Named for Remick Park, in town of Littleton, according to letter dated Aug. 20, 1935.

Remmel granodiorite.

Jurassic (?): Southern British Columbia and central northern Washington (Okanogan batholith).

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). "Seems to compose the cliffs of Mount Remmel, Wash., 5 mi. S. of Int. Bdy."

Renault formation. (Of Chester group.)

Mississippian: Southwestern and southeastern Illinois and western Kentucky.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 122). *Renault fm.*—Series 80 to 100 ft. thick, of sss., aren. shales, variegated shales, calc. shales with thin platy ls. layers, dense aren. lss., nearly pure crystalline lss., oolitic lss., and, in N. part of Waterloo quad., ls. cgl. Uncon. overlies Brewerville [Aux Vases] ss. and underlies, probably uncon., Yankeetown chert.

Named for Renault Twp, Monroe Co., SW. Ill. Typically developed in valley of Horse Creek and its tributaries in E. part of the Twp.

See under *Ohara ls. memb.*

Rench sand.

A name locally applied, in Mount Poso oil field (E. side of San Joaquin Valley, NE. of Bakersfield, Kern Co., Calif.), "to basal sand of Jewett micaceous silt memb. of the Lower Temblor." (See A. Diepenbrock, Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, 1933, p. 16, pl. 2.)

†Renfroes marl.

Upper Cretaceous: Western Georgia.

J. O. Veatch, 1909 (Ga. Geol. Surv. Bull. 18, pp. 86–89). *Renfroes marl.*—Massive gray micaceous, calc. sands, with layers of nodular lss.; black plastic clays, fossil-bearing; and various colored sands with layers of laminated silty clays. Thickness 500 ft. Is upper marl of Ripley fm. Underlies, through gradual transition, the Providence sand, and overlies Cusseta sand. Below Florence, Stewart Co., probably merges with Blufftown marl, which underlies Cusseta sand.

Comprises bulk of Ripley fm., and name is therefore unnecessary. (See J. O. Veatch and L. W. Stephenson, Ga. Geol. Surv. Bull. 26, p. 153, 1911.)

Named for exposures at Renfroes, Chattahoochee Co.

Rennie shale.

Middle Cambrian: Northern Idaho (Pend Oreille district).

E. Sampson, 1928 (Idaho Bur. Mines and Geol. Pam. 31, p. 9). *Rennie sh.*—Consists of "paper" sh.; in outcrop in stream along W. side of Rennie Ridge (one of the spurs on S. side of Packsaddle Mtn) it is a very thin-bedded yellowish sh. Is very soft and so easily eroded and covered with debris that there are few places where its presence would be suspected. Thickness probably 50 to 75 ft. Contains abundant Middle Camb. fauna. Underlies Lakeview ls. and overlies Gold Creek qtzite.

Rennix limestone.

Upper Ordovician (Richmond): Southeastern Kentucky.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, p. 435). *Rennix lss.*—Thin-bedded nonfossiliferous lss., 21 to 56½ ft. thick, in southern Ky. Lithologically do not resemble Sil., and hence are included in top of Richmond. Underlain by Fowler ls. and uncon. overlain by Chattanooga black sh.

Named for Rennix Creek, Cumberland Co.

Reno formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1934 (Canada Dept. Mines, Geol. Surv. Mem. 172, No. 2345, p. 8).

Rensselaer graywacke.

Lower Cambrian (?): Eastern New York.

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, pp. 301–340 and map). *Rensselaer grit.*—Grit or graywacke, a dark-green, exceedingly tough rock, in some places calc. and generally thick-bedded and granular; quartz grains apparent, and upon closer inspection the feldspar grains also. Traversed by numerous veins of quartz and sometimes of epidote. Is interbedded with strata of purplish or greenish sl. (phyllite) varying in thickness from a few in. to perhaps 100 ft. Rests uncon. on Hudson River sh.; also, without evidence of uncon., on Berkshire schist, which is contemp. with and grades into Hudson River sh. Is of Upper Sil. age and=Oneida cgl. Thickness 1,200 to 2,000 ft. Forms upper part of E. side of Rensselaer grit plateau, eastern N. Y., also the SE., W., and N. faces of the plateau.

In 1906 (N. Y. State Mus. 60th Ann. Rept., vol. 1, pp. 53–58) J. M. Clarke expressed opinion that this nonfossiliferous grit is of Dev. age and "most naturally connected with either the Oriskany invasion or the Catskill embayment," and he reiterated this opinion in 1909 (N. Y. State Surv. Mem. 9 and Bull. 133).

In 1907 (N. Y. State Mus. Bull. 107, pp. 51–52) C. A. Hartnagel expressed opinion that Rensselaer grit is not of Shawangunk age and that it cannot be correlated with Oneida cgl. In 1912 (N. Y. State Mus. Hdb. 19, p. 70) he expressed opinion that it is of Dev. age, and in his chart he doubtfully assigned it to Catskill epoch.

In 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 448–449) J. Barrell assigned the Rensselaer to Middle Dev., stating that it resembles Bellvale flags of Middle Dev. much more closely than it does the Oneonta or Catskill fm. In 1929 (Geol. Soc. Am. Bull., vol. 40, pp. 410+) R. Ruedemann assigned *Rensselaer grit* to Upper Dev., and stated that it is underlain by Tackawasick ls., of Trenton age. He repeated his assignment of *Rensselaer grit* to Upper Dev. in 1930 (N. Y. State Mus. Bull. 285, pp. 25, 27).

In 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 283–284) L. M. Prindle and E. B. Knopf tentatively assigned *Rensselaer graywacke* to Lower Camb. because it dips in apparent conformity under Rowe schist of Taconic Mtn, which is considered by writers to represent the horizon of Lower Camb. Mettawee sl.; and the U. S. Geol. Survey accepted *Lower Camb. (?)* as the age of the Rensselaer. In 1932 (Am. Petrol. Inst., Div. of Production, Dallas, Tex., p. 4) P. D. Torrey and others stated that *Rensselaer grit* is believed to be an outlier of Catskill shore line, and that recent work by Ruedemann has shown it to be of Upper Dev. age. In 1933 (16th Int. Geol. Cong. Guidebook 1, p. 15, map), Ruedemann assigned *Rensselaer graywacke* to *Camb. (?)*. (This map accompanies Ruedemann's text, but whether he is author of map, and assigned the Rensselaer to Camb. (?) is not explained.) H. Vaughan and T. Y. Wilson, 1934 (Am. Jour. Sci., 5th, vol. 27, p. 460) definitely assigned *Rensselaer graywacke* to Lower Camb. on basis of fossil evidence "presented here for the first time."

Renwick shale member.

Upper Devonian: Central southern New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 202). *Renwick sh. memb.* (basal memb. of Middlesex sh.), 8 to 20 ft. thick, underlies Six Mile sh. memb. and overlies West River and Standish fms. in Ithaca region. Is Middlesex according to Fralich. Has been correlated, erroneously, with Rhinestreet in the past. [Derivation of name not stated.]

Repetto formation.

Repetto siltstone.

Pliocene (lower): Southern California (Los Angeles region).

R. D. Reed, 1932 (16th Int. Geol. Cong. Guidebook 15, p. 31). *Repetto fm.* is here used for the siltstone exposed in Repetto Hills. This name was proposed in 1930, by a committee of Pacific section of Soc. of Econ. Paleontologists and Mineralogists, and is now in general use among Calif. geologists. Type loc. lies along W. side of Atlantic Boulevard, where exposed thickness is 2,000± ft. Foraminifera abundant. Lower part of fm. not exposed along Atlantic Boulevard but may be imperfectly seen along Fremont Ave., ½ mi. farther W., where an additional thickness of 500 ft. is represented by poorly exposed siltstone that carries only a few fossils. The siltstone rests on diatomaceous shales referred to Puente fm. (upper Mio). Top of Repetto fm. is drawn at top of 3 beds of coarse feldspathic ss. ranging in thickness from a few inches to several ft. Siltstone similar to the siltstone of Repetto fm. overlies the ss. It carries a mixture of Repetto Foraminifera, possibly reworked, and others characteristic of younger horizons and probably represents lower part of overlying Pico fm. The Repetto is a mappable unit in Repetto, Puente, and San Pedro Hills and in Ventura Basin. On basis of strat. position and distinctive foraminiferal fauna it is referred to lower Plio.

W. P. Woodring, 1932 (16th Int. Geol. Cong. Guidebook 15, p. 35), showed Repetto fm. (lower Plio.) in San Pedro Hills as resting conformably on Modelo fm. and as uncon. overlain by Pleist. calc. beds.

W. S. W. Kew, 1932 (16th Int. Geol. Cong. Guidebook 15, p. 49), in describing region btw. Los Angeles and Santa Barbara, stated that *Repetto fm.* consists of siltstone, ss., and cgl. which are considerably more indurated than those of conformably overlying Pico fm. Grades down into the brown sandy sh. that forms uppermost memb. of Modelo fm.

According to W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, fig. 1, pp 129, 146), the Repetto of Palos Verdes Hills is all siltstone, and they called it *Repetto siltstone.* [Elsewhere *Repetto fm.* is regarded as the preferable name.]

†Republic formation.

Pre-Cambrian (Huronian): Northwestern Michigan (Marquette district).

M. E. Wadsworth, 1890 and 1891 (Lake Superior along the south shore, by Julian Ralph, pp. 77–99; 1st ed. 1890; 2d ed. 1891). *Republic fm.*—Fragmental jaspilite and ore, with their associated qtzites and schists, of Cascade, Republic, Humboldt, Ishpeming, Negaunee, and elsewhere in Marquette dist. Overlies Cascade fm. and underlies Holyoke fm. Named for town in Marquette region.

M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891–92, pp. 63–66, 84–85, 102–127). *Republic fm.*—Consists of porphyrite, diabase, diorite, porodite, granite, felsite, argillite, schist, jaspilite and associated iron ores, dol., qtzite, and (at base) cgl., breccia and conglomeratic schist. Uncon. underlies Holyoke fm. and uncon. overlies Cascade fm. [The qtzite immediately overlying the basal cgl. is called *Republic qtzite* on p. 103.]

Named for occurrence at Republic, Marquette Co.

Republic quartzite.

Pre-Cambrian (Huronian): Northwestern Michigan (Marquette district).

See 1893 item under †*Republic fm.*

Republic chert.

Pennsylvanian: Southwestern Missouri.

E. M. Shepard, 1898 (Mo. Geol. Surv. vol. 12, pt. 1, pp. 125–126, 141). *Republic chert.*—Peculiar knotted chert in alternating light and dark bands highly fossiliferous, also in places conglomeratic. Included in top of Cherokee stage of Des Moines series in Greene Co. Nowhere found bedded. Seems to be widely spread in small blocks and masses as residual material left by breaking down and destruction of superincumbent beds.

Named for Republic, Greene Co.

†Republic reef.

Name locally applied to basal mottled ls. memb. of Gallatin fm. in New World ("Cooke City") mining dist., SE. cor. of Park Co., central southern Mont.

Republic granite.

Pre-Cambrian: Northern Michigan.

C. A. Lamey, 1933 (Jour. Geol., vol. 41, No. 5, pp. 487–500). The larger part of the pre-Camb. rocks of northern Mich. known as Southern Complex, and previously designated Archean, is thought to be composed of a post-Upper Huronian granite which has intruded and extensively metamorphosed the Huronian sediments and which probably extends westward some distance beneath the Upper Huronian rocks in vicinity of Lake Michigamme. Because of its excellent development in vicinity of Republic, it is suggested this granite be called *Republic granite*.

Republican Creek limestone.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 78; map). *Republican Creek ls.*—Chiefly massive white to light bluish-gray fine-grained ls., in places banded and stratified; locally coarse-grained and slightly argill.; in places alternates with argill. lss. of medium bluish-gray tint. Occupies belt a little over 1 mi. wide just S. of Lead Point argillite. Extends from head of Republican Creek SW. past N. end of Deep Lake. Thickness 1,200± ft.

†Republican River formation.

Pliocene (lower): Northern Kansas and central southern Nebraska.

H. F. Osborn, 1907 (Am. Mus. Nat. Hist. Bull., vol. 23, pp. 250, 251), and W. B. Scott, 1907 (Textbook geol., p. 724), applied this name to lower Plio. strata exposed along Republican River in southern Nebr. and northern Kans. that form part of Ogallala fm.

†Requienia ("Caprotina") limestone.

A paleontologic name applied by R. T. Hill (Biol. Soc. Wash. Proc., vol. 8, pp. 10–15, 1893) to a bed of aggl. lying 100 ft. below top of Glen Rose ls. of Tex.

Reserve shale member.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 5, 9). *Reserve sh.*—Middle memb. of Falls City ls. fm. Is blue-gray, argill., and about 4½ ft. thick. Underlies Lehmer ls. memb. and overlies Miles ls. memb. Type loc. in upland near State line NW. of Reserve, Kans.

Reservoir granite.

Pre-Cambrian: West Point quadrangle, southeastern New York.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, map and passim). *Reservoir granite.*—Rather coarse-grained gray gneissoid granite, including large blocks of dark banded gneiss. Differs from Canada Hill granite in its higher biotite content and greater continuity of mica bands. Intrusive into Grenville series. [Map block includes Mahopac granite.] Type loc. at N. end of Boyd Corners reservoir, Putnam Co.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68), classified this granite as of post-Glenarm pre-Camb. age.

Reservoir Hill granite.

Pre-Cambrian: Northwestern New York (Gouverneur quadrangle, St. Lawrence County).

H. P. Cushing and D. H. Newland, 1925 (N. Y. State Mus. Bull. 259, pp. 42–47). [In several places the pre-Camb. granite of Reservoir Hill is called *Reservoir Hill granite*, which is described as comparatively fine-grained, with only traces of porphyritic texture, and with few inclusions. It is also called *Reservoir sill*. Intrudes Grenville rocks.]

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 55-59). *Reservoir Hill granite mass* forms Reservoir Hill phacolith, lying just SE. of Gouverneur. Writer believes this mass belongs with Alexandria type, as it is nonporphyritic. Intrudes Grenville series.

Restigouche volcanic series.

Devonian: New Brunswick.

W. V. Howard, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 479).

Rest Island granite.

A name applied by I. H. Cram (Jour. Geol. vol. 40, No. 3, 1932, pp. 270-278) to the granite of Rest Island batholith, in Rainy Lake area of Minn. and Ont., which he classified as Algoman.

Restoration Point horizon.

Oligocene: Washington.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, btw. pp. 751 and 770). *Restoration Point horizon* has been described by C. E. Weaver as *Blakeley horizon*, locally known as *Sala gettysburgensis* zone.

Revard sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

D. E. Winchester, K. C. Heald et al., 1918 (U. S. G. S. Bull 686G, pp. 60-64). *Revard ss.*—Massive ss., very similar to the younger Cheshewalla ss., with lentils of red sh. which range in length from a few ft. to a mile or more and in thickness from a few in. to 6 ft. Top interfingers with overlying red sh. Thickness 30 to 80 ft. in T. 25 N., R. 10 E. Lies 145± ft. below Labadie ls. and 70± below Cheshewalla ss. Type loc. is at Revard Point, sec. 13, T. 26 N., R. 10 E.

P. V. Roundy, K. C. Heald, and G. B. Richardson, 1922 (U. S. G. S. Bull. 686Z, pp. 398-399, pl. 55). *Revard ss.* in T. 26 N., R. 10 E., is a massive ss. 30 to 40 ft. thick. In its NE. extension into T. 27 N., R. 11 E., it thickens and in places contains much sh. In T. 27 N., R. 12 E., it is 70± ft. thick and becomes differentiated into 3 distinct medium-heavy to massive-bedded ss. zones, separated by shales containing thin sss. In T. 28 N., R. 12 E., the Revard ss. breaks up into more ss. zones separated by shales, so that, for purposes of oil geology, it is better considered as several separate sss. In that twp parts of the Revard were mapped under following names (descending): (1) Mission ss. at top; (2) Possum ss. 13± ft. lower; (3) Gap ss. 15± ft. lower; and (4) Hulah ss. 18± ft. above base. Lies 20 to 50± ft. above Buck Point ss.

