascade Range are believed to belong to same fm. Overlies Upper Cret. marine strata.

B. Willis, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 400–436). *Puget group,* 5,480 to 9,000± ft. thick, divided into (descending) Pittsburg fm., Wilkeson fm., and Carbonado fm. [He later replaced *Pittsburg fm.* with *Burnett fm.*]

For many years the age of these beds was in doubt. They were originally assigned to Cret., and later were assigned in part to Mio., also to Olig. Knowlton considered the plants indicate Puget group is all upper Eocene. E. W. Berry, 1929 (Flora of Green River age in Wind River Basin), stated he considered Puget group is late Eocene or Olig. The U. S. Geol. Survey at present classifies the Puget as Eocene, which seems to be the generally accepted classification.

Pugh formation. (In Pottsville group.)

Pennsylvanian: Northeastern West Virginia.

J. A. Taff and A. H. Brooks, 1896 (U. S. G. S. Buckhannon folio, No. 34). *Pugh fm.*—Blue and black clay sh., thin brown ss., false-bedded gray ss., in places white ss. and cgl., and a few thin coal beds. Thickness 300 to 450 ft. Overlies Pickens ss. and underlies Upshur ss. Named for exposures at Pugh P. O., Webster Co.

Is a local name for rocks approx. equiv. to Kanawha fm.

Pugh sand.

A subsurface sand in Robberson field, central southern Okla., lying lower than Simpson sand and higher than Dunlap sand. The Simpson sand is assigned to Ord. in Okla. Geol. Surv. Bull. 40Q, 1928, p. 179.

Pulaski shale.

Upper Ordovician: New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 373–374). *Pulaski shales.*—In last rept called *shales of Salmon River.* Shales predominate at lower part of village of Pulaski, with some lime carbonate, while above the village the ss. begins to predominate. Occur at Pulaski [Oswego Co.] unaccompanied by any other mass, hence the name. Underlie Salmon River [Oswego] ss. and overlie Frankfort sl.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, Geol. of 2d dist., pp. 119–123, 401, 429). *Lorraine shales.*—Thin beds of gray ss. alternating with fine argill. slates of greenish color, even-bedded; upper part highly fossiliferous. Overlain by the Grey ss. [Oswego] that underlies Medina ss., and underlain by Utica sl. In ann. repts this mass has been designated *Pulaski shales,* a name which it would have been well to have retained, if it had embraced the whole series; but at Pulaski only upper part is visible; while at Lorraine the entire mass is exposed and cut through by Sandy Creek, from the grey ss. to Trenton ls. Lorraine is therefore a locality far more important than Pulaski; and hence, according to modern practice of giving names, the former is to be preferred to the latter. [As thus defined *Lorraine* included Pulaski shales and Frankfort sl. of Vanuxem, and it did not supplant *Pulaski sh.*, but in some repts it was itself replaced by †Hudson River group, and in other repts it was dropped from classification, *Pulaski* and *Frankfort* being used alone.]

Pulaski sh. is in good standing as originally defined by Vanuxem. In 1925 (N. Y. State Mus. Bull. 258) R. Ruedemann classified it as top fm. of Lorraine group, the lower fm. being called *Whetstone Gulf fm.* in Black River region and *Frankfort sh.* in Utica Basin. The present N. Y. State Survey divides Lorraine into Pulaski sh. (above) and Frankfort sh. (below). Thickness of Pulaski has been given as 400 ft.

†Pulaski shale.

Mississippian: Southwestern Virginia.

M. R. Campbell, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 171, 178, pl. 4). *Pulaski sh.*—Bright-red shales overlying Price (Pocono) ss. and underlying the Carbf. Umbral ls. in Pulaski, Wythe, and Montgomery Counties. [In later repts thickness is given as 20 to 750 ft. or more.]

Preoccupied. *Maccrady fm.* was introduced to replace this preoccupied name, but according to C. Butts the *typical* †Pulaski sh. did not include at top any beds of Warsaw age, while *typical* Maccrady fm. did include beds of Warsaw age. He, however, later restricted Maccrady sh. to the pre-Warsaw beds, and that is present approved definition of Maccrady.

Named for Pulaski, Pulaski Co.

†Pulaski formation. (In Arago group.)

Eocene: Southwestern Oregon.

J. S. Diller, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 319–320). *Pulaski fm.*—Main body of Arago fm. Distinguished from Coaledo fm. (the coal-bearing part of Arago fm.) by fact that it contains mere traces of coal and that strata containing brackish-water fossils are rare. Forms the hills about head of Pulaski Creek and Pulaski arch, which separates Beaver Slough and Coquille coal basins.

J. S. Diller, 1901 (U. S. G. S. Coos Bay folio, No. 73). *Pulaski fm.*—Chiefly rather soft yellowish ss., contrasting strongly with the ss. of underlying Myrtle fm. in color and freedom from cracks; some sss.; and locally shales and traces of ls.; also mere traces of coal. Embraces all Eo. strata of Coos Bay quad. not included in the coal field. Uncon. overlies Myrtle fm. and underlies Coaledó fm.

This name is preoccupied and was discarded by U. S. Geol. Survey many years ago. The beds are essentially equiv. to Tyee ss. and Umpqua fm.

Pulaski sand.

A subsurface sand bed, about 40 ft. thick, in Vaqueros ss. in Coalinga dist., Calif., lying about 40 ft. below the Sauer Dough.

†Pulliam formation.

Upper Cretaceous (Gulf series): Southern Texas.

T. W. Vaughan, 1900 (U. S. G. S. Uvalde folio, No. 64, p. 2). *Pulliam fm.*—Brown ferruginous sss., occurring in ledges or slabs; some beds of clay; near top a bed of soft unconsolidated sand impregnated with asphalt, overlain by several very fossiliferous layers; at top an aggl. of oyster *Ostrea cortex*. Thickness probably 100 to 200 ft. Overlies Anacacho fm. and underlies Eocene Myrick fm.

Same as Escondido fm., older name.

Named for Pulliam ranch, on Nueces River, Zavalla Co.

Pumpkin Creek limestone member (of Dornick Hills formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 14). *Pumpkin Creek ls.*, top memb. of Dornick Hills fm., has max. exposed thickness of 70 ft., including 20 ft. of shaly beds.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 33–34). Uppermost memb. of Dornick Hills fm. is designated *Pumpkin Creek ls.*, from excellent outcrops on Pumpkin Creek in SE¼ sec. 19, T. 6 S., R. 3 E. The upper lss. of Dornick Hills fm. are also well exposed in secs. 10 and 15, T. 6 S., R. 2 E., where main part of Pumpkin Creek memb. forms a strong topog. ridge and reaches thickness of 70 ft., including 20 ft. of shaly beds. Its ls. strata here vary from medium- to coarse-grained, pure to sandy, nearly barren to quite fossiliferous. Most distinctive type, which is found also on other side of Overbrook anticline in N½ sec. 7, T. 6 S., R. 2 E., and in nearly all outcrops of this memb. btw. there and Dornick Hills (N. of Ardmore), is a very coarsely granular cross-bedded, rather sandy gray ls. which weathers to a sort of coarse gray calcitic sand. About 150 ft. below the main Pumpkin Creek ls. on S. line of sec. 10, T. 6 S., R. 2 E., occurs another bed of fossiliferous ls. only 2 ft. thick. Between the two are some very fossiliferous shales in which the cavities in some of the shells, especially crinoid stems and high-turreted gastropods, are filled with bluish chert. Disk-shaped masses of siliceous (sponge?) spicules, the disks up to 2½ in. in diam., constitute a unique element in this fauna. Four or five hundred ft. lower in section, at same locality, occurs a 15-ft. stratum of lumpy, chalky ls. closely interbedded with chalky shales, all highly fossiliferous. This type of rock occurs in much closer association with main Pumpkin Creek ledge N. of Ardmore, where it has been mapped as part of that memb., and is probably the bed mentioned by Goldston as carrying *Campophyllum torquium*, near top of his Cup Coral memb. It weathers in many places to white chalky soil, full of a great abundance and variety of easily collected fossils, including large cup corals. On S. line of sec. 10, T. 6 S., R. 2 E., the main ledge of Pumpkin Creek memb. occurs about 2,000 ft. above Bostwick memb. This interval diminishes rapidly northwestward, with especially pronounced convergence in secs. 4 and 5, T. 6 S., R. 2 E.; N. and W. of Ardmore it is only 900 to 1,000 ft.

Punchbowl volcanics.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 55–60). Punchbowl tuff crater consists of 3 rock fms. younger than Koolau basalt, which underlies the flanks. The oldest is the tuff, which makes up main mass of the crater. The second and third are the closely associated black ash and basalt of much more recent date. The *Punchbowl tuff* is of typical palagonitic variety, somewhat coarser than Diamond Head tuff. Its thickness is 2 to 50 ft. No partly altered ash was seen in the Punchbowl mass.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Punchbowl volcanics.*—Tuff and basalt composing Punchbowl cone, near center of Honolulu. Included in Honolulu volcanic series [q. v.]. Assigned to late Pleist. Younger than Koolau volcanic series. [Evidently includes the Punchbowl tuff of Wentworth and the overlying basalt of Wentworth.]

Puncheon Creek sandstone. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky (Magoffin County).

I. B. Browning and P. G. Russell, 1919 (Ky. Geol. Surv., 4th ser., vol. 5, pt. 2, p. 13). *Puncheon Creek ss.*—Massive coarse-grained white to brownish-white cliff-forming ss. 60 ft. thick, underlain by 30 to 50 ft. of fine-grained massive, sometimes shaly ss. which usually does not form cliffs. Total thickness 70 to 120 ft. Overlies Fugate coal and underlies Hindman coal. Named for Puncheon Creek of Licking River, Magoffin Co., where it is well developed.

†Punta de la Mesa sandstone member. (In Mesaverde formation.)

Upper Cretaceous: Central northern New Mexico.

C. L. Herrick, 1900 (Am. Geol., vol. 25, pp. 331–346; N. Mex. Univ. Bull., vol. 2, pt. 1, pp. 3–63, pt. 2, pp. 1–17). *Punta de la Mesa ss.*—Massive ss., 50 to 75 ft. thick in Albuquerque quad., 25 to 50 ft. thick in western Socorro and Valencia Counties. Underlies Prieta sss. Lies 225+ ft. above Tres Hermanos ss., and 80 to 100 ft. above the cephalopod zone, 25 ft. thick.

W. T. Lee, 1912 (Geol. Soc. Am. Bull., vol. 23, pp. 592–598). *Punta de la Mesa ss.* at its type loc. in Rio Puerco field is here placed at base of Mesaverde fm., inasmuch as it is lowest ss. of the coal-bearing fm. But it seems to be age equiv. of part of Mancos sh. as developed farther N.

W. T. Lee, 1917 (U. S. G. S. P. P. 101, pp. 172–174, 179). Later investigations show that *Punta de la Mesa ss. memb.* (50 ft. thick) occurs 850 ft. below top of Mancos sh. as developed farther N., and it is here treated as a memb. of Mancos sh. It was previously included in Mesaverde fm. on assumption that that fm. extended downward to include all of the massive sss. At Casa Salazar it lies 1,147± ft. above Tres Hermanos ss. memb. of Mancos.

Named for Punta de la Mesa, N. of San Ignacio, Guadalupe Co.

According to later work by C. B. Hunt the Punta de la Mesa ss. is E. extension of middle and major part of Gallup ss. memb. of Mesaverde fm., and the name has been discarded by U. S. Geol. Survey.

Punta Maisi limestone.

Miocene: Cuba.

S. Taber, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 4, p. 588).

Purcell series.

A term applied by Canadian geologists to rocks of Purcell Mtns, British Columbia and adjacent part of NW. Mont., which they correlate with the typical pre-Camb. Belt series of Mont. and Idaho. (See S. J. Schofield, The geology of East Kootenay, B. C., abstr. of thesis, Mass. Inst. Tech., p. 3, 1912, and Canada Geol. Surv. Summ. Rept. 1911, p. 159, 1912.) Includes Mooyie fm. at top and Creston qtzite at base. These rocks are included in Belt series by U. S. Geol. Survey.

Purcell basalt.

A term applied by Canadian geologists to altered basalt, of pre-Camb. age, underlying Mooyie fm. and overlying Kitchner fm. in SW. Alberta, SE. British Columbia, and NW. Mont. (Glacier Nat. Park). "Since it has its max. known thickness in McGillivray div. of Purcell Mtn system, the fm. has been called *Purcell lava*." (R. A. Daly, 1913, Can. Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 207.) Daly mapped the fm. in 1912 (Can. Geol. Surv. Dept. Mines Mem. 38, several sheets). C. H. Clapp, 1932 (Mont. Bur. Mines and Geol. Mem. 4, pp. 21–22), says "Purcell lava consists of basalt flows in Siyeh and Missoula groups of Belt series."

Purcell sandstone lenses. (In Hennessey shale.)

Permian: Northern central Oklahoma (Kingfisher County).

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, p. 1465). *Purcell ss. lenses.*—In vicinity of Purcell the upper 250 ft. of Hennessey sh. is filled with ss. lenses, the most prominent of which may be seen in river bluff just N. of the town. In this zone the sss. are highly lenticular and are cross-bedded. Lower part of zone forms a topog. ridge that can be followed from Purcell to Table Mtn area in Garvin Co. At Table Mtns, T. 3 N., R. 3 W., the top of zone is capped by a well-stratified bench-forming bed that can be followed many mi. W. and SW. At Purcell the zone of lenses is 230 ft. thick and the base is 150 ft. above Garber ss. On S. side of Washita River, in area SW. of Maysville, a good sh. section, 160 ft. thick, lies btw. base of Purcell lenses and the Antioch ss.

Purefoy's Mill series.

Age (?): Northern central North Carolina (Chapel Hill area).

W. H. Fry, 1911 (Elisha Mitchell Sci. Soc. Jour., vol. 27, p. 124). Chapel Hill area is in northern central N. C., in "Carolina metamorphic slate and volcanic belt." Bounded on S. by igneous slates of unknown age, generally spoken of as *Purefoy's Mill series*; on SE., E., and NE. by Triassic sss.; on N. and W. by very basic crystalline plutonics and acid volcanics of comparatively recent age, probably Triassic. The rocks composing the area are mainly granites.

Purgatoire formation.

Lower Cretaceous (Washita): Eastern Colorado, central northern and northeastern New Mexico, and Oklahoma Panhandle.

G. W. Stose, 1912 (U. S. G. S. Apishapa folio, No. 186). *Purgatoire fm.*—Upper third largely sh. with minor thin platy sss.; lower two thirds is almost wholly ss., of lighter color than overlying Dakota ss. Thickness 220 ft. Conformably overlies Morrison fm. and conformably underlies Dakota ss. as here recognized. Was formerly regarded as part of Dakota ss., but contains marine fossils which T. W. Stanton says are of Washita (Comanche) age, and therefore older than Dakota ss. Named for Purgatoire Canyon, in Mesa de Maya quad., Colo.

Purgatory conglomerate.

Carboniferous: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 364–374). *Purgatory cgl.*—Coarse cgl., overlying Aquidneck shales, also overlying Sakonnet ss. [of R. I.]. Is latest Carbf. fm. in S. part of Narragansett Basin. Typically developed at Purgatory. Thickness 380 to 600 ft.

Purington shale.

Name applied by H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 804, and Ill. Geol. Surv. Bull. 60, pp. 179–193), to an undescribed sh. in lower part of Carbondale fm. (Penn.) of central western Ill., shown as 0–50± ft. thick; as lying lower in section than No. 4 coal and higher than No. 2 coal (from both of which it is separated by other rocks, the overlying rocks being called *Pleasantview ss.* and the underlying rocks *Oak Grove memb.*); and as in places cut out by Pleasantview ss. Derivation of name not stated.

Purisima formation.

Pliocene: Western California (Santa Cruz Mountains).

H. L. Haehl and R. Arnold, 1904 (Am. Phil. Soc. Proc., vol. 43, pp. 16–53). *Purisima fm.*—Fine-grained sss. and sh., 700 ft. thick, resting on basal cgl. 20 ft. thick. At top grades into beds having fauna somewhat similar to that of Merced fm. Its upper limit may be defined as base of Merced. Rests uncon. on Monterey sh.

Named for exposures near Purisima and along Purisima Creek, San Mateo Co.

Purslane sandstone. (In Pocono group.)

Mississippian: Northeastern West Virginia and western Maryland.

G. W. Stose and C. K. Swartz, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Purslane ss.*—Massive hard coarse white ss. and milky-white quartz cgl. alternating with softer cross-bedded ss. with a little sh. and thin coal seams. Thickness 180 to 310 ft. Underlies Hedges sh. and overlies Rockwell fm.; all included in Pocono group. Purslane Mtn, Morgan Co., W. Va., is formed of this ss.

Put-in-Bay dolomite member (of Bass Islands dolomite).

Silurian (Cayugan): Southeastern Michigan and northern Ohio.

W. H. Sherzer and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 546). *Put-in-Bay dolomites.*—Middle memb. of Lower Monroe fm. [Bass Islands dol.]. Underlies Raisin River beds and overlies Greenfield dol. [On a later page (553–556) thickness is given as 100+ ft. Later repts give thickness 0 to 220± ft.]

See under *Tymochtee sl.*

Named for exposures on Put-in-Bay Island, Lake Erie.

Putnam gneiss.

Late Carboniferous or post-Carboniferous: Eastern Connecticut and southern Massachusetts.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 129, 133, 134, 136, 140, and map). *Putnam gneiss.*—Consists of bands of schist, gneiss, qtzite, and igneous intrusions in great variety. In texture varies from compact bluish-black sl. and qtzite through fine black schist to coarse gray quartzose schist and feldspathic gneiss. Includes beds of ls., intrusive sheets of Sterling granite gneiss and pegmatite, amphibolite, and layers of black granite porphyry. In composition shows gradations from hornblende-biotite schist (or sedimentary amphibolite?) with little or no feldspar, through quartz-biotite schist and gneiss (or crystalline arkose?) to qtzite. Of sed. origin. In town of Preston there are 2 main varieties—a gray schist, often feldspathic, and a fine biotite-hornblende schist, both thoroughly injected with intrusive sheets and stringers of granite and pegmatite. The fine black schist evidently underlies the gray feldspathic variety. Evidence indicates Putnam gneiss underlies Scotland schist. The two fms. are conformable and pass into each other without noticeable change.

G. F. Loughlin, 1912 (U. S. G. S. Bull. 492, p. 16). The northward continuation of *Putnam gneiss* into Mass. is represented in Bolton gneiss, which Emerson and Perry assign to Carbf.

Putnam formation. (In Wichita group.)

Permian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 40). *Putnam fm.*—Composed of Santa Anna Branch sh. memb. (below) and Coleman Junction ls. memb. (above). Thickness 125 to 150 ft. in Colorado Valley; about 175 ft. in

Brazos Valley. Top fm. of Cisco group. Conformably overlies Sedwick ls. memb. of Moran fm. Named for town in Callahan Co.

This fm. was transferred to Perm. Wichita group by E. H. Sellards in 1933 (Univ. Tex. Bull. 3232), and Perm. is present age designation of U. S. Geol. Survey.

Putnam limestone. (In Putnam formation.)

Permian: Central northern Texas (Shackelford County).

O. F. Hedrick, E. Owens, P. A. Meyers, 1929 (Tex. Bur. Econ. Geol. geol. map of Shackelford Co.). *Putnam ls.*, 5± ft. thick, lies 55± ft. below top of Cisco, and overlies Putnam ss.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 170). *Putnam ls.*, in Putnam fm., preoccupied by Putnam fm. and discarded. Putnam fm. transferred to Perm. Wichita group.

Putnam sandstone. (In Putnam formation.)

Permian: Central northern Texas (Shackelford County).

O. F. Hedrick, E. Owens, and P. A. Meyers, 1929 (Tex. Bur. Econ. Geol. geol. map of Shackelford Co.). *Putnam ss.*, 5± ft. thick, underlies Putnam ls. and lies 110± ft. above Sedwick ls., all in Cisco group.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 170). *Putnam ss.*, in Putnam fm., preoccupied by Putnam fm. and discarded. Putnam fm. transferred to Perm. Wichita group.

Putnam erosion cycle.

Name applied by G. R. Mansfield (U. S. G. S. Bull. 713, 1920, p. 15) to a Pleist. erosion cycle in SE. Idaho, well developed in vicinity of Mount Putnam.

Putnam Hill limestone member (of Allegheny formation).

Pennsylvanian: Eastern Ohio.

E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 84, 85). *Putnam Hill ls.*—Blue ls., 4 ft. thick, in midst of coal measures. Underlain by 6 ft. of black bituminous sh. with thin layers of coal and overlain by 25 ft. of sh. and fissile ss. Is 78 ft. above Maxville ls.

Later repts state it overlies Brookville or No. 4 coal, and belongs near base of Allegheny fm.

Named for Putnam Hill, Muskingum Co.

Putnamville stone.

Trade name for a ls., of pre-Chester Miss. age, quarried at Putnamville, Ind. (See Collett, Ind. Dept. Statistics and Geol. 2d Ann. Rept., 1880, p. 409.)

Puyallup sand.

Pleistocene (pre-Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Puyallup sands.*—Stratified sand, 40± ft. thick. Included in Puyallup interglacial epoch. Underlie Douty gravels. Overlie Orting gravels. Occur at a number of sections in Puyallup Valley; the occurrence on W. side of valley may be considered typical. [Some geologists consider this deposit to be of glacial origin.]

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54), gave thickness of *Puyallup sands* as 40 to 200 ft.

Puyallup interglacial epoch.

Pleistocene (pre-Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Puyallup interglacial epoch.*—Preceded Vashon glacial epoch and followed Admiralty glacial epoch. Includes Puyallup sands, Orting gravels, and Tacoma delta, which occur in Puyallup Valley.

Some geologists consider the deposits covered by this term to be of glacial origin.

Puyer formation.

Eocene: Central Washington (Pierce County).

J. Daniels, 1915 (Geol. Soc. Am. Bull., vol. 26, No. 1, p. 132). *Puyer fm.*, of Eo. age, Pierce County coal field, Wash., 12,000 to 14,000 ft. thick. [Not defined.]

Pyburn limestone member (of Olive Hill formation).

Lower Devonian (Helderbergian): Western Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, p. 685). *Pyburn ls.*—It appears possible to divide Linden bed into two subdivisions, *a lower, Camarocrinus or Ross ls.*, and *an upper, or Pyburn ls.* The upper half appears to contain a greater quantity of softer, clayey material, which weathers readily. It appears to give rise to greater number of exposures at which Linden bed fossils may be collected free from the rock. The exposures at Perryville, Linden, and Cumberland City appear to belong to upper or Pyburn horizon, which appears to have a greater eastward extension than the lower, overlapping latter.

W. F. Pate and R. S. Bassler, 1908 (U. S. Nat. Mus. Proc., vol. 34, pp. 427–429). *Pyburn beds* of Foerste consist of blue shales and thin lss. overlying Ross bed.

C. O. Dunbar, 1919 (Tenn. Geol. Surv. Bull. 21, p. 47). *Pyburn ls. memb. of Olive Hill fm.*—Thin-bedded impure, dirty and cherty ls. with occasional bands of chert 2 to 10 inches thick; lower part somewhat softer, but upper 14 ft. or more is heavy-bedded and lithologically closely resembles underlying Ross ls. Occupies more or less the strat. position of Bear Branch memb. of Olive Hill fm., but lithology is distinctly different and they occur in different regions, so that both names will be useful. [Detailed section at Pyburn Bluff given. Thickness 43½ ft. at Pyburn Bluff, where it is discon. overlain by Hardin ss. This is present approved definition of Pyburn ls.]

Named for exposures in Pyburn Bluff, Hardin Co.

Pyramid shale.

Cretaceous (?): Eastern New Mexico.

C. R. Keyes, 1905 (Am. Jour. Sci., 4th, vol. 20, p. 424). In E. part of N. Mex. the Comanche sss. are uncon. underlain by *Pyramid shales*, 100 ft. thick, which overlie Amarillo sss. and are correlated with Zuni shales of western N. Mex. [Derivation of name not given.]

Pyramid conglomerate.