Revett quartzite. (Of Ravalli group.)

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and northwestern Montana.

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, pp. 277-285). *Revett qtzite.*—White qtzites, generally rather thick-bedded, interstratified with subordinate quantities of micaceous ss. Thickness 1,000± ft. Underlies St. Regis fm. and overlies Burke fm. Named for exposures surrounding Revett Lake, Coeur d'Alene dist., Idaho. Description of general geol. of region is based almost wholly on work of F. C. Calkins.

Reward conglomerate.

Pennsylvanian: Eastern California (Inyo Range).

E. Kirk, 1918 (U. S. G. S. P. P. 110). *Reward cgl.*—Cgl. of coarse material, of both angular and rounded fragments of red, brown, and white grits, together with jasper, brown hornstone, and green cherty pebbles firmly held together by a siliceous cement. A brownish-weathering ss. with dark-brown patches and layers forms uppermost 100 ft. of the Reward N. of Union Wash. Thickness of fm. 100 to more than 350 ft. Uncon. underlies Owenyo ls. (Perm.), and conformably overlies Penn. ls. and sh. Named for bold exposures just S. of Reward mine.

Rex chert member (of Phosphoria formation).

Permian: Eastern Idaho, northeastern Utah, southwestern Montana, and southwestern Wyoming.

R. W. Richards and G. R. Mansfield, 1912 (Jour. Geol., vol. 20, pp. 683-689). *Rex chert memb.*—Top memb. of Phosphoria fm. Thickness in region of Bannock overthrust (SE. Idaho and NE. Utah) 0 to 450 ft. In sec. 12, T. 10 S., R. 44 E., it consists of (descending): (1) Black cherty sh. weathering red brown to purple, 80 ft.; (2) chert in heavily iron-stained ledges, 60 ft.; (3) gray ls. banded with ashy-gray to black chert, 100 ft. Rests on phosphatic shales comprising rest of Phosphoria fm. and is overlain by Woodside sh. (Triassic). Named for Rex Peak, in Crawford Mtns, 4 mi. E. of Randolph, Rich Co., Utah, where the chert forms an anticlinal cap. This locality has been described by H. S. Gale, and the selection of the name for the memb. was originally made by him. Gale regards upper 129 ft. of Boutwell's typical section of Park City fm. as approx.=Rex chert memb., and the underlying 112 ft. as representing the phosphatic shales of Phosphoria fm. The hard Rex chert memb. is conspicuous part of Phosphoria fm. Locally 50 to 75 ft. above its base the Rex chert gives way to ls., and in other places a dark-gray to black or purplish flinty or cherty sh. occupies major part of Rex chert interval, but more generally the shaly facies is present near top and is occasionally with difficulty distinguished from Woodside sh. [Fossils listed.]

Rexmount volcanics.

Eocene (?): British Columbia.

C. W. Drysdale, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 78).

Rexmount porphyry.

Tertiary: British Columbia.

W. S. McCann, 1922 (Canada Geol. Surv. Mem. 130, p. 39).

Reynales limestone member (of Clinton formation).

Silurian: Western New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Reynales ls.*—Fossiliferous ls. [in lower part of Clinton fm.] exposed at Rochester, Lockport, and Niagara. Is older than Wolcott ls., with which it has heretofore been confused, and is overlain by true Sodus sh. Westward it is a persistent massive memb., but eastward it grades into sh., and finally is indistinguishable in the sections from overlying Sodus sh. Thickness 7 to 24 ft. In Lakeport well is underlain by 7 ft. of unnamed dark sh. that may be a part of Reynales. Fossils listed. Named for exposures at Reynales Basin (also spelled Reynolds), 8 mi. E. of Lockport.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 191), placed *Reynales ls.* below Bear Creek sh. and above Maplewood sh., and included *Furnaceville sh.* in the Reynales. This classification was followed by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 324–326). She stated: Above Maplewood sh. is a tripartite ls. about 18 ft. thick, called *Reynales ls.* Lower 4 ft. of this ls. contains representation of *Furnaceville iron ore.* This lower part is typical Reynales ls., consisting of thin ls. and sh. The overlying thicker beds, which for present are also referred to Reynales ls., consist of dark-gray or bluish even-grained, sometimes dolomitic ls. The upper 5 ft. contain some nearly pure ls. layers filled with *Pentamerus oblongus.* While the name is provisionally adopted for all of this ls., it is believed (Ulrich) that this name should be restricted to lower 4 or 5 ft. (the typical Reynales), which alone are present at Reynales Basin. It pinches out about 100 mi. E. of Rochester at some place beyond Lakeport.

J. T. Sanford, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 194). The former *Bear Creek* of Genesee Gorge is designated as *Brewer Dock memb.* of the Reynales, as the fm. at Bear Creek is younger.

Reynolds sandstone member (of Hignite formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 43). *Reynolds ss. memb.*—Massive cliff-making ss., 50 to 100 ft. thick, in Hignite fm., lying 180 ft. above base of fm.

Named for Hanging Rock of Reynolds Mtn, Bell Co., Ky.

Reynolds limestone. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 301, 426). *Reynolds ls.*—Gray shaly bed, 10 to 75 ft. thick, with marine fossils. Underlies Ada sh. and overlies Bickett sh.; all members of Bluefield

POLITECHNIKA ŚLĄSKA ZAKŁAD GEOLOGII

group [fm.]. Type loc. in public road 0.3 mi. eastward from Reynolds School and 0.6 mi. NW. of Knobs village, Monroe Co. Also observed in Mercer and Summers Counties.

†Reynosa formation.

Reynosa limestone. (Mexico.)

Pliocene and late Pleistocene or Recent: Tamaulipas, Mexico, and southern Texas.

R. A. F. Penrose, Jr., 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 57, 58, 63). *Reynosa ls.*—Hard white ls., composed of very hard calc. nodules ½ inch to 3+ in. diam., of white to creamy-brown color, in places showing concretionary structure, embedded in soft white material of same composition. Though usually hard, yet in places on surface it is soft and crumbly, and in this softer material were found many specimens of *Bulumulus alternatus* Say, a shell found now in great quantities on Rio Grande. These prove the late origin of at least the material in which they were embedded, and it apparently blends into the harder rock. Unfortunately time did not permit a thorough investigation of the region, and consequently, though it is probably true that the whole of the ls. is of same late origin, its relations and extent have not been studied. It undoubtedly overlies Fayette beds, a small outcrop of which occurs at water edge at Reynosa, Tamaulipas, Mexico.

W J McGee, 1891 (U. S. G. S. 12th Ann. Rept., pt. 1, p. 500). Dumble has announced (Geol. Soc. Am. at Columbus, Dec. 30, 1891) a division of Fayette beds, and designated the uncon. upper portion the *Reynosa marl*. It is this upper memb. which represents Lafayette fm. in Tex.

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 229–230). *Reynosa beds.*—In May 1889 I observed along line of Southern Pacific R.R. btw. San Antonio and Eagle Pass and N. of Eagle Pass a deposit usually consisting of a larger or smaller quantity of gravel cemented by a very porous or tufaceous ls. In some places the gravel seemed to be entirely missing and only the ls. present. Thickness of this deposit, 3 to 30 ft. In some places overlain by the yellow silt flanking the Rio Grande. At town of Reynosa, in Mexican State of Tamaulipas, and opposite Edinburg, Tex., we found a much larger and firmer deposit of ls. (containing such fossils as *Bulimus alternatus*), which was described by Penrose in 1st Ann. Rept. of Tex. Surv. under name *Reynosa ls.* This lies higher than Fayette sands. J. A. Taff, of Tex. Survey, in his work along line of Texas-Mexican Ry btw. Corpus Christi and Laredo, observed the same lime and gravel with *Bulimus alternatus* overlying Fayette sands at various places. I joined his party at Cotulla, and during my work with them up the valleys of Nueces and Leona Rivers I found many exposures of the gravel and lime and of the firmer ls. in such connection as to prove conclusively that they are mere local variations of one and same deposit. I therefore extend name *Reynosa* to include the entire series of deposits for the present. These deposits cover a very large area in western Tex. and extend into Mexico. They appear to rest uncon. on underlying Cret., Eocene, and Neocene beds. They lie above the Fayette sands and beneath the coastward clays of the Port Hudson (Columbia fm. of McGee) and appear to be a different phase of Lafayette fm. to E. Assigned to Neocene.

E. T. Dumble, 1894 (Jour. Geol., vol. 2, pp. 560–563). *Reynosa div.*—Lithologically the most characteristic of all Neocene deposits. Is a very variable series of beds. Usually has at base a cgl. of pebbles of various sizes, embedded in a lime matrix, often indurated, sometimes tufaceous, sandy, or even clayey. Above this is often, but not always, a series of interbedded clays, lime clays, limy sands, and sss., with some pebbles. This closely resembles Lagarto clays. *The whole is capped by Reynosa ls.*, a tufaceous lime rock, often so mixed with clay or sand as to lose that character. There are few exposures which show entire series of beds. In places along middle Rio Grande the basal bed of cgl. is all that is present, while on the divides the basal and uppermost beds are usually found, but without the intermediate Lagarto. The Reynosa in its typical form is only found W. of the Colorado, so far as I have observed. East of the Guadalupe the lime is gradually replaced by iron; the Orange sand phase appears in the Colorado drainage and E. of that stream becomes the prevailing form, although some lime is present at many localities. No fossils have been found which can be said to be indigenous to this deposit. A number of shells of *Bulimus* were found embedded in an upper crumbly layer of it, but they are simply on the surface and probably later. No other Tert. bed has anything like so wide a distribution. I found it at top of the escarpment of Llano Estacado in Garzo Co. at point marked "T i" on map of Llano Estacado accompanying 3d Ann. Rept. of this Survey, and also just S. of Big Springs, resting on N. slope of Cret. hills. In canyons on S. edge of plateau its presence has been reported by Hill and Taff. While erosion has removed the Reynosa from a large part of Guadalupe and Nueces Valleys, it still caps the divides and higher elevations and forms the surface of that plateau btw. the Nueces and the Rio Grande which is in many respects the homolog of the Llano Estacado and may well be called Reynosa Plateau. On this plateau it attains an elevation of over 800 ft. above sea level in an area which appears on all topog. maps as lying below the 200-ft. contour.

A. Deussen, 1924 (U. S. G. S. P. P. 126). *Reynosa fm.* of Tex. Coastal Plain W. of Brazos River is 560 to 1,505 ft. thick. It is of Tert. (?), Plio. (?) age, uncon. underlies Lissie gravel (Pleist.), and uncon. overlies Lagarto clay (Plio.). Is of nonmarine origin. Until more definite information can be obtained regarding age of Reynosa ls. of Penrose it is considered advisable to continue Reynosa as it was used by Dumble and Kennedy, it being well established in the literature with that significance. The "Uvalde fm." of previous repts is now regarded as an upstream facies of Reynosa. The Reynosa consists of a cgl. of flint or siliceous manganese-stained ls. pebbles, cemented with lime, very hard in some places but in others soft and tufaceous; lenses of pink manganese-stained limy clay; coarse limy sand and ss.; and soft tufaceous ls. Bedding very irregular. Small ridges and knolls are capped with the ls., and the intervening depressions are occupied by red or brown loam. No fossils have been found in fm., which extends NE. through Duval, McMullen, Live Oak, Bee, Goliad, DeWitt, Lavaca, Waller, Colorado, and Austin Counties.

A. C. Trowbridge, 1932 (U. S. G. S. Bull. 837, pp. 20, 201–202, as summarized by W. A. Price in A. A. P. G. Bull., vol. 17, No. 5, p. 492, 1933), pictures the post-Oakville or post-Lagarto peneplain as accumulating, to an appreciable depth, residual material which, with the uplift of Edwards Plateau, and perhaps of plateaus and mtns farther W., was washed down seaward across the plain by the rejuvenated rivers, collecting in greater thickness toward the coast. This alluvium formed "a sort of compound fan" upon which stretched "a sort of piedmont plain." Some rivers, as the Nueces W. of Bordas scarp, have eroded this alluvium so deeply as to expose the underlying rocks, in which they have cut "gorgelike trenches."

Further work by many geologists raised considerable discussion regarding the appropriateness of the name *Reynosa* as applied in the literature. J. T. Lonsdale and J. R. Day stated (U. S. G. S. Press Bull. 68861, Feb. 9, 1933) that *Goliad fm.* had been proposed by Tex. geologists and is being considered as a substitute for *Reynosa*.

A. W. Weeks, 1933 (A. A. P. G. Bull., vol. 17, No. 5, May, pp. 455–487). *Reynosa caliche* (*Pleist.*).—In this paper *Reynosa* is applied to the caliche deposits of Reynosa Plateau region, and thus is limited to a variety of deposits similar to that of type section. From data thus far collected no objection can be seen to assigning a Beaumont (Pleist.) age to much of the caliche, although it may have begun to form during Leona time. I consider Leona to be younger than Uvalde, and Uvalde to be=Lissie fm. (Pleist.). Some question may be raised as to advisability of giving the caliche a name. If the main caliche mantle in area discussed should not be given a name, then *Reynosa* should be abandoned. Thickness of the caliche is 1 to 12 ft. It is younger than Upper Lagarto, which contains Plio. fossils. The Reynosa ls. of Penrose at Reynosa, Tamaulipas, Mexico, rests on the Lagarto instead of on Fayette.

A. Deussen, 1933 (A. A. P. G. Bull., vol. 17, No. 5, pp. 483–484). *Reynosa fm.* should not be abandoned, although it may be that some material that has been included in Reynosa should be excluded, notably the high-level gravels referred to the *Uvalde* and the limy flint cgl. capping Bordas escarpment, both of which I now think are probably interior equivalents of the Lissie. But there is a definite strat. unit in Live Oak, Bee, Goliad, and Victoria Counties, lying uncon. above the Lagarto and dipping below the Lissie, which was included by me in the Reynosa. It is this series of beds to which I would prefer to apply *Reynosa*. This unit consists of lss. and some characteristic pinkish-red and white mottled clays, that are readily distinguished from underlying Lagarto and overlying Lissie. There is pronounced uncon. at base, and in many places a gravel bed or cgl. forms the base, in which late Plio. fossils have been found. The *Goliad ss.* of geologists in SW. Tex. I consider to be the basal portion of Reynosa fm.

A. W. Weeks, 1933 (A. A. P. G. Bull., vol. 17, No. 5, pp. 485–486). I understand Deussen would like to give name *Reynosa* to all or part of what I have called

Upper Lagarto. This would exclude from his Reynosa all material from other strat. units which he and [A. C.] Trowbridge once included in it. I do not advise adoption of *Reynosa* for all or part of my Upper Lagarto, because it appears Dumble gave name *Lagarto* to this section in 1894, and because *Reynosa* was applied by Penrose to the caliche deposits at Reynosa, Tamaulipas, Mexico, and vicinity in 1890.

W. A. Price, 1933 (A. A. P. G. Bull., vol. 17, No. 5, pp. 488–520). Reynosa ls. of Penrose is calc. caliche (porous earthy, impure ls.). The ss. on which it rests is not Fayette ss., as Penrose thought, but belongs to Reynosa fm. of later writers. Dumble's Reynosa included Penrose's ls. bed at top. Other geologists have divided Reynosa of Dumble and Deussen into two divisions, the upper of which is caliche of early Pleist. age, and the lower of which consists of sss. and clays containing fossil bones of horses that seem to indicate Plio. age. The max. thickness of 600 to 1,500 ft. that has been assigned to the Reynosa by various authors is greatly in excess of true thickness. Max. thickness of Reynosa caliche or Upper Reynosa is 85 ft. The Lower Reynosa uncon. underlies Upper Reynosa; its thickness is not much greater than that of Upper Reynosa. The Reynosa is uncon. overlain by Lissie sands and it overlaps Lagarto, Oakville, Catahoula tuff, and Frio in Reynosa Plateau. Some geologists think *Reynosa* should be restricted to Upper Reynosa and a new name be given to Lower Reynosa. H. A. Noble and I. K. Howeth have called (but not yet published) it *"Goliad ss.,"* but that name has not yet any standing.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 751, 755, 761, 777, 782). Old name *Reynosa*, which has been applied by Dumble, Udden, Baker, Böse, Trowbridge, and Deussen to the beds here named *Goliad fm.*, is considered invalid for these beds, because the gravels at type loc. for the Reynosa, at Reynosa, Mexico, are terrace gravels and are of same age or younger than Lissie fm., while the Goliad strata are below and older than Lissie fm.

A. N. Sayre, 1933 (letter dated Dec. 29). Reynosa at Reynosa, Mexico, is not a ls. It is younger than Lissie and younger than Uvalde. Penrose found Recent shells in it. It may = Leona fm. At least part of it is late Pleist. or Recent. I recommend restricting name to its type loc. at Reynosa, Mex.

The Tex. Geol. Survey and U. S. Geol. Survey have discontinued the use of *Reynosa fm.* in Tex. The U. S. G. S. now divides the late Cenozoic deposits of southern Tex. into (descending):

Beaumont clay Lissie fm.	Leona fm.	Pleist.
Uvalde gravel Goliad sand	Tert.? (Plio.?).	
Lagarto clay (Plio.).		

†Rhems shale.

Eocene (lower): Eastern South Carolina (Williamsburg County).

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, pp. 449, 451, 452, 453). *Rhems sh. or subphase*.—Light-gray to black sh. interlaminated with thin seams of fine-grained sand and mica. Some layers partly silicified. Encloses small variety of *Venericardia planicosta*. Overlain by Williamsburg pseudobuhr. Is initial phase of Upper Black Mingo. Best exhibited at Rhems Landing, on Black Mingo River.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). †*Rhems sh.*, placed by Sloan at bottom of his †Upper Black Mingo, is gray to black brittle clay or fuller's earth exposed at Rhems Landing, on Black Mingo Creek. It appears not to differ materially from his †Lower Black Mingo or †Black Mingo shales, the type loc. of which is Perkins Bluff, Black River, only 5 mi. from Rhems, Williamsburg Co.

Is a part of Black Mingo fm., of Wilcox age.

Rhinestreet shale.

Upper Devonian: Western and west-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 23 and chart). *Rhinestreet sh.* (black sh.) underlies Angola sh. and overlies Cashaqua sh. Included in Naples beds of western N. Y. [See also N. Y. State Mus. Mem. 6, 1904.]

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1000–1029). *Rhinestreet black sh.* extends from Yates Co. to Lake Erie. Thickness 53 ft. In gorge of Genesee

River underlies Hatch sh. and overlies Cashaqua sh. In Lake Erie section underlies Angola sh., overlies Cashaqua sh., and is 185 ft. thick. Included in Portage group.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 75–76). *Rhinestreet sh.* named for exposures along Rhinestreet N. from Naples, Ontario Co. Is 200 ft. thick on Lake Erie; thins to 2 ft. in Seneca Lake Valley, where it overlies Parrish ls., the intervening upper part of Cashaqua sh. having thinned out. In western N. Y. overlain by Angola sh.; in west-central N. Y. overlain by Hatch sh.

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157) and 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), showed that Rhinestreet sh. of Lake Erie section includes at top the Hatch sh. of Genesee River section, and is larger unit than typical Rhinestreet (which lies btw. Cashaqua sh. below and Hatch sh. above). He therefore (1923 citation) applied *Attica sh.* to the Lake Erie Rhinestreet.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). Rhinestreet sh. underlies Hatch sh. and overlies Cashaqua sh. All included in Portage group.

Rhinoceros Hill beds. (In Ogallala formation.)

Pliocene (lower): Western Kansas (Wallace County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7, pp. 159–163). *"Rhinoceros Hill" beds and diatomaceous marl of the Ogallala.*—In NE. part of Wallace Co., in basin of north fork of Smoky Hill River near Marshall ranch, a somewhat different type of Tert. sediments occurs, which, according to rich vertebrate fauna collected in them, must be contemp. with typical "mortar beds" of Wallace Co. referred by writer to the Ogallala. The large collection [listed] of fossil mammals was obtained from greenish-gray sand immediately underlying a bed of snow-white diatomaceous marl (4 to 11 ft. thick) that lies near top of the local Tert. section, and that must belong to about middle of Ogallala fm. These bones are pronounced by H. T. Martin to be Lower Plio. The marl is capped by a thin ledge of white ls., overlain by 10 ft. of slightly cemented grit, containing fragments of similar mammal bones, which completes the 115-ft. local Tert. section. The bones were collected on Rhinoceros Hill, SE¼ NE¼ sec. 11, T. 11 S., R. 38 W., in NE. part of Wallace Co. The hill was named by H. T. Martin, "the head of the expeditions." About 3 mi. N. and slightly W. of Rhinoceros Hill in SW¼ sec. 26, T. 10 S., R. 38 W., in Sherman Co., Kans., another "sand quarry" in the "fine silty deposit" of the Tert. was opened by Martin, the fauna of which, though closely related to "Rhinoceros Hill" vertebrates, includes some varieties that are considered by him to indicate a slightly greater age than latter, though still in Lower Plio. It appears to writer that these unconsolidated "fine silty" beds of Sherman Co., which are called by Martin "Edson beds" (from a small town in Sherman Co.), must belong somewhere low in "Rhinoceros Hill" section, probably about 50 to 80 ft. below the bed from which fauna of "Rhinoceros Hill" was collected. Pierre sh. must not be far below "Edson beds" of Sherman Co. and at a somewhat lower elev. than the fossiliferous sand of Rhinoceros Hill.

Rhode Island formation.

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 159–201). *Rhode Island Coal Measures.*—Alternations of fine and medium quartz, qtzite, and granitic pebble cgls. with pebbly sss., graywacke, shales, and coal beds, becoming metamorphic southward. Underlies Dighton cgl. group and overlies Wamsutta group of red beds, but lower part is believed to be time equiv. of part of Wamsutta red beds. Thickness 10,000 ft. Includes [descending order as arranged in table on p. 134] Westville shales and Seekonk sss., Tenmile River beds, Mansfield beds, and Cranston beds.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 54–55 and map). *Rhode Island fm.*—Makes up greater part of rocks of Narragansett Basin, both in thickness and extent. Consists of shaly and slaty coal-bearing beds intercalated with sss. and cgls. Named for fact that the graphite coal beds of Rhode Island are a part of it. Underlies Dighton cgl. to N. and Purgatory cgl. to S. Overlies Wamsutta fm.

Rhodes sand.

A subsurface sand, of early Penn. (Cherokee) age, in central and central northern Okla., lying lower than Bartlesville sand and correlated with Dutcher sand.

Rhododendron formation.

Pliocene or Pleistocene: Central northern Oregon (east side of Cascade Mountains).

E. T. Hodge, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 157). The *Coriba erosion surface* (late Plio.) was buried beneath late Plio. or early Pleist. pyroclastics (*Rhododendron fm.*) which are water-sorted only adjacent to valleys of the Coriba stage and on E. side of Cascade Mtns. These pyroclastics buried all lowlands of Coriba surface and created a barrier across the small progenitor of Columbia River which had a course many miles to S. This stream aggraded its course to elev. of 1,900 ft. above sea level and produced shallow Condon Lake E. of the volcanic zones. The aggraded stream and playa lake eventually transgressed Horse Heaven Hills and diverted waters of upper Columbia-Snake River drainage systems westward. Thus "foreign" gravels were carried westward by this extended river to Willamette Valley, where they were deposited in a great piedmont fan (Pleist. *Troutdale fm.*); these "foreign" gravels are more numerous and the fm. is thickest 15 mi. S. of Columbia Gorge. In gorge itself they occur only on E. slope of Willamette Valley. The new Rhododendron surface then was at same elev. as north-central Oreg., except for widely scattered explosive volcanoes. This surface was eventually buried by basaltic, andesitic, and trachytic lava flows which formed the constructional Cascade Mtns. The lava flows dammed Columbia River and deepened Condon Lake until it spilled over the col formed by Cascade fm. on S. and by the south-dipping Coriba surface on N. In this new course the still consequent Columbia River rapidly superposed itself on *Troutdale*, Columbia River basalt, and Eagle Creek fms. and quickly cut a gorge at places 4,000 ft. deep.

Derivation of name unknown.

Ribbon gneiss.

Pre-Cambrian (?): Central Washington (Douglas County).

A. Waters, 1927 (Jour. Geol., vol. 35, pp. 159–160). *Ribbon gneiss.*—Granitic gneiss of unknown age in Lower Corbaley Canyon. In most localities intruded by innumerable stringers and veinlets of alaskitic and pegmatitic material, which follow the planes of the gneissic banding and produce a ribboned effect. Ribbon Rock, Ribbon Cliff, and Ribbon Mesa have been named for this peculiarity. Following this system of nomenclature the writer has called this series of *metamorphosed igneous rocks* the *Ribbon gneiss.* Has general petrographic resemblance to Orient gneiss of Ferry and Stevens Counties, which C. E. Weaver regards as possibly pre-Camb.

Ribbon limestone.

Carboniferous: Cape Breton Island, Nova Scotia.

P. D. Trask, 1929 (Nova Scotia Rept. on Mines 1928, p. 279).

Rib Hill quartzite.

Pre-Cambrian (middle Huronian?): Central northern Wisconsin (Marathon County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 41). *Rib Hill qtzite.*—Coarse white qtzite. Estimated thickness btw. 1,000 and 4,000 ft. Occurs in irregular areas partly or wholly separated from one another. Largest single exposure is Rib Hill, SW. of Wausau, Marathon Co. Assigned to lower Huronian (?). May be=Powers Bluff qtzite.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this qtzite to middle Huronian.

Ribolt clay shale.

Silurian (Niagaran): Northeastern Kentucky (Lewis County) and southwestern Ohio (Hillsboro).

A. F. Foerste, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 171, 172, 173, 189, 202). In Lewis Co., Ky., no trace of Waco ls. can be identified. Here a clay sh., at least 100 ft. thick, directly overlies Dayton ls. At Peebles, Ohio, it is 85 ft. thick; at Hillsboro, Ohio, it is 75 ft. thick. At all these localities the upper part of the clay sh. is interbedded with thin indurated layers, often only ¼ in. thick, which are characterized by a distinctively Clinton fauna (listed), which corresponds to middle part of upper Clinton of N. Y., Pa., Md., and Va. That part of the clay sh. section which includes the indurated layers containing this middle upper Clinton fauna is here named *Ribolt sh.*, to distinguish it from underlying Estill sh., which is not known to be fossiliferous. The Ribolt has been identified with certainty only in Lewis Co., but it may extend farther southward.

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 128). Type exposure of *Ribolt sh.* is at Ribolt, Lewis Co., 10 mi. W. of Vanceburg. In Lewis and Adams Counties it is 30± ft. thick; at Hillsboro, Ohio, 20± ft. No trace of this sh. N. of Hillsboro. [On pp. 134–140 he amplified his description, under heading *Ribolt clay sh.* See also under *Alger fm.*]

Ribstone Creek formation.

Cretaceous: Alberta.

S. E. Slipper, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 8). Included in Belly River series.

Rican series.

A term applied by C. R. Keyes to Carbf. deposits in Colo. stated by him to be older than his Moenkopian series and younger than his Aubreyan series. Is probably applied to Rico fm. (Perm.) of other geologists.

Ricardo formation.

Pliocene (lower): Southern California (Kern and San Bernardino Counties).

J. C. Merriam, 1914 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 8, pp. 276, 278). The *Ricardo Plio.* is next faunal stage known after the Mohave in the Great Basin. A series of beds, occurring at Ricardo [Kern Co.], on W. border of Great Basin, representing a faunal and strat. stage which is distinctly pre-Pleist., is certainly much later than the Mohave Upper Mio., and presumably represents early Plio. Doubtful that much, if any, of the Plio. of King really represents the *Ricardo stage*.

J. C. Merriam, 1915 (Pop. Sci. Monthly, vol. 86, pp. 252–254). The *Ricardo beds* contain Plio. mammals.

J. C. Merriam, 1917 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 10, pp. 430–443). *Ricardo fm.*—Thickness 3,000 to 5,000 ft. Contains Plio. fauna. The beds in which the fauna occurs consist in large part of tuffs with desert cgls. or fangls. and other deposits formed on land or in evanescent water bodies. Fauna seems to be a unit not divisible into sharply separated stages and indicates an earlier stage than Thousand Creek and Rattlesnake, which is supported by greater degree of induration and deformation of the Ricardo. **Is younger than Barstow fm.**

J. C. Merriam, 1919. (See under †*Red Rock Canyon beds*.)

Rice Bay granite gneiss.

Pre-Cambrian (Laurentian): Western Ontario (Rainy Lake region).

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 55).

Rice Brook sand.

A subsurface sand, of probable Dev. age, in western N. Y., lying higher than Richburg sand.

Rice Lake series.

Pre-Cambrian: Manitoba.

E. S. Moore, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 264).

Riceville shale member (of Chemung formation).

Upper Devonian: Northwestern Pennsylvania (Erie and Crawford Counties).

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q4). *Riceville shales.*—Very fossiliferous drab or bluish-gray sandy shales, sometimes shaly sss.; no black or red layers. Thickness 80 ft. Well exposed on Oil Creek in bluff just W. of Riceville, Crawford Co. Contain Chemung fossils. Underlie Cussewago ss. and overlie Venango oil sand group.

W. A. VerWiebe, 1917 (Am. Jour. Sci., 4th, vol. 44, pp. 39–47), gave 50 to 200 ft. as thickness of *Riceville fm.* and assigned it to Dev.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), correlated *Riceville sh.* with Oswayo fm.; called overlying beds *Cussewago ss.* and underlying beds

Venango group; correlated Venango with Cattaraugus fm.; correlated both Riceville and Venango with upper part of Chagrin sh. of Ohio; and treated Riceville and Venango as basal part of Bradfordian. He repeated this classification in 1924 (N. Y. State Mus. Bull. 251, p. 157) and in 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 455–464). [The U. S. Geol. Survey at present classifies Chagrin sh. of Ohio as Upper Dev. and Bradfordian and Oswayo as Dev. or Carbf.]

K. E. Caster, Feb. 28, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Riceville fm.* restricted to lower part of Riceville of previous repts, and included in Venango group. Oswayo sh. memb. of Riceville fm. restricted (lower Riceville of previous repts) represents all of Riceville fm. restricted. Upper or Miss. part of Riceville of previous repts here named *Smethport sh. memb. of Knapp fm.* The Oswayo includes Wild Cat coquinite and Smethport includes Marvin Creek ls.

G. H. Chadwick, Oct., 1933 (Pan-Am. Geol., vol. 60, No. 3, pp. 195, 197), included Riceville restricted in Conewango (=Venango group) and stated (pp. 197 and 281) that Caster's fossils locate Miss.-Dev. bdy within former Riceville sh.; and he adopted Caster's restricted Riceville.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61), divided his *Riceville stage* (*Riceville monothem*) into Oswayo sh. memb. and Roystone (replaces Wild Cat, preoccupied) coquinite memb., excluded it from his Venango stage, and treated it as a distinct "stage." On p. 47 he stated: Riceville fm. is dual sequence, lower part of which is of Dev. age and upper part of basal Miss. age. Riceville sh. proper is here included in Dev. The Miss. portion is called *Kushequa sh. memb.* of Knapp monothem and included at base of Oil Lake series, of the Miss.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 305–354), adopted Riceville restricted, but he included both Riceville and overlying Kushequa in Upper Dev.