Upper Cretaceous: Southwestern (?) New Mexico.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, p. 338). *Pyramid cgls.* is proposed for basal beds of Dakotan section as outcropping in Pyramid Butte, N. Mex.

Pyrites granite.

Pre-Cambrian: Northwestern New York (Canton quadrangle).

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 66, 71–73, 96). *Pyrites granite mass* is located just NE. of Pyrites, in SW. corner of Canton quad. Forms Pyrites phacolith. The granite and its border zone have been mapped by J. C. Martin (N. Y. State Mus. Bull. 185, 1916), who, however, refers to it as a boss. Intrudes Grenville series. [According to p. 52 this granite is of his Alexandria type.]

Quabin quartzite.

Carboniferous: Western central Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 60, 72–75, and map). The Paxton quartz schist persists with its usual features for a long distance beyond border of the Brimfield, but at length it changes to a sugary white friable qtzite, once in demand for furnace hearthstones, which becomes more or less sericitic or chloritic, and at Amherst is full of large irregular masses of garnet. This rock is called *Quabin qtzite.* It also grades into Oakdale qtzite. Composes a great portion of Quabin and Felton Mtns.

Quaco conglomerate.

Triassic: Nova Scotia and New Brunswick.

S. Powers, 1916 (Jour. Geol., vol. 24, p. 6).

Quadrant quartzite.

Quadrant formation.

Pennsylvanian (early) and upper Mississippian: Montana (rather widespread, except in Stillwater to Rosebud Counties region of central southern Montana) and northwestern Wyoming.

A. C. Peale, 1893 (U. S. G. S. Bull. 110, on Three Forks, Mont., region). *Quadrant fm.*—Thin-bedded cherty lss. and qtzite layers (150 ft. thick) underlain by 200 ft. of red aren. lss. At one place (N. of Gallatin) the basal bed of fm. is a cgl. ls. Bdy btw. the red lss. and the cherty lss. is a shifting one. The fm. rests conformably on Madison ls. and is overlain by Ellis fm. [Upper Jurassic] in vicinity of Three Forks, Mont. Fossils [Miss. and Penn.] listed. The names for Paleozoic fms. in this area were selected after consultation with Mr. Arnold Hague's division [to which Mr. Weed belonged].

W. H. Weed, 1896 (U. S. G. S. Yellowstone Park folio, No. 30). *Quadrant qtzite.*—White, yellowish, and occasionally pink beds of qtzite, with intercalated beds of drab saccharoidal lss. The qtzite is generally compact and in beds 4 to 25 ft. thick. Thickness of fm. averages 400 ft. in Gallatin Range. Named for Quadrant Mtn, in Gallatin Range [NW. corner of Yellowstone Park, Wyo.], where it forms a picturesque bluff encircling the mtn, rests on Madison ls., and is separated from overlying Ellis fm. by 200 ft. of sss., gray lss., and calc. shales named *Teton fm.* [Perm. and Triassic]. [In this original definition of Quadrant fm. at its type loc. the Perm. strata were included in Weed's overlying Teton fm. In subsequent repts on areas in Mont. to NW. of Yellowstone Park *Quadrant fm.* was applied to rocks that included the Perm. strata later identified as northward extension of Phosphoria fm. In 1919 (U. S. G. S. P. P. 120 F) D. D. Condit restricted Quadrant fm. to Weed's original definition, called the overlying Perm. strata *Phosphoria fm.* and the underlying rocks *Madison ls.*, and stated that typical Quadrant had yielded Miss. and Penn. fossils. In many subsequent repts the name was applied to strata of Penn. and Miss. age resting on Madison ls. over large areas in Mont., but in Stillwater and Rosebud Counties region of central southern Mont. the corresponding rocks have been divided into Tensleep ss. and Amsden fm.]

H. W. Scott, 1935 (Jour. Geol., vol. 43, No. 8, pp. 1011–1032). Basal 109 ft. of type section of Quadrant fm., consisting of ls. and sh., were originally called "talus," and cannot be considered part of the fm. *This lower zone is Amsden fm.*, which rests on Madison ls. [Scott's graphic section at Quadrant Mtn (p. 1016) shows his Amsden fm. as consisting in upper half of massive ls. and in lower half of shaly ss. and sh., from which it looks as if Weed included these beds in his Madison ls.] The Quadrant is westward extension of Tensleep ss.; it is marine; strat. and paleontologic evidence indicates it is basal Penn. The strat. and paleontologic evidence shows Amsden is Miss., probably Chester. [Lower part of Amsden fm. has long been correlated by U. S. Geol. Survey with Brazer ls., of upper (Chester) and middle Miss. age.] As determined by tracing, true Quadrant wedges out 5 mi. NE. of Lombard, Mont. It is unknown in central Mont., where the rocks that have been called *Quadrant fm.* consist of the older Amsden fm. underlain by Big Snowy group, divided into 3 fms. [See under *Big Snowy group.*] The Quadrant is present NW. of Lombard, also in vicinity of Helena, and in extreme SW. and west-central Mont.—Philipsburg, Melrose, and Dillon areas. In most areas the Quadrant and the Tensleep are uncon. on Amsden fm., but the uncon. is not angular, and in vicinity of Three Forks there is evidence that would support theory of continuous deposition. A few sections show upper part of Amsden ls. interbedded with qtzite, which becomes more and more dominant until massive qtzites of the Quadrant are reached.

Quail porphyry.

Eocene: Western central Colorado (Tenmile district).

S. F. Emmons, 1898 (U. S. G. S. Tenmile Special folio, No. 48). *Quail porphyry.*—Hornblende rock. Largest sheet occurs under White Quail group of mines, Tenmile quad.

†Quakertown group. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2, between pp. xxi–xxxvi and 319–333). *Quakertown group.*—Underlies Middle Mercer shales and overlies Connoquenessing Lower ss. Includes (descending) Quakertown coal, Quakertown fire clay, and

Quakertown iron shales. Included in Connoquenessing ss. [In some repts these beds have been called *Quakertown coal group.*]

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3), gave following strat. succession in Mercer Co., Pa. (descending): Connoquenessing Upper ss., 40 ft.; *Quakertown over shales and ore*, 10 ft.; Quakertown coal, 0 to 2 ft.; *Quakertown under shales and ore*, 20 to 50 ft.; Connoquenessing Lower ss., 0 to 90 ft.

I. C. White, 1880 (2d Pa. Geol. Surv. geol. map of Crawford and Erie Counties). *Quakertown shales*, 50 [ft.]. Underlie Connoquenessing Upper ss. and overlie Connoquenessing Lower ss.

Quakertown shale. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2, p. 66). *Quakertown iron shales* contain iron ore in nodules. Are 40 ft. thick. Underlie Quakertown coal and overlie Lower Connoquenessing ss. The Quakertown coal occurs at the "Falls" on Quakertown Run, near Quakertown Station, Lawrence Co., Pa.

See also under †*Quakertown group*, I. C. White, 1880.

Quakertown fire clay. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2, p. 332). *Quakertown fire clay*, with iron ore balls, underlies Quakertown coal and overlies Quakertown iron shales.

Quakertown coal group.

See under †*Quakertown group*, 1879.

Quakertown slate. (In Kanawha formation.)

Pennsylvanian: Northern West Virginia and western Maryland.

D. B. Reger, 1918 (W. Va. Geol. Surv. Rept. Barbour and Upshur Counties, p. 273). *Quakertown black sl.*—Hard, fissile, carbonaceous, fossiliferous; 0 to 4 ft. thick. Lies 0 to 7 ft. below Quakertown rider coal and overlies Quakertown (Coalburg?) coal. Not previously noted or described. Named for relation to Quakertown coal.

D. B. Reger, 1921 (W. Va. Geol. Surv. Rept. Nicholas Co.). *Quakertown black sl.*—Named for occurrence along Tygart Valley River in northern Randolph Co., where it lies just above Quakertown (Winifrede?) coal. Its supposed position is below Coalburg coal (Quakertown Rider?) and above Little Coalburg coal.

Quall limestone.

Lower Devonian (Oriskany): Western Tennessee.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 746). *Quall ls.*—Heavy-bedded fine-grained cherty gray ls. in layers 18 to 20 in. thick. Weathers to very porous, rotten white and buff chert with yellow clay. Thickness 0 to 10± ft. Fauna clearly upper Oriskany. Lies uncon. above Decaturville chert and uncon. below Harriman chert. Confined to S. part of State.

Named for development on farm of Jim Quall, in valley of Dry Creek, a small stream entering Tenn. River near Walnut Grove, Hardin Co.

Quanah gypsum.

Permian: Southwestern Oklahoma and central northern Texas.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 356 (footnote), 357). *Quanah gyp.*—Gyp. underlying Groesbeck dolomites in Hardeman Co., Tex., and Greer Co., Okla. Is a lower gyp. than Collingsworth gyp. May belong to Cave Creek fm.

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, pl. 1). *Quanah gyp.* lies lower than Guthrie dol. and overlies San Angelo fm.; all included in Double Mtn group.

Named for Quanah, Hardeman Co., Tex.

Quanah granite.

Pre-Cambrian: Southwestern Oklahoma (Wichita Mountains).

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 137–138). *Quana granite.*—Granite eruptive into Camb. and Ord. fms. in Wichita Mtns, Okla. Named for a prominent chief near whose lodge it is well exposed.

J. A. Taff, 1904 (U. S. G. S. P. P. 31), mapped the granite of Wichita Mtns as pre-Camb.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

C. H. Taylor, 1915 (Okla. Geol. Surv. Bull. 20). *Quanah granite (pre-Camb).*—Medium-grained flesh-red hornblende granite. Intrusive. The latest granite mass of Wichita Mtns dist. Named for Quanah Mtn.

Quanah granophyre.

A name applied by M. G. Hoffman (Okla. Geol. Surv. Bull. 52, 1930, geol. map of Wichita Mtns, Okla.) to the Quanah granite of previous repts.

Quantico slate.

Upper Ordovician: Northeastern Virginia.

N. H. Darton, 1894 (U. S. G. S. Fredericksburg folio, No. 13). *Quantico sl.*—A narrow belt of black slates [mapped] overlying the crystalline rocks and underlying Potomac fm. Named for Quantico Creek. Resembles the roofing slates on James River which carry lower Sil. fossils.

T. L. Watson and S. L. Powell, 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 36–43). *Quantico slates.*—Gray to dark-gray and black slates with beds of green and maroon slates; also dense, homogeneous black graphitic slates of fine texture. Laid down at about same time as Martinsburg sh. W. of the Blue Ridge. Named for Quantico Creek, Prince William Co.

T. L. Watson, 1916 (Va. Geol. Surv. geol. map of Va.). [Map explanation of Ord. (Cincinnatian) block reads "Includes the Arvonia and Quantico slates of the Piedmont Plateau province."]

J. T. Lonsdale, 1926 (Jour. Geol., vol. 34, pp. 159–166). *Quantico sl.* occurs in narrow discontinuous belt, rarely more than 1 mi. wide, extending for more than 40 mi. in a NE-SW direction along E. border of NE. Piedmont dist. Is known to be of Cincinnatian age through work of Watson and Powell, who reported a Cincinnatian fauna from it in Powell's Creek section near Dumfries, Prince William Co. The sl. varies from black graphitic to a gray type closely related to phyllite.

W. A. Nelson, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Quantico sl.* is in part graphitic and includes rhyolite flows in northern areas. Mapped near Quantico, Prince William Co. Assigned to Ord.

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, pp. 6, 25), assigned this fm. to Upper Ord. (See under *Arvonia sl.*)

Quapaw chert.

See under *Lincolnville chert.*

Quarry Creek limestone.

Pennsylvanian: Southeastern Illinois (Clark County).

A. H. Worthen, 1875 (Ill. Geol. Surv., vol. 6, pp. 10–17). *Quarry Creek ls.* (also *Quarry Creek and Martinsville ls.*).—Ls., 20 to 30 ft. thick, near top of Coal Measures of Clark Co. Upper part heavy bedded; lower part thinner-bedded, becoming shaly at base and locally passing into fossiliferous green clay sh. with thin plates and nodules of ls. Overlain by heavy ss., 30 to 40 ft. thick, forming top part of Coal Measures in this county; underlain by sh., the lower part of which is bituminous.

According to J. E. Lamar and H. B. Willman (Ill. Geol. Surv. Bull. 61, 1934, pp. 129–138) this ls. is same as LaSalle ls. memb. of McLeansboro fm.

Named for Quarry Creek, 1½ mi. E. of Martinsville, Clark Co.

Quartermaster formation.

Permian: Southwestern and northwestern Oklahoma and eastern part of Panhandle of Texas.

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 57). *Quartermaster div.*—Soft red sss. and aren. clays and shales, 300 or more ft. thick. Overlies Greer div., which consists of red clays, sh., and sss., and includes several gyp. beds, named, in descending order, Delphi, Collingsworth, Cedartop, Haystack, Kiser, and Chaney. Underlies Tert. or later deposits.

L. C. Snider, 1913 (Okla. Geol. Surv. Bull. 11). *Quartermaster fm.*, 300 ft. thick, contains no important gyp. deposits in Okla. The underlying Greer fm. is 150 to 300 ft. thick, and overlies Day Creek dol. memb. of Woodward fm.

In 1924 C. N. Gould introduced *Cloud Chief gyp.* for the rocks underlying Quartermaster fm. that were formerly known as "eastern area of Greer fm." (See under *Cloud Chief gyp.*)

R. W. Sawyer, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 312–320). *Quartermaster fm.* overlies Cyril gyp., which Gould referred to as "eastern area of Greer." The Cyril overlies Day Creek dol. [These fms. were mapped in order here stated.]

The downward strat. succession of Quartermaster fm., Cloud Chief gyp., Day Creek dol., and Whitehorse ss. was given in repts by C. N. Gould, 1924; C. N. Gould and F. E. Lewis, 1926; C. N. Gould, 1926; R. L. Clifton, 1926; F. Gouin, 1927; C. N. Gould, 1927; N. Evans, 1927; N. Evans, 1928; A. M. Lloyd and W. C. Thompson, 1929; G. G. Suffel, 1930; A. F. Freie, 1930; R. L. Clifton, 1930; and R. L. Six, 1930. The 1926 rept of Gould and Lewis suggested that "it might be well to consider the Day Creek dol. the basal part of Cloud Chief gypsum." In 1930 (Okla. Geol. Surv. Bull. 40,I) C. M. Becker stated that "Day Creek dol. and Cloud Chief gypsum are thought by some to occupy the same stratigraphic position." The 1928 rept of N. Evans (A. A. P. G. Bull., vol. 12, p. 708) identified in Weatherford area, Okla., 5± ft. of dol. lying btw. Quartermaster fm. above and Cloud Chief gyp. below as *Quartermaster dol.*, and showed Cloud Chief gyp. ("massive pinkish-white gypsum") as separated from underlying Day Creek dol. by 20 to 60 ft. of red to buff ss. with gyp. lentils, which he stated "is apparently Whitehorse." The 1930 rept of G. G. Suffel (Okla. Geol. Surv. Bull. 49) stated that in some places Day Creek dol. appeared to be below top of Whitehorse ss.

R. W. Sawyer, 1929 (Okla. Geol. Surv. Bull. 40HH). The term "Day Creek dol." of Cragin has been applied to Weatherford dol., Greenfield dol., and Quartermaster dol. It is believed its continued use will only serve to confuse. Writer does not know what bed, if any, in SW. Okla., corresponds to Day Creek dol. of Kans.

R. L. Clifton, 1930 (A. A. P. G. Bull., vol. 14, pp. 161–172). *Cloud Chief* as originally defined by Gould includes beds from top of Day Creek up to base of Quartermaster fm. Evidences in field suggest Cloud Chief is not a geol. unit, but that it represents a group of more or less continuous strat. units. Writer believes Cloud Chief as a fm. name should be dropped and that another fm. name should be adopted to include the beds from base of Day Creek dol. up to base of Quartermaster, and there is some evidence to suggest that even the Quartermaster might well be included in this suggested revision. At any rate a new fm. to include Day Creek dol., Hackberry sh., Big Basin ss. and the Perm. beds overlying the Big Basin, up to base of Quartermaster, seems necessary if geologic designation is to be more strictly applicable to NW. Okla. and adjacent areas.

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 408–432). Day Creek dol. overlies Cloud Chief gyp., instead of underlying it, as previously believed, and all Perm. beds above Day Creek dol. in Okla. and Kans. belong to Quartermaster fm. The Kans. terms "Hackberry" and "Big Basin" should be dropped. Writer has not anywhere seen beds of gyp. in Quartermaster fm. The Quartermaster rests conformably on Day Creek dol. The Cloud Chief is here made a memb. of Whitehorse fm.

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437), does not regard Evans' interpretation of strat. relations of various fms. as proved.

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1454, 1458, 1473), divided Quartermaster fm. of central and west-central Okla. into (descending) (1) *Elk City ss. memb.*, (2) *Doxey sh. memb.*, and (3) *Cloud Chief memb.* (consisting of ss., gyp., and dol. facies); and defined it as uncon. overlying Rush Spring fm.

Named for exposure along banks of Quartermaster Creek, Roger Mills Co., Okla.

Quartermaster dolomite. (In Quartermaster formation.)

Permian: Western Oklahoma (Custer County).

Name applied by some geologists to a dol. memb., 0 to 15 ft. thick, lying short distance above base of Quartermaster fm. in Weatherford dist., Custer Co. See Noel Evans, 1928 (A. A. P. G. Bull., vol. 12, No. 7, pp. 706, 708), and G. G. Suffel, 1930 (Okla. Geol. Surv. Bull. 49, pp. 107, 114, 124, 128).

Quartzite Range formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1934 (Canada Dept. Mines Geol. Surv. Mem. 172, No. 2345, p. 8).

Quaternary period (or system).

Includes all post-Tertiary time and the rocks formed therein. Divided into Pleistocene epoch (or series) and Recent epoch (or series). See U. S. G. S. Bull. 769, pp. 43–49.

Quaternic.

A variant of *Quaternary* employed by some geologists.

Quatsino limestone.

Triassic: British Columbia (Vancouver Island).

H. C. Gunning, 1933 (Canada Geol. Surv. Summ. Rept., pt. A2, p. 33).

Quealy sand.

A subsurface sand occurring in transition zone at base of Mesaverde fm., lying at depth of 1,050 to 1,100 ft. in Saddleback Hills anticline, Carbon Co., Wyo.

Quebec group.

Ordovician, Cambrian, and pre-Cambrian: Quebec.

W. E. Logan, 1860 (Canadian Nat., vol. 5, pp. 472–477), 1861 (Can. Jour., n. s., vol. 6, pp. 40–46), and 1863 (Can. Geol. Surv. Rept. 1843–63, pp. 225–297, 844–880). *Quebec group;* Cambro-Sil.

A. R. C. Selwyn, 1883 (Can. Roy. Soc. Proc. and Trans., 1882–83, vol. 1, sec. 4, pp. 1–13). Quebec group includes pre-Camb., Camb., and Cambro-Sil.

Subsequent Canada Geol. Survey repts divided these rocks into (descending) Sillery, Lauzon, and Levis fms. Many repts assigned them to Ord., some assigned them to Camb., others assigned them to "Cambro-Ord." More recent repts seem to restrict name to Ord.

†Quebecan substage (of Wisconsin stage).

Pleistocene: Great Lakes region.

M. M. Leighton, 1931 (Jour. Geol., vol. 39, pp. 51–53). *Quebecan substage (early and middle Wisconsin).*—Includes Shelbyville moraines back to but not including Port Huron and its correlatives. Named for Quebec, a very large area in eastern Canada, over which general area the center was most potent and from which it extended farthest S. and SW. during this substage. During latter part of Quebecan substage the ice field grew westward into the Patrician area and gave rise to a considerable lobe moving S. across Lake Superior and to SW., depositing the extensive sheet of red drift or Patrician drift of that region. It also gave rise to the notable Green Bay deployment, and retained its power in the East.

M. M. Leighton, 1933 (Sci., vol. 77, p. 168), withdrew *Quebecan substage* and replaced it by *Cary substage* (middle Wisconsin) and *Tazewell substage* (early Wisconsin).

Quebec City formation.

Ordovician: Quebec.

P. E. Raymond, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 356). *Quebec City fm.*, Ord., Quebec.

Quebradillas limestone.

Miocene: Puerto Rico.

T. W. Vaughan, 1924 (Geol. Soc. Am. Bull., vol. 35, No. 4, table 3).

Queen sandstone member (of Chalk Bluff formation).

Permian: Southeastern New Mexico (Eddy County).

F. S. Prout, 1929 (A. A. P. G. Bull., vol. 13, p. 656). *Queen sand zone* to N. toward Carlsbad is in top of San Andres ls. [?] and Seven Rivers gyp. is above it.

K. H. Crandall, 1929 (A. A. P. G. Bull., vol. 13, pp. 929, 940). *Queen sand.*—Brown and buff ss., 100 ft. thick, underlying Seven Rivers gyp. Named for extensive outcrops in vicinity of Queen P. O., sec. 30, T. 24 S., R. 22 E., Eddy Co., N. Mex.

W. G. Blanchard, Jr., and M. J. Davis, 1929 (A. A. P. G. Bull., vol. 13, pp. 972, 983, 987). A sandy ls. and sand zone, 0 to 500 ft. thick, notable near old post office at Queen, Eddy Co., N. Mex., is often referred to by N. Mex. geologists as "*Queen ss.*" The "Queen ss." consists primarily of reddish-brown and gray sss. interbedded with hard gray lss. that are locally sandy. These ss. lenses lie in uppermost part of San Andres ls. [?], and *Queen sand zone* is considered the top of that fm. Because there are several of these lenses within 200 ft. or more of section the term *zone* is applicable. These sss. have been traced from their type loc. SW. to El Paso Gap, through Dog Canyon to Bush Mtn (a high mass in the Guadalupes) and S. to approx. 5 mi. S. of N. Mex. line and 1 mi. NE. of El Capitan. The upper lenses of *Queen zone* are stratigraphically within 300 ft. of top beds of El Capitan. Several mi. E. of Queen P. O. the Queen outcrop dips steeply N. and NE. and is at base of gyp. beds in Carlsbad memb. [In pl. 11 they show Queen ss. underlying Carlsbad fm., and in one place they say it is very close to strat. position of Frijole ls. *Queen sand zone* and *Queen ss.* as here used include much more than the Queen sand of Crandall, which outcrops in vicinity of Queen, Eddy Co., N. Mex., is 100 ft. thick, and, according to W. B. Lang, can be traced 20 or more mi. in outcrop.]

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *Queen ss. memb. of Chalk Bluff fm.* is a brown and buff ss., 100 ft. thick, exposed on Queen Mesa, in upper Dark Canyon and along N. slope of Hess Hills in Gaudalupe Mtns. It underlies Seven Rivers gypsiferous memb. of Chalk Bluff fm. and overlies Dog Canyon ls. [According to Lang (personal communication) his Queen ss. memb. corresponds to Queen sand of Crandall, and is the upper ss. of the thick series of sss. and lss. which has been called *Queen sand*, *Queen ss.*, and *Queen sand zone* by the oil geologists, and which includes Dog Canyon ls. of Lang. This is approved definition of U. S. Geol. Survey.]

†Queen sand.

†Queen sand zone.

Permian: Southeastern New Mexico.

See under *Queen ss. memb. of Chalk Bluff fm.*

Queen sand.

A subsurface sand, 23 ft. thick, of probable Chemung age, occupying interval btw. 1,406 and 1,429 ft. in Ulf well No. 1, near Tidioute, Warren Co., Pa. Lies 181 ft. above Speechley sand. (See C. R. Fettke, Geol. Soc. Am. Bull., vol. 44, No. 3, p. 604, 1933.)

Queen Charlotte Island formation.

Lower Cretaceous: British Columbia.

J. F. Whiteaves, 1883 (Roy. Soc. Canada Trans., vol. 1, sec. 4, p. 85); and J. W. Dawson, 1889 (Am. Jour. Sci., 3d, vol. 38, pp. 120–127).

Has also been called *Queen Charlotte Islands group*, *Queen Charlottes Island fm.*, *Queen Charlotte series*, and *Queen Charlotte group*.

Queen City sand member (of Mount Selman formation). (In Claiborne group.)