The U. S. Geol. Survey has not yet had occasion to modify its classification, which treated Riceville sh. as a memb. of Chemung fm.

Riceville stage.

Riceville monothem.

See 1934 entry under *Riceville sh. memb.*

Richard sandstone member (of Pierre shale).

Upper Cretaceous: Central northern Colorado (Larimer County).

M. W. Ball, 1924 (A. A. P. G. Bull., vol. 8, pp. 81–87). *Richard ss.*, 59 ft. thick, lies 171 ft. above Larimer ss. Is exposed along N. bank of Richard Lake, sec. 30, T. 8 N., R. 68 E. [In Larimer Co.] Named and mapped [unpublished repts] by A. T. Schwennesen, E. W. Krampert, and C. H. Henley. [See also 1924 entry under *Hygiene ss. memb.*]

K. F. Mather, J. Gilluly, and R. G. Lusk, 1924 (U. S. G. S. Press Bull. 1825) and 1928 (U. S. G. S. Bull. 796B). *Richard ss. memb. of Pierre sh.*—Ordinarily thin-bedded and somewhat limy, with many concretionary masses. Thickness 0 to 70 ft.; usually btw. 25 and 60 ft. Lies 2,775 to 5,275 ft. below Fox Hills ss. and 100 to 200 ft. above Larimer ss. memb.

Richardson subgroup.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 4, 5, 9). Top subgroup of Wabaunsee group. Includes Brownville ls. at top and extends down to top of Tarkio ls. Named for Richardson Co. Type loc., the Big Nemaha Valley of southern Richardson Co. btw. points S. of Humboldt and SW. of Falls City.

Richburg sand.

An oil sand in northern Bolivar Twp, Allegany Co., N. Y. Lies 1,600 ft. below Olean cgl. Mentioned by J. F. Carll in 1883 (2d Pa. Geol. Surv. Rept. I_4, p. 165). According to C. A. Ashburner (Am. Inst. Min. Engrs. Trans., vol. 16, pp. 927–928, 1888) is local name for Allegany oil and gas sand, of Allegany Co., N. Y., and top is 1,729–1,734 ft. below base of Olean cgl. According to C. R. Fettke (Geol. Soc. Am. Bull., vol. 44, No. 3, pp. 625, 631, 1933) the *Richburg sand* is 28 ft. thick in Gilbert No. 1 well, on Gilbert farm, 2 mi. N. of Richburg, Allegany Co., N. Y., and occupies interval btw. 1,156 and 1,184 ft., the *Richburg Stray sand*, 16 ft. thick, lying 26 ft. higher and occupying interval btw. 1,114 and 1,130 ft.

Richfield formation.

Pre-Cambrian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 12). [Assigned to pre-Camb. (?), but many later repts. by other geologists, definitely assign the fm. to pre-Camb.]

Rich Hill limestone member (of Cherokee shale).

Pennsylvanian: Central western Missouri (Bates and Vernon Counties).

F. C. Greene and W. F. Pond, 1926 (Mo. Bur. Geol. and Mines vol. 19, 2d ser., pp. 37, 51–53). *Rich Hill ls. memb. of Cherokee fm.*—Ls. beds in upper part of Cherokee fm., commonly known as "Rich Hill Lime" in Rich Hill-Panama dist., of Bates and Vernon Counties. Upper 12 ft., gray nodular concretionary and unevenly bedded ls., which in places is represented by 10 ft. of ls. nodules embedded in clay and in places, in W. part of Co., is absent. Middle part consists of 4 to 5 ft. of sh., which in places thins to a shaly parting. Basal 2 ft. is dark-gray and dense ls., locally called, in W. part of Vernon Co., the "Diamond Rock," because of tendency to break into diamond-shaped or rhomboidal blocks. The memb. is overlain by clay bed beneath Williams coal and underlain by sh. Probably same as "Ardmore" ls. of Gordon of Bevier dist. of northern Mo.

This ls. is now called *Ardmore ls. memb.* by Kans. Geol. Survey.

Named for occurrence at Rich Hill, Bates Co.

Richland limestone and flint.

Mississippian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pl. opp. p. 933). *Richland ls. and flint* shown in columnar section of vicinity of Hamden Junction, Vinton Co. Overlain by cgl. in places, which is succeeded upward by Logan ls.; underlain by traces of coal resting on cgl.

Probably belongs to Logan fm.

Probably named for Richland, Vinton Co.

†Richland sandstone.

Pennsylvanian: Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxv). *Richland-Gordon sss.*—Basal rocks of undoubted Carbf. age on eastern border. In Colorado coal field these sss., with the underlying clays and sands, are given name of Richland sss., and in Brazos coal fields sss. of similar position and composition have been named *Gordon sss.* (probably for Gordon, Palo Pinto Co.).

R. S. Tarr, 1890 (Am. Geol., vol. 6, pp. 147–153; Tex. Geol. Surv. 1st Ann. Rept., p. 204). *Richland ss.* consists of ss., with some interbedded sh. and cgl.; upper 3,500 ft. coal-bearing. Includes, at top, Rochelle cgl. bed (50 ft. max. thickness). Total thickness 4,500 ft. Is Tex. equiv. of Millstone grit. Underlies Milburn shales and uncon. overlies Lower Carbf.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 98). Milburn shales are now included in Brownwood div., which rests on Richland ss.

C. H. Gordon, 1911 (Jour. Geol., vol. 19, p. 117). Richland of Tarr=Strawn fm.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 35; Univ. Tex. Bull. 2132, p. 13), show Richland of Tarr practically=Strawn fm. and treat Rochelle cgl. as basal bed of Brownwood.

Named for Richland Creek, San Saba Co.

Richmond group.

Upper Ordovician: Indiana, southwestern Ohio, Kentucky, Illinois, Missouri.

N. H. Winchell and E. O. Ulrich, 1897 (Minn. Geol. and Nat. Hist. Surv. Final Rept. vol. 3, pt. 2, p. ciii). *Richmond group.*—Alternating thin-bedded shales and lss., with, at some localities, a ss. at top. Overlies Lorraine group and forms uppermost part of Lower Sil. [Ord.] in SW. Ohio, SE. Ind., and north-central Ky. Thickness 350 ft.

In some early repts the Arnheim sh. was excluded from Richmond group, but for many years it has been included in the Richmond by most geologists and is so included by U. S. Geol. Survey. In SE. Ind. and SW. Ohio the Richmond group includes the deposits that have been called (descending) Elkhorn ls., Whitewater fm., Saluda ls., Liberty ls., Waynesville sh., and Arnheim sh. In southern Ill. and eastern Mo. it includes Maquoketa sh. (also the contemp. Thebes fm.) and the underlying Fernvale ls.

The age of the Richmond group has been the subject of much discussion in recent years. Originally (1897) it was assigned to the Ord. by Winchell and Ulrich. Subsequently it was thus classified by all geologists and paleontologists until 1911, when E. O. Ulrich (Geol. Soc. Am. Bull., vol. 22) placed it in Sil. At present the group is classified as Ord. by apparently all geologists and paleontologists except E. O. Ulrich, R. S. Bassler, and R. Ruedemann, but the present N. Y. State Survey (W. Goldring, N. Y. State Mus. Hdb. 10, 1931) assigns Queenston sh. (which is generally regarded as of Richmond age) to Sil., and the present Pa. Geol. Survey assigns Juniata fm. (=Richmond) to Sil.

Named for Richmond, Ind.

†Richmond earth.

Miocene: Eastern Virginia (Richmond region).

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, p. 197). The nearly pure diatomaceous earth of Chesapeake fm. can be traced from Eastern Shore of Md. entirely across the State and thence southward into Va. From its wide occurrence in vicinity of Richmond it is sometimes known as "Richmond earth."

W. B. Clark and B. L. Miller, 1906 (Va. Geol. Surv. Bull. 2, pt. 1). Diatomaceous earth is present in Choptank fm. and is especially well developed in lower part of Calvert fm. It has been called "Richmond earth."

Richmond formation.

Eocene: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, pp. 53–56).

Richmond group.

Pre-Cambrian (middle Huronian?): Canada (east shore of Hudson Bay).

C. K. Leith, 1910 (Econ. Geol., vol. 5, pp. 232–245). A thick series of clastics, of possible Middle Huronian age, underlying Nastapoka series with some erosional uncon. Occurs on Richmond Gulf.

†Richmond sandstone.

A name applied in some early repts of Wis., Minn., and Iowa, also in late papers by C. R. Keyes, to the ss. beds long known as *New Richmond ss.*

Richmondian.

A time term that has been used by some geologists to cover the epoch during which the Richmond group was deposited.

Richmondville sandstone.

Mississippian: Michigan (Lower Peninsula).

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891–92, p. 66). *Richmondville or Berea ss.*, 65 ft. thick, underlies Coldwater shales and overlies St. Clair shales.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2, btw. pp. 1 and 31). *Richmondville or Berea ss.*, 65 ft. thick, underlies Black bituminous sh. and overlies St. Clair black shales.

C. H. Gordon, 1900 (Mich. Geol. Surv. vol. 7, pt. 3, btw. pp. 1 and 20). *Richmondville ss.*, 50 to 80 ft. thick, lies in Coldwater shales, 100 to 200 ft. below their top. Has been erroneously correlated with Berea ss. of Ohio.

W. H. Sherzer, 1913 (Mich. Geol. and Biol. Surv. Pub. 12, geol. ser. 9, btw. pp. 187 and 221). *Richmondville ss.* first defined by Lane as=Berea grit, but has since been regarded by Lane as a "stray ss." somewhat higher up.

Named for exposures at Richmondville, Sanilac Co.

Rich Mountain conglomerate. (In middle of Pottsville group.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1918 (W. Va. Geol. Surv. Rept. Barbour and Upshur Counties, p. 292). Writer has no hesitation in declaring his belief that *Rich Mtn cgl.* of this region, often so called from its abundant exposure along that range, will prove to be Sharon cgl. of western Pa. and same as Upper Raleigh ss.

Richter sand.

A subsurface sand, of Penn. age and 50± ft. thick, in Tonkawa field, Kay Co., central northern Okla., which lies lower than Tonkawa sand, higher than Layton sand, and is correlated with a part of Ochelata fm.

Richter Mountain hornblendite.

Age (?): Southern British Columbia and central northern Washington.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 433). Cuts Anarchist series (Carbf.?).

Ricker sandstone member (of Mineral Wells formation).

Pennsylvanian: Central Texas (Brown County, Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 386). *Ricker bed.*—Ss. and cgl., 50 to 200 ft. thick, with 25 to 75 ft. of sandy clay at top; usually of bluish color, though purple or yellowish clays occur. Top memb. of Strawn div. Overlies Indian Creek bed and underlies Canyon div.

Wallace Lee and C. O. Nickell (Univ. Tex. Bull. about to go to press) included *Ricker ss. memb.* in Mineral Wells fm., the upper fm. of Strawn group.

Named for Ricker, Brown Co.

Ricketts oil sand.

A subsurface sand in lower part of Penn. section in Graham field, NW. part of Carter Co., southern Okla., 78 to 125 ft. below Atlantic oil sand and 54 to 110 ft. above Graham oil sand.

Rico formation.

Permian: Southwestern Colorado, southeastern Utah, and northwestern New Mexico.

W. Cross, 1899 (U. S. G. S. Telluride folio, No. 57). In Rico quad. an invertebrate fauna has been found in lower 200 or 300 ft. of "Red Beds," which is assigned by G. H. Girty to Permo-Carbf., in the sense of a transition series. The complex of strata characterized by this fauna will be described as *Rico fm.* In absence of fossil evidence the red strata btw. the Rico Permo-Carbf. and the overlying beds containing Triassic remains are grouped with latter, here named *Dolores fm.*

W. Cross, 1899 (U. S. G. S. La Plata folio, No. 60, p. 8). [See 1st entry under *Hermosa fm.*]

A. C. Spencer, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 59). It is here proposed to apply the name *Rico* to a fm. assumed to be about 300 ft. thick, occurring btw. the Hermosa or characteristic Penn. Carbf. and strata assigned at present to Trias of San Juan region—the *Dolores fm.* The Rico is composed of sss. and cgls. with intercalated shales and sandy fossiliferous lss. In Rico region is conformable on Hermosa and is followed by the Dolores with seemingly perfect parallelism of stratification. The bdy btw. Rico and Dolores fms. is at present entirely artificial, being based upon highest known occurrence of Rico fossils. [In 1905 the Dolores fm. as first defined was divided into Cutler fm. below and Dolores fm. (restricted) above. (See under *Cutler fm.* and *Dolores fm.*) The fm. that overlies Rico fm. is therefore now called *Cutler fm.*, instead of *Dolores*.]

W. Cross, 1905 (U. S. G. S. Rico folio, No. 130). *Rico fm.*—Consists of 300 ft. of sss. and cgls. with intercalated sandy shales and thin fossiliferous sandy lss.; color chocolate or dark maroon. Rests conformably on Hermosa fm. Conformably overlain by Cutler fm., which comprises lower 1,600 ft. of Dolores fm. as originally defined. Base of Rico fm. can usually be very accurately located in field by its lowest fossil-bearing stratum. The bdy btw. Rico and Cutler fms. is, however, quite arbitrary, being based on highest known occurrence of Rico fossils. The former is made to include only that part of the section characterized by the Permo-Penn. fauna, while the Cutler comprises the apparently unfossiliferous "Red Beds" of this region, extending to horizon at which Triassic fossils are known to occur. The fm. was named by A. C. Spencer.

Where the lss. of Rico fm. are absent in SE. Utah, the red beds corresponding to Rico fm. are now included in Cutler fm. (See U. S. G. S. Bull. 863, 1935, by C. H. Dane.)

Named for exposures in Rico Mtns, Colo.

Riddlesburg shale member (of Pocono formation).

Mississippian: Western Pennsylvania (Bedford County) and southwestern Virginia (Alleghany County).

D. B. Reger, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 156–157, abstract, March; vol. 38, pp. 397–410, June 30). In type section, 1½ mi. N. of Riddlesburg, Bedford Co., Pa., the *Riddlesburg sh.* consists of 75 ft. of greenish-black siliceous sh., exfoliating into pencil forms, with marine fossils in lower part. Included in Pocono series, lying 410 ft. below base of Logan (Burgoon) ss., the top div. of Pocono series. Overlain by 20 ft. of green ss. and underlain by 15 ft. of greenish-gray shaly ss. Also present 1½ mi. SE. of Saxton, Bedford Co., and probably near Hopewell, Bedford Co. Preserves its lithology NE. to Lehigh Valley, but loses its fauna. What seems to be same black sh. occurs also in Alleghany Co., Va., along Chesapeake & Ohio Ry btw. Alleghany Station and Lewis tunnel, but with a somewhat changed fauna.

Rideau sandstone.

Ordovician: Ontario, Canada.

H. M. Ami, 1902 (Sci., vol. 15, p. 82). *Rideau ss.* overlies pre-Camb. rocks and is succeeded, without break, by Birdseye, Black River, and Trenton.

See also Ont. Bur. Mines, 25th Ann. Rept., pt. 3, pp. 2, 40, 1916; Canada Geol. Surv. Econ. Geol. ser., No. 9, p. 21, 1932.

G. M. Kay, 1935 (Geol. Soc. Am. Bull., vol. 46, p. 227), included *Rideau* in Pamelia and tentatively included Pamelia in Black River group, at base.

Ridenhower shale. (Of Chester group.)

Mississippian: Southeastern Illinois and western Kentucky.

C. Butts, 1917 (Ky. Geol. Surv., Mississippian fms. of western Ky., pt. 1, p. 73). *Ridenhower sh.*—Predominantly sh. Underlies Cypress ss. and overlies Bethel ss. in Crittenden and Livingston Counties, Ky., and in southern Ill. Named, at suggestion of S. Weller, for Ridenhower, Johnson Co., Ill., where it is 60 ft. thick and includes considerable ls., which is fairly fossiliferous, and some thin sss. The Gasper oolite is not known W. of E. part of Crittenden Co., Ky. The Ridenhower is regarded = in part at least Gasper oolite, but possibly represents only upper part of Gasper.

Riders Brook formation.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Riders Brook fm.*—Gray sandy ls. carrying *Bellerophon randomi.* Overlain by sh. Forms top fm. of Clarenville series. Overlain discon. by Kelly Island fm. and underlain by Maidment fm. [Derivation of name not stated.]

†Ridge limestone.

A descriptive term locally applied to Nineveh ls. memb. of Greene fm. of Pa.

Ridgeley sandstone. (In Oriskany group.)

Lower Devonian: Central Pennsylvania to central western Virginia and eastern West Virginia.

C. K. Swartz et al., 1913 (Md. Geol. Surv. Lower Devonian vol., p. 92 and table opp. p. 30). *Ridgely ss. memb.*—Calc. ss., which passes into an aren. ls. Top memb. of

Oriskany fm. Thickness 50 to 250 ft. Closely resembles Oriskany of N. Y. in lithology and fauna. Overlies Shriver chert memb. and uncon. underlies Romney fm., which contains Onondaga fauna in basal beds. Named for Ridgely, W. Va. [This town is spelled *Ridgeley* in U. S. Postal Guide, and that is spelling adopted by U. S. Geographic Board in 1924.]

Ridgely sand.

A subsurface sand in Pottsville fm. (Penn.) of Lawrence Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

†Ridgely sandstone.

Lower Devonian: Pennsylvania, Maryland, Virginia, and West Virginia. See *Ridgeley ss.*, the approved spelling.

Ridgetop shale.

Mississippian (early): Western Tennessee (Tennessee Valley region).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29). *Ridgetop sh.* [Shown in chart as overlying Chattanooga sh. and uncon. underlying New Providence fm.]

R. S. Bassler, 1911 (U. S. Nat. Mus. Proc., vol. 41, p. 216). *Ridgetop sh.* (*Kinderhook*).—Underlies Fort Payne chert and overlies Maury green sh. Locally developed along N. and W. sides of Nashville dome. In section along Louisville & Nashville R. R. from Bakers to Ridgetop, the fm. consists of (descending): (1) Light-blue to green clay sh. holding many ostracodes and brachiopods, 15 to 20 ft.; (2) aren. sh. with bands of porous chert, yielding silicified fossils, 2 ft.; (3) light-blue to green sh. with same fossils as in No. 1, 36 ft.; (4) unfossiliferous blue sh., 4 ft.; (5) thin-bedded argill. ls. and compact dark sh. with many fossils, 5 ft.; (6) dark compact clay sh. with few fossils, 15 ft.; (7) fine-grained argill. ss. weathering red and forming a conspicuous line in the section, 1 ft.; (8) light-blue to green unfossiliferous sh., 20 ft.; and (9) sandy unfossiliferous chert, 1 ft. All these beds were included in Tullahoma by Safford and Killebrew and by Hayes and Ulrich, but they represent a distinct group—the Kinderhook—and hence the new name *Ridgetop sh.* is proposed. In section 12 mi. N. of Nashville 35 ft. of New Providence fm. intervenes btw. Ridgetop sh. and Fort Payne chert.

N. F. Drake, 1914 (Tenn. Geol. Surv. Res. of Tenn., vol. 4, No. 3, p. 105), included in base of Ridgetop sh. of Waynesboro quad. the Maury glauconitic memb., a thin bed closely associated with overlying sh. and carrying similar fossils. There is some question whether the Ridgetop of Hardin Co. is of same age as typical Ridgetop.

R. S. Bassler, 1932 (Tenn. Dept. Ed., Div. Geol. Bull. 38, p. 144). More recent study of type section of Ridgetop sh. (along Louisville & Nashville R. R. btw. Bakers and Ridgetop) has shown that upper 30 ft. of supposed Ridgetop held the bryozoan fauna of New Providence sh. These New Providence beds consist of blue calc. sh. with occasional thin argill. ls. bands with 2 ft. of sandy layers at base, and they are here called *New Providence sh.*, and *Ridgetop sh.* is restricted to the underlying beds, consisting of (descending): (1) Gray-green sh. becoming calc. toward top, 12 ft.; (2) blue-green to gray-green soft sh. with 6-in. glauconite band at top and at base, 4 ft.; (3) gray-green siliceous sh., 10 ft.; (4) siliceous ls. with conchoidal fracture weathering yellow and containing Ostracoda, 1 to 2 ft.; (5) calc. green and finely sandy gray-green sh. with a few geodes in upper half and ostracodes in several layers, 20 ft.; (6) yellow platy chert with fossils [listed], 1 to 1.3 ft.; (7) green sh. with phosphated nodules 0.5 to 1 ft.; (8) green sh. passing gradually downward into black Chattanooga sh., 0.25 to 0.33 ft.

C. W. Wilson, Jr., and E. L. Spain, Jr., 1936 (Geol. Soc. Am. Proc. 1935, p. 375). Faunal and strat. studies show "Ridgetop sh." to be a phase of New Providence fm., and to be of Fern Glen, rather than Kinderhook, age, as previously assigned. Of 22 sp. of invertebrates collected by writers from this sh. at its type loc. (Ridgetop Station, Robertson Co., Tenn.), 21 commonly occur in Fern Glen or younger beds, and 3 occur also in the Kinderhook, but only 1 is typically Kinderhook. Detailed tracing of beds through the 5 mi. btw. type loc. of "Ridgetop sh." and the local type loc. of New Providence fm. shows that the drab-green and gray siltstones of the "Ridgetop" can be traced laterally into green sh. and the local crinoidal ls. lenses of the New Providence. Similar lateral correlation has been made at other localities in central Tenn. The green sh., the local crinoidal ls., and the drab siltstone (that was formerly separated as "Ridgetop") of New Providence fm., contain fossils characteristic of each different facies, but all are predominantly of Fern Glen age. [Type loc. of New Providence fm. is in Clark Co., Ind.]

Named for Ridgetop, Robertson Co.

Ridgway till.

Ridgway glacial epoch.

Eocene: Southwestern Colorado.

W. W. Atwood, 1915 (U. S. G. S. P. P. 95, p. 16, map). *Ridgway till.*—Upper memb. is pebble till; lower memb. is boulder till. Type loc. is 1 mi. W. of Ridgway, where the till is overlain by Telluride cgl. (of Eo. age) and underlain by Mancos sh.

W. W. Atwood and K. F. Mather, 1932 (U. S. G. S. P. P. 166). A long erosion interval separates *Ridgway till* from underlying Animas fm., of late Cret. or earliest Tert. age.

†Ridgway shale member.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). [See 1933 entry under *Knapp fm.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 61, 112), replaced this preoccupied name with *East Kane sh.*

Riding Mountain beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 124).

Ridley limestone. (In Stones River group.)

Lower Ordovician: Central Tennessee.

J. M. Safford, 1869 (Geol. Tenn., pp. 258–267). *Ridley ls.*—Heavy-bedded light-blue or dove-colored fossiliferous ls., 95 ft. thick. Included in Trenton or Lebanon [Stones River] group. Underlies Glade [Lebanon] ls. and overlies Pierce ls.

Named for Judge Ridley's mill (now Davis's mill), near Old Jefferson, Rutherford Co.

Ridout series.

Pre-Cambrian (Keewatin): Ontario.

W. H. Collins, 1933 (Canada Geol. Surv. map 155A, 3d ed., Lake Huron sheet, Pub. 1553).

H. C. Rickaby, 1933 (Canadian Min. and Met. Bull. 253, p. 207).

Rift shale. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 217). *Rift sh.*—Dark gray, laminated, argill., with siliceous layers carrying thin lenses of iron ore. Thickness 15 to 30 ft. Underlies Flattop Mtn ss. and overlies Pocahontas No. 7 coal. Exposed at Rift, McDowell Co.

†Riga schist.

Ordovician: Northwestern Connecticut and southwestern Massachusetts.

W. H. Hobbs, 1893 (Jour. Geol., vol. 1, pp. 717–736, 780–802). *Riga schist.*—Porphyritic rock, strictly speaking a gneiss, but in order to distinguish it from more feldspathic and more or less granitoid gneisses lying E. of Housatonic River, it is best to refer to it as a schist, which it most resembles in structure. Underlies Egremont ls. and overlies Canaan dol. Most typically developed on Mount Riga Peak, Conn. Correlated [correctly] with Berkshire schist. Included in Mount Washington series.

Same as Berkshire schist. The supposedly overlying "Egremont ls." is now known to be a local bed of Stockbridge ls., which underlies Berkshire schist. See U. S. G. S. Bull. 597, 1917, and Conn. Geol. Surv. Bull. 7, 1907, in which this schist is mapped as Berkshire schist.

†Riley series.

Upper Cambrian: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxi, 286–289). *Riley series.*—In general sss., light red, shiny black, brown, yellow, and white. Includes some compact light-colored ls. Thickness probably 300 to 400 ft. Uncon. overlies Hickory series and uncon. underlies Katemcy or "Potsdam" series.

Includes Hickory ss. and part of Cap Mtn fm. of present nomenclature. Named for Riley Mtns, Llano Co.

Riley sand.

A subsurface sand, of Upper Dev. (Chemung) age, in W. Va. that lies at or near horizon of Cooper sand.

Rincon shale.

Miocene (middle or lower): Southern California (coastal region from Ventura to Santa Barbara).

P. F. Kerr, 1931 (Econ. Geol., vol. 26, No. 2, pp. 156, 157). *Rincon fm.*—A sequence of gray sh. containing concretionary dolomitic layers, underlying the bentonite bed at base of Modelo fm. in Ventura quad., and overlying Vaqueros fm. Thickness 2,150± ft. as exposed in a type section along Los Sauces Creek E. of Rincon Mtn, Ventura Co.

W. P. Woodring, 1932 (16th Int. Geol. Cong. Guidebook 15, pl. 2), showed *Rincon sh.* as (1) underlying Modelo fm. and overlying Vaqueros ss. on S. slope of eastern Santa Ynez Range; (2) as in part equiv. to Topanga fm. in Santa Clara and Simi Valleys, and as both underlain and overlain by Topanga deposits. He stated (personal communication) that in his opinion Rincon and Topanga fms. are two distinct facies, with distinct faunas, and that the Rincon facies is not present in type Topanga, but that it includes time equiv. of at least part of the Topango and of upper part of Vaqueros.

W. S. W. Kew, 1932 (16th Int. Geol. Cong. Guidebook 15, p. 50). *Rincon fm.* is a well-defined strat. unit that can be traced along the coast for nearly 100 mi. Consists essentially of dark-gray clay sh. or mudstone, which commonly contains concretions of impure yellow ls. and carries Foraminifera of late lower or early middle Mio. age. Thickness 300 to 2,000 ft. Underlies Modelo fm. and overlies Vaqueros fm.

R. M. Kleinpell, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 165), stated that foraminiferal fauna of uppermost typical Vaqueros fm., middle typical Rincon fm., and lower middle typical Temblor fm. is of equiv. age and characteristic of a distinct subzone.

Rincon limestone.

Upper Cambrian: Southeastern Arizona (Whetstone Mountains).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 469, 471, 472, 480–482). *Rincon ls.*—Youngest Upper Camb. fm. in Whetstone Mtns. Is cliff-forming pink, mostly crystalline ls. carrying *Billingsella coloradoensis* and abundance of other fossils. Thickness 42 ft. Overlies Abrigo fm. [as here restricted] and underlies Martin ls. (Dev.). Type loc., Rincon Mtns, 25 mi. SE. of Tucson. Correlated with Copper Queen ls. (new) of Bisbee dist. and with Peppersauce Canyon ss. (new) of Santa Catalina Mtns. [See last sentence under *Peppersauce Canyon ss.*]

Rindgemere formation.

Carboniferous (Pennsylvanian?): Southwestern Maine and southeastern New Hampshire.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 199). *Rindgemere fm.*—Qtzite, slates, and mica schists, but predominantly carbonaceous sericite phyllites which contain chiastolite. Occupies broad area in Rochester, N. H., and Acton and Lebanon [Twps], Maine.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, pp. 173–175). *Rindgemere fm.*—Sl., phyllite, and schist derived from somewhat carbonaceous sh. and argillite, with subordinate amounts of interbedded argill. qtzite, graywacke, and ls. Generally thin-bedded and fine-grained. White and light-gray or bluish colors in qtzite, graywacke, and ls. beds; dark bluish, gray, and black in argill. beds. Estimated thickness about 1,000 ft. Underlies Towow fm. Believed to overlie Gonic fm. Assigned to Penn. (?). Named for exposures at Rindgemere Station (East Rochester), Strafford Co., N. H.

Ringold formation.

Probably Pleistocene: Southeastern Washington (Franklin County) and northwestern Oregon.

J. C. Merriam and J. P. Buwalda, 1917 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 10, No. 15, pp. 255–266). *Ringold fm.*—Chiefly light-colored muddy sss. and sandy clays, and in minor part fine gravels, volcanic ash, and calc. strata. [Detailed section.] From 12 mi. above town of Pasco, bluffs several hundred ft. high extend 30± mi. NW. along E. bank of Columbia River. Because of their light color these magnificent exposures have commonly been known as the White Bluffs. They clearly represent a fm. distinct from the Ellensburg, as indicated by their faunas and by the physical evidence. Known thickness is 500± ft., but as Columbia River has not cut down to base of the fm. the total thickness is not known. Appears to occupy an area of at least 300 sq. mi. and may extend over 500 or 600 sq. mi. These beds have formerly been included in Ellensburg fm. [Miocene] as that name has been applied in this area, but they are now known to be younger than Ellensburg, and evidence favors Pleist., rather than latest Plio., as their age. Named for Ringold P. O., which is situated at base of the White Bluffs.

Rio conglomerate.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 278).

Rio Blanco series.

Cretaceous: Puerto Rico.

B. Hubbard, 1923 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 1, p. 26).

Rio Culebrinas series.

Cretaceous: Puerto Rico.

B. Hubbard, 1923 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 1, p. 25).

Rio de la Plata series.

Lower Cretaceous: Puerto Rico.

E. T. Hodge, 1920 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 2, p. 130).

Rio Descalabrados series.

Eocene: Puerto Rico.

E. T. Hodge, 1920 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 2, p. 161).

Rio Dulce limestone.

Miocene: Guatemala and British Honduras.

C. Schuchert, 1935 (Hist. geol. of Antillean-Caribbean region, pp. 346, 355).

Rio Grande series.

Tertiary (late): Central northern New Mexico (Albuquerque region).

C. L. Herrick, 1898 (Am. Geol., vol. 22, pp. 26–43), called the river gravels overlying Cret. sss. and shales in environs of Albuquerque *Rio Grande series*, also *Albuquerque series*, and divided them into (descending): (1) Yellowish white marl, 6 ft., "which occurs on both sides of Rio Grande, and which may henceforth be known as the *Albuquerque marl*;" (2) gravel and rounded sands, 2 to 20+ ft. thick, evidently the debris from the metamorphic series, and designated "*Rio Grande gravels*;" (3) sandy loess passing into clay, depth not known, but recognized everywhere, designated "*Rio Grande loess.*"

K. Bryan, 1909 (N. Mex. Univ. Bull., geol. ser., vol. 3, No. 1). *Rio Grande gravels* extend up Galisteo Creek and form part of group described there as *Santa Fe marl.* One of most prominent features of deposits of valley is the marl bed which caps the mesas. That over Sandia Mesa has been described by Herrick as *Albuquerque marl*, while that on Albuquerque Mesa he called *Santa Fe marl.* It seems best to place both under one name—*Albuquerque marl.* [See also under *Rio Grande loess.*]

Rio Grande gravels.