Eocene (middle): Eastern Texas.

W. Kennedy, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 50–52). *Queen City beds.*—Uppermost memb. of Lignitic beds. Appears to be a series of laminated or thinly stratified white and red sands and sandy clays, frequently merging into one another and forming a mottled sandy clay or clayey sand. *Best developed in neighborhood of Queen City, Cass Co.*, where it has known thickness of 65 ft. In Marion Co., near Jefferson, and in Harrison Co. the beds appear at various places immediately underlying a yellowish-brown ss. or altered glauconite containing occasional casts of fossils and belonging to Mount Selman or lower memb. of the

Marine beds. They occur also near Tyler, Smith Co., and as far S. as within 2 mi. of Troupe. To N. they occur at Gladewater, Gregg Co., and from Wilkins' mill, Upshur Co., westward to within short distance of Big Sandy. They rest on a series of black, blue, and gray micaceous sands, blue, brown, and gray clays with thin strata of sss. and ls., and also contain many small seams and several heavy deposits of lignites.

See additional entries under *Mount Selman fm.*

A. Deussen, 1914 (U. S. G. S. W. S. P. 335). *Queen City sand memb. of Wilcox fm.*—Littoral deposits comprising top memb. of Wilcox fm. Consists of 50 to 200 ft. of white porous, loose water-bearing sands, with some interstratified clays.

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 83–84). *Queen City-Carrizo.*—Oldest fm. of Claiborne group. In E. Tex. is known as *Queen City*, and consists of 50 to 200 ft. of laminated or thinly stratified white or red sands and sandy clays. In western [southern] Tex. is known as *Carrizo*, and consists of at least 150 ft. of sss. of varying color, texture, and thickness, prevailingly grayish yellow, weathering light brown, some beds white when freshly broken; the beds ranging from fairly hard ss. 2 to 4 or more ft. thick, to beds thin, slabby, fairly soft, and almost shaly. Regarded by Vaughan as lower Wilcox, but in Rio Grande country the Carrizo overlaps the Wilcox and Midway.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1342, 1345, pl. 14). *Queen City memb. of Claiborne fm.*—First described by Wm. Kennedy (Geol. Surv. Tex. 3d Ann. Rept.). Strat. position is below Weches memb. of Claiborne and above Reklaw memb. of Claiborne. According to present knowledge is limited to Tex. side of Sabine uplift. As a well-defined massive sand extends from Queen City, Cass Co., S. through Smith and Cherokee Counties, attaining thickness of 400 ft. In Houston Co. it thins to 110 ft. and in western Angelina Co. to 90 ft. From San Augustine E. it is only a few ft. thick, finally disappearing.

According to recent work of Tex. geologists and Julia Gardner the Queen City sand contains Claiborne fossils, underlies Weches greensand memb. of Mount Selman fm. and overlies Reklaw memb. of Mount Selman. (See U. S. G. S. 1932 geol. map of Tex.)

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 630). *Queen City fm.* of eastern Tex. divided into (descending): (1) Upper memb., 200 to 230 ft. of thin-bedded, cross-bedded sand, containing 2 layers of bentonite in upper 100 ft. and 2 layers of brown lignite in lower 100 ft.; (2) *Omen greensand memb.*, dark-green and black, partly cross-bedded, friable, sandy, unfossiliferous glauconite, 10 to 15 ft. thick; (3) lower memb., 140 to 150 ft. of gray and brown sand and gray sandy sh. with irregularly shaped lentils of sand.

Queen Hill shale. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northwestern Missouri, and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 44, 46, 47). *Queen Hill sh.*—Bluish and argill. in upper part, and black, fissile, and somewhat carbonaceous in lower part. Thickness 5 to 5½ ft. in Nebr., 6 ft. at Folsom, Iowa, 5 ft. N. of Amazonia, Mo., and 5 to 6 ft. S. of Atchison, Kans. Underlies Cullom ls. [later named *Beil ls.* and still later abandoned] and overlies Big Springs ls., all in Lecompton ls. Named for Queen Hill, NE. of Rock Bluff, Nebr.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). The so-called Queen Hill sh. of Bull. 1 Nebr. Geol. Surv. is Cherryvale sh. memb.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12). *Queen Hill sh.* underlies Beil ls. and overlies Big Springs ls., all included in Lecompton fm.

Queens River moraine.

Pleistocene (Wisconsin stage): Rhode Island (Narragansett Bay) and Massachusetts.

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, table opp. p. 988).

Extends from highland SW. of Providence northeastward into Mass.

Queenston shale.

Upper Ordovician (Richmond): Western New York and Ontario.

A. W. Grabau, 1908 (Sci., n. s., vol. 27, pp. 622–623). *Queenston shales*—red Medina shales. Of Richmond (Ordovicic) age. Thickness 1,100 ft. Named for town on Niagara River opposite Lewiston, N. Y., "where these beds are partly exposed." [The same year (in vol. 28 of Sci., pp. 346–348) G. H. Chadwick proposed *Lewiston sh.* for these beds, which he stated underlie the "upper or true Medina" with suggested discon. Because of priority of publication *Queenston sh.* is the generally recognized name.]

In 1909 (Jour. Geol., vol. 17, p. 238) Grabau introduced *Whirlpool ss.* for basal bed of the Sil. and of his restricted Medina ss. (which rests on Queenston sh.), and correlated the Queenston with the Juniata and the Richmond.

In 1911 (Geol. Soc. Am. Bull., vol. 22) E. O. Ulrich used Chadwick's name *Lewiston* (with *Queenston* in parens), correlated the fm. with Juniata, and assigned all to Ord.; but he considered the Richmond younger, and assigned it to Sil. He also showed a great hiatus btw. the Queenston and the overlying Medina ss., to which he restricted the name *Medina*.

In 1912 (N. Y. State Mus. Hdb. 19) C. A. Hartnagel included Queenston sh. in the Medina and assigned all to Sil.

In 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 107–108) E. O. Ulrich recommended that well-established Pa. name *Juniata* be used in N. Y., to replace *Lower Medina* and also the recently introduced name *Queenston sh.*, he being satisfied of equivalency of the two. He also transferred the *Juniata* (*Queenston*) to Sil., and stated that Lower Medina is=greater part if not all of the Richmond. The same year (12th Int. Geol. Cong., Canada, p. 28) Ulrich stated that "the Richmond passes laterally into the lower Medina (or Queenston) of N. Y.," and that the Queenston is uncon. with overlying Albion ["Upper Medina" of early literature]. In Niagara folio of U. S. Geol. Survey (No. 190, 1913) the Queenston sh. was described as consisting of 1,200 ft. (only 300 ft. exposed) of cherry-red and green sh. and green or gray ss., and it was retained in Medina group, but, because of lack of fossils and disagreement among geologists as to its exact age, it was classified as *Ord. or Sil.* In Canada Geol. Surv. Guidebook 4, 1913, W. A. Parks assigned Queenston sh. to Ord., stating that at Collingwood, Ont., a distinct Richmond fauna had been collected from it, although in Niagara and Hamilton, Ont., sections it is unfossiliferous. He described it as consisting of red shales with an occasional green band and an occasional bed of ls., and stated that it overlies the marine type of Richmond.

In 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 277–320) C. Schuchert assigned Queenston sh. to Ord. and to "Richmondian," but favored excluding it from Medina, and stated that, although originally included in Medina, "at the Medina type locality, along Orchard Creek, Medina, N. Y., these beds are practically not seen." He also stated that Whirlpool ss. is everywhere discon. on Queenston. The same year (Canada Geol. Surv. Summ. Rept. 1913, pp. 179–188), also in 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser.), M. Y. Williams stated that Whirlpool ss. overlaps Queenston sh.

In 1916 (Canada Dept. Mines, Geol. Surv. Mem. 83, pp. 175–176) A. F. Foerste stated: "The Queenston shales appear to be merely the estuarine representatives of a part of those marine strata which elsewhere are known under the term Richmond fm.," and he correlated them with upper fms. of Richmond group of Mississippi Valley.

In 1923 (Md. Geol. Surv. Sil. vol., p. 347) E. O. Ulrich showed Albion uncon. on Queenston.

In 1924 (Canada Dept. Mines Geol. Surv. Mem. 138) A. F. Foerste correlated Queenston sh. of N. Y. with upper part (chiefly Whitewater) of the

Richmond of SW. Ohio and Ind., and stated that Queenston sh. of different parts of Canada ranges in age from upper Waynesville to Whitewater, both inclusive, and that "strictly speaking, the Queenston is merely a lithological designation, not an accurate time unit."

The U. S. Geol. Survey now classifies Queenston sh. as Upper Ord., and regards its Richmond age as established. (See also under *Richmond group.*)

Queniult formation.

Pliocene: Northwestern Washington.

See *Quinault fm.*, the spelling approved by U. S. Geographic Board.

Quercan sandstone.

Miocene: Central western California (San Pablo Bay region).

C. E. Weaver, 1909 (Calif. Univ. Pub., Bull. Dept. Geol., vol. 5, p. 251). *Quercan ss.*, top div. of Monterey fm. in San Pablo region, closely resembles San Pablo ss. Overlies Herculean sh. memb. [Derivation of name not stated.]

Approx. same as Briones ss.

Quesnal Lake crystalline series.

Pre-Cambrian: British Columbia.

A. Bowman, 1889 (Canada Geol. Surv., n. s., vol. 3, pt. 1, p. 25C).

Quesnal River beds.

Cretaceous: British Columbia.

A. Bowman, 1889 (Canada Geol. Surv., n. s., vol. 3, pt. 1, pp. 17C to 19C). Is= upper part of Shasta group of Calif.

Quesnal River series.

Cretaceous (?): British Columbia.

C. H. Crickmay, 1927 (Stanford Univ. Abstracts of dissertations 1924–26, vol. 1, p. 132). Assigned to Cret. [G. Hanson (Canada Geol. Surv. Summ. Rept. 1933, pt. A, p. 35, 1934) assigned these beds to Jurassic and Cret. (?).]

Quiet Lake intrusives.

Late Jurassic or Cretaceous: Yukon Territory, Canada.

E. J. Lees, 1934 (Royal Canadian Inst. Trans., vol. 20, pt. 1, p. 26).

Quillayute formation.

Miocene (?): Northwestern Washington.

A. B. Reagan, 1909 (Kans. Acad. Sci. Trans., vol. 22, p. 203). *Quillayute fm.*—In interior region, where exposed along Bogachiel River, it is composed of ss. and bluish-gray sh., but base not seen there. The coast exposures are all cgls. or coarse gravelly rock resting uncon. upon older rocks. Occupies valley of Quillayute River and country drained by its eastern tributaries eastward at least to their respective middle courses, thence W. to Waatch Strait, and in places to the coast. Thickness not ascertained. Fossils are Plio.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, p. 604). Reagan's description of Quillayute fm. is based on glacial filling of valley of Quillayute River. If Reagan had visited the locality from which the fossils he describes from the Quillayute were brought by the Indians, he would have found it to be about 2 mi. from Devils Club Swamp, where he says they occur, and the fm. very different lithologically from what he describes. It is typical Empire ss.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 268–276). Quillayute fauna appears to be a mixture much the same as the Quinaielt, but the Quillayute suggests that the fauna is slightly lower and more like upper Mio. in faunal aspect, and therefore it is probably somewhat lower than Quinaielt fauna and may be in part of upper Mio. age.

R. H. Palmer, 1927 (A. A. P. G. Bull., vol. 11, No. 12, pp. 1321–1328). *Quillayute fm.* consists of soft slate-gray ss., probably not more than 50 ft. thick, locally carrying a plentiful upper Mio. fauna.

Quinaielt formation.

Pliocene: Northwestern Washington.

See *Quinault fm.*, the spelling approved by U. S. Geographic Board.

Quinault formation. (Approved spelling.)

Pliocene: Northwestern Washington.

R. Arnold, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 451–468, map). *Quinaielt fm.*—Coarse cgl. and fine shales, with minor ss. and clay. Thickness 2,260 ft. Most important area is in great syncline btw. Capes Elizabeth and Greenville through which trough of Quinaielt River empties into sea. Fossils are lower Plio. Uncon. overlies Clallam fm.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, table opp. p. 604), assigned *Quinaielt fm.* to upper Mio. and lower Plio.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 268–276). Fauna of *Quinaielt fm.* is possibly a mixture, although it appears to be lower Plio., as Arnold suggested.

Quincy syenite.

C. H. Hitchcock, 1872 (Am. Jour. Sci., 3d, vol. 3, p. 47). *Quincy syenite* lies contiguous to porphyritic granite in Abington, Mass.

Quincy granite.

Carboniferous (probably Mississippian): Eastern Massachusetts and Rhode Island.

W. O. Crosby, 1876 (Rept. on geol. map of Mass., pp. 1–42), referred, in several places, to *Quincy granite*, and said that the hornblendic granite is quarried at Quincy and Rockport, Mass.

B. K. Emerson and J. H. Perry, 1907 (U. S. G. S. Bull. 311, p. 51). *Quincy granitic group* occupies whole area btw. the green schist and the Carbf. rocks along NE. border of the green schist from Diamond Hill southward to Berkeley, forming a southern lobe of the broad Quincy band in Boston Basin.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 167, 188–196, and map). The normal *Quincy granite* is a moderately coarse-grained rock composed of dominant quartz, feldspar, and hornblende with accessory aegirite, zircon, titanite, and ores. Type area is in Quincy and Milton, Mass., but largest area is in eastern Essex Co., Mass.

L. LaForge, 1932 (U. S. G. S. Bull. 839). *Quincy granite* in Mass. intrudes Lynn volcanic complex, which is probably contemp. with Mattapan volcanic complex, of Dev. or Carbf. age.

Quincy amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Same as Pewabic amygdaloid. The mineralized part is the Quincy lode. Named for occurrence in Quincy mine, Houghton Co. Is in Ashbed group.

Quincy flow.

Same as Pewabic flow. Includes Quincy amygdaloid and underlying trap.

Quincy Pewabic amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pl. 18).

Belongs in Ashbed group. Same as Pewabic amygdaloid. The mineralized part is the Quincy Pewabic lode.

Named for occurrence in Quincy and Pewabic mines, Houghton Co.

Quincy Pewabic flow.

Includes Quincy (Pewabic) amygdaloid and underlying trap.

Quindaro shale.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 92, 97). [See under *Wyandotte ls.* Derivation of name not stated.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 59). *Quindaro sh. memb. of Wyandotte ls.*—Gray argill. or limy sh., 3± ft. thick, underlying Argentine ls. memb. and overlying Frisbie ls. memb. Named for a political twp in Wyandotte Co., Kans. Typically exposed in floor of Boyn's quarry, near NW. cor. sec. 30, T. 10 S., R. 25 E.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Quiniault formation.

See *Quinault*, the approved spelling.

Quinn sand.

A subsurface sand, of Penn. age, in Lyons-Quinn oil pool of south-central Okla. Is the middle zone in Wapanucka fm. Lies higher than Ingram sand of Lyons-Quinn pool, which is=Sykes sand of Wewoka pool.

Quinnesec ore-formation.

Huronian: Northern Peninsula of Michigan (Menominee iron region).

C. L. Rominger, 1881. [See under *Lake Hanbury sl. group*.]

J. Fulton, 1888. [See under *Lake Hanbury sl. group*.]

Quinnesec greenstone.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Menominee district).

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62). *Quinnesec schists.*—Greenstone schists, gabbros, diabases, and diorites, cut by dikes of gabbro, diabase, diorite, and granite. Quinnesec Falls is on some of harder ledges of these rocks. Assigned to Archean, and treated as oldest fm. of region. [In 1911 (U. S. G. S. Mon. 52) C. R. Van Hise and C. K. Leith assigned these schists to late upper Huronian (post-Michigamme sl.).]

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), changed name of fm. to *Quinnesec greenstone* and classified it as older than Michigamme sl.

†Quinnimont beds.

†Quinnimont coal group.

Pennsylvanian: Western Pennsylvania, West Virginia, and southwestern Virginia.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_2, pp. xxii–xxiv). Recent correspondence with Prof. Fontaine has convinced me that use of term "*Kanawha River system*" will lead to future embarrassment, because Kanawha River does not receive that name until it has passed to W. of the great outcrops of that system, retaining its name of New River as low down as mouth of Gauley River, where the "Kanawha River system" has mainly or entirely gone under water level. The term New River system cannot be employed, because it is required for the coal measures of Montgomery and Wythe Counties, Va., and I have therefore substituted the name *Quinnemont beds*, with which I understand Prof. Fontaine to acquiesce, at least for the present and until a better name can be suggested. [The *Sharon and Quinnimont coal group* is shown as = "Pottsville cgl. (Seral), No. XII."]

W. G. Platt, 1878 (2d Pa. Geol. Surv. Rept. H_4), excluded *Sharon and Quinnimont coal group* from Pottsville fm.

J. J. Stevenson, 1880 (Am. Phil. Soc. Proc., vol. 19, pp. 219–262). *Quinnimont group or Seral (Pottsville) cgl.*—Mapped in parts of Lee, Wise, Scott, and Washington Counties, Va. Thickness 1,000± ft. Includes, at top, ss., 135 ft. thick, known as "Bee Rock," succeeded below by a series of shales, sss., and 6 or 7 coals, and at base cgl. 45 ft. thick. Overlies Mountain ls.

J. J. Stevenson, 1880 (Am. Phil. Soc. Proc., vol. 19, pp. 498–505). *Quinnimont coal group.*—Includes Purdue coal (100 ft. below top in Mercer Co., W. Va., and Tazewell Co., Va.), St. Clair coal, Reed coal, Tabor coal, Coal Branch coal, Nelson coal, and older unnamed coals.

J. J. Stevenson, 1885 (The Virginias, vol. 6, p. 71). *Quinnimont group* of Va. and W. Va. is=Rogers No. XII or Lower Coal Measures.

Quinnimont shale. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26). *Quinnimont sh.*—Sh. with thin beds of ss. and a few coal seams called the Horsepen group. Quinnimont coal is basal bed. Underlies Raleigh ss. and overlies Clark fm. Thickness 300 ft. Named for exposures at Quinnimont, Fayette Co., W. Va.

M. R. Campbell, 1902 (U. S. G. S. Raleigh folio, No. 77). *Quinnimont sh.*—Sandy sh., 180 to 225 ft. thick. Includes Beckley coal at top and Quinnimont coal at base. Underlies Raleigh ss. and overlies Thurmond fm. (=Clark and Pocahontas fms. of Pocahontas folio).

Quinnimont shale. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 206). *Quinnimont sh.*—Dark gray, laminated, with both argill. and aren. layers. Thickness 0 to 75± ft. Underlies Quinnimont ss. and overlies Fire Creek (Quinnimont) coal. Named for exposures at Quinnimont, Fayette Co.

This is a part only of Quinnimont sh. of Campbell, 1896. (See W. Va. chart I.)

Quinnimont sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 206). *Quinnimont ss.*—Current- to heavy-bedded medium-grained light-gray to buff ss., 0 to 100 ft. thick. Underlies Beckley ("War Creek") coal and overlies Quinnimont sh., and in places cuts out Quinnimont sh. and rests on underlying Fire Creek (Quinnimont) coal. Included in Middle Pottsville or New River group. Named for exposures at Quinnimont, Fayette Co.

Quitman bed. (In Trinity group.)

Lower Cretaceous (Comanche series): Western Texas (El Paso County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 728, 736). *Quitman bed.*—Across Quitman Mtn at Quitman Gap consists of (descending): (1) Massive *Caprotina* ls., 60 ft.; (2) thickly bedded siliceous shell ls., 20 ft.; (3) calc. flaggy and yellow friable ss. containing large *Exogyra* and oyster resembling *O. owenana*, 250 to 300 ft. Is younger than Mountain bed and overlies Bluff bed; all included in Washita div.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745, p. 21). Quitman bed and Bluff bed of Taff belong to Finlay ls.; his Mountain bed belongs to underlying Cox ss.

Named for Quitman Mtn and Quitman Gap, El Paso Co.

†Quitman limestone.

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., pp. 54-55). *Quitman cap rock.*—Massive argill ls. capping Quitman or No. 9 coal.

Same as Howard ls. memb. of Shawnee fm., according to H. Hinds and F. C. Greene (1915) and R. C. Moore (1936).

Named for exposures at Quitman, Nodaway Co.

Quivira shale. (In Kansas City formation.)

Pennsylvanian: Northeastern Kansas and northwestern Missouri.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Quivira sh.*, new name; overlies Dekalb ls. (which rests on Cherryvale sh.) and underlies Drum ls.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 91, 97). *Quivira sh.*—Sh. forming top memb. of Cherryvale sh. in southern Kans. Underlies Drum ls. and overlies Dekalb ls. [On p. 45 it is described as consisting of (descending): (1) Greenish-gray clay sh., 1 ft.; (2) carbonaceous sh., ½ ft.; (3) greenish-gray clay sh., 6 ft.; and (4) black fissile sh., 1 ft.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 43). *Quivira sh.*—Thin argill. and bituminous sh. underlying Cement City memb. of Drum ls. and overlying Westerville ls. (not DeKalb, but younger). Is=top part of Cherryvale sh. of SE. Kans. Named for Quivira Lake on Kansas River E. of Holliday, where the fm. is exposed below the dam. Also typically shown at E. edge of Holliday, Kans. Was erroneously considered lower part of Chanute sh. by Mo. geologists.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Quoddy shale.

Silurian (Niagaran): Southeastern Maine (Eastport quadrangle, Washington County).

E. S. Bastin and H. S. Williams, 1913 (Maine Water Storage Comm. 3d Ann. Rept., p. 168; Geol. Soc. Am. Bull., vol. 24, pp. 378, 379). [Name mentioned but not defined. Refers to Eastport folio.]

E. S. Bastin and H. S. Williams, 1914 (U. S. G. S. Eastport folio, No. 192, pp. 3, 10). *Quoddy sh.*—Chiefly hard sh., some portions of which are slaty or even schistose. Contains minor amounts of volcanic rocks, both flows and tuffs, chiefly rhyolite but some diabase. Greatly disturbed and altered by intrusives. The few fossils indicate very early Niagaran. Oldest fm. in Eastport quad. Named for exposures at West Quoddy Head (easternmost point of land in United States), Washington Co.

On 1933 geol. map of Maine, by A. Keith, the sedimentary rocks of West Quoddy Head are mapped as Miss. and the igneous rocks as Dev.

Quoggy Joe quartz trachyte.

Age (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 109, 111, 164–168). *Quoggy Joe quartz trachyte* forms entire mass of Quoggy Joe group of hills, Aroostook Co.

Rabbitskin sandstone.

Cretaceous: Canada (Mackenzie).

E. J. Whittaker, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 99).

Rabbit Spring formation.

Tertiary (Pliocene?): Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 71, etc.). *Rabbit Spring fm.*—Ss., apparently derived from underlying Spearhead rhyolite, with lenses of cgl. composed of pebbles of volcanic rock. Thickness 10 to 15 ft., possibly 25 ft. Upper part merges with overlying Malpais basalt. Probably fluviatile. Exposed in bluffs above Rabbit Spring and in other places along edge of Malpais Mesa, Goldfield dist. If Siebert [Esmeralda] fm. ever covered this part of Goldfield dist. it was eroded away before Rabbit Spring fm. was deposited.

Rabble Run red sandstone member (of McKenzie formation).

Silurian: Western Maryland.

C. K. Swartz, 1923 (Md. Geol. Surv. Sil. vol., p. 36). *Rabble Run red ss. memb.*—These red strata lie about 100 ft. below top of McKenzie fm. in Washington Co. In passing E. they make their first appearance in Cacapon Mtn, W. of Hancock, as thin tongues of red strata a few ft. thick, separated by gray bands. Farther E. increase in thickness until they finally merge to form one nearly continuous mass of red beds that attain a thickness of nearly 100 ft. on Rabble Run in North Mtn. Closely resemble the younger Bloomsburg red ss.

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 660), show *Rabble Run red bed*=basal part of *Bloomsburg red beds.*

Raccoon shale.

Mississippian: Central Ohio.