Tertiary: New Mexico.

C. L. Herrick, 1898. [See under *Rio Grande series.*]

K. Bryan, 1909 (N. Mex. Univ. Bull., geol. ser., vol. 3, No. 1). [See under *Rio Grande series.*]

Rio Grande loess.

C. L. Herrick, 1898. [See under *Rio Grande series.*]

K. Bryan, 1909 (N. Mex. Univ. Bull., geol. ser., vol. 3, No. 1). The term "Rio Grande loess" was applied by Herrick to the portion of Rio Grande beds exposed underneath the Rio Grande gravels. The term does not seem applicable, for reason that these stratified silts and sands can hardly be called loess.

†Rio Grande series.

Pennsylvanian: New Mexico.

A time term used by C. R. Keyes (Rept. Gov. N. Mex. to U. S. Secy Interior, 1903) to cover 500 ft. of Penn. lss. which he calls Madera terrane.

Rio Grande marl.

See 1903 entry under *Placita marl.*

Rio Grande drift.

Pleistocene: Southwestern Texas (Presidio County).

J. A. Udden, 1904 (Tex. Univ. Min. Surv. Bull. 8, p. 41, on Shafter dist.). As we approach the flats of the Rio Grande the bedrock everywhere disappears under a drift, which at first seems to be a continuation of the land drift, but which, as we come near to the great waterway, becomes mingled with material of distant origin. Still farther out this becomes intermingled with layers of finer alluvial material which has been deposited by that stream before it had cut its changing channel down to its present depth. All of this material may properly be called the *Rio Grande drift.*

Rio Jueyes series.

Eocene: Puerto Rico.

E. T. Hodge, 1920 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 2, p. 149).

Rio Yauco series.

Cretaceous: Puerto Rico.

G. J. Mitchell, 1922 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 3, p. 249).

Ripley formation.

Upper Cretaceous: Southern Illinois, southeastern Missouri, western Kentucky and Tennessee, northern and central Mississippi, Alabama, and Georgia.

E. W. Hilgard, 1860 (Geol. and Agric. Miss., pp. 3, 62, 83–95). *Ripley group.*—Consists of (1) hard crystalline white lss., generally somewhat sandy, and often glauconitic; underlain by (2) black or blue micaceous marls containing admirably preserved fossils. Thickness 45 to 50 ft. Uppermost Cret. fm. Underlies Northern Lignitic group and overlies Rotten ls. group. [The hard crystalline white lss. described by Hilgard as composing upper part of Ripley group are of Eocene (Midway) age, according to L. W. Stephenson, and were long ago separated from the Ripley and named *Clayton fm.*]

L. W. Stephenson, 1914 (U. S. G. S. P. P. 81). The typical beds of *Ripley fm.* consist of more or less calc, and glauconitic sands, sandy clays, impure lss., and marls of marine origin, reaching estimated max. thickness of 250 to 350 ft. in eastern Gulf region. Rest conformably in part upon Paleozoic rocks, in part upon Eutaw fm. (in Tenn.), and in part upon Selma chalk. In some areas Ripley replaces Selma chalk and upper part of Eutaw fm. and rests on Tombigbee sand memb. of Eutaw. Includes McNairy sand memb. [See also L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26), and 1917 (Wash. Acad. Sci. Jour., vol. 7, No. 9).]

Later the Owl Creek deposits (which overlie the McNairy sand memb. of the Ripley in western Tenn. and NE. Miss.) were treated as a tongue of Ripley fm. (See L. W. Stephenson, Wash. Acad. Sci. Jour., vol. 7, 1917, pp. 243–250, and many subsequent repts.) In April 1937 L. W. Stephenson and W. H. Monroe proposed (and U. S. Geol. Survey adopted): (1) The elev. of Owl Creek to rank of a fm., called *Owl Creek fm.*, and the corresponding restriction of Ripley fm. to the beds beneath the Owl Creek and the Prairie Bluff deposits; and (2) the restriction of Selma chalk to the beds underlying the Prairie Bluff, the chalk beds formerly called *Oktibbeha tongue of Selma chalk* to hereafter be included in Prairie Bluff chalk (redefined) and "Oktibbeha" to be discarded. (See L. W. Stephenson and W. H. Monroe, A. A. P. G. Bull., 1937.)

Named for Ripley, Tippah Co., Miss.

Ripleyan series.

A term applied by C. [R.] Keyes to *Ripley fm.* (See Iowa Acad. Sci. Proc., vol. 22, 1915, p. 252.)

Ripogenous series.

Silurian: Western Maine (Piscataquis County).

F. W. Toppan, 1932 (Geol. of Maine, Contr. Dept. Geol. Union Coll., Schenectady, pp. 71–72). *Ripogenous series.*—In ascending order: Coarse grit, 15 ft.; sandy ls. with a few ft. of greenish banded qtzite and Niagara fossils, 50± ft.; clean white qtzite, 50± ft.; a monotonous series of gray-green qtzites. Thickness 2,000± ft. Exposed in Ripogenous Gorge, where it is intruded by Katahdin granite, just below the prominent rock known as the "Little Heater." [On p. 93 he said the lss. occur at Ripogenous.]

Ripple quartzite.

Pre-Cambrian: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines Mem. 38, map 7, 117° to 117°30'). *Ripple fm.*—Massive white qtzite. Underlies Beehive fm. and overlies Dewdney fm.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 155, tables at 178, 194). *Ripple fm.*—Heavy-bedded rippled white qtzite, 1,650 ft. thick. Forms summit of Mount Ripple, B. C. Conformably underlies Beehive fm. and conformably overlies Dewdney fm., all of which belong to Summit series of Selkirk Mtns at 49th par.

Ripton conglomerate.

Pre-Cambrian: Northwestern Vermont (Addison County, Brandon quadrangle).

W. G. Foye, 1919 (11th Rept. Vt. State Geol., pp. 84–85, in description of Rochester quad.). *Ripton cgl.* is basal layer of Mendon series (Algonkian). Is iron-gray and contains distorted and elongated pebbles of blue quartz, phyllite, and gneiss. To E. it is so metamorphosed that its conglomeratic appearance is lost.

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., p. 284). *Ripton cgl.*—Quartz-mica schist showing pyrite in striking amounts, muscovite, microcline, and microperthite; in places looks like augen gneiss. Is Lower Camb.

See also L. M. Prindle and E. B. Knopf, Am. Jour. Sci., 5th, vol. 24, p. 266, 1932, who assign Mendon schist to pre-Camb.

Ripton is in Brandon quad., Addison Co.

Rising Bull member (of Grinnell argillite).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Rising Bull memb.*—Upper memb. of Grinnell fm. Consists of 425 to 750 ft. of dark-red to greenish metargillite, in beds 1 to 3 ft. thick, showing slaty cleavage, interbedded with red, gray, white, and greenish qtzite and cgl. Argillite balls abundant in some qtzite layers. Mud cracks and coarse current ripple marks common. Some layers bear rain prints. Qtzite increasingly prevalent toward top. Base intergrades with Red Gap memb. (lower memb. of Grinnell fm.). [Derivation of name not stated.] Well exposed along trail over Gunsight Pass, in Two Medicine region, and on mtns bordering Swift Current Valley.

Rising Wolf member (of Appekunny argillite).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Rising Wolf memb.*—Top memb. of Appekunny fm. Consists of 200 to 500 ft. of thick-bedded greenish to red qtzite, with subordinate beds of gray and reddish metargillite. Mud cracks and ripple marks common. The metargillites contain much sand in thin sheets and lenses. Overlies Appistoki memb. of Appekunny fm. Is exposed on S. flank of Rising Wolf Mtn and on many other peaks.

Ritchie red beds. (In Monongahela formation.)

Pennsylvanian: Northern West Virginia and eastern Ohio.

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 30, 44). *Ritchie red beds* (also *Ritchie reds*).—Underlie Uniontown coal bed or its place, and overlie Tyler red beds. Have been reported from southern Marshall, Marion, Wetzel, Doddridge, Tyler, Ritchie, Jackson, southwest Harrison, and northeast Gilmer [Counties] of W. Va., as well as Washington, Monroe, Meigs, and Guernsey [Counties] of Ohio. Are seldom more than 20 ft. thick in Ohio, and at times continuous with Tyler reds below. Chief area is in Ritchie [Co.], W. Va.

Rittman conglomerate lentil (of Cuyahoga formation).

Mississippian: North-central Ohio (Wayne County).

G. W. Conrey, 1921 (Ohio Geol. Surv., 4th ser., Bull. 24, p. 56). *Rittmann cgl. lentil of Cuyahoga fm.*—At Rittmann, Wayne Co., consists of (descending): (1) Medium-grained grayish-buff fossiliferous ss. with pebbles, 1 ft. 3 in.; (2) brown sh., 4 in.; (3) coarse cgl., 6 in.; (4) coarse-grained ss., in part conglomeratic, 1 ft.; (5) fine-grained ss., 2 ft.; (6) yellowish green ss., 1 ft. 4 in. Underlies 2 ft. of Armstrong memb. [P. O. Guide spells the town *Rittman*.]

River John series.

Mississippian: Nova Scotia.

W. A. Bell, 1926 (Canada Geol. Surv. Summ. Rept. 1924, pt. C, p. 158). [Assigned to Carbf.]

J. S. Stewart, 1932 (Nova Scotia Dept. Pub. Works and Mines Ann. Rept. on Mines, 1931, pt. 2, p. 36). River John series assigned to Miss.

River Portal mica schist.

Pre-Cambrian: Central western Colorado (Gunnison River region).

J. F. Hunter, 1925 (U. S. G. S. Bull. 777). Quartz-mica schists of metamorphic complex of Gunnison River region found on Vernal Mesa and along adjacent portion of Black Canyon from a little more than 1 mi. E. of mouth of Cimarron Creek to beginning of Vernal Mesa granite mass, in vicinity of Big Draw and Grizzle Gulch. These rocks may for convenience of description be divided into 2 types—the mica schists proper, with local quartzose phases, and the quartz-mica schists of Mesa Creek zone. The portion of the Black Canyon walled by these rocks is one of wildest and most picturesque along the Gunnison, being in few places less than 1,000 ft. deep. Named for excellent exposures in vicinity of the river portal of Gunnison tunnel. Might be regarded as a part of Black Canyon schist, or may be younger.

On 1935 geol. map of Colo. this fm. was assigned to Gunnison River series (pre-Camb.), which comprises all of oldest exposed sed. and igneous rocks in Colo.

†River Quarry beds.

Middle Ordovician: Southwestern Ohio.

E. Orton, 1873 (Ohio Geol. Surv. vol. 1, pp. 370–387). *River Quarry beds.*—Alternating beds of thin-bedded compact crinoidal blue ls. and blue sh., 50 or 75 ft. thick, forming lowest div. of Cincinnati beds proper. Inferior limit low water of the Ohio at Cincinnati. Overlain by Eden sh. and underlain by Point Pleasant beds; all included in Cincinnati group.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, pp. 53+). Point Pleasant beds are same as River Quarry beds. Unquestionably of Trenton age.

Named for river quarries at Cincinnati.

Riversdale formation.

Carboniferous: Canada.

H. M. Ami, 1900 (Canadian Rec. Sci., vol. 8, pp. 154–160).

Riverside sandstone.

Mississippian: Western and southern Indiana.

T. C. Hopkins, 1896 (Ind. Dept. Geol. and Nat. Res. 20th Ann. Rept., pp. 196, 317, pl. 9). *Riverside ss.*—Fine-grained impure ss. [thickness not stated] forming topmost Miss. fm. in Fountain Co., where it is uncon. overlain by Mansfield ss. and underlain by Miss. lss. and shales with some sss. Included in Knobstone group. Quarried at Riverside [Fountain Co].

E. M. Kindle, 1899 (Bulls. Am. Pal., vol. 3, No. 12). *Riverside ss.* in southern Ind. consists of 200 ft. of massive sss. and sandy shales overlying New Providence sh. and underlying Harrodsburg ls.

J. F. Newsom, 1903 (Ind. Dept. Geol. and Nat. Res. 26th Ann. Rept.). Knobstone group of Ind. divided into (descending): Knobstone ss. (called "Riverside ss." by Hopkins and quarried at Riverside), 75 to 450 ft.; Upper Knobstone sh., 200 to 250 ft.; New Providence sh., 50 to 120 ft.

T. C. Hopkins, 1904 (Ind. Dept. Geol. and Nat. Res. 28th Ann. Rept.). New Providence sh.=*Riverside ss.*, which should be abandoned.

H. S. Williams and E. M. Kindle, 1905 (U. S. G. S. Bull. 244, pl. 1, pp. 17–19). *Riverside ss.*—Massive to shaly ss. and sandy shales, with 1 to 10 ft. of oolitic ls. in upper part. Thickness 200 ft. Underlies Harrodsburg ls. and overlies New Providence sh.

E. R. Cumings, 1912 (Ind. Acad. Sci. Proc. for 1911, pp. 111+). Upper 100 ft. of Knobstone fm. is known as *Riverside ss.* It underlies Harrodsburg ls. and overlies New Providence sh., which is 400 to 500 ft. thick.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, p. 150). *Riverside ss.* of Ind. is represented in Rosewood sh. and probably in lower part of Holtsclaw ss.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, p. 76). At Borden, Clark Co., Ind., the upper 100 ft. or so of Keokuk rocks is ss., of which upper 20 ft. is rather massive and probably represents Holtsclaw ss., while lower 80 ft. probably represents upper part of Rosewood sh. and may be same as *Riverside ss.* of Ind. repts.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 490). It seems very probable that Holtsclaw is a synonym of *Riverside*, and writer has therefore given latter name preference.

W. N. Logan, 1923 (Pan-Am. Geol., vol. 40, p. 111), and 1926 (Ind. Dept. Cons., Div. Geol., Pub. 55, p. 8), applied *Riverside ss.* to ss. underlying Harrodsburg ls. and overlying Rosewood sh., or to Holtsclaw ss. of Butts.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 293). The original "Riverside ss." of Hopkins (1896, pp. 196, 293–297) is northern Ind. representative of Edwardsville fm. and not=Holtsclaw ss., but younger. There are several reasons for not continuing the use of "Riverside ss." for a subdivision of fm. rank in Borden group. In first place the name is from a locality remote from the unglaciated region of abundant exposures in southern Ind. Writer has selected all fm. names of Borden group from southern area, where the relations of the fms. to one another are seen within short distances. Also, at type loc., in quarries near

Riverside, the strat. boundaries of fm. are not shown, the bottom not being reached and the top eroded. Hopkins himself applied the name to rocks much lower than those intended by definition, and other geologists have applied the name to various Borden units. The rock in quarries at Riverside is of Edwardsville age. Fauna in upper part resembles that in Mount Ebel ss. memb. Hopkins recognized that the stone at Riverside is very different from any Borden stone in S. part of Ind., being a quarry ss. of commercial value. Since the rock is somewhat different, as well as quite remote from the Edwardsville facies, the writer proposes to call it *Riverside ss. facies of Edwardsville fm.* In quarry ¼ mile SW. of Riverside, Fountain Co., its exposed thickness is 50 ft.

Riverside sand.

Tertiary (Miocene?): Northwestern Iowa.

H. F. Bain, 1896 (Iowa Geol. Surv., vol. 5, pp. 255, 277–279). *Riverside sands.*—[Name used, in table only, for coarse white sand in Woodbury Co., Iowa, that is described (pp. 277–279) as containing small pebbles, chiefly granitic, with chips of wood and a few fossils. In general character resembles Neocene or Plio. sands a few mi. to W. in Nebr. and S. Dak. Age doubtful. Overlain uncon. by Kansan drift and underlain uncon. by Cret.]

According to C. [R.] Keyes (1912, 1913, 1914) this sand is of Mio. age, and an eastward outlier of Arikaree fm.

Named for Riverside, Woodbury Co.

Roan gneiss.

Pre-Cambrian: Western North Carolina, northwestern South Carolina, eastern Tennessee, and northern Georgia.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 2). *Roan gneiss.*—Hornblende gneiss, hornblende schist, and diorite, with some interbedded mica schist and gneiss. Chiefly hornblende schists. The hornblendic beds are dark greenish or black; the micaceous beds dark gray. The mica schist and gneiss beds range in thickness from few in. to 100 ft., and are frequent only near Carolina gneiss, into which they form transition. Assigned to Archean. Appears to cut Carolina gneiss, but contacts so metamorphosed that the fact cannot be proved. [Is now known to cut Carolina gneiss.]

Named for development on Roan Mtn, Carter Co., Tenn.

Roaring Branch sandstone. (In Pocono formation.)

Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 56–57, 235). Buffish-white and massive ss., 125 ft. thick. Overlain by 200± ft. of buff sandy shales and underlain by *Roaring Branch shales* (265 ft. of shales with gray current-bedded sss.). All included in Pocono. Along Roaring Branch it is an uninterrupted pile of layers from 1 to 4 ft. thick, of moderately fine-grained, very hard, somewhat current-bedded buff-colored ss. [On pp. 56–57 he calls this ss. *Lackawanna ss.*; on p. 235 he calls it *Roaring Branch ss.*]

Roaring Branch shales. (In Pocono formation.)

Mississippian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 56–57, 235). [See under *Roaring Branch ss.*]

†Roaring Creek sandstone. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 462). *Roaring Creek ss.*—Very massive and often pebbly ss., 50 to 200 ft. thick, cropping a short distance below Upper Freeport coal [not Upper Freeport]. Well developed along Roaring Creek, Randolph Co., forming the falls of that stream, 50 ft. or more in height. Appears to be same as Upper Freeport ss.

This name is no longer in use, the equivalency of the ss. along Roaring Creek to Homewood ss. memb. having been established many years ago.

Robbins shale member.

Pennsylvanian: Southeastern Kansas.

R. C. Moore and N. D. Newell, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, 153, etc.). *Robbins sh. memb. of Stranger fm.*—Marine gray argill. and silty sh., 1 to 100 ft. thick, forming top memb. of Stranger fm. in southern Kans. In Chautauqua Co. some massive ss. beds appear abruptly in the Robbins and probably continue into Okla. Is uncon. overlain by Ireland ss. and underlain by Haskell ls. Heretofore included in Lawrence sh., but uncon. at base of Ireland ss. memb. of Lawrence sh. restricted extends clear across Kans. Therefore Lawrence sh. is restricted to beds above the uncon. Type loc., the Robbins farm, in sec. 11, T. 26 S., R. 15 E., SW. of Yates Center, Kans.

Roberts sand.

Miocene (?): Southwestern Alabama.

W. H. Dall and J. Stanley-Brown, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 167, 170). Chipola series may be summarized as containing Chipola marl, the *Roberts* (Escambia Co., Ala.) *sands*, and the Alum Bluff beds.

W. H. Dall, 1903 (Wagner Free Inst. Sci. Trans., vol. 3, pt. 6, pp. 1563, 1564). *Roberts sand.*—Included in "Grand Gulf." Underlies Hattiesburg clays and overlies Grand Gulf ss. Correlated with Chipola marl.

Appears to be same as Catahoula ss., which is present at Roberts.

Named for exposures at Roberts, Escambia Co.

Roberts formation.

Pre-Cambrian: Central eastern California (Inyo Range).

J. H. Maxson, 1934 (Pan-Am. Geol., vol. 61, No. 4, p. 311). Wyman Canyon section, Inyo Range, consists of Silver Peak shales, lss. and sss. bearing *Olenellus;* the Campito ss., 2,000 ft.; Deep Springs fm., 2,100 ft.; Reed dol., 2,900 ft.; *Wyman schists*, 3,700 ft.; and *Roberts schist*, 2,500 ft.

J. H. Maxson, 1935 (Geol. Soc. Am. Proc. 1934, p. 314). *Roberts fm.*—Contorted schists and dolomites, 2,500± ft. thick in Wyman Canyon section, Inyo Range, in Bishop quad. Underlies (uncon.?) Wyman fm. Is pre-Camb.

Robervel formation.

Pre-Cambrian: Quebec.

J. A. Dresser, 1916 (Canada Geol. Surv. Mem. 92, p. 26).

Robervel granite.

Pre-Cambrian: Quebec.

J. H. C. Martens, 1927 (Canadian Min. and Met. Bull. 177, p. 116).

Robinett flags.

Trade name of ss. in Pleasanton group (Penn.) of SE. Kans., quarried on land of A. G. Robinett, in sec. 13, T. 30 N., R. 20 E. E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 108), stated: The flagging stone on Neosho River may be called *Robinett flags*, while of course those at Fort Scott will retain the name of the city near which they occur.

Robinson limestone member (of Maroon formation).

Pennsylvanian (?): Tenmile district, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215-230), 1886 (U. S. G. S. Mon. 12, pp. 69, 198, 279, 598, 646), and 1898 (U. S. G. S. Tenmile Special folio, No. 48). *Robinson ls.*—Light bluish-gray or drab compact ls., resembling lithographic stone; conchoidal fracture; somewhat dolomitic at base. Basal memb. of Maroon fm.

Named for fact it forms the ore-bearing horizon of Robinson mine, in Tenmile dist.

Robinson formation.

Pennsylvanian: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370-394). *Robinson beds.*—Slates, cgls., tuff, and ss., of which the last two are most important. Thickness

1,150 ft. Uppermost Carbf. fm. in Taylorsville region. Fossiliferous. Younger than Shoofly beds and older than Hosselkus ls. and Swearinger sl.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Robinson fm.*—A succession of variable sediments ranging from sh. to cgl., and composed chiefly of igneous material with occasional lentils of ls. Most characteristic part is gray ss. that weathers reddish brown. Contains more or less disseminated carbonate of lime forming small lentils up to 15 ft. in thickness. Below the calc. horizon the reddish-brown thin-bedded tuffaceous ss. and sh. extend to bottom of fm. Above the calc. horizon the pyroclastic material becomes somewhat coarser and passes into a tuffaceous cgl. containing fossiliferous ls. nodules and beds of reddish-brown ss., with here and there crinoid stems like that of principal horizon below. [Fossils listed.] Is separated from the older Peale fm. by Reeve meta-andesite. Is uncon. overlain by Hosselkus ls.

Named for exposures on Robinson ranch (where it makes up the mound E. of the house), near Taylorsville.

†Robinson quartzite.

Lower Cambrian: Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 620–622). *Robinson qtzite.*—White qtzite, with several beds of greenish, yellowish, and reddish clay slates near top, and occasionally beds of fine quartz cgl. The fm. weathers brownish red. Exposed thickness 7,000 ft. Is oldest fm. in Tintic dist. Underlies Eureka ls. In Tintic folio the Robinson qtzite will be renamed *Ophir fm.*, to avoid duplication of names. [Map shows that it forms qtzite ridge N. of town of Robinson, Juab Co., and that it is exposed in Tintic Canyon and at other places in Tintic dist. In Tintic folio (No. 65, 1900, by G. O. Smith) the fm. was not named *Ophir fm.* but was named *Tintic qtzite*, by which name it has since been known.]

Robinson diorite.

Miocene or Pliocene: Central southern Montana (Little Belt Mountains).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Diorite whose composition is nearly monzonite. Occurs on W. of main summit of Castle Mtn, btw. Robinson and Blackhawk. Assigned to Neocene.

Robinson sands.

Subsurface sands in Carbondale and Pottsville fms. (Penn.) of Ill. (See Ill. Geol. Surv. Bull. 54, index.) According to T. E. Savage (Ill. Geol. Surv. Bull. 40, 1919) the Robinson sand of Flat Rock oil pool, Crawford Co., Ill., is in Pottsville fm. and is also known as *Flat Rock sand*.

†Robinson shale.

Mississippian: Central eastern Nevada (Ely district).

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 52) and 1924 (Pan-Am. Geol., vol. 41, p. 78). *Robinson shales*, 1,000 ft. thick, underlie Joana ls. and overlie Combs ls. Basal fm. of Pincan series. [The 1924 definition is as follows: "Name is proposed for A. C. Spencer's Pilot sh. of Ely dist., which term is preoccupied in Missouri [not preoccupied in Mo.] for the Pilot (Knob) conglomerates."]

Roca shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 84, 86, 88). *Roca sh.*—Bluish-gray, olive-green, and reddish argill. sh.; thin seams of fossiliferous ls. in upper part. Thickness 18 to 20 ft. in Nebr., 20 to 44 ft. in Kans. Top bed of Elmdale sh. memb. Overlies Howe ls. memb. and underlies Neva ls. Named for Roca, Lancaster Co., Nebr.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 8), showed *Neva ls.* as separated from *Roca sh. fm.* by (descending): Salem Point sh., 7 to 8 ft.; Burr ls., 10 to 11 ft.; Legion sh., 6 ft.; and Sallyards ls., 1± ft.; but stated that "Kans. Geol. Surv. correlates Legion sh. and Sallyards ls. with Roca sh. fm."

In 1936 (Kans. Geol. Surv. Bull. 22) R. C. Moore transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Rochdale limestone. (In Beekmantown group.)

Lower Ordovician: Southeastern New York (Dutchess County).

W. B. Dwight, 1887 (Am. Jour. Sci., 3d, vol. 34, p. 32; and Vassar Bros. Inst. Trans. Sci. Sect., vol. 4, pt. 2, p. 213; both papers describing the rocks of Dutchess Co., N. Y.). *Rochdale group (Calciferous?)*.—This group, with its unique set of numerous fossils, yet only very partially described, is the one which in previous papers I have called the "Calciferous," because I consider it manifestly most closely related to what has been generally covered by that title. It is evident, however, that the proper limits of both "Calciferous" and "Chazy" are undergoing severe review in light of recent developments, and that many fossils heretofore assigned to one may ultimately be found to belong to the other. I have therefore decided to designate these strata provisionally by the name of the locality where their faunas are most richly represented. It must not, however, be inferred that these are the only strata found at Rochdale, for at least the Trenton and Hudson River strata are also well represented there. The rocks of Rochdale group are apparently found everywhere in this ls. belt. Conformably underlies Trenton ls. and overlies Potsdam or Upper Camb.

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148), describing the rocks of Poughkeepsie quad., recognized *Beekmantown (Calciferous-Rochdale group)* along W. margin of Fishkill ls., where it was said to be uncon. overlain by Trenton ls. and underlain by ls. containing Potsdam fossils.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 31). The *Rochdale group* (1887, Dwight) consists of a series of beds typically exposed at Rochdale, Dutchess Co. They are regarded as=Beekmantown but have not been mapped separately from Wappinger ls.

E. B. Knopf, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 429–458), divided the rocks of Beekmantown age in E. part of Dutchess Co. into two fms., Copake ls. above and *Rochdale ls.* below, both of which were included in Dwight's Rochdale group. She described her Rochdale ls. as consisting of (1) a thick succession of thin-bedded gray banded lss. weathering to a bluish surface, and mottled blue and gray lss. that weather to a reticulated aren. surface, alternating with thicker beds of fine-grained pale-gray dol. that weathers to a chamois or cream-colored surface; (2) thin-bedded white dolomitic lss. that weather into snow-white flat blocks. The mottled blue and gray lss. of No. 1 contain Beekmantown fossils. Thickness of fm. probably 600 ft. in Wappinger Valley. Is overlain, probably conformably, by Copake ls., also of Beekmantown age, and underlain, apparently conformably, by Hoyt dol. Is="lower Calciferous" of Dwight. Named for village of Rochdale, where upper strata are richly fossiliferous.

Rochdale group.

See under *Rochdale ls.*

Rochelle conglomerate. (In Graford formation.)

Pennsylvanian: Central Texas (McCulloch County, Colorado River region).

R. S. Tarr, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 204, 205; Am. Geol., vol. 6, pp. 147–153). *Rochelle cgl.*—Band of cgl. of variable thickness but 50 ft. thick at Rochelle, forming top memb. of Richland ss. At SW. end is coarsely conglomeratic; to NE. is finer-grained, cross-bedded, and interbedded with ss. layers, becoming, near the Colorado, a conglomeratic ss. with thin layers of cgl. Of Upper Carbf. age.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, p. 388). *Rochelle cgl.*, 20 to 50 ft. thick, underlies Brownwood bed and seems to have been deposited shortly after the Coral ls. beds, 10 to 12 ft. thick, which form basal bed of Canyon div.

L. S. Kempher, 1918 (Remarks on geol. of north-central Tex. oil and gas region). The *Rochelle cgl.* described by Drake as one of lowermost members of Canyon div. is in reality of Trinity (Cret.) age. It carries pebbles containing Fort Scott and Canyon fossils.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 35; Univ. Tex. Bull. 2132, pp. 59, 96, 97). *Rochelle cgl. memb.* is basal bed of Brownwood memb. of Graford fm. in Colorado River Valley, and rests on Palo Pinto ls. Is best exposed on San Saba-Brady road, 4 mi. E. of Rochelle (McCulloch Co.). The true Rochelle cgl. was deposited only near the mtns, probably slightly before but almost contemporaneously with Capps ls. lentil of Brownwood area. Thickness 6 to

25± ft. [In this rept the Rochelle cgl. is in places included in Brownwood memb. and in other places excluded from the Brownwood and treated as basal memb. of Graford fm.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 111). *Rochelle cgl.* occurs locally in Colorado River Valley near base of Brownwood sh.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197, 198), treated this cgl. as basal memb. of Graford fm., underlying Brownwood sh. memb.

Roche Miette limestone.

Devonian: Alberta.

D. B. Dowling, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 206).

Roche Percée group.

Eocene: Canada.

G. M. Dawson, 1875 (Geol. and res. 49th Par., p. 86), and 1879 (Canada Geol. Surv. Rept. 1879–80, pp. 12A–55A).

Rochester shale member (of Clinton formation).

Silurian: New York.

T. A. Conrad, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 62–63). [Lists fossils from *Rochester shales.*]

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 289, 327). *Rochester shale.*—Calc. sh. underlying Lockport ls. and overlying green sh. and iron ore [Clinton fm. as used until redefined by E. O. Ulrich in 1911 (Geol. Soc. Am. Bull., vol. 22, p. 392 and pl. 28), to include Rochester sh.]. Named for exposures at Rochester.

The Rochester sh. was treated as a distinct fm., btw. Lockport dol. above and Clinton fm. below, until 1911, when E. O. Ulrich included it in the Clinton. (See further explanation under *Clinton fm.*) In some early repts the Rochester sh. memb. was called "Niagara sh." According to E. O. Ulrich the Rochester sh. is included in and forms top div. of typical Clinton.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29), proposed to restrict Rochester sh. by removal of 20 ft. of calc. beds ("really a ls.") at its top, which are present at Rochester and heretofore included in Rochester sh. He named these beds *Gates ls.*, q. v.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), treated *Rochester sh.* as top memb. of *Clinton*, and included in it the limy beds at top.

Rochester quartzite.

Name casually applied by W. G. Foye (11th Rept. Vt. State Geol., 1919, p. 87) to pre-Camb. qtzite exposed along the Mine R. R. in Rochester, Vt.

Rochester biotite granite.

Devonian (?): Southeastern New Hampshire.