L. E. Hicks, 1878 (Am. Jour. Sci., 3d, vol. 16, pp. 216, 219). *Raccoon shales.*—Blue and gray shales full of concretionary masses of iron ore, which are mere shells filled with marl or sand; 300 ft. thick; near bottom some layers are massive enough for quarrying. Overlain by Black Hand cgl. or Granville beds; underlain by Sunbury black sl. All included in Waverly group.

Same as Cuyahoga fm. of C. S. Prosser, C. R. Stauffer, J. A. Bownocker, G. D. Hubbard, and others, but lower part only of Cuyahoga fm. of J. E. Hyde (Jour. Geol., vol. 23, 1915, pp. 655–682, 757–779).

Named for exposures on Raccoon Creek, Licking Co.

†Raccoon River beds.

Pennsylvanian: Central southern Iowa and northwestern Missouri.

H. F. Bain and A. G. Leonard, 1898 (Geol. Soc. Am. Bull., vol. 10, pp. 11–12). *Raccoon River beds.*—Sandy shales, 30 to 70 ft. thick, forming top memb. of Des Moines beds in central Iowa. Overlie Appanoose beds. Probably same as Haworth's Pleasanton fm., but local name preferable.

Same as Pleasanton fm., older name.

Named for Raccoon River, Dallas Co., Iowa.

Racine dolomite.

Silurian (Niagaran): Southeastern Wisconsin and northeastern Illinois (?).

J. Hall, 1861 (Wis. Geol. Surv. Rept. 1860, pp. 1–7). I have arrived at certain results fortified by occurrence of numerous fossils which lead me to conclude that *Racine ls.*, mentioned in a former rept [where?], is upper memb. of Niagara group, while the heavy-bedded mass below is but the expansion of the lss. of Clinton group.

J. Hall, 1862 (Wis. Geol. Surv. Rept. 1, p. 67). *Racine ls.*—Friable yellow or ocherous ls.; gray, rarely bluish-gray, or buff-colored mag. ls. of crystalline texture, very tough and compact in some portions but extremely porous. Thickness 250 to 500 ft. Absent in SW. Wis. Best developed at Racine. Rests on Waukesha ls. at Waukesha. Extends from Kewaunee to S. line of State. Contains Niagara fossils. May represent upper memb. of Niagara group of western N. Y.

T. C. Chamberlin, 1877 (Wis. Geol. Surv. vol. 2, pp. 360–377). *Racine beds redefined.*—Equiv. to what has been known as *Racine ls.* (Geol. Wis., 1862, p. 67) except that upper portion (consisting of rough, thick-bedded irregular dol., usually free from impurities and of buff, gray, or blue color) is now separated as Guelph beds, and the reefs and associated rocks W. of Milwaukee, which have been referred to a lower horizon, are now included in it. Rests on Waukesha beds. Where separation btw. Racine and Waukesha is not distinct it is best to regard the chertless beds as Racine and the cherty beds as Waukesha. The Racine beds consist of mag. ls. of very irregular texture, forming reef-like masses of conglomeratic rock, which on denuded surface appear as mounds or ridges, and which graduate into various kinds of porous, granular, irregularly bedded rock, or into fine-grained, compact, even-bedded strata. In its N. portion, where it rests on Upper Coral beds, it has a much more uniform character. At Racine (whence the fm. takes its name), as exposed at rapids of Root River, it is a blue, gray, or buff brittle dol. with somewhat glassy fracture, subcrystalline structure in part and earthy in part, and contains many geodic cavities filled with calcite and pyrite and sometimes mammillary deposits; texture uneven, sometimes granular, sometimes brecciated, usually coarse and porous, but sometimes fine and compact; bedding irregular, but usually rather heavy, from 5 ft. downward. Fossils abundant. To N. (Sheboygan region) Racine ls. rests on Upper Coral beds, which appear = upper part of Waukesha beds.

In subsequent repts the Racine was treated by some writers as excluding Guelph and by other writers as including Guelph.

G. M. Ehlers, 1920 (Mich. Acad. Sci. 21st Rept., pp. 87–90). The division of the Racine of Wis. into Guelph and Racine by Professors Chamberlin and Whitfield is apparently unwarranted, in opinion of writer and of E. O. Ulrich. Ulrich states there is no strat. nor paleontologic break btw. beds of Racine fm.

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93), treated Racine and Guelph as two distinct units in SE. Wis., and stated that both are of Lockport age.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 27). Although there is some doubt that the Racine of eastern Wis. can be definitely recognized in NW. Ill. and NE. Iowa, in all probability equiv. beds occur in sections to be seen today, and the term *Racine* appears in these sections [overlain by Port Byron ls. and underlain by Waukesha dol.].

Radcliff formation.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group*. Derivation of name not stated.]

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct., 1932, pp. 329–356). *Radcliff fm.*—Chiefly flaggy, corrugated, impure, aren. ls., gray when fresh, reddish brown when weathered, intercalated with a dark-gray thinly banded lime-silicate rock, containing muscovite, biotite, diopside, epidote, zoisite, vesuvianite, and abundant pyrrhotite; also gray and white sss., gray and white mottled crystalline lss., and finely striped gray and green sl. and phyllite. Thickness 600± ft. Conformably overlies Sentinel dol. and conformably underlies Redlands dolomitic ls., all included in Telescope group (lower Paleozoic?), of S. part of Panamint Range. [Derivation of name not stated and not apparent from his maps.]

†Raddatz porphyry.

Miners' local name for the porphyry of Tert. (Eocene?) age in Stockton dist., central northern Utah, first cut by mine workings near Stockton under supervision of Mr. Raddatz. (See U. S. G. S. P. P. 173, pp. 52, 53, 1932.)

Raft lake beds.

Pliocene (middle ?): Southern Idaho (Cassia County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Raft lake beds.*—Buff-colored clay, silt, sand, often in lenticular form and in places filled with concretions; partly consolidated; weathers to brown sandy loam, forming rounded hills except along Snake River, where it forms a terrace. Thickness 200± ft. Exposed along S. shore of Lake Walcott as far as mouth of Raft River. Form bluff along Lake Walcott Reservoir. Basal cgl. is exposed at head of Fall Creek. Older than Banbury volcanics and younger than Rockland Valley basalt. In places rest uncon. on Paleozoic ls.

Raft River formation.

Pliocene (?): Northwestern Washington.

A. B. Reagan, 1909 (Kans. Acad. Sci. Trans., vol. 22, p. 202). *Raft River fm.*—An outcrop on N. side of mouth of Raft River, which contains concretionary ss. and gray sh., which Dr. Arnold considers=part of Quinaielt fm.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, p. 604). The Raft River Plio. of Reagan contains a small but characteristic Empire fauna.

Ragan sand.

A subsurface sand of late Penn. age in central northern Okla. In Perry pool, Noble Co., it is 100 ft. thick and lies at 1,805 ft. depth, the Vann sand lying at 1,587 ft. and the Tonkawa at 2,714 ft.

Ragged Point series.

Tertiary: West Indies.

J. W. W. Spencer, 1902 (London Geol. Soc. Quart. Jour., vol. 58, p. 360).

Raggedy Mountain gabbro.

Pre-Cambrian: Southwestern Oklahoma.

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 136). *Raggedy Mtn gabbro.*—Gabbro, including a considerable variety of basic rocks regarded as facies of one magma. Possibly eruptive through Carrollton Mtn porphyry. Assigned to Archean (?). Named for Raggedy Mtns, Kiowa Co.

Ragland sandstone.

Middle Devonian (Hamilton): Eastern Alabama (St. Clair County).

C. Butts, 1927 (Wash. Acad. Sci. Jour., vol. 17, pp. 128–129; Am. Jour. Sci., 5th, vol. 14, pp. 365–380; U. S. G. S. Bessemer-Vandiver folio, No. 221, p. 9, footnote). *Ragland ss.*—Sss. of Hamilton age in Ala. Heretofore included in Frog Mtn ss. At type loc. the fm. is uncon. overlain by Fort Payne chert and uncon. underlain by Little Oak ls., and it consists of (descending): (1) Thick-bedded ss., some layers coarse-grained, others fine-grained with nodular chertlike bands, some dark sh., scattered fossils, 48 ft.; (2) ss. and sh., ferruginous, brown, rotten, highly fossiliferous, 2½ ft.; (3) hard fine-grained calc. ss., fossiliferous, 1½ ft.; (4) dark argill. sh., fossiliferous, ½ ft.; (5) ls., rather coarsely crystalline, dark, sandy, fossiliferous, 1 ft. Named for exposures in abandoned quarry 1½ mi. S.-SW. of Ragland, St. Clair Co.

Ragland sand.

A subsurface sand, lying at top of or above Ohio sh., in eastern Ky. The name has also been applied to an older sand, of Middle Dev. (Onondaga) age, in eastern Ky., but the true Ragland is the younger sand.

Rail Canyon sandstone member (of Vermejo formation).

Upper Cretaceous: Northeastern New Mexico (Raton coal field).

W. T. Lee, 1924 (U. S. G. S. Bull. 752). *Rail Canyon ss. memb.*—Massive cross-bedded ss., 0 to 50 ft. thick, lying near middle of Vermejo fm. in Raton coal field. Is readily recognized by its numerous inclusions of clay balls. Forms roof of mines in many places in Dawson dist. and extends to southern extremity of that dist., but its relation to beds S. of this dist. is not known. Named because of economic importance in making a firm roof in Dawson mines, in Rail Canyon. Rests uncon. on 0 to 65± ft. of sh. and sss. forming lower part of Vermejo fm., and lies 100± ft. below top of Vermejo fm.

Railroad Ridge basalt.

Pliocene: Northwestern Nevada.

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, p. 14). South of Pueblo Mtn. and immediately W. of tilted spur formed by southern extension of the volcanic series as it plunges southward, lies Thousand Creek Basin. This basin, which is but superficially eroded, contains stratified tuffs of unknown thickness, which directly overlie Pueblo Mtn series, which writer correlates with upper flows exposed on Steens Mtn. From vertebrate fauna Merriam considered these beds lower Plio., but later studies by C. Stock (personal communication) indicate they are "definitely Pliocene and fairly late in that period." These light-colored tuffs are locally capped by a thin flow known as *Railroad Ridge basalt.* This lava was thought to have originally filled a river bed.

†Rainbow beds.

Pliocene or Miocene: Southern California (Fresno and Kings Counties).

F. M. Anderson, 1905. (See 1905 entry under *†Coalinga beds.*)

Rainbow series.

Post-Franciscan: Northern California (Humboldt County).

W. Stalder, 1915 (Calif. State Min. Bur. Bull. 69, pp. 447–449). *Rainbow series.*—Post-Franciscan and pre-upper Mio. rocks of Rainbow Ridge, divided into Walker Ridge sss. above, 50 to 750 ft. thick, and Walker Ridge shales below, 500 to 1,500 ft. thick. Underlies Bear River series (upper Mio.) and overlies post-Franciscan rocks called basal ss. series.

Rainbow member (of Richfield formation).

Pre-Cambrian: British Columbia (Cariboo district).

G. Hanson, 1935 (Canada Dept. Mines Geol. Surv., Bur. Econ. Geol. Mem. 181, No. 2396, p. 4).

Rainbow Bend sand.

A subsurface sand in lower part of Cherokee sh. in Rainbow Bend field, Cowley Co., Kans. Is correlated by D. R. Snow and D. Dean with Burbank sand of Okla. and assigned to Bartlesville sand zone.

Raines Corner limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 404). *Raines Corner ls.*—Dark and hard; weathers gray; 5 to 10 ft. thick; marine fossils. Underlies Indian Mills sh. and overlies Raines Corner sh.; all members of Bluefield group [fm.]. Type loc. in bed of Indian Creek, ½ mi. NW. of Raines Corner, Monroe Co. Also observed in Mercer and Summers Counties, W. Va., and has been traced as far S. as Big Stone Gap, Va.

Raines Corner shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 409). *Raines Corner sh.*—Green or grayish sandy deposit, 5 to 20 ft. thick, with marine and plant fossils. Underlies Raines Corner ls. and overlies Raines Corner coal; all members of Bluefield group [fm.]. Type loc. on W. side of Indian Creek along the State road, about 1½ mi. NE. of Raines Corner, Monroe Co. Observed also in Mercer and Summers Counties, W. Va., and in Giles Co., Va.

Rainy limestone member (of Clear Fork formation).

Permian: Central northern Texas (Taylor County).

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, p. 27, pl. 1). *Rainy ls.*—Dark-gray to brown fossiliferous ls., locally white, 1 to 3 ft. thick, separated from underlying Lueders ls. by red and blue sh. and lying considerably lower in the section than Standpipe ls., the intervening beds consisting of some unnamed lss. and blue and brown shales. Type loc. along Rainy Creek, 6 mi. E. of Abilene, Taylor Co. Forms escarpment S. of T. & P. R. R. The name is used in unpublished rept. of W. A. Riney. Included in Wichita-Albany fm.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, pl. 9, pp. 948, 949). *Rainy ls.* has been followed as far N. as eastern Haskell Co. and may be present as a thin stringer as far as southern Baylor Co. Lies in basal part of Clear Fork fm., about 70 ft. above its base and about 30 ft. below Lytle ls.

Rainy Mountain limestone.

Lower Ordovician: Southwestern Oklahoma.

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 138–140). *Rainy Mtn ls.*—Blue and gray ls. in Wichita Mtns, folded and metamorphosed by Quana granite. Conformable on Blue Creek series (Camb.). Assigned to Ord.

Appears to be same as Arbuckle ls. See **J. A. Taff, 1904 (U. S. G. S. P. P. 31, pl. 2).**

Named for Rainy Mtn, Kiowa Co.

†Raised Beach formation.

Pleistocene: Southern California (San Pedro and vicinity).

R. Arnold, 1902 (Calif. Acad. Sci. Mem., vol. 3), applied this nongeographic term to beds younger than San Pedro series.

Raisin River dolomite member (of Bass Islands dolomite).

Silurian (Cayugan): Southeastern Michigan, western Ontario, and northern Ohio.

W. H. Sherzer and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 546). *Raisin River beds.*—Top memb. of Lower Monroe fm. [Bass Islands dol.]. Discon. overlain by Sylvania ss. and underlain by Put-in-Bay dolomites. [On a later page (553–556) thickness is given as 200± ft.]

Named for exposures on Raisin River, Monroe Co., Mich.

Raker Peak pyroxene andesites.

See under *West Prospect basalt.*

Rakes Creek shale. (In Tecumseh shale.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 47, 53). *Rakes Creek sh.* is proposed for upper unit of Tecumseh sh. memb., i. e., for interval btw. Ost ls. below and Rock Bluff ls. above, from a locality in NW¼ sec. 5, T. 10 N., R. 14 E., on Rakes Creek, Cass Co., Nebr. Thickness 20± ft.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 48, 180). *Rakes Creek sh. memb.* of Tecumseh sh. is light-bluish to brownish clayey and sandy sh., and in most places includes a fairly persistent ss.; is mostly unfossiliferous. Thickness 10± ft. Overlies Ost ls. Recent study by me in Nebr., W. Iowa, and NW. Mo. indicates that Rock Bluff ls., which next overlies Rakes Cr. sh., is certainly = "middle Deer Creek ls." in Kans.; but this need not make use of Rakes Creek sh. inapplicable in Kans. Upper bdy of Rakes Creek may be considered as extending to slightly higher strat. plane in N. than in S. [Moore's 1936 revised classification for Kans. shows, on p. 48, Rakes Creek sh. separated from Rock Bluff ls. by Ozawkie ls. and Oskaloosa sh.]

Raleigh sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, pp. 487, 493). *Raleigh ss.*—The cgl. bed at top of section exposed on road from Prince to Raleigh. Been traced by writers from Tug River and Great Flat Top Mtn. in Pocahontas field, through Wyoming and Raleigh Counties, to New River, and along that stream from Glade to Cotton Hill. Varies in thickness from 40 to 100 ft., and in character from a massive pebbly rock to a series of flaggy sss.; very often it is a cgl. Overlies Royal fm. and underlies Sewell fm.

M. R. Campbell, 1896 (U. S. G. S. Pocahontas folio, No. 26). *Raleigh ss.*—Coarse, massive ss., 80 to 150 ft. thick. Overlies Quinnimont fm. and underlies Sewell fm. Covers a large portion of surface of Raleigh Co., W. Va.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2a, p. 198), divided Raleigh ss. into *Upper Raleigh ss.*, 60 to 137 ft. thick, and *Lower Raleigh ss.*, 64 to 93 ft. thick, the two being separated by 1 to 37 ft. of sh., coal, and fire clay, and these names have been used in some subsequent W. Va. Geol. Surv. repts.

Ralls Ford shale.

See *Rolls Ford sh. memb.*

Ralston group.

Pennsylvanian and Permian: Central northern Oklahoma.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, pp. 7, 13). *Ralston group.*—Includes all beds btw. base of Pawhuska fm. of J. P. Smith below and base of Wreford ls. (or its southern continuation the Payne ss.) above.

Named for Ralston, Pawnee Co.

†Ralston formation.

Eocene (basal): Northern Wyoming (Bighorn Basin region).

W. J. Sinclair and W. Granger, 1912 (Am. Mus. Nat. Hist. Bull., vol. 31, pp. 60–62). *Ralston beds or fm.*—A vertebrate faunal horizon near top of Fort Union (?) fm. on N. side of Shoshone River in bluffs opp. Ralston Station, where the beds dip below *Systemodon* horizon. Appears to underlie Knight fm. (of Wasatch group), but discovery in them of *Limnocyon* and *Bathyopsis* makes further study desirable. If the beds prove to be older than the Knight, and it is deemed desirable to give them a fm. name, they may be referred to as *Ralston beds* or *Ralston fm.*

W. Granger, 1914 (Am. Mus. Nat. Hist. Bull., vol. 33, pp. 202–205). The 1912 work in Clark Fork and Bighorn Basins proved the horizon for which *Ralston beds* or *Ralston fm.* was previously suggested is very distinct, older than Gray Bull, and perhaps representing top of Paleocene series. *Ralston* is preoccupied, so *Clark Fork beds* is here substituted, from Clark Fork Basin.

Ralston formation.

Pre-Cambrian: Central northern Colorado (Boulder region).

See under *Coal Creek qtzite*, 1934.

Ramah series.

Pre-Cambrian: Labrador.

A. P. Coleman, 1921 (Canada Geol. Surv. Mem. 124, p. 25).

†Rambler formation.

Miners' local name for 180 ft. of thin-bedded siliceous ls. in lower part of Oquirrh fm. (Penn.), lying 213± ft. below Galena King ls. and overlying the Rambler ls. of the miners. Exposed in Rambler claim of Stockton dist., central northern Utah. (See U. S. G. S. P. P. 173, 1932.)

Rambler limestone.

Miners' local name for 4 ft. of rather pure ls. underlying Rambler fm. of miners and lying 90 ft. above their Hercules ls., in lower part of Oquirrh fm. (Penn.) of Stockton dist., central northern Utah. Exposed in Rambler claim. (See U. S. G. S. P. P. 173, 1932.)

†Ramona formation.

Pennsylvanian: Northeastern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 36). *Ramona fm.*—Strata btw. top of Skiatook fm. below and top of Avant ls. memb. above. Divided into three members, Dewey ls. at base, Ochelata sh. in middle, and Avant ls. at top. Thickness 100 ft. Name to be applied btw. Arkansas River and line approx. coincident with Claremore and Nowata quads.

Includes Dewey ls. and lower part of Ochelata fm. of present nomenclature. Named for Ramona, Washington Co.

Rampart group.

Mississippian (probably lower): Yukon-Tanana region, Alaska.

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 155–169). *Rampart series.*—Characterized by green color (which changes to dark red on exposure), by a peculiar massive structure and firm texture, and by presence of volcanic material. Consists of diabase flows, tuffaceous sediments, impure lss. (often glauconitic), hard green shales and slates, and some ss. Some of the rocks are light gray and appear to be very fine-grained siliceous sediments or novaculites. Green color is due partly to glauconite in tuffs and impure sediments, but chiefly to presence of serpentine, chlorite, and other green minerals arising from decomposition of the igneous rocks. The rocks of Rampart series are occasionally cut by diabase dikes and later intrusions. Thickness great. Overlies Fortymile series and underlies Upper Carbf. Tahkandit series. Named for fact they are exposed in Lower Ramparts of the Yukon.

Further work showed that Rampart series of Spurr included Middle Dev. and Miss. rocks equiv. to Woodchopper volcanics (Middle Dev.), Circle volcanics (Miss.), and probably a younger Miss. fm., but that at type loc. its fossils are Miss. (See J. B. Mertie, Jr., U. S. G. S. Bull. 816, 1930, pp. 75–95.) The name is now restricted to rocks corresponding to those at type loc.

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). *Rampart group* (Mississippian) of Yukon-Tanana region consists of sed. rocks (chert, sh., sl., argillite, ss., and a few beds of ls. and calc. grit) and bedded greenstones, tuffs, and breccias. Associated with the group are coarse-grained intrusives, in part contemp. and in part younger. Sediments probably constitute one-third to one-half of the group. The rocks are closely folded and locally faulted and brecciated. Of Miss. age. Thickness may be 5,000 to 10,000 ft.

Rampart limestone.

Ramparts limestone.

Devonian: Canada (Mackenzie).

T. O. Bosworth, 1921 (Geol. Mag., vol. 58, p. 287, and Inst. Pet. Technologists Jour., vol. 7, No. 28). [In both of these publications *Rampart ls.* is used. All subsequent Canada Geol. Surv. repts. by E. M. Kindle and G. S. Hume, use *Ramparts ls.*]

Ramp Creek member (of Harrodsburg limestone).

Mississippian: Southern Indiana.

P. B. Stockdale, 1929 (Ind. Acad. Sci. Proc., vol. 38, pp. 233–242). *Ramp Creek memb. of Lower Harrodsburg ls.*—Variable siliceous ls., with irregularly distributed crinoid lenses, and characterized by prevalence of geodes and chert. Thickness 16 to 28 ft. Basal memb. of Lower Harrodsburg ls. Underlies Leesville ls. memb. and overlies Borden group. Completely exposed in ravines tributary to Ramp Creek, SE. part of Monroe Co.

Ramsey sand.

A subsurface Penn. sand in NE. Okla., lying lower than Checkerboard lime and higher than Big lime (Oologah ls.). In Osage Co., Okla., the name has been applied to a sand, 5 ft. thick, lying 40 ft. above Peru sand. In SW. Okla. the name has been applied to a sand, 300 ft. thick, correlated with part of Wellington fm. (Perm.). The name has also been used in SE. Kans.

Ramsey Lake graywacke conglomerate.

Pre-Cambrian: Ontario.

A. P. Coleman, 1905 (Ont. Bur. Mines Rept. 1905, vol. 14, pt. 3, p. 14).

Ramshorn slate.

Ordovician (Lower and Middle?): Central Idaho (Custer County region).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Ramshorn sl.*—Dark, thin-bedded unfossiliferous sl. and argill. qtzite containing Beekmantown graptolites. Thickness 2,000± ft. Older than Kinnikinic qtzite and overlies (uncon.?) Bayhorse dol. Named for well-known mine near head of Bayhorse Creek, Custer Co.

C. P. Ross, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 945, etc.). *Ramshorn sl.*—Composes all Ord. argill. rocks below Kinnikinic qtzite in Bayhorse region. Overlies Bayhorse dol. Forms country rock of well-known Ramshorn mine. Extends in a band, 2 to 5 mi. wide, from Mill Creek, on N. border of Bayhorse quad., southward past Clayton, a distance of 20± mi. Smaller isolated outcrops emerge at intervals through the cover of Challis volcanics, all the way to S. bdy of Bayhorse quad. Is almost exclusively a thin-banded dark-green to purplish argill. rock with well-developed slaty cleavage cutting the banding at high angles. Locally (in N. part of quad.) cgl. at base; some beds are more qtzitic or more calc. than the average. Locally lenses of ls. and qtzite are interbedded. Max. observed thickness of conglomeratic beds is a little more than 500 ft. Est. thickness of fm. 2,000+ ft. Fossils.

Ramshorn volcanic series.

Tertiary (post-middle Eocene): Central Wyoming (Owl Creek Mountains).

D. Love, 1934 (Geol. Surv. Wyo. Bull. 24, pt. 4, pp. 21–22). At W. end of Owl Creek Mtns a series of [unnamed] aggls. and breccias of post-Green River age is uncon. overlain by 0 to 700 ft. of soft coarse-bedded white andesitic tuff, which forms lower part of the rocks here named *Ramshorn volcanic series*. Lying on these white tuffs is a series of tuffs, pink andesite flows, and coarse pink to gray aggl. or breccia, 0 to 600 ft. thick, which forms upper part of Ramshorn volcanic series. All that can definitely be said of the age of this series is that it is post-Green River. Named for The Ramshorn, a mountainous ridge lying 12 mi. W. of area studied, which is composed of rocks of this volcanic series.

Rancocas group (also **formation**).

Eocene (lower): New Jersey and Delaware.

W. B. Clark, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, pp. 337–338, and Jour. Geol., vol. 2, pp. 161–177). *Rancocas fm.*—Largely greensand, although much more highly glauconitic in lower than in upper half. Lower half largely a pure greensand, but in some parts of State it becomes very argill. toward base, forming the so-called "chocolate marl." Is Middle Marl Bed of previous repts. Thickness 45 ft. Underlies Manasquan fm. and overlies Redbank fm. Rancocas Creek, Burlington Co., N. J., cuts through the fm., exposing its full sequence.

Later repts give thickness as 0 to 125 ft., and divide the deposits in N. J. into Vincentown sand above and Hornerstown marl below. In Delaware the subdivisions are not recognized and the deposits are there called *Rancocas fm.*

Rand schist.

Pre-Cambrian: Southern California (Randsburg quadrangle, Kern and San Bernardino Counties).

C. D. Hulin, 1925 (Calif. State Min. Bur. Bull. 95, pp. 23–29, map). *Rand schist.*—Predominately mica-albite schist, showing highly developed schistosity; usually dark silvery gray, but weathers yellowish brown. Amphibole schists are next in order of abundance, and are only slightly subordinate in amount to the mica albite schist. Actinolite schist, actinolite-talc schist, talc schist, and hornblende schist also occur in minor amounts. The mica-albite schist and the amphibole schists are interbedded with qtzite and ls. in beds from 1 to 10 ft. thick. Greenstone schist, of igneous origin, is present in small, irregular, and isolated masses. Rest of fm. is of sed. origin. Is believed to uncon. overlie Johannesburg gneiss and to uncon. underlie the rocks of Paleozoic age. Assigned to Archean. Thickness exposed is probably btw. 1,500 and 2,000 ft. Composes bulk of Rand Mtns, Kern Co.

Randels Island gneiss.

R. P. Stevens, 1867 (N. Y. Lyc. Nat. Hist. Annals, vol. 8, pp. 116–120). [*Randels Id. gneiss* is used on "Section across New York [Manhattan] Island along southern shore of Spuyten-Duyvel Creek and Harlem River."]

Randlett horizon. (In Duchesne River formation.)

Oligocene: Eastern Utah (Uinta Basin).

J. L. Kay, 1934 (Carnegie Mus. Annals, vol. 23, pp. 357–359). To facilitate correlation and reference of specimens now in Carnegie Mus., Duchesne River fm. is divided into 3 horizons, from lowest to highest, the *Randlett*, the *Halfway*, and the *Lapoint*. Type loc. of Randlett horizon is N. and E. of town of that name, and it consists of 478½ ft. of brown, red, bluish-gray, and variegated clays alternating with brown and gray sss. These beds are capped by a 10-ft. stratum of cgl., which is taken as base of Halfway horizon. Latter horizon is well exposed along Halfway Hollow, the basin which drains that dist. in Twps 4 and 5 S., btw. Rs. 19 and 20 E. Salt Lake meridian. There are 557½ ft. of sediments, chiefly sss. and shales with several cgl. members, referred to *Halfway horizon*. The sss. in general are coarser than those of the Randlett. Overlying the Halfway horizon is 22 ft. of bluish-white clay, which can be seen just N. of Vernal-Lapoint road and which is quite persistent throughout the area. This is considered basal memb. of *Lapoint horizon*, the uppermost div. of Duchesne River fm. The Lapoint horizon is typically seen along head of Halfway Hollow E. and N. of town of Lapoint. The Lapoint includes 336 ft. of conglomeratic sss., sandy clays, and coarse cgls.

Randolph limestone.

Mesozoic (Lower Cretaceous?): Southeastern Arizona (Tombstone district).

W. P. Blake, 1902 (Tombstone and its mines). *Randolph ls.* (Paleozoic, probably Carbf.) overlies ancient sed. strata of ls.

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3–37). *Randolph ls.*, 300 ft. thick, underlies Ajax qtzite in Tombstone min. dist., Ariz. [Is oldest fm. mentioned.]

F. L. Ransome, 1920 (U. S. G. S. Bull. 710D). Randolph ls. of Church is Mesozoic, probably Comanche (Lower Cret.).

Randolph phyllite.

Middle Ordovician: Northeastern Vermont (Orange County) and southeastern Vermont (Windsor County).

C. H. Richardson, 1924 (14th Rept. Vt. State Geol., p. 90). *Randolph phyllite*.—Fine-grained phyllites, of either very dark-gray or bluish-gray color, and with schistose structure. Are interbedded and interstratified with Waits River ls. Are the phyllite part of Memphremagog group, and in Bethel Twp, and doubtless to southward, are the predominant phase of that group. Extend in N.–S. direction, entirely across Randolph Twp [Randolph quad., Orange Co.]. Are older than Bradford schists, which overlie Waits River ls., and younger than Orleans phyllite, which underlies Waits River ls.

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 208–246). *Randolph phyllite* belongs to Memphremagog group. This phyllite and younger Brattleboro phyllite are interstratified with Waits River ls.; all assigned to Ord. It forms a continuous terrane across W. part of Reading and Cavendish and extends into Chester.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 13, p. 360). In central Green Mtns, Vt., the Ord. consists of *Randolph phyllite* (correlated with Black River ls. of N. Y.), Waits River ls. (Chazy fossils), and Memphremagog sl. (Beekmantown fossils).

Randolph granite.

Late Devonian or late Carboniferous: Northern New Hampshire (White Mountains).

See 1928 entry under *Chatham granite*.

M. Billings, 1935 (letter dated July 19). Type loc. of *Randolph granite* is in Ravine of the Castles, 1 mi. NW. of Mount Jefferson, in Mount Washington quad. [This ravine lies S. of Randolph Range and Randolph Twp.]

M. Billings, 1935 (letter dated Aug. 27). *Randolph granite* belongs to New Hampshire magma series [which he classifies as late Dev. or late Carbf.].

Randolph granite.

Devonian: Northeastern Vermont (Orange County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Quarried at Randolph, Randolph Twp, Orange Co.

Random formation.

Pre-Cambrian (Keweenawan): Newfoundland.

C. D. Walcott, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 3–5). *Random terrane*, Algonkian, Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Random fm.*—Red sss., shales, and qtzites, uncon. underlying Lower Camb. Bonavista fm. and uncon. overlying Signal Hill fm. (Huronian). No fossils. Assigned to Keweenawan epoch of Algonkian. [Derivation of name not stated.]

Random Sound series.

Cambrian: Newfoundland.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 196).

Randville dolomite.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Crystal Falls and other districts).

C. R. VanHise, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 9–16). *Randville dol.*—A nonclastic sediment in Crystal Falls dist., Minn. Believed to make a period of subsidence and transgression of the sea to NE. Thickness 500 to 1,500 ft. Thickest on Fence River. Overlies Sturgeon qtzite and underlies Mansfield sl. Correlated with Kona dol. of Marquette dist. [Also described by J. M. Clements on pp. 34+ of this rept. (in detailed description of Crystal Falls dist.), where Clements expressed opinion this dol. is same as Kona dol. of Marquette dist., but stated that, since Smyth had introduced Randville dol. for Crystal Falls dist., he would use Randville.]

H. L. Smyth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 110–114). *Randville dol.*—Consists, so far as known, almost wholly of crystalline dolomitic rocks. A few thin layers of schist and qtzite are shown by drills to be interbedded in the dol. Color most commonly pinkish or bluish white. Thickness 500 to 1,500 ft. Overlies Sturgeon qtzite and underlies Mansfield fm. Named for exposures within a short distance of Randville station.

Rangeley conglomerate.

Devonian (?): Western Maine (Franklin County).

E. S. C. Smith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 147–154). *Rangeley cgl.*—One memb. (probably the older) consists of about 400 ft. of dark-gray, coarse-grained arkose, containing much blue quartz and feldspar and some biotite. The other memb. consists of about 3,900 ft. of medium coarse cgl. with intercalated sandy or arkosic layers. Rests on argillite and is overlain by argillite. No fossils, but is probably Dev. Named for development near Rangeley and at SE. end of Rangeley Lake, Franklin Co.

On 1933 geol. map of Maine, by A. Keith, the rocks around Rangeley and Rangeley Lakes are mapped as Sil., Ord., and Camb.

†Ranger formation. (In Canyon group.)

Pennsylvanian: Central northern Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., p. lxvii), used *Brownwood-Ranger series*. See under †*Brownwood div.*

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Ranger fm.*, approx. 215 ft. thick, includes all strata btw. top of Graford ls. memb. of Graford fm. and top of heavy Ranger ls. (top memb. of Ranger fm.). Underlies Eastland fm. and overlies Graford fm.

Replaced by Brad fm. by F. B. Plummer and R. C. Moore, 1922.

Named for exposures in vicinity of Ranger, Eastland Co.

†Ranger series.

Pennsylvanian: Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii). *Brownwood-Ranger series.* [See 1st entry under *†Brownwood div.* Later repts state †Brownwood is practically=Canyon group.]

Ranger limestone member (of Brad formation).

Pennsylvanian: Central and central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Ranger ls.*, top memb. of Ranger fm., forms a scarp that can be seen W. of Ranger and is responsible for the beautiful and wild topography in western Palo Pinto Co., where Brazos River has cut deep canyons into the scarp. The abundance of chert nodules and brown iron-stained layers in Ranger ls. distinguishes it from all other members of Canyon div.

C. S. Ross, 1921 (U. S. G. S. Bull. 726G, p. 306). *Ranger ls. memb. of Canyon fm.*, 66 ft. thick, is exposed in SE. part of Lacasa area. Consists of (descending): (1) Thin-bedded buff ls., 4 ft.; (2) sh., 12 ft.; (3) light-gray massive ls., 50 ft. [Nos. 1 and 2 are now included in overlying fm., and are not considered a part of Plummer's Ranger ls.]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 35; Univ. Tex. Bull. 2132, pp. 109+). *Ranger ls. memb.*, massive and very cherty ls., 10 to 50 ft. thick. Is here defined as top memb. of Brad. fm., of Canyon group. Occurs in both Colorado River Valley and Brazos River Valley. Is the "Cherty" ls. of Drake.

Named for exposures W. of Ranger, Eastland Co.

Ranger marble.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 622, 642). *Ranger marble.*—Massive light bluish-gray fine-grained marble of dolomitic composition is most characteristic rock. Comparatively little jasper or other siliceous material, and schistose members are few and thin. Thickness 2,395 ft. Underlies Towner greenstone with probable conformity and conformably overlies Anderson phyllite. Exposed at various points northeastward to Brooklyn ranger station, for which it is named. Assigned to early Algonkian.

Ranger oil sand.

A subsurface sand in Marble Falls ls. (Penn.) of Ranger field, central northern Tex., lying 190 to 200 ft. below top of Marble Falls ls.

Rapid limestone.

Middle Devonian: Central eastern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, p. 149) and 1913 (Iowa Acad. Sci. Proc., vol. 20, pp. 205, 206). *Rapid terrane.*—Series of lss. in lower part of Cedar Valley ls., consisting of (descending) 2 ft. of gray massive, compact coralline ls.; 3 ft. of bluish heavy-bedded ls. containing *Cladopora*; 6 ft. of blue massive, compact ls. containing ***Cystiphyllum***; and 20 ft. of gray shaly unfossiliferous ls. Overlies Solon ls. and underlies Coralville ls. Included in Senecan.

Named for locality (not stated) in Johnson Co.

Rapid River conglomerate.

Pre-Cambrian (Huronian?): Quebec.

J. B. Mawdsley and G. W. H. Norman, 1935 (Canada Dept. Mines, Bur. Econ. Geol., Geol. Surv. Mem. 186, Pub. 2409, p. 10).

†Rapids schist.

Early Paleozoic or older: Northern Alaska (Chandler River region).

F. C. Schrader, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 473). *Rapids schist.*—Narrow belt of highly metamorphosed or altered mica schist, traversed by Chandler River in region of the rapids, where it forms low anticline, with much quartz, in bight of the fold. Extends for several mi. downstream nearly to West Fork. Seems to underlie Lake qtzite schist, but may prove to be a lower memb. of that series. Supposed to rest on basal granite. Noted only along the river and does not seem to ascend high into mtns.

Is now considered to be an indefinite unit of early Paleozoic or older age.

†Rappahannock series.

Lower Cretaceous: Eastern Virginia.

L. F. Ward, 1895 (U. S. G. S. 15th Ann. Rept., p. 321). *Rappahannock series.*—Chiefly sands; in places clay seams and large masses of clay. Thickness 250 ft. The earliest mention I have been able to find of the principal rock by which this memb. is characterized is that of Mr. Latrobe in 1784, who called it "Rappahannock freestone," and mentioned fact that lighthouse at Cape Henry was constructed of it. In later times it has more frequently been called "Fredericksburg freestone" or "Aquia Creek freestone," from position of principal quarries. Fredericksburg is preoccupied, and in vicinity of Aquia Creek the most typical deposits belong to a higher series of Potomac fm. Uncon. underlies Mount Vernon series and uncon. overlies James River series, the basal clays of the Potomac fm.

W. B. Clark and B. L. Miller, 1912 (Va. Geol. Surv. Bull. 4). The *Rappahannock series* is included in Patapsco and Patuxent fms. of present nomenclature.

Rappahannock freestone.

Trade term for ss. quarried from Potomac group on Rappahannock River, Va.

See under †*Rappahannock series.*

Raquet series.

Carboniferous: Yukon-Alaska boundary, between Porcupine and Yukon Rivers.

D. D. Cairnes, 1912 (Canada Geol. Surv. Summ. Rept. for 1911, pp. 27–32). Mainly crystalline lss., of white, gray, and almost black colors, cherts, and cherty cgls. Thickness at least 1,500 ft. Underlies Mesozoic Orange group (whether conformably or uncon. not ascertained) and overlies Porcupine group (Sil. and Ord.). Named for Raquet Creek, a tributary of Stony Fork of Black River, Yukon. Of local significance only.

Rarden shale member.

Mississippian: Southern Ohio and northeastern Kentucky.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 762). *Rarden sh. memb.*—Alternating red and gray clay shales, 8½ ft. thick at Vanceburg, Ky., increasing northward to 58 ft. at Elm Grove, Pike Co., Ohio. Included in Cuyahoga fm. [Cuyahoga fm. as here used included lower part of Black Hand fm.] Underlies Vanceburg memb. of Cuyahoga and overlies Buena Vista ss. memb. Along W. margin of outcrop belt, in Adams Co., where Buena Vista memb. becomes insignificant, Rarden memb. probably rests on and is indistinguishable from underlying Henley memb. Not recognized outside of Vanceburg facies of Cuyahoga sh., upper limit being lost with disappearance of overlying ss.

Named for Rarden, Scioto Co., Ohio.

†Raritan clay.

Upper Cretaceous: New Jersey and eastern Maryland.

T. A. Conrad, 1869 (Am. Jour. Sci., 2d, vol. 47, pp. 360–363). *Raritan clay.*—Includes (descending) light-colored clay, 20+ ft.; black clay, 4 ft.; ash-colored clay, 4 ft. All contain fossil leaves. Considered by Rogers to be base of Cret. system. Plants go far to prove Raritan clay is Triassic. Rests uncon. on gray quartzose sand. Occurs along Raritan River, N. J.

G. H. Cook and J. C. Smock, 1877 (N. J. Geol. Surv. map of clay dist. of Middlesex Co.) *Raritan clay includes* (descending): *Raritan fire-clay bed*, 15 ft.; sand and lignite, 4 ft.; *Raritan potters clay bed*, 20 ft.

Is lower part of Raritan fm.

Raritan fire clay.

Economic term for bed of clay, 15 ft. thick, near base of Raritan fm. in NE. N. J. Lies 4 ft. above *Raritan potter's clay* (20 ft. thick), an economic term applied to basal bed of Raritan fm. in that area. See G. H. Cook and J. C. Smock, 1877 (N. J. Geol. Surv. map of clay dist. of Middlesex Co.), and G. H. Cook, 1878 (N. J. Geol. Surv. Rept. on clays, p. 34).

Raritan formation.

Upper Cretaceous: Eastern New Jersey, Delaware, and Maryland.

G. H. Cook, 1888 (Am. Geol., vol. 2, p. 260). *Raritan clays.*—Include (descending): Sand, clay, and lignite, 50 ft.; clay and sand, 40 ft.; stoneware clay bed, 30 ft.; sand and clay, 50 ft.; South Amboy fire-clay bed, 20 ft.; kaolin, 13 ft.; feldspar, 5 ft.; micaceous sand bed, 20 ft.; laminated clay and sand, 30 ft.; pipe clay, 15 ft.; Woodbridge fire-clay bed, 20 ft.; fire-sand bed, 15 ft.; Raritan fire-clay bed, 15 ft.; Raritan potter's clay bed, 24 ft. Underlies Clay Marls [Matawan group] and rests on Archean. [As thus defined Cook's *Raritan clays* are 347 ft. thick and include Magothy fm. of present nomenclature.]

W. B. Clark, 1893 (N. J. Geol. Surv. Ann. Rept. 1892, pp. 181–186). *Raritan fm.*—Largely sands and clays, many of them of great economic value. Thickness 347 ft. Underlies Clay Marl fm. [Matawan]. The term Raritan, employed as the distinctive name of this fm., is one which has been so long used by Cook, Newberry, Smock, and others for a greater or less portion of the series under consideration, that its retention and wider application seems fully warranted. Best exposed in vicinity of Raritan River [and Raritan Bay]. Is=Plastic Clays of Cook. [Clark then quoted Cook's subdivisions, enumerated above, as "affording the most accurate sequence of the chief deposits of Raritan fm. available at present time."]

The foregoing definition of Raritan fm. was employed until 1904.

W. B. Clark, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 435–440). *Magothy and Cliffwood beds.*—Transitional deposits, 10 to 100 ft. thick, btw. Matawan fm. above and Raritan fm. restricted below. Consist of a lens of clays and interbedded sands lying beneath typical Matawan at Cliffwood, N. J., on shores of Raritan Bay, and included by writer in that fm. in his "Prel. geol. map of portions of Monmouth and Middlesex Counties, N. J." accompanying rept of State Geol. for 1892. Kümmel and Knapp in recent rept have referred these beds to Raritan, but from structural relations, lithologic character, and contained fossils it is impossible to refer them to that fm., and they should be given independent rank as a fm. Darton was first to name this fm., should it be ultimately shown to represent a single strat. unit. But it is highly probable the Md. [Magothy] strata represent a somewhat lower horizon than the fossiliferous beds at Cliffwood, and may be=in part at least to the "laminated sands" which underlie the lignitic beds at Cliffwood. The base of Darton's Magothy may thus prove to be base of "laminated sands," and may necessitate the transfer everywhere of certain upper sands hitherto regarded as Raritan to the Magothy-Cliffwood series.

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6), drew top of *Raritan clay series* at base of Merchantville clay, as did S. Weller, 1905 (N. J. Geol. Surv. Ann. Rept. 1904; Am. Geol., vol. 35, p. 179; Jour. Geol., vol. 13, pp. 324–337).

E. W. Berry, 1906 (N. J. Geol. Surv. Ann. Rept. 1905), drew top of Raritan fm. of N. J. at top of Amboy stoneware clay, which he stated is uncon. overlain by Magothy fm. (including "Cliffwood clays").

S. Weller, 1907 (N. J. Geol. Surv. Pal., vol. 4), described Magothy fm. of N. J. as consisting of (descending): (1) "Laminated sands" of Kümmel, 40 ft.; (2) Cliffwood clays; (3) sand. Conformably overlain by Merchantville clay marl and uncon. underlain by *Raritan fm., restricted sense*, the top memb. of Raritan being called Amboy stoneware clay. [This is commonly accepted definition of Raritan fm. In N. J. the thickness ranges from 150 to 500± ft., and in Md. from 0 to 100 ft. For several years the Raritan was included in Potomac group, but as its Upper Cret. age has been proved it is no longer included in that group.]

Raspberry Mountain granite.

See 1900 entry under *Pikes Peak granite*.

Rat Creek quartz latite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). A series of lava flows with some interbedded tuff, the flows and the tuff consisting of quartz latites of very similar character; differ but little from underlying quartz latite tuff and overlying Nelson Mtn quartz latite. Thickness 0 to 500 ft. A subdivision of Piedra group of Potosi volcanic series. Named for development on Rat Creek.

Raton formation.

Eocene: Southeastern Colorado and northeastern New Mexico.

F. V. Hayden, 1869 (U. S. Geol. Surv. Colo. and N. Mex. 3d Ann. Rept., pp. 89–91). The next group comprises the coal beds of the Raton Hills, which I suspect is also a portion of the great lignite group, and will eventually be found to be synchronous with it. I have called it *Raton Hills group.*

W. T. Lee, 1913 (Am. Jour. Sci., 4th, vol. 35, p. 531). *Raton fm.* is name recently adopted by U. S. Geol. Survey for the coal-bearing rocks above the uncon. in Raton Mesa region of southern Colo. and northern N. Mex. The coal-bearing rocks below the uncon. have been named *Vermejo fm.* The two constitute what has heretofore been called *Laramie* in this region. The data upon which they were separated are contained in a forthcoming paper by W. T. Lee and F. H. Knowlton, on Raton Mesa region, which will be published by U. S. Geol. Survey.

W. T. Lee, 1917 (U. S. G. S. P. P. 101, pp. 40, 56–61). *Raton fm.*—The name *Raton* was first used by Hayden to indicate all coal-bearing rocks which he observed near Raton Mesa. As used by him it included the beds now assigned to Vermejo fm., but as the Vermejo is not conspicuously exposed along the route traversed by Hayden, and as most of the rocks he called "Raton Hills group" belong to the coal-bearing fm. above the Vermejo, the name *Raton* has been adopted for this fm. The type area of *Raton fm.* is in the high mesa region btw. Trinidad, Colo., and Raton, N. Mex., erroneously called mtns, that culminates in Fishers Peak. No complete section of the rocks is exposed in the slopes of this highest mesa, called Raton Mesa, but in the side of Bartlett Mesa, N. of town of Raton [N. Mex.], from locality 75 (see pl. 1, in pocket) to S. point of the mesa, these rocks are well exposed. In Raton Mesa the top of Raton fm. is 2,000± ft. higher than its base, and probably at no other locality in region is so great a thickness of this fm. preserved. The rocks of the fm. vary in character from coal and carbonaceous sh. to sandy sh., ss., and cgl.; in most places they weather yellowish brown. Most of cgl. occurs at base of fm., but in SW. part of Raton field cgls. were found far above the base. The base in nearly all parts of Raton Mesa region is conglomeratic. Coal occurs throughout fm. In W. part of region the cgl. at base contains much arkosic material, is several hundred ft. thick, coarse, massive, and resistant, but it thins and becomes finer-grained toward E. The Raton (of Eo. age) rests uncon. on Vermejo fm. (of Montana, Upper Cret., age) and is overlain by Poison Canyon fm. Near Trinidad there are many places where it is difficult to draw line separating Raton fm. from the Vermejo, but in W. part of region, S. of Spanish Peaks, in southern and eastern parts as far N. as Canadian River, and in E. part of Trinidad coal field N. of Trinidad, there is little difficulty in recognizing the conglomeratic ss. that constitutes base of Raton fm. The Raton has generally been regarded as uncon, with Poison Canyon fm. It seems possible the Poison Canyon and Raton fms. may differ but little in age, and that their physical differences may be due to local variations in conditions of sedimentation.

F. H. Knowlton, 1917 (U. S. G. S. P. P. 101, p. 241). Plants correlate Raton fm. with Denver and Arapahoe fms. of Denver Basin, and latter is practically continuous with Dawson arkose.

Ratonan series.

A term introduced by C. [R.] Keyes to cover the earliest Eocene deposits of N. Mex., including Raton fm. (See Iowa Acad. Sci. Proc., vol. 22, 1915, pp. 257–259.)

†Raton Hills group.

Eocene and Upper Cretaceous: Southeastern Colorado (Raton Mesa region).

See first two entries under *Raton fm.*

Raton Pass coal group. (In Raton formation.)

Eocene: Eastern Colorado (Elmoro region).

R. C. Hills, 1899 (U. S. G. S. Elmoro folio, No. 58), applied "Raton Pass group" to 50± ft. of strata lying 500 ft. above Wooten coal. These strata belong to Raton fm. of present terminology.

Rattlesnake formation.

Pliocene: Central northern Oregon (John Day country).

J. C. Merriam, 1901 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 2, No. 9, p. 310). *Rattlesnake fm.*—Gravels, ash, tuff, and rhyolitic lava; mainly gravels derived from Columbia [River] lava. Sometimes confused with Mascall fm. Type exposure on Rattlesnake Creek about 1 mi. W. of Cottonwood. Includes (descending): Gravel, 100 ft.; rhyolite, 30 ft.; soft brown tuff, 25 ft.; coarse basal gravels, 30 to 200 ft. Uncon. overlies Mascall fm. (upper Mio.). Cannot be older than early or middle Plio. and cannot be later than Plio.

F. C. Calkins, 1902 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 3, No. 5). *Rattlesnake fm.* appears to be of fluviatile origin in large part.

†Rattlesnake beds.

†Rattlesnake formation.

Upper Cretaceous (Gulf series): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 41–54). *Rattlesnake beds.*—Fossiliferous littoral deposits, 600 ft. thick, of white, gray, yellow, brown, and blue sss., muddy and peaty clays and silts, some ls., and some thin gravel beds. Grade into overlying Tornillo clays and into underlying Terlingua beds. Is=coal-bearing horizon at Eagle Pass.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, p. 505), introduced *Aguja fm.*, to replace *Rattlesnake fm.*, preoccupied by Plio. fm. in Oreg.

Named for Rattlesnake Mtn, Brewster Co.

Rattlesnake granite.

Probably pre-Cretaceous: Southern California (San Diego County).

F. S. Hudson, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 6, pp. 181, 207–208, map). *Rattlesnake granite.*—A true granite, varying from an alaskite to a biotite-hornblende granite. Intrudes rocks of probable Triassic age.

Named for Rattlesnake Valley, Cuyamaca region, San Diego Co.

Ravalli group (also **Ravalli formation**).

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and northwestern Montana (Cabinet Mountains, Mission Range, Philipsburg district).

C. D. Walcott, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 7, 9). *Ravalli series.*—Basal series of Belt terrane in Mission Range, Mont. Consists of (descending): (1) Purple and gray beds, 2,550 ft.; (2) gray beds, 1,060 ft.; (3) greenish gray beds, 4,645 ft. Underlies Blackfoot series.

F. C. Calkins, 1909 (U. S. G. S. Bull. 384, map, p. 38). *Ravalli group.*—Overlying Prichard fm. in this area [map covers Purcell Mtns, Cabinet Mtns, Bitterroot Mtns, and W. to Coeur d'Alene Lake, Idaho] is an assemblage of light-colored siliceous rocks varying from very pure white qtzite to siliceous sh., much of it in rather subdued tones of gray, green, purple, and red. In Coeur d'Alene dist. this group comprises 3 distinct fms., in ascending order Burke fm., Revett qtzite, and St. Regis fm. To N. and E. of Coeur d'Alene dist. the Revett is not everywhere present as a definite fm. and the Burke and St. Regis fms. are not sharply differentiated from each other. For this reason the name *Ravalli*, applied by Walcott to these rocks in Swan Range section, appears most suitable. Thickness of Ravalli group in Coeur d'Alene dist. is 4,200± ft.; increases to N. Is overlain by Newland ("Wallace") fm. [Geologic map of this rept covers the Purcell, Cabinet, and Bitterroot Mtns, the Coeur d'Alene dist., and extends nearly as far E. as Ravalli, which lies N. of Missouri and W. of Mission Range. The Ravalli group is mapped over large parts of this area and N. to and beyond Int. Bdy. The group was probably named for occurrence at or near town of Ravalli.]

Ravallian series.

A term applied by C. [R.] Keyes (Pan-Am. Geol., vol. 44, 1925) to part of Belt series of Mont.

Ravenna plutonic series.

Mesozoic (?): Southern California (Los Angeles County).

O. H. Hershey, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pl. 1, map). [Maps but does not describe *Ravenna plutonics*. As mapped lies btw. Cret. shales above and the granite below.] Also Am. Geol., vol. 29, 1902, p. 284). *Ravenna plutonic series.*—I predict it will be found to be Mesozoic in age and just a little older than the granitic series.

Probably named for occurrence at Ravenna Station, Los Angeles Co., around which it is mapped.

Ravenscrag beds.

Upper Cretaceous or Tertiary: Saskatchewan.

N. B. Davis, 1918 (Canada Dept. Mines, Mines Branch, Rept. clay resources southern Saskatchewan, p. 10). [Assigned to Eocene.]

In subsequent repts, by other geologists, variously assigned to Cret., to Cret. or Tert., to Cret. and Tert., to Tert., to "Paleocene," to Mio., to Eo., to Olig., and to Upper Cret.

Ravenswood granodiorite.

Pre-Cambrian: Southeastern New York (Queens County).

C. P. Berkey, 1910 (N. Y. Acad. Sci. Annals, vol. 19, p. 250). *Ravenswood granodiorite* is massive rock intrusive into Fordham gneiss. Named for typical development in Long Island City [a part of which is called Ravenswood].

V. Ziegler, 1911 (N. Y. Acad. Sci. Annals, vol. 21, p. 1). *Ravenswood granodiorite* is light to dark gray rock. Believed to be distinct from Harrison diorite, which has been more thoroughly metamorphosed. Exposed along W. shore of Long Island.

C. P. Berkey and J. R. Healy, 1912 (Columbia Univ. Contr., vol. 20, pp. 1907–1912). *Ravenswood granodiorite* ranges from a true granite almost to a typical diorite. Probably most ancient igneous or strictly intrusive rock in N. Y. City. Type loc. is at Ravenswood, Queens Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 24). *Ravenswood granodiorite* is related to Harrison diorite and considered to be of essentially same age. Intrusive into Fordham gneiss.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, p. 140). *Ravenswood granodiorite* assigned to late pre-Camb., much later than Manhattan schist.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68), classified this fm. as post-Glenarm Algonkian.

Rawhide formation.

Carboniferous: British Columbia.

O. E. Le Roy, 1912 (Canada Geol. Surv. Mem. 21, pp. 19, 27, 40).

Rawley andesite.

Tertiary (Miocene?): Southern Colorado (Bonanza district, Saguache County).

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Rawley andesite.*—Mostly thin flows, with some latites and breccias. Thickness 1,000 to 1,500 ft., possibly 2,000 in places. Underlies Bonanza latite. Oldest of Tert. volcanic rocks in Bonanza dist. Exposed on slopes of Rawley Gulch and in Rawley mine.

Rawlins sandstone.

Commercial term for sss. quarried from basal part of Mesaverde fm. (Upper Cret.) in central part of Carbon Co., Wyo., in which is town of Rawlins.

Rawson moraine.

Pleistocene: Northern Indiana.

F. Leverett, 1915 (U. S. G. S. Mon. 53, table opp. p. 30).

Ray sand.

A subsurface sand, 20 to 45 ft. thick, in Strawn fm. (Penn.) of Ranger field of central northern Tex., lying 1,200 ft. below Ranger ls. The name has also been applied to a sand at base of Frio clay (Olig.?) in Pettus area, Bee Co., SE. Tex.

Raymond limestone. (In Monongahela formation.)

Pennsylvanian: Western West Virginia (Putnam County).

I. C. White, 1882 (The Virginias, vol. 3, p. 142). *Raymond ls.* (also *Raymond City ls.*).—Occurs in white-looking roundish nodules, 1 in. to 1 ft. diam., in a matrix of red sh. Thickness 5 ft. Lies 180 to 190 ft. above Pittsburg coal. Exposed at Raymond City P. O., Putnam Co.

I. C. White, 1885 (The Virginias, vol. 6, pp. 7–16). *Raymond City ls.*, 5 ft. thick, lies 75 ft. beneath Waynesburg coal and 130 ft. above Pittsburg ss. along Kanawha River btw. Point Pleasant and Quinnimont.

Raymond City limestone.

See *Raymond ls.*

Raymond Quarry beds.

Devonian: Central eastern Iowa.

M. F. Arey, 1906 (Iowa Geol. Surv. vol. 16, pp. 420–448), divided Cedar Valley ls. of Blackhawk Co. into (descending): Lithographic and stromatoporoid beds, 20 ft.; *Raymond Quarry beds*, 26 ft.; *Acervularia* beds, 7 ft.

Raysor marl.

Miocene (upper): Southern South Carolina (Colleton County).

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). *Raysor marl* is here proposed for deposits of upper Mio. age older than Duplin marl in S. C. The name is taken from Raysor Bridge, on Edisto River, 8 mi. SW. of St. George, near which the only known outcrops of the fm. occur, and where it comprises 3¼ ft. of marl consisting of shells in a dark-blue soft matrix and underlies Wicomico fm. and overlies Cooper marl. Believed to be=lower part of Yorktown fm. of N. C. and Va. W. C. Mansfield correlates it with *Ecphora* zone of Fla. and with contemp. *Pecten clintonius* zone, the basal part of Yorktown fm. of Md. and Va.

Raytown limestone bed. (In Kansas City formation.)

Pennsylvanian: Northwestern Missouri, eastern Kansas, and southwestern Iowa.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13, 2d ser., pp. 7, 27–28, 118). *Raytown ls. bed.*—Thin but fairly persistent bed of thin-bedded gray fossiliferous ls., lying 5 to 30 ft. below top of Chanute sh. memb. Thickness 3 to 6 ft. To N. becomes shaly in middle. Is "Calico ledge" of quarrymen. Possibly="Earlton ls." of Adams. Named for Raytown, Jackson Co., Mo.

R. C. Moore (1932) showed this ls. is top memb. of true Iola ls. (See 1932 and 1935 entries under *Iola ls.* and Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 113, 115). Raytown ls. is not a bed in Chanute sh. Main body of Iola ls. is traced into it at Kansas City. Accordingly 3 members of Iola ls. are recognized (descending)—Raytown ls., Muncie Creek sh., and Paola ls. It is clear the Raytown of Hinds and Greene did not include Muncie Creek and Paola. The Raytown is 5± ft. thick near Kansas City; 6± ft. in Miami Co., Kans; and 28 ft. near Iola. Is persistent in northern Mo. and Iowa, but locally absent where underlying Muncie Creek and Paola members occur.

Razburg sandstone member (of Pottsville formation).

Pennsylvanian: Northern central Alabama (Warrior coal field).

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175, p. 9). *Razburg ss. memb.*—Gray, generally thick-bedded, rather coarse ss., 20 to 30 ft. thick. Gwin coal lies close above this ss., and Cobb coal lies 120 ft. below it, the two latter being separated by sh. Is top memb. of Pottsville fm. in Warrior coal field.

Named for Razburg, Jefferson Co., in Brookwood quad.

Razor Mountain group.

Pre-Ordovician: Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 27).

Reade formation.

See *Reed fm.*, the approved spelling.

†Reading sandstone.

Lower Cambrian: Southeastern Pennsylvania (Berks County).

E. V. d'Invilliers, 1883 (2d Pa. Geol. Surv. Rept. D_3, vol. 2, pp. 99–100), proposed *Reading ss.* for ss. known as *Potsdam ss.* in Berks Co. Well exposed S. of Reading, in cuts of Phila. & Reading R. R.

Same as Chickies qtzite, the older name and the one in current use. Has also been called *Reading qtzite.*

Reading limestone. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

A. J. Smith, 1905 (Kans. Acad. Sci. Trans., vol. 19, p. 150). *Reading blue ls.*—Fossiliferous ls., 3 ft. thick, formerly called *Emporia blue ls.* Extends across Greenwood, Lyon, and Osage Counties, and probably much farther. Underlies Olpe shales (restriction of Adams' definition of Olpe) and overlies Humphrey shales.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10). *Reading ls.*, bluish gray, 1 or 2 beds, weathers brownish; 3± ft. thick. Basal memb. of Preston ("Emporia") ls. fm. Underlies Harveyville sh. (memb. of Preston fm.) and overlies Auburn sh. fm. The Preston is overlain by Willard sh.

R. C. Moore's 1936 revised classification (Kans. Geol. Surv. Bull. 22, p. 49) showed *Reading ls.* (1) as basal memb. of old Emporia ls. (which he discarded); (2) as underlying Harveyville sh.; and (3) as overlying Auburn sh., the latter sh. resting on Wakarusa ls. On p. 219 Moore stated: Beede's original Wakarusa ls. is identified as unit here called *Reading ls.*, and Wakarusa ls. as now defined by usage, mainly by Condra, was included in upper part of Beede's "Stanton" (=Burlingame) ls. On pp. 224, 225 Moore made following statements: The name Wakarusa (Beede 1898) has priority over *Reading*, and if we are correct in concluding that Beede's term was applied to same unit later called *Reading*, then proper designation for this ls. is *Wakarusa*. Application of latter name to another unit by Condra, however, and desirability of retaining this usage as applied to many sections in recent papers, lead us to selection of Smith's term as next one available. Type loc. in vicinity of Reading, Lyon Co., Kans. Well exposed in roadcut near NW. cor. sec. 33, T. 17 S., R. 13 E., 1 mi. W. and 1 mi. N. of Reading. Thickness is 1½ to 15 ft., and fm. is continuous from southern Nebr. to northern Okla.

Reading gneiss.

Upper Cambrian: Southeastern Vermont (Windsor and Windham Counties).

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., p. 237 and table opp. p. 288). *Reading gneiss.*—Embraces a widely distributed group of rocks in Reading, Cavendish, Baltimore, and Chester Twps, whose essential mineral composition is quartz, orthoclase, or microcline, or both, and albite to albite-oligoclase and muscovite or biotite, or both. Essentially an ortho-gneiss, that is, one derived from the shearing or metamorphism of a granite. It may be in part a para-gneiss, that is, one derived from the metamorphism of highly feldspathic sediments. It seems better to writer to regard Reading gneiss in all its variations as originally a great granite batholith, essentially a biotite granite, which has become subsequently sheared into a granite gneiss, rather than to believe that the foundation of this fm. was qtzite converted into gneiss by introduction of feldspars, albite to albite-oligoclase and orthoclase, and that the orthoclase was in part subsequently converted into microcline. As mapped some sed. beds may be included. Named for fact that its outcrops occupy whole of southern part of Reading. The rock cut just N. of village of Felchville is in this gneiss. [In chart opp. p. 288, prepared by Richardson and A. J. Foyles, this gneiss is assigned to Upper Camb.]

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., pp. 192–237). Most igneous gneisses of Springfield, Vt., are closely related in mineral composition and texture to Reading gneiss, and therefore they are listed as *Reading gneiss* in this rept. Occurs in Grafton and Rockingham.

C. H. Richardson and J. E. Maynard, 1933 (18th Rept. Vt. State Geol., pp. 316–347). *Reading gneiss* was named for Reading Twp [in Woodstock and Ludlow quads.], where this gneissoid rock is particularly rich in microcline, which shows the characteristic grating structure. Such a gneiss appears in Athens and Brookline Twps, Windham Co., and it does not seem necessary to introduce a new name for it. It is light-gray, fine-grained, well banded, and shows the biotite, feldspar, and quartz arranged in definite layers. [Is listed among the acid intrusives.]

Reading syenite.

A local quarry term for part of Quincy granite in Boston region, Mass.

Readsboro schist.

Upper Cambrian (?): Southwestern Vermont (Bennington County) and southeastern Vermont (Windham County).

G. D. Hubbard, 1924 (14th Rept. Vt. State Geol., pp. 282–288, 291, 294, and map). *Readsboro schist.*—Essentially quartz-biotite schist, with considerable variation in texture, general appearance, and mineral composition. Quartz usually makes up at least half of the rock, in places as much as 80 to 85 percent. Biotite may run as high as half, but usually constitutes 25 to 40 percent. Hornblende and, in some beds, calcite make up most of the rest of fm. Much of rock is so feldspathic as to be gniess, and it becomes more so northward. Is believed to be of sed. origin. Thickness 4,000 and may possibly reach 6,000 ft. Underlies Halifax schist, with which it is interbedded at contact, and overlies Hartwellville schist, from which it is rather sharply separated. Correlated with Hoosac schist, Rowe schist, and Chester amphibolite of Emerson's map of Mass.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this fm. to Upper Camb., but without discussion.

Named for extensive outcrops in Readsboro Twp and around Readsboro, Wilmington quad.

Reagan sandstone.

Upper Cambrian: Central southern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Reagan ss.* [incorrectly spelled Regan on map legends].—In Atoka quad. is represented by a single outcrop. [See 1903 definition in type region.]

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Reagan ss.*—Lower part (in contact with the granite) where fm. is thickest is poorly sorted coarse granitic material composed chiefly of grains of quartz with some feldspar. This basal arkose memb. is variable in occurrence as well as in thickness and in places is absent altogether, allowing the purer ss. beds higher in section to rest in contact with the granite. The middle part is composed chiefly of quartz grains, varying in size from that of a pea to fine particles. The upper part is calc. and shaly ss., successive beds of which become more limy upward until the purer ls. of Arbuckle fm. is reached. Thickness a few ft. to 500± ft. Named for village [10 mi. N. of Tishomingo], which is situated near the small area of the fm. on N. side of the granite.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 624, 642, 661, 666, pl. 27), introduced *Honey Creek ls. memb. of Reagan ss.* for lss. which he stated were originally included in Arbuckle ls. but are now transferred to Reagan ss.

H. D. Miser, 1926 (Okla. geol. map), followed Taff's original definitions of Arbuckle ls. and Reagan ss., and included the ls. memb. in Arbuckle ls. This is definition of Reagan ss. that is followed by U. S. Geol. Survey.

E. O. Ulrich, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, p. 742). *Reagan ss.* as defined by Taff (Atoka and Tishomingo folios) included a considerable thickness of calc. beds which were separated from Arbuckle ls. because they were thought to contain a Middle Camb. fauna. This fauna was subsequently recognized as Upper Camb., and in the Revision (Geol. Soc. Am. Bull. vol. 22, 1911) I proposed *Honey Creek ls. memb.* for these strata, still considering them a part of the Reagan. Later work in Llano-Burnet area in [central] Tex. has resulted in a threefold division of the Camb. into the Hickory, Cap Mountain, and Wilberns fms. The first corresponds essentially to the Reagan of Okla. and the main portion of the last to Honey Creek memb., leaving Cap Mtn fm. unrepresented in Okla. section except at a single locality on S. side of Arbuckle Mtns in Pickens ranch sec., 10 mi. NW. of Tishomingo. Because of known absence of strata corresponding to the Cap Mtn in most sections examined in Arbuckle and Wichita Mtns, Okla., it seems *advisable to raise Honey Creek memb. to rank of a fm.* which is essentially=Wilberns of [central] Tex., the Davis of Mo., and the Franconia of Wis.

The U. S. Geol. Survey now treats Honey Creek ls. as a distinct fm. This involves a slight redefinition of Arbuckle ls., in which the Honey Creek has heretofore been included.

Recapture shale member (of Morrison formation).

Upper Jurassic: Southeastern Utah (San Juan County).

H. E. Gregory (U. S. G. S. P. P. 188, in press). *Recapture sh. memb. of Morrison fm.*—Dark-red and variegated calc. and gypsiferous shales and thin white siliceous sss., 100 to 300 ft. thick. Overlain with local uncon., by Westwater Canyon ss. memb. and underlain by Bluff ss. memb. Well exposed near mouth of Recapture Creek, San Juan Co.

Recent epoch (or series).

The post-Pleist. part of Quat. period and the rocks formed therein. For definition see U. S. G. S. Bull. 769, pp. 46–47.

†Receptaculites limestone.

A paleontologic term applied in early Mo. repts to Kimmswick ls. of present nomenclature.

†Red Beds.

A term used in a titular sense in early repts for the Perm. and Triassic redbeds of Western States.

red clastic series.

A descriptive term that has long been applied to red sss. and shales underlying Mount Simon ss. (Upper Camb.) in SW. Wis. and SE. Minn.; also to similar rocks that outcrop at Hinckley and along Kettle River in Pine and Carlton Counties, central eastern Minn., which underlie the Hinckley ss., of pre-Camb. (Keweenawan) age. At present the U. S. Geol. Survey classifies these rocks as Camb. and pre-Camb. (See under *Hinckley ss.*)

Redbank sand. (In Monmouth group.)

Upper Cretaceous: New Jersey.

W. B. Clark, 1894 (N. J. Geol. Surv. Ann. Rept. 1893, p. 337, and Jour. Geol., vol. 2, pp. 165–166). *Redbank fm.*—Bright-red sands, glauconitic throughout, but great preponderance of coarse aren. sediments has facilitated oxidation of greensand, changing green color to red or brown. Lower part often black sand or sandy clay. At top an indurated clayey layer, generally of greenish color. Thickness 100 ft. Is Red Sand of previous repts. Underlies Rancocas fm. [group] and overlies Navesink fm. Well developed in vicinity of Red Bank, Monmouth Co.

S. Weller, 1905 (N. J. Geol. Surv. Ann. Rept. 1904, pp. 147, 154–159), separated 22 ft. of beds at top, under name *Tinton beds,* and restricted *Redbank sand* to the underlying beds.

The U. S. Geol. Survey has since 1909 (U. S. G. S. Trenton folio, No. 167) treated Redbank sand as top fm. of Monmouth group, and Tinton sand as top memb. of Redbank sand, but most repts of N. J. Geol. Survey still treat the Tinton as a distinct fm.

Red Bluff clay. (In Vicksburg group.)

Oligocene (lower): Southern Mississippi and southwestern Alabama.

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., p. 135). *Red Bluff group.*—Irregular masses of fine-grained ferruginous rock, embedded in a brownish or greenish clayey mass, both with well-preserved fossils. Thickness 12 ft. Seems to stand intermediate, by position as well as fossils, btw. Vicksburg group and Jackson group, but fauna seems on whole to approach more nearly the Vicksburg than the Jackson.

E. W. Hilgard, 1867 (Am. Jour. Sci., 2d, vol. 43, pp. 32, 37). *Red Bluff group*.—Concomitant green clays and stiff clay marls, 0 to 100 ft. thick. Treated as basal div. of Vicksburg group, because it seems to be more or less coextensive with Vicksburg group and regularly associated with it as a subordinate feature. At Red Bluff it rests on Jackson group.

E. W. Hilgard, 1871 (Am. Jour. Sci., 3d, vol. 2, geol. map of Miss. opp. p. 390), treated *Red Bluff* (12 ft. thick) as a distinct unit underlying Vicksburg and overlying Jackson. But A. Heilprin, 1884 (Jour. Acad. Nat. Sci. Phila., 2d ser., vol. 9, pt. 1, pp. 120, 144–150), included it in Vicksburg, as did W. B. Clark, 1891 (U. S. G. S. Bull. 83, pp. 66–67). W. H. Dall and G. D. Harris, however, excluded it from both Vicksburg and Jackson in U. S. G. S. Bull. 84, pp. 160–167, 1892, as did Harris in Am. Jour. Sci., 3d, vol. 47, pp. 303–304, 1894. In 1897 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 334, 337, 339, 341) Dall included it in his *Vicksburgian stage* but treated it as distinct from his *Vicksburg*. T. W. Vaughan, 1900 (U. S. G. S. Mon. 39, pp. 15–32), and C. J. Maury, 1902 (Bull. Am. Pal., vol. 3, No. 15, pp. 71–76, 81), followed Dall's 1897 treatment, Miss Maury stating that Red Bluff beds are now considered to be hardly separable faunally from the Vicksburg, of which they represent a lower phase. T. L. Casey, however (Phila. Acad. Nat. Sci. Proc., vol. 53, pp. 513–518, 1902), included the Red Bluff in the Jackson, stating: Because of existence of most of these Eocene forms [discussed] in *Red Bluff bed* I am inclined to consider that horizon more closely related to the Jackson than to the Vicksburg, in spite of greater proportion of its species which have been identified with the Vicksburgian.

C. W. Cooke, 1915 (U. S. G. S. P. P. 95), treated *Red Bluff clay memb.* (25 to 40± ft. thick) as basal memb. of Vicksburg ls. in Miss., as did E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12), who stated that its fossils are more closely related to Vicksburg than to Jackson, and who gave its thickness as 60 ft. But Lowe included his †Madison sands (50 to 75 ft. thick) in Jackson, although stating that they might belong to either Jackson or Vicksburg. The relations of the latter beds to Red Bluff clay had not at that time been established. But C. W. Cooke (Wash. Acad. Sci. Jour., vol. 8, No. 7, pp. 186–198, 1918) stated that the exceedingly shallow-water deposits of Forest Hill sand (which name he introduced to replace Madison sand, preoccupied) are "believed to be largely contemp. with Red Bluff clay," and he included both in Vicksburg group. He described *Red Bluff clay* as consisting chiefly of stiff blue or greenish gypseous marine clay, but containing discontinuous ledges of indurated marl or ss. and a thin bed of shell marl, as being 70 ft. thick on Buccatunna Creek, as resting conformably on the Jackson, and as overlain by Marianna ls. E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14), referred to Cooke's "recent" assignment of Forest Hill sand to Vicksburg group, and stated that "under present interpretation it is to be placed in Vicksburg group as a distinct facies of Red Bluff fm." The U. S. Geol. Survey treats the Forest Hill sand and Red Bluff clay as distinct contemp. fms., one nonmarine and the other marine.

The present generally approved definition of Vicksburg group includes at base the contemp. or approx. contemp. fms. Red Bluff clay (to east) and Forest Hill sand (to west).

Red Bluff formation.

Pleistocene: Northern California (Redding region).

J. S. Diller, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pp. 413–416 and map, pl. 44). *Red Bluff fm.*—Gravels, clay, and sand of Pleist. age, overlying Tuscan tuff.

J. S. Diller, 1906 (U. S. G. S. Redding folio, No. 138). *Red Bluff fm.*—Chiefly gravel and sands, with small proportion of clay and a few large boulders. Uncon. overlies Tuscan tuff. Thickness more than 200 ft.

Named for exposures at Red Bluff, Tehama Co.

See under *Klamath gravels*, N. E. A. Hinds 1933 entry.

†Red Bluff sandstone. (In Cimarron group.)

Permian: Central southern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 40). *Red Bluff sss.*—Light-red friable and porous sss. and shales, 175 to 200 ft. thick, composing next to lowest fm. and major part of Kiger div. Overlies Dog Creek shales and underlies Day Creek dol. [Later repts give max. thickness 500+ ft.]

Preoccupied. Replaced by Whitehorse ss.

Named for exposures at former post office of Red Bluff, Comanche Co., Kans.

Red Bluff epoch.

Pleistocene: California.

O. H. Hershey, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pp. 1–29). *Red Bluff epoch (deposition).*—Divided into *Red Bluff proper* above, and below a sheet of alluvium of same material as Red Bluff proper. Believed that Arnold's Lower San Pedro series corresponds in part at least with Red Bluff fm. It seems proper to extend the term *Red Bluff* to the marine Pleist. in Los Angeles and to the alluvial material of the 400-foot terrace of Soledad Cañon. [See under *Sierran*.]

Red Bridge limestone member (of Liston Creek formation).

Silurian (Niagaran): Northeastern Indiana (Wabash County).

E. R. Cumings and R. R. Shrock, 1927 (Ind. Acad. Sci. Proc., vol. 36, pp. 74–75). *Red Bridge ls.*—Reddish-yellow impure argill. ls., 6 in. to 6 ft. thick. Overlies Mississinewa sh. and underlies Liston Creek ls. Outcrops along Mississinewa River at village of Red Bridge, Wabash Co., and elsewhere. No fossils found. Included in Niagaran.

E. R. Cumings and R. R. Shrock, 1928 (Ind. Cons. Comm., Div. Geol. Pub. 75, pp. 71–94). *Red Bridge ls. memb. of Liston Creek fm.*—[See explanation under *Liston Creek fm.*] No fossils yet identified. It is very doubtful if any of geologists who have worked in northern Ind. ever recognized this bed, for no mention is made of it. It has been seen in Wabash Co. only and probably was not deposited elsewhere. Thickness 0 to 12 ft.

Red Canyon member.

Triassic (?): Southeastern Colorado (Las Animas, Otero, and Bent Counties).

J. T. Duce, 1924 (Colo. Geol. Surv. Bull. 27, pt. 3, pp. 81–82). A massive cross-bedded oolitic maroon ss., upper part much cross-bedded and in some parts leached of its coloring matter. Possibly of eolian origin. Thickness 240 ft. Is upper memb. of Lykins fm. in counties mentioned. Overlies Chaquaqua memb. of Lykins fm. and uncon. underlies gypsiferous beds regarded as lower memb. of Morrison fm.

Probably named for exposures in E. end of Red Rock Canyon, Las Animas Co.

Red Cave.

A term applied by drillers of western Pa. to subsurface strata correlated with sh. beds in Conemaugh fm. that are known as "Pittsburgh Reds." Also applied to a subsurface sand in Double Mtn fm. (Perm.) of Tex.

Red Creek quartzite.

Pre-Cambrian: Northeastern Utah (Uinta Mountains).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 42, 62, 70, 137). *Red Creek qtzite.*—A qtzite (very crystalline and white) with intercalated beds of hornblendic, chloritic, and micaceous schists, all greatly implicated. Thickness 10,000 ft. Uncon. underlies the red Uinta ss. Well exposed in Red Creek Canyon and at head of Willow Creek. Believed to be Eozoic. Red Creek Canyon separates Quartz Mtn and Mount Wheeler [NE. corner of Uinta Co., Utah].

A. R. Schultz, 1920 (U. S. G. S. Bull. 702), remapped the white *Red Creek qtzite*, assigned it to the pre-Camb., stated that the intercalated schists are intrusives, and that H. S. Gale (U. S. G. S. Bull. 415, 1910) included these qtzites in his Uinta qtzite.

Redd sand.

A subsurface sand in the Penn. (probably in either Dudley or Ladore sh.) of SE. Kans. (Chautauqua and Montgomery Counties).

Red Eagle limestone member (of Elmdale formation).

Pennsylvanian: Central northern Oklahoma and southern Kansas.

K. C. Heald, 1916 (U. S. G. S. Bull. 641, p. 24). *Red Eagle ls.*—A number of distinct beds of ls., btw. which are beds of sh. in some localities. One of most distinctive features of top bed of the ls. in much of Foraker quad. is character of the fresh surface, which shows an abundance of tiny grains of crystalline calcite, giving the surface the appearance of having been covered with frost or light snow. Thickness of Red Eagle ls. is at least 17 ft. in some places; in other places probably much less. Lies 18 ft. above Foraker ls. and 71 ft. below Neva ls. Named for excellent exposures near Red Eagle School, SW. of Foraker.

H. D. Miser, 1926 (geol. map of Okla.). Cushing ls. memb. is same as Red Eagle ls. memb. [which has priority].

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 8), extended this name into NW. Mo. and SE. Nebr.; called it *Red Eagle ls. fm.*, which he defined as underlying his Roca sh. fm. and overlying his Johnson sh. fm.; and divided it into (descending) Howe ls., Bennett sh., and Glenrock ls. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

N. W. Bass, 1935 (personal communication). *Red Eagle ls.* persists into Kans. at least as far N. as Cottonwood River valley.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

†Red Eagle shale. (In Elmdale formation.)

Pennsylvanian: Central northern Oklahoma.

G. C. Clark and C. L. Cooper, 1927 (Okla. Geol. Surv. Bull. 40H), applied *Red Eagle* to 19 ft. of red and gray shales described as lying 65 ft. below Neva ls. and 12 ft. above Cushing [Red Eagle] ls. in T. 22 N., Rs. 2 W.–5 E., and as resting on 3 ft. of ls. The name is preoccupied by the ls. in the Elmdale.

Red Fork sand.

A subsurface sand, 0 to 60± ft. thick, in Cherokee sh. (early Penn.) of S. and SE. parts of Osage Co., NE. Okla. Said to lie higher than Glenn sand, lower than Skinner sand, and to be the upper sand of the series to which the name *Bartlesville sand* was formerly applied. In type loc. (Red Fork pool, Tulsa Co.) this sand lies at 1,275 ft. depth, at approx. horizon of Burbank sand.

Red Gap member (of Grinnell argillite).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Red Gap memb.*—Lower memb. of Grinnell fm. Consists of 1,050 to 1,800 ft. of metargillite, in thin minor but thick major beds, interbedded near bottom and top with minor layers of qtzitic ss. and red sandy argillite. Forms mass of Mount Rockwell, in Two Medicine Valley, Glacier Nat. Park. Underlies Rising Bull memb. of Grinnell fm. and overlies Rising Wolf memb. of Appekunny fm. [Derivation of name not stated.]

Redgut Bay granite.

Age (?): Ontario (Rainy Lake district).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 99).

Red Head formation.

Carboniferous: New Brunswick.

G. A. Young, 1913 (12th Int. Geol. Cong. Guidebook 1, pp. 369, 374).

Redhill sandstone.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 61, 80). *Redhill sss.* is local name used in Furnace Canyon borate camps for a thick aren. bed immediately and uncon. overlying Greenwater volcanics. Consists of fine-grained cgl. and ss. Thickness 300 ft. Underlies Millett clays. Is bottom fm. of Furnacean series in Nev. [Death Valley region]. Tentatively considered to be of Mio. age. [Derivation of name not stated, but may have been named for the red ss. mtn. N. of Ryan and E. of Furnace Creek Wash, Inyo Co., Calif.]

Redlands limestone.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group.* Derivation of name not stated.]
F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). *Redlands dolomitic ls.*—White crystalline cherty, dolomitic ls. in which bedding is not readily recognized. Probably a lenticular body. Thickness 600± ft. Conformably underlies Hanaupah fm. and conformably overlies Radcliff fm.; all included in Telescope group (lower Paleozoic?) of S. part of Panamint Range. [Derivation of name not stated and not apparent from his maps.]

Red Lion formation.

Upper Cambrian: Central western Montana (Philipsburg region).

F. C. Calkins and W. H. Emmons, 1913 (U. S. G. S. P. P. 78). *Red Lion fm.*—Upper 250 ft. consists of ls. with closely spaced siliceous laminae. Fossils are said by Walcott to be Upper Camb. Probably=Yogo ls. Lower 25 ft. is calc. sh., mostly coal black, locally interbedded with thin layers of mag. ls. The lower memb. probably=Dry Creek sh. [which is now considered Upper Camb.]. Named for a mine at head of North Fork of Flint Creek. The spur N. of this mine is a hogback of the fm. and affords good exposure of middle part.

†Red Medina.

Name applied in some early repts to Queenston sh. of N. Y. and to Juniata fm. of Pa. and Md.

Redmond formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Redmond fm.*—White ss. Overlain by unnamed ss. and sh. and underlain by unnamed grits and shales. Included in Bell Island series. [Derivation of name not stated.]

†Red Mountain group.

Devonian, Silurian, Ordovician, and Cambrian: Northern Alabama.

M. Tuomey, 1850 (Ala. Geol. Surv. 1st Bien. Rept., pp. 9, 10). The group of rocks under consideration is made up of common blue ls., white, gray, and variegated marble, mag. ls. (both the crystalline and earthy variety), cherty ls., hornstone, ss., cgl., iron ore, black aluminous sh., and clay sl. It would be premature to attempt a subdivision of the Sil. rocks of Ala. by referring them to those groups adopted in N. Y., where they are developed on a scale so magnificent. I shall therefore content myself by applying to our rocks the term *"Red Mtn group,"* already known in the State, which will distinguish them from the Carbf. system, with which they are intimately associated. Although these rocks occupy anticlinal valleys, they also rise into a range of hills which are generally known as "Red Mtns."

In above-cited rept the rocks of Ala. are divided into following systems: Tertiary system, Cretaceous system, Carboniferous system, Silurian system, Metamorphic system, and Primary system. As defined in this rept the "Red Mtn group" includes rocks of Dev., Sil., Ord., and Camb. ages, all of which are exposed on Red Mtn.

Named for Red Mtn, E. of Birmingham.

Red Mountain formation.

Silurian (Clinton and Medina): Northern Alabama and northwestern Georgia.

E. A. Smith, 1876 (Ala. Geol. Surv. Rept. Prog. for 1876, pp. 11, 23, 25, 34, 42, 207-208). Of these three groups [Medina, Clinton, Niagara] of Niagara period, so far as is known, only the second, *the Clinton*, has been certainly identified in Ala. In Tenn. the group has received name of *Dyestone group* from Prof. Safford, on account of occurrence in it of the red ore, or dyestone. In Ala. no more fitting name could be given to it than *Red Mtn group*, for outcrops of the rocks are found in ridges, or mtns, as they are called, extending almost without interruption from Bibb Co. to Ga. and beyond. From the red ore, which seems always to be present in them, in greater or less thickness, these ridges have local name of Red Mtn. The name Clinton, however, has already been applied to this group of rocks, and a multiplication of names for the same thing is to be avoided if possible. The rocks of the Clinton group in Ala. are chiefly thin sss. and shales, variously colored, green, yellowish, brown and red colors being predominant. The group contains also several beds of lenticular or fossiliferous red iron ore. For characteristic sections of strata of Clinton group the reader may be referred to section near Tannehill and that at mines of Eureka Co. The mtn near Columbiana has along its base a cgl. which probably underlies the Red Mtn rocks proper and belongs to Medina group. [According to C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14) the Red Mtn fm. is absent in Montevallo and Columbiana quads., and the cgl. referred to is of Dev. age.]

The rocks in northern Ala. that for many years were called "Clinton fm." have been shown, by E. O. Ulrich and C. Butts, to contain beds of both late Medina (Albion) and Clinton ages, and to them Smith's name *Red Mtn fm.* is now applied. In some places beds of Richmond age and of Dev. age have been mapped with the Red Mountain, but they are not properly a part of the fm. (See Ala. Geol. Surv. Spec. Rept. No. 14, 1926, and U. S. G. S. Bessemer-Vandiver folio, No. 221, 1927.) Big seam of iron ore is base of beds of Clinton age, according to C. Butts (U. S. G. S. Bessemer-Vandiver folio, No. 221, 1927, p. 7).

Named for development on Red Mtn (presumably East Red Mtn), E. of Birmingham, Ala.

Red Mountain formation.

Carboniferous or Triassic: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 45, 61). [Assigned to Carbf.]

H. S. Bostock, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. A, pp. 203, 207, 210), assigned this fm. to Triassic.

Red Mountain rhyolite.

Tertiary: Central Colorado (Bonanza-Monarch-Tomichi-Pitkin region).

J. V. Howell, 1919 (Colo. Geol. Surv. Bull. 17). *Red Mtn rhyolite.*—Light-gray to white siliceous rhyolite containing finely disseminated pyrite, which on weathering produces red iron oxide, the material which is responsible for the brilliant coloring of Red Mtn, Chaffee Co. Has two rather distinct phases—the normal or massive phase and a brecciated form. Is certainly older than Grizzly Peak rhyolite, which is believed to be of Tert. (Eocene?) age, and appears to be younger than late Cret. porphyry dikes, so it is certainly post-Cret.

This name has been discarded by J. T. Stark and F. F. Barnes, as explained under *Grizzly Mtn rhyolite.*

Red Mountain andesite.

Miocene (upper): Southern California (Randsburg quadrangle, Kern and San Bernardino Counties).

C. D. Hulin, 1925 (Calif. State Min. Bur. Bull. 95, pp. 55–58, map). *Red Mountain andesite.*—Chiefly lava flows, but with prominent amounts of aggls. and tuffs. General composition of series is that of basic andesite. Overlies Rosamond series, usually with angular uncon., and uncon. underlies Black Mountain basalt. Forms thick capping of Rosamond series in Red Mtn [San Bernardino Co.], where it reaches approx. thickness of 1,400 ft. of flows and pyroclastics. Believed to be early Plio. [On map is assigned to upper Mio.]

Red Mountain pyroxene basalts.

Age (?): Northern California (Lassen Volcanic National Park).

H. Williams, 1932 (Calif. Univ. Dept. Geol. Sci. Bull., vol. 21, No. 8, geol. map).

Redoak granite.

Pre-Cambrian: Central southern Virginia (Charlotte and Mecklenburg Counties).

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, pp. 35–36, map). *Redoak granite.*—Medium-grained light-gray biotite granite, rather quartzose, containing about equal amounts of orthoclase and plagioclase feldspars. Small masses or areas of coarse porphyritic granite which occur in Redoak granite in vicinity of Buffalo Lithia Springs are named *Buffalo granite.* [Named for occurrence at Redoak, Charlotte Co., Va.]

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Red Oak granite.*—Biotite-quartz monzonite with Buffalo granite porphyritic facies. Is of pre-Camb. age and intrusive into Glenarm series (Algonkian?).

Redoute limestone.

Cambrian: Quebec.

J. Marcou, 1862 (Boston Soc. Nat. Hist. Proc., vol. 8, pp. 248–253). St. Albans group divided into (descending): (1) Green, brown slates with large lenticular masses of whitish-gray ls. (*Redoute ls.*), which is very fossiliferous and 80 to 100 ft. thick; and (2) Sillery and Chaudiere red slates and sss. The Redoute ls. forms the lenticular mass of La Redoute, so called by older Canadians because there was a redoubt there during last French war.

†Red River group.

Upper Cretaceous (Gulf series): Northeastern Texas.

B. F. Shumard, 1860 (St. Louis Acad. Sci. Trans., vol. 1, pp. 583, 589). *Red River group.*—Fossiliferous blue marly clay, occasionally variegated with red and brown, and with thin bands of ss. interstratified. Clay contains crystals of selenite and, in upper part, flattened nodules of compact brown and blue ls.; also, near base, septariae of compact blue ls. reticulated with brown, yellow, and purple spar. Thickness 50 to 150 ft. Underlies Fish Bed.

Includes Eagle Ford clay and Woodbine sand.

J. A. Taff, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 269–279), applied "Red River div." to beds beneath Eagle Ford sh. and uncon. above †Vola ls.

Named for exposures along Red River, NE. Tex.

Red River loess.

Pleistocene: Southwestern Arkansas, Louisiana, northeastern Texas, and southeastern Oklahoma.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 29–32, 188). *Red River loess.*—Intensely red loam, in color approximating present red sediments of the river. Is 50 ft. above present high-water mark, and extends inland, often several mi. from present stream. Continues far into La. and W. of Denison, Tex. In general appearance is difficult to distinguish from residual debris of Camden series and from the other aren. post-Cret. and Cret. fms. of the South, and writer will not attempt at present to differentiate it from them. Assigned to *Quaternary (pre-Recent).*

C. H. Dane, 1929 (Ark. Geol. Surv. Bull. 1, pl. 1), mapped the deposits in Red River Valley at Fulton as Recent and Pleistocene, the Pleistocene probably being Red River loess of Hill.

Named for exposures in Red River Valley at Fulton, Hempstead Co., Ark.

Red River formation.

Ordovician: Manitoba.

A. F. Foerste, 1929 (Denison Univ. Bull., vol. 29, No. 2, Sci. Lab. Jour., vol. 24, pp. 35, 37).

Red Rock channel sandstone.

Pennsylvanian: Central southern Iowa (Jasper and Marion Counties).

C. R. Keyes, 1891 (Am. Jour. Sci., 3d, vol. 41, pp. 273–276). *Red Rock ss.*—Bright vermilion, yellow, and buff ss., 0–150 ft. thick, chiefly massive but thin-bedded above, passing into fine-grained ferruginous cgl. Overlain uncon. by coal-bearing shales and underlain uncon. by St. Louis ls.

Represents sand deposited in old erosion channel in Des Moines group. May be of either Des Moines or Missouri age.

Named for Red Rock, Marion Co.

Red Rock member.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

See under *Temperance River memb.*

Redrock Canyon sandstone member (of Santa Margarita formation).

Miocene (upper): Southern California (Cuyama Valley, southwestern part of Kern County).

W. A. English, 1916 (U. S. G. S. Bull. 621, pp. 191–215). *Redrock Canyon ss. memb.*—Basal memb. of Santa Margarita fm. in small area in Redrock Canyon (Cuyama Valley), to which it is limited. Thickness 500 ft. Consists of bright-red ss., clay, and cgl., the materials of which were derived from an adjacent land mass of pre-Monterey rocks. Rests uncon. on pre-Monterey rocks, the Monterey group being absent, probably through erosion. Is conformably overlain by Whiterock Bluff sh. memb. of the Santa Margarita.

†Red Rock Canyon beds.

Pliocene (lower): Southern California (eastern part of Kern County).

J. C. Merriam, 1919 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, No. 5). There may be some justification for name *Red Rock Canyon beds, fm., or group*, for strat. sequence containing Ricardo fauna, but G. K. Gilbert (Geog. and Geol. Expl. W. 100th Mer., pp. 142–143, 1875) and H. W. Fairbanks (Am. Geol., vol. 17, pp. 68–69, 1896) did not use the name for nomenclature purposes. Following the discovery that the fauna from the beds in Red Rock Canyon [at Ricardo, E. part of Kern Co.] is sharply distinct from that in Barstow section, writer has described numerous mammalian forms from Red Rock Canyon section as representing the *Ricardo fauna, Ricardo beds*, or *Ricardo Pliocene*, and he therefore prefers the name *Ricardo fm.* or *Ricardo group* for the deposits containing them.

Red Spring sandstone member (of Hignite formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 43). *Red Spring ss. memb.*—Cliff-making ss., underlying Red Spring coal, topmost bed of Hignite fm.

Named for association with Red Spring coal in Cumberland Gap coal field.

Redstone limestone member (of Monongahela formation).

Pennsylvanian: Western Pennsylvania and Maryland and northern West Virginia.

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_3, pp. 55–104, 286). *Redstone ls.*, 8 to 10 ft. thick, is basal memb. of Pittsburg ls. group, and lies 30 ft. above Pittsburg coal and below Redstone coal.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 62–63). *Redstone ls.*, 0 to 20 ft. thick, was so named because it occurs immediately below Redstone coal, which outcrops along Redstone Creek, Fayette Co., Pa.

†Redstone quartzite.

Name loosely applied by F. W. Sardeson (Geol. Soc. Am. Bull., vol. 19, pp. 221–242, 1908) to the qtzite composing Redstone Hill, in Courtland Twp, midway btw. towns of New Ulm and Courtland, central southern Minn. Although he used Redstone qtzite frequently throughout his rept, he stated that he intended the local geologic name to be *Courtland qtzite*, and that the qtzite is same as Sioux qtzite.

Redstone sandstone. (In Monongahela formation.)

Pennsylvanian: Western Maryland (Georges Creek Basin).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 567–596), and C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, p. 74, pl. 7). *Redstone ss.*—Underlies upper bench of Redstone coal and overlies lower bench of Redstone coal. In places is absent; in other places 40 ft. thick.

Probably named for its relation to Redstone coal.

Redstone granite.

Pennsylvanian (?): Southeastern Connecticut (Stonington region) and adjacent areas in Rhode Island.

L. H. Martin, 1925 (Conn. State Geol. and Nat. Hist. Surv. Bull. 33). *Redstone granite.*—The last distinct phase of Sterling granite gneiss. Resembles the granite gneiss in composition but is generally without banding. Cuts Sterling granite gneiss and also Stonington gneiss. Is a coarse-grained rock of medium-red to greenish-red color and much more massive than the other varieties of Sterling granite. At Redstone Ridge it broadens from a few ft. in thickness on W. to a mass ½ mi. wide near Westerly. It is the Westerly Red granite. Is at least post-middle Pennsylvanian.

Redstone clay. (In Monongahela formation.)

Name applied to clay underlying Redstone coal in western Pa. and eastern Ohio.

Redstone member. (In Monongahela formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include (descending) Fishpot ls., Redstone coal, and Redstone ls.

Redstone Ridge group.

Silurian: Central Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, p. 823). *Redstone ridge group.*—Hard strata, each 1 or 2 ft. thick and almost sandy enough to be called red sss. In some places the single group of 25 ft. is separated into two groups by 5 or 6 ft. of green limy sh. Traversed by irregularly segregated seams of quartz. These hard beds make Redstone ridge. Included in middle of lower Salina (Bloomsburg) red shales.

Redtop formation.

Carboniferous: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 43, 49). *Redtop fm.*, Carbf., B. C., included in Cache Creek group.

S. J. Schofield, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 38).

Red Top limestone.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 80; map). *Red Top ls.*—Varies in character, but is typically argill. bluish-gray ls. with good bedding planes. In places appears schistose and becomes a quartz-mica schist. On Red

Top Mtn it is white fine-grained banded marble interbedded with bluish-gray argill. ls. Thickness 1,000± ft. Relations to other named units not determined. Is separated from Fish Creek argillite by a fault.

Redtops formation.

Triassic: British Columbia.

H. S. Bostock, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. A, p. 203).

Red Valley sand.

Drillers' name for a sand composing lower memb. of Hundred-foot sand in Foxburg region, western Pa. Probably lies in upper part of Catskill fm.

Redwall limestone.

Mississippian (lower): Northern Arizona.

G. K. Gilbert, 1875 (U. S. G. and G. S. W. 100th M., vol. 3, pp. 162, 177–186, 197, figs. 81, 82). *Redwall ls. group.*—In descending order: (1) Alternating sss. and compact lss., 200 to 500 ft.; (2) *Redwall ls.* (sheer escarpment), 800 ft.; (3) lss. in lesser escarpments and calc. shales, 800 to 1,365 ft. Underlies Aubrey group and overlies Tonto group [Camb.]. May include some Dev. Named for red appearance of its escarpment on either side of Grand Canyon.

C. D. Walcott, 1889 (Geol. Soc. Am. Bull., vol. 1, p. 50), reported beneath Redwall ls. in Grand Canyon 94 ft. of Dev. ls., which he named *Temple Butte ls.*

N. H. Darton, 1910 (U. S. G. S. Bull. 435, pp. 21+). The name Redwall was given by Gilbert on account of red color of the cliffs, but the rock itself is light gray. A type loc. recently selected is Redwall Canyon, in Shinumo drainage basin, on N. side of Grand Canyon, where it consists mostly of the usual heavily bedded massive ls. and is 800± ft. thick. At other places in Grand Canyon region thickness varies from 550 to 992± ft. Gilbert gave thickness of 2,165 ft. at mouth of Grand Canyon, but this includes at top 510 ft. of alternating ls. and ss. which I believe belong to Supai fm. Fossils of Redwall ls. are Penn. and Miss., according to G. H. Girty.

L. F. Noble, 1923 (U. S. G. S. P. P. 131, pp. 26+, 54+). *Redwall ls. restricted* to Miss. part of original Redwall ls., which consists almost wholly of bluish-gray crystalline ls. whose distinctive features are massive appearance, hardness, and relatively great thickness. Thickness in Grand Canyon 500 to 700 ft. There is probably an uncon. at top of Redwall ls. as here restricted. The upper 250± ft. of red sandy sh., purplish and gray ls. with red chert, and reddish to buff calc. ss. of Penn. age, which have heretofore been included in Redwall ls., are here transferred to overlying Supai fm. [This is present adopted definition of Redwall ls.]

Redwall breccia.

Cambrian: British Columbia.

F. P. Shepard, 1926 (Jour. Geol., vol. 34, p. 626).

Red Warrior limestone.

Devonian (?) and Silurian (?): Southwestern Utah (southeast of Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Red Warrior ls.*—Heavy-bedded blue and gray ls., in part dolomitic; lenses of qtzite near base. Thickness 1,500 ft. Underlies (conformably) Mowitza sh. and overlies (apparently conformably) a qtzite that is tentatively correlated with Morehouse qtzite of Frisco region. Type loc., Red Warrior mine, SE. of Frisco dist. No fossils. Tentatively assigned to Dev. (?) and Sil. (?).

Red Wing stone.

Commercial term for stone quarried from Oneota dol. at Red Wing, Minn. (See O. Bowles, U. S. G. S. Bull. 663, 1918.)

Redwood formation.

Oligocene: Southeastern Alaska (Katalla district, Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 770–782). Writer has divided Katalla fm. of Martin into 2 conformable fms., largely on basis of lithology. There is no strat. break btw. the 2 fms., but a decided change in lithology. The lower, 3,600+ ft. thick, is here called *Katalla fm.;* the upper, 5,100± ft. thick, is here named *Redwood fm.* The Katalla occupies fully 85 percent of Katalla dist.; the Redwood is restricted to a broad, steeply plunging syncline btw. Redwood and Burls Creeks and to ridge btw. Cave and Hey Points. Fossils rare and as a rule poorly preserved, but the sediments (marine) are lithologically similar to the fossiliferous beds of Yakataga dist., which are pronounced by B. L. Clark to be upper Olig., and they are here designated upper Olig. The Redwood fm. is divided into 2 members: The upper (here named *Puffy sh.*) consists of 4,000+ ft. of sh. with many thin ss. layers and many sh.-matrix cgls., in part of glacial origin; the lower (here named *Point Hey ss.*) consists of 1,100 ft. of ss. and cgl. with thin sh. beds, and with heavy cgls. at top. The Redwood fm. overlies Katalla shales in Nichawak dist.

See also *Stillwater fm.*

The U. S. Geol. Survey classifies typical Katalla fm. as Mio. (?).

Ree beds.

E. D. Cope, 1892 (Am. Ass. Adv. Sci. Proc., vol. 40, p. 285), in a description of the Ree Hills, S. Dak., described a chalky matrix, of Olig. or Eo. age, underlying the glacial drift and containing many fossil fishes, "probably fresh water," but not enough fossils to determine age. "Should the calc. stratum in which these fossils are found not turn out to be an outlier of the White River beds I propose that they be called the *Ree beds.*" There is a Ree Heights in Hand Co., S. Dak.

Reed formation.

Mississippian (upper): Central northern Utah (central Wasatch Mountains).

F. F. Hintze, Jr., 1913 (N. Y. Acad. Sci. Annals, vol. 23, p. 109). *Reade fm.*—In descending order: (1) Light-yellow, cherty, argill. ls. with large zaphrentoid corals, 5 ft.; (2) thin-bedded fossiliferous blue ls., 350 ft.; (3) brown and red sh., 35 ft. (no fossils); (4) cream-colored ss., 250 ft. (no fossils); (5) massive blue ls. with *Productus*, 300 ft. Total thickness 940 ft. Overlies Benson ls. with no observed discon. Underlies, with angular uncon., Weber qtzite. Exposed in Big Cottonwood Canyon, at N. end of Reade & Benson Ridge, which separates South Fork from Day's Fork.

Fossils collected from this fm. in 1916 and 1917 have been identified by G. H. Girty as of upper Brazer (probably Chester) age.

The present approved spelling of the ridge for which this fm. was named is *Reed & Benson*, *Reed* being the name of the man for whom the ridge was named. This spelling has recently been adopted for the next edition of U. S. G. S. topog. map.

Reed dolomite.

Pre-Cambrian: Eastern California (Inyo Range).

E. Kirk, 1918 (U. S. G. S. P. P. 110). *Reed dol.*—Heavy-bedded dol., much jointed and breaking up into large angular blocks that form rough talus slopes. Varies from aphanitic to coarsely crystalline. White or slightly bluish on fresh fracture. Weathers slightly creamy to buff. Thickness about 2,000 ft. Uncon. underlies Deep Spring fm. Is underlain by thin-bedded aren. slates which grade down into more heavily bedded sss. Named for exposures for several mi. along E. side of Reed Flat; best section is in canyon at head of Wyman Creek, in sec. 7, T. 6 S., R. 35 E.

J. H. Maxson (1934) applied *Wyman fm.* to the rocks uncon. underlying Reed fm. in Wyman Creek section, Inyo Range.

†Reeder sandstone.

Upper Cretaceous: Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 381, 382). The leaf-bearing *Reeder (Dakota?) ss.* surmounts Kiowa shales [Lower Cret.] in upper valley of Medicine Lodge River near post office at Reeder.

C. N. Gould, 1898 (Am. Jour. Sci., 4th, vol. 5, pp. 169–175). Cragin's term *Reeder ss.* is here used to include all ss. btw. Kirby clays below and true leaf-bearing

Dakota ss. above. Consists of 20 to 150 ft. of dark-brown massive ss., often cross-bedded, containing many pebbles and nodular concretions. Is top fm. of Medicine beds (the transition series), and is separated from underlying Kiowa sh. by (descending) Kirby clays, Greenleaf ss., and Spring Creek clays.

W. H. Twenhofel, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 281-297) and 1924 (Kans. Geol. Surv. Bull. 9), discarded *Medicine beds* and treated *Reeder ss.* and *Kirby clay* as members of his *"Dakota" fm.*

The U. S. Geol. Survey several years ago discarded *Reeder ss.* as a synonym of Dakota ss.

There is no longer a post office or town in Kans. called Reeder. The upper valley of Medicine Lodge River is in Kiowa and Barber Counties.

Reeds Spring limestone.

Mississippian (Osage): Southwestern Missouri.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines, vol. 21, 2d ser., pp. 143-145, 161-163, 169, 170, 190, 191, 193, 225). *Reeds Spring ls. memb. of Boone fm.*—Blue ls., very compact, fine-grained, subcrystalline, in thin beds alternating with dark flinty bands of chert. In some sections a thin bed of sh. (4 in. to 1 ft. 4 in.) is included at base. It rests conformably on noncherty St. Joe ls. memb. of the Boone and is in most places discon. overlain by Grand Falls chert memb., the Upper Burlington ls. being absent, except near Mount Vernon (Lawrence Co.), at Crane (Stone Co.), and at Springfield and elsewhere in Greene Co., where it is intercalated btw. Reeds Spring ls. and strata of Keokuk age. Thickness varies from 130 to 225 ft.; average in Joplin dist. about 150 ft. Judged by lithologic characters in drill cuttings the Reeds Spring extends many mi. beneath the plains of Kans. and Okla. Fossils clearly indicate it is older than Upper Burlington. It is believed to be time equiv. of Lower Burlington (and possibly in part of Fern Glen age), although it is lithologically very unlike any part of typical Burlington of other dists.

R. H. Hall, 1933 (Kans. Geol. Soc. 7th Ann. Field Conf. Guidebook, pp. 9, 14, 16). *Reeds Spring ls.* (pp. 9, 16), *Reed Springs ls.* (p. 14).—Dove-colored ls., very fine-grained, well-bedded, becoming blue gray and cherty near top. Thickness 10 ft. Overlies St. Joe ls. [Rests uncon. on Pierson ls. in one section given.] Underlies Upper Burlington ls.

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245) assigned this ls. wholly to Fern Glen epoch (basal Osage).

Named for exposures in vicinity of Reeds Spring, Stone Co.

Reedsville shale.

Upper Ordovician: Central Pennsylvania to southwestern Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). In central Pa. *Reedsville sh.* underlies Oswego (Bald Eagle) and overlies Lower Trenton ls. Includes beds of Upper Trenton, Eden, and lower Maysville age.

E. O. Ulrich, 1913 (12th Int. Geol. Cong., Canada, p. 42). *Reedsville sh.*—A great mass of sh., aren. at top, occupying whole interval btw. top of Trenton ls. and base of Oswego ss. Seems to constitute an indivisible formational unit. Top is characterized by fossils that seem to belong to top of Fairview div. of Maysville. Lower part is of Eden age.

Reedsville sh. as recognized by U. S. Geol. Survey applies to western belt of rocks of Utica, Eden, and lower Maysville age, from central Pa. to SW. Va., the eastern belt of rocks of these ages being represented in upper part of Martinsburg sh. In Blair Co., Pa., the Reedsville is 1,000 ft. thick. According to C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227) the Utica is represented in Reedsville. In SW. Va. the Reedsville is overlain by Sequatchie fm.

Named for exposures at Reedsville, Mifflin Co., Pa.

reef beds.

Miocene: Southern California.

See under †*Coalinga beds.*

Reef Ridge shale.

Miocene (upper): Southern California (Fresno, Kings, and Kern Counties).

W. F. Barbat and F. L. Johnson, 1933 (ms. read before Pal. and Min. Div. of A. A. P. G. at Houston meeting March 24, 1933).

W. F. Barbat and F. L. Johnson, April 1933 (Pan-Am. Geol., vol. 59, No. 3, p. 239). *Reef Ridge* is proposed for a sh. fm. exposed on Reef Ridge, Fresno and Kings Counties, that overlies siliceous sh. (McLure sh. of Henny) that is correlated with Santa Margarita (upper Mio.) and underlies lower Etchegoin sands (lower Plio.). In past this sh. has been grouped with both underlying and overlying fms.

T. W. Koch, 1933 (A. A. P. G. Bull., vol. 17, No. 6, p. 695). *Reef Ridge* (Upper Mio.); 550 ft. (in wells) of clay shales, slightly sandy at top. Underlies Etchegoin and overlies Maricopa.

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, pp. 1169, 1175). Blue sh. and sandy blue sh., 600 to 800 ft. thick, that weathers brown along flanks of Reef Ridge just SW. of Kettleman Hills has been named *Reef Ridge sh.* by Barbat and Johnson. Arnold and Anderson (U. S. G. S. Bull. 398, 1910) included this sh. as an upper memb. of their Santa Margarita (?) fm. in SE. end of Reef Ridge, but in NW. end of Reef Ridge they mapped it as "Transition zone mapped as Jacalitos." [See also under *McLure sh.*]

R. D. Reed, 1933 (Geol. Calif., p. 254, footnote). *Reef Ridge sh.* seems to be Mio., rather than Plio. [On several preceding pp. he assigned it to Plio.]

W. F. Barbat and F. L. Johnson, 1934 (Jour. Pal., vol. 8, No. 1, pp. 1–17). *Reef Ridge sh.* is proposed for a fm. of uppermost Mio. age underlying Etchegoin sands (lower Plio.) and overlying the redefined "McClure" sh. of Coalinga dist. The Reef Ridge sh. and "McLure sh." correlate with parts of Maricopa sh. and Monterey sh. The Reef Ridge sh. is upper div. of "Santa Margarita (?)" of Arnold and Anderson in U. S. G. S. Bull. 398, p. 92, 1910. It is typically exposed in a belt of degraded relief on NE. side of Reef Ridge, Fresno and Kings Counties, from Little Tar Canyon to Jasper Canyon. The belt is flanked on SW. by the more resistant "McLure sh." and the underlying ridge-forming Temblor fm. In type area the fm. is chiefly characterized by soft blue (brown-weathering) clay sh. with minor beds of sandy sh. Toward NW. end of type belt there is increase in sandiness, and beds of brownish-gray ss. occur. Thickness, 170 to 855 ft. North of Reef Ridge the fm. overlaps onto Cret. It contains a small but distinctive foraminiferal fauna; is stratigraphically higher than Santa Margarita beds; and in certain areas there is uncon. at top and also at base.

W. P. Woodring, 1934 (U. S. G. S. geol. map and structure sections of Kettleman Hills). *Reef Ridge sh.* (caving sh. of drillers) overlies McLure sh. (brown sh. of drillers) and underlies Jacalitos ss. (Plio.) in this area.

B. L. Clark, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 7, pp. 1049–1050), assigned this fm. to Plio.

H. W. Hoots, S. C. Herold, W. D. Kleinpell, 1935 (Geol. of nat. gas, A. A. P. G., pp. 126, 145). *Reef Ridge fm.* is herein considered upper fm. of Monterey group and of Upper Mio. age.

Reelsville limestone.

Mississippian (Chester): Southwestern Indiana and northern Kentucky.

C. A. Malott, 1919 (Ind. Univ. Studies, vol. 6, No. 40, pp. 7–20). *Reelsville ls.*—Compact to semicrystalline ls., frequently quite oolitic in texture, and almost always suboolitic. Contains considerable pyrite. Persistent over wide areas. Exposed at Reelsville, Putnam Co., Ind. From there to middle part of Crawford Co. it forms a single ledge, but in middle Crawford several other thin ledges come in on top of the main one. Underlies Elwren ss. and overlies Brandy Run ss. Can be traced over a wide area in Meade and Breckinridge Counties, Ky. [Later repts give thickness 0 to 35 ft.]

Reese formation.

Tertiary? (Eocene?): Central southern Montana (Livingston quadrangle).

W. R. Calvert, 1912 (U. S. G. S. Bull. 471, p. 412). *Reese fm.*—Water-laid material, mainly of volcanic origin and Eocene (?) age, uncon. overlying beds of Montana (Upper Cret.) age and uncon. underlying igneous flows called Neocene in Yellowstone folio. Consists of (descending): Coarsely conglomeratic strata; poorly exposed, 100 ft.; coarsely cross-bedded sandy beds; light-colored nearly structureless beds, largely volcanic ash and andesitic pebbles; coarse to pebbly bedded ss. of reworked volcanic material. Thickness 600 ft. in Electric coal field.

Type loc., Reese Creek, Park Co.

Reeve meta-andesite.

Pennsylvanian: Northern California (Taylorsville region).

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Reeve meta-andesite.*—Volcanic, tuffaceous porphyritic meta-andesite, about 200 ft. thick. Occurs as a definite flow and tuff. Is intimately associated with Robinson fm., into which it grades. Appears to be younger than Kettle meta-andesite.

Named for an unidentified locality near Genesee, E. of Taylorsville.

Reformatory granite.

Pre-Cambrian: Southwestern Oklahoma (Greer County).

C. H. Taylor, 1915 (Okla. Geol. Surv. Bull. 20). Coarsest granite in Wichita Mtns. Is medium-grained, flesh red. Intruded after solidification of Headquarters granite. Earlier than Lugert granite. [Appears to be named for State Reformatory, at Granite, Greer Co.]

Refugian stage.

Tertiary: California.

H. G. Schenck and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, pp. 215–225), introduced *Refugian stage* for a faunal zone of the Pacific slope Tert. of Calif., Wash., and Oreg. "Probably=in age part of upper Eo. or lower Olig. series of Europe," and including Lincoln, San Emigdio, Tumey, and Gaviota fms., also lower part of Pleito, lower and middle parts of San Lorenzo, lower part of Kirker, and *Turritella variata* zone; also many fms. (enumerated) of Wash. and Oreg. Type loc. is Cañada de Santa Anita, on S. side of Santa Ynez Mtns, Santa Barbara Co., Calif., about 5 mi. W. of Gaviota pass, the name being derived from the Spanish land grant "Nuestra Señora del Refugio," shown on Lompoc topog. sheet of U. S. Geol. Survey, 1905 ed. The base of the stage corresponds to base of Gaviota fm. at its type loc. in Cañada de Santa Anita. Fossils discussed.

Refugio sand.

A subsurface sand in Frio clay of Driscoll pool, Duval Co., Tex.

Regan sandstone.

See *Reagan ss.*

Regina clay.

Pleistocene: Saskatchewan.

H. E. Simpson, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 73).

Reklaw member (of Mount Selman formation).

Eocene (middle): Eastern Texas (Houston to Sabine Counties) and northwestern Louisiana.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). (Name proposed by E. A. Wendlandt and G. M. Knebel.) *Reklaw memb. of Claiborne fm.*—A series of chocolate-brown glauconitic shales with glauconitic concretionary ledges; brown, carbonaceous, micaceous sandy shales, in places lignitic; and greensands; lignitic brown sands in lower part. Occurs below Queen City memb. and above Carrizo sands in Tex. and above Cane River memb. [restricted] of Claiborne in La. Thickness 1 mi. E. of Reklaw, Cherokee Co., Tex., on Tex. & New Orleans R. R., 20½ ft.

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, pp. 1351–1355). *Reklaw memb. of Mount Selman fm.*—Consists of those glauconites and glauconitic clays above the Carrizo and underlying the sands and clays of Queen City memb. of Mount Selman. Line btw. Reklaw and Queen City memb. is usually arbitrarily drawn where the glauconitic streaks end upward in the section. Consists of (descending): (1) 0 to 100 ft. of brown clay with streaks of sand and greensand and zones of clay-ironstone concretions; (2) 4 to 15 ft. of rather pure clayey glauconite containing plentiful fossils; (3) 20 to 40 ft. of brown to dark-blue micaceous sandy clay with stringers of glauconite and zones of clay-ironstone concretions. Well exposed at Reklaw, Cherokee Co., Tex.

In NW. La. these beds form part of Cane River glauconitic memb. of St. Maurice fm. as originally defined by Spooner and used by U. S. Geol. Survey. In eastern Tex., as far W. as Atascosa Co., the basal memb. of

Mount Selman is the Reklaw; to S. of Atascosa Co. the contemp. beds, which differ lithologically, are now called *Bigford memb. of Mount Selman fm.* by U. S. Geol. Survey. The Bigford was formerly included in Wilcox group, but is now assigned to Claiborne group by most geologists.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 619–620), treated Reklaw as a *fm.* and recommended that Bigford be replaced by Reklaw.

Relay quartz diorite.

Pre-Cambrian: Northeastern Maryland (Baltimore County).

E. B. Knopf and A. I. Jonas, 1929 (Md. Geol. Surv. Baltimore Co. Rept., pp. 104, 130). *Relay quartz diorite.*—Pink quartz diorite, composed of oligoclase, quartz, and muscovite, which occurs at Relay, on Patapsco River. Intrudes Glenarm series. Is assigned to late pre-Camb.

Relay Creek dolomite.

Permian: Northwestern Oklahoma.

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 405–432). The dolomites at or near top of Marlow memb. of Whitehorse fm. have been known as "Greenfield" dolomites, but this name is preoccupied, and it seems well to offer a new name. The name *Relay Creek* is suggested for these beds, from exposures both N. and S. of Relay Creek, in T. 15 N., R. 12 W., and adjoining twps on S. and E. There are ordinarily 2 beds of dol. separated by approx. 25 ft. of red ss. and sh. Each bed is 1 or 2 ft. thick, but in other areas the thickness decreases to almost nothing. Locally there is a third bed of dol. 7 or 8 ft. below the lower of the two. The 2 beds commonly occurring are here designated Upper Relay Creek dol. and Lower Relay Creek dol. The third or lowest bed is associated so closely with Lower Relay Creek dol. that it is merely mentioned, with no distinguishing name. Color of these dolomites varies from light gray, where the beds are 1 or 2 ft. thick, to almost black, where the beds are very thin. In type area, where thickness is almost maximum, the color is gray.

See also under *Day Creek dol.*

Relief quartzite.

Mississippian: Northern California (Colfax quadrangle).

W. Lindgren, 1900 (U. S. G. S. Colfax folio, No. 66). *Relief fm.*—Very hard grayish or yellowish siliceous rock of fine grain and clastic origin, which might be characterized as very fine-grained qtzite alternating with streaks of siliceous clay slates. The qtzite is completely filled by small irregular bunches and veinlets of white quartz. No fossils. Corresponds to part of Calaveras fm. Overlies Blue Canyon fm. and underlies Cape Horn sl. Named for exposures at Relief. Best exposures in canyons of South Fork of Yuba River below Relief, in canyon of Bear River and of Steep Hollow N. of Dutch Flat.

According to later work by H. G. Ferguson (Am. Inst. Min. and Met. Engrs. Tech. Pub. 211, p. 4, 1929, and U. S. G. S. P. P. 172, 1932) two fms. (Tightner below and Kanaka above), composed of interbedded sed. and igneous rocks, are now discriminated btw. Blue Canyon fm. and Relief qtzite.

Relizian stage.

Tertiary: California.

See under *Zemorrian stage*, R. M. Kleinpell, 1934.

H. G. Schenck and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 224). *Relizian stage* includes Gould sh., "button bed," and *Siphogenerina hughesi* zone, etc.

Remick tonalite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke, Littleton, and Whitefield quadrangles).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., maps, p. 28). *Remick tonalite* is late Dev. or late Carbf. Assigned to New Hampshire magma series.