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, pp. 148, 149). *Rochester biotite granite* cuts Gonic schist and may be a pre-Carbf. intrusive. Is cut by pegmatite veins.

Probably named for exposures at Rochester, Strafford Co.

Rochester trachyte.

Triassic (Middle ?): Northwestern Nevada (Rochester district).

A. Knopf, 1924 (U. S. G. S. Bull. 762). *Rochester trachyte.*—Lavas, tuffs, and breccias; more than half is breccias and tuffs. "Felsite is a highly appropriate field name for these volcanic rocks." Thickness exposed 5,000 ft. Oldest fm. in Rochester dist. Is prevailing rock in Rochester Canyon. Of Triassic (Middle ? Tr.) age.

Rochester rhyolite.

Triassic: Nevada.

C. P. Jenney, 1935 (Nev. Univ. Bull., vol. 29, No. 6, p. 23). "Same as Rochester trachyte of Knopf."

Rochester moraine.

Name applied to a Pleist. moraine in central N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 627+, 1932.)

Rociada limestone.

Pre-Cambrian: Central northern New Mexico (Las Vegas region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 10). *Rociado lss.*—Main body of Archeozoic lss. in Solitario Mtn dist., NW. of Las Vegas. Thickness 250 ft. [Derivation of name not stated. On p. 4 is spelled with final *a;* on p. 10 with final *o*. The P. O. is spelled with final *a*.]

Rock Bluff limestone. (In Deer Creek limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 43, 50). *Rock Bluff ls.*, basal bed of Deer Creek ls., 8 in. to 2½ ft. thick in Nebr., and thickens somewhat southward to NW. Mo. (5+ ft.) and NE. Kans. (6 ft.). Underlies Larsh sh. and overlies Tecumseh sh. Named for exposures high in Missouri River bluffs NE. of Rock Bluff, Nebr. [This definition was followed by Condra and R. C. Moore in several charts up to and including Oct. 1932.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12). *Rock Bluff ls.* underlies Larsh sh. and is separated from Tecumseh sh. by Oskaloosa sh. (4 to 7 ft.) and the underlying Ozawkie ls. (5 ft.). [This is definition of Rock Bluff ls. followed by R. C. Moore in his 1936 rept. (Kans. Geol. Surv. Bull. 22). Moore explained (pp. 163, 182–187) how he came to misidentify *Rock Bluff ls.* and *Larsh sh.* in Kans., and introduced *Ozawkie ls.* and *Oskaloosa sh.* as names for the beds in Kans. that he previously had called *Rock Bluff ls.* and *Larsh sh.*]

Rock Canyon conglomeratic member (of Moenkopi formation).

Lower Triassic: Southwestern Utah (Washington County) and northwestern Arizona.

H. Bassler and J. B. Reeside, Jr., Aug. 15, 1921 (U. S. G. S. Bull. 726C, pp. 90–92). *Rock Canyon conglomeratic memb. of Moenkopi fm.*—Irregular complex of ls., ls. and chert cgl., sh., and gyp. Thickness 0 to 170 ft. [0 to 288 ft. in U. S. G. S. P. P. 129D, p. 55, 1922]. Basal memb. of Moenkopi fm. in this region. Lies 360 ft. below Virgin ls. memb. of Moenkopi. Rests uncon. on Kaibab ls. Named for Rock Canyon, 5 mi. N. of Antelope Spring, Mohave Co., Ariz.

†Rockcastle group. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky.

A. R. Crandall, 1889 (Ky. Geol. Surv. Whitely Co. Rept.). *Rockcastle group.*—Name provisionally applied to cgls., with interbedded shales and sss., 10 to 450 ft. thick, forming lower part of Coal Measures along border of coal field. Overlies Chester group and underlies 1,500 ft. of Coal Measures shales and sss. Its greatly thickened (1,500 ft.) equiv. in Pine Mtn region is called Pine Mtn group.

Includes Lee fm. and probably younger rocks.

Named for Rockcastle River, central Ky.

Rockcastle sandstone. (In Lee group.)

Rockcastle conglomerate member (of Lee formation).

Pennsylvanian: East-central Kentucky to central Tennessee.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46, p. 3). *Rockcastle cgl. lentil.*—Coarse cgl., 0 to 175 ft. thick, forming basal memb. of Lee fm. in Richmond quad., Ky. Underlain uncon. by Pennington sh. (Miss.).

Rockcastle ss. adopted by U. S. Geol. Survey for topmost fm. of Lee group in central Tenn., where it consists of 200–300 ft. of coarse qtzite or conglomeratic ss., underlain by five fms., aggregating 840 ft., belonging to Lee group. In some parts of eastern Ky. this ss. represents all of Lee group that is present; in other places the *Rockcastle cgl. memb.* is top memb. of Lee fm.

Named for exposures along Rockcastle River, Ky.

Has also been called "Rockcastle series." (A. M. Miller, 1910, Ky. Geol. Surv. Bull. 12.)

Rockcastle freestone.

Trade name for Wildie ss. memb. of Warsaw fm. in SE. Ky.

†Rock City conglomerate.

Name applied in some early repts to Olean cgl. of Cattaraugus and Chautauqua Counties, N. Y., which has been undermined and separated, by vertical joints, into huge blocks, often many ft. apart, called "rock cities," for which the village of Rock City, SW. of Olean, N. Y., was named.

Rock Creek limestone member (of McLeansboro formation).

Pennsylvanian: Central western Illinois (Menard County).

A. H. Worthen, 1873 (Ill. Geol. Surv., vol. 5, pp. 309, 312, 314, 315). *Rock Creek ls.*—Fine-grained, compact, bluish gray ls., in upper Coal Measures of Menard Co., and probably also in Sangamon Co., lying 85 ft. above Coal No. 5. Regarded as strat. equiv. of Collinsville ls.

Is a local memb. of McLeansboro fm. Lies in interval btw. coals Nos. 7 and 8, and is=Lonsdale ls., according to G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. Series Bull. 26, pp. 203–223), and according to T. E. Savage, 1921 (Ill. Geol. Surv. Extr. from Bull. 38). Named for outcrops along Rock Creek, Menard Co.

†Rock Creek beds.

Pleistocene: Panhandle of Texas.

J. W. Gidley, 1903 (Am. Mus. Nat. Hist. Bull., vol. 19, pp. 622, 625). *Rock Creek beds.*—Fine white sand, coarse sand, bluish clay, and gravel, sharply cross-bedded and indicating alluvial depositions by river or smaller streams. Fossiliferous. Thickness at least 90 ft. Uncon. overlies Plio. Blanco beds. Local name proposed for equiv. of Sheridan (*Equus*) beds.

W. D. Matthew, 1925 (Geol. Soc. Am. Bull., vol. 36, p. 221). *Rock Creek beds* are later than Panhandle beds, except perhaps the capping layers.

Named for Rock Creek, Swisher Co.

Rock Creek granodiorite.

Rock Creek gabbro and diorite.

Jurassic: Southern British Columbia and northeastern Washington.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 401). *Rock Creek gabbro and diorite,* Jurassic, intrusive. *Rock Creek granodiorite,* Jurassic intrusive, cuts Rock Creek diorite. Occurs near forks of Rock Creek. Uncon. underlies Kettle River fm. (Olig.).

Rock Creek limestone. (In Nelagoney formation.)

Pennsylvanian: Central northern Oklahoma (Osage County).

F. C. Greene, 1918 (A. A. P. G. Bull., vol. 2, p. 122). About 220 ft. above Wild Horse ls. is *Rock Creek ls.,* well developed in T. 26 N., R. 10 E., but very thin in SW. corner of next twp to S. Is probably about 325 ft. below top of Elgin ss., and immediately overlain by 150 ft. of ss. interbedded with red sh. Assigned to Penn. [Type loc. not stated.]

Rockdale formation. (In Wilcox group.)

Eocene: Eastern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 583). *Rockdale fm.* is proposed to designate all nonmarine strata of Wilcox group, which extend from top of Caldwell Knob oyster bed (top memb. of Seguin fm.) or its equiv. beds to base of marine strata of Sabinetown fm. Where Sabinetown fm. is absent the Rockdale is limited at top by Carrizo sand, of Claiborne group. Type loc., exposures in central Milam Co., in vicinity of Rockdale, where the lignitic members of fm. are mined. The fm. occupies approx. middle ⅗ of Wilcox section and comprises all its nonmarine strata. Most of its strata are lenticular and it is impossible to divide the fm., but in central and southern Tex., especially btw. Brazos and Frio Rivers, it is divided into following 3 members (descending): Calvert Bluff clay beds, 1,000 ft.; Simsboro sand, 240 ft.; and Butler clay, 400 ft. Thickness of fm. 1,000 to 1,640 ft. Rests conformably on Seguin fm. (marine).

Rockdale moraine.

Rockdale drift.

Pleistocene (late Wisconsin): Northeastern Illinois (Joliet quadrangle). See D. J. Fisher, 1925 (Ill. Geol. Surv. Bull. 51, pp. 17, 69, 71, 87–89, and map), and M. M. Leighton, 1932 (16th Int. Geol. Cong. Guidebook 26, pp. 16, 51). Named for village of Rockdale, 2 mi. SW. of Joliet.

Rock Falls series.

Mississippian: Eastern Michigan (Huron County).

A. C. Lane, 1900 (Mich. Geol. Surv., vol. 7, pt. 2, pp. 252–253), in a description of fossils collected from Marshall and Coldwater fms. in Huron Co., used, in heading, *Rock Falls series* (*Cuyahoga*), and described it as consisting of blue shales, poor in fossils, except in thin sandy seams and nodules of carbonate of iron. Derivation of name not stated.

Rockfish conglomerate.

Pre-Cambrian (Glenarm series): Western Virginia (Nelson County).

W. Nelson, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 15, pp. 456–457). *Rockfish cgl.*—Coarse cgl., about 800 ft. thick, forming basal cgl. of Lynchburg gneiss. Lower 120 ft. contains pebbles and boulders, both angular and rounded (of quartz, granite, and fine-grained siliceous gneiss), from 2 to 12 in. diam., embedded in metamorphosed sediment now composed of feldspar, blue quartz, and mica; it lies next to Lovingston quartz monzonite and has appearance of augen gneiss or mylonite; its pebbles and boulders occur in clusters, generally 1 to 2 ft. apart separated by 4 or 5 ft. of almost barren cgl. Above this lower 120 ft. occurs 285 ft. of cgl. full of pebbles, from 2 to 6 in. diam., which become more scattered toward top. Next above lies 345 ft. of cgl. containing pebbles from 1 to 4 in. diam. This upper part grades into mica gneiss that is correlated with Lynchburg gneiss. The Lynchburg gneiss occupies belt about 1 mi. wide at this point and its exposed thickness is 5,000± ft. The cgl. and Lynchburg gneiss strike N. 30° E., dip 70°–80° NW., and are slightly overturned. On N. side of Rockfish River the Lovingston quartz monzonite outcrops at base of the cgl., while on S. side of the river an amphibolite dike crops out which occupies the place of contact btw. the Lovingston and the cgl. Near middle of the cgl. occurs a 75-foot offshoot of this dike. This cgl. does not contain any pebbles of amphibolite, granodiorite, or Catoctin schist. Type loc. is on Rockfish River. Further work will probably show that this cgl. extends to S. in Lynchburg area and to N. into edge of Albemarle Co.

Rockford limestone.

Mississippian (Kinderhook): Indiana.

F. B. Meek and A. H. Worthen, 1861 (Am. Jour. Sci., 2d, vol. 32, pp. 167–177). *Rockford goniatite bed.*—Mottled brownish and ash-colored argill. ls. overlying the Black sl. Only 2 ft. exposed.

E. M. Kindle, 1899 (Bull. Am. Pal., vol. 3, No. 12). *Rockford ls.*, 3 to 6 ft. thick in southern Ind., underlies New Providence sh. and overlies New Albany black sh.

E. R. Cumings, 1922 (Hdb. Ind. Geol. pt. 4, Sep. Pub. 21, pp. 486, 487). *Rockford ls.* is thin and local in its distribution. Typically exposed in bed of White River at Rockford, Jackson Co., but may be seen wherever contact of Knobstone and New Albany fms. come to view btw. Rockford and Ohio River. It does not extend into Ky.

Basal fm. of Mississippian in Ind.

†Rockford shale.

Upper Devonian: Central northern Iowa.

S. Calvin, 1878 (Am. Jour. Sci., 3d, vol. 15, pp. 460–462). *Rockford shales.*—Argill. shales exposed at and near Rockford, Iowa, and frequently called Rockford shales. Thickness 70 ft. Included in Dev. Overlie Dev. lss.

See under *Hackberry sh.*

Named for Rockford, Floyd Co.

Rockfordian series.

A term employed by C. [R.] Keyes (Pan-Am. Geol., vol. 60, No. 3, 1933, p. 226) to include the Upper Dev. deposits of Iowa that have been variously designated Chemung, Rockford, Hackberry, Owen, Sheffield, Cerro Gordo, and Juniper. (See Iowa correlation chart.)

†Rock Fort sandstone.

Lower Ordovician: Central eastern Missouri.

H. King, 1851 (Am. Ass. Adv. Sci. Proc., vol. 5, p. 189). Generally white ss.; occasionally slightly colored by iron; sometimes hard but usually soft or friable and easily reduced to condition of sand. No fossils. Thickness 150 or 250 ft. Underlies Blue ls. regarded by Hall as=Trenton ls. of N. Y. Overlies 500 ft. of light-yellow or buff mag. ls. Frequently appears in top of hills btw. Ste. Genevieve and Meramec River, presenting a bold wall-like escarpment or bluff. In these cases it has received the common name *Rock Fort* in the county.

Same as St. Peter ss., older name.

Not geographic name.

Rock Grove substage.

Upper Devonian: Central northern Iowa.

C. H. Belanski, 1927 (Am. Mid. Nat., vol. 10, No. 10). *Rock Grove substage.*—Mag. ls., shaly ls., and impure dol., 21+ ft. thick, uncon. underlying First *Actinostroma* zone of Nora ls. [redefined] and uncon. overlying Mason City substage [restricted use of Mason City]. Divided into *Schizophoria* zone above and *Paracyclas* zone below. Named for great development in *Rock Grove Twp*, Floyd Co. Typically developed on E. (left) bank of Shell Rock River a short distance SE. of Nora Springs. Is middle substage of Shell Rock stage, which is assigned to Upper Dev.

See also under *Shell Rock ls.*

Rockhill limestone. (In Graford formation.)

Pennsylvanian: Central northern Texas (Wise County).

E. Böse, 1918 (Univ. Tex. Bull. 1758, pp. 14–16). *Rockhill ls.*—In Dry Creek is generally light-gray or dark-gray ls. in layers of moderate size. Very good horizon marker. In certain parts contains numerous crinoids and brachiopods. To SW. a mass of gray marls, 25 to 30 ft. thick, is intercalated in lower part. Thickness of fm. 30 to 150 or more ft.; thickest to W. It forms high part of Rockhill Range. Rests on a series of gray marly shales with intercalated sss., and is separated from overlying Devils Den ls. by 305± ft. of sss. with intercalated shales. Lies 180± ft. above Bridgeport ls. Appears to belong to Strawn fm.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 30). *Rock Hill ls. memb. of Graford fm.* overlies Lake Bridgeport shales and underlies Jasper Creek shales. It forms the flat top of the long, narrow ridge (Rock Hill) that extends SW. from S. end of Lake Bridgeport dam. It is a tongue of Chico Ridge ls.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 105, 111), included this ls. in Graford fm.

Rock House sandstone.

Mississippian: Western Kentucky.

See under *Tar Springs ss.*, 1856 item.

Rockhouse shale.

Lower Devonian (Helderbergian): Western Tennessee.

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 736). *Rockhouse sh.*—Bluish-green or greenish-gray calc. glade-forming sh. interbedded with occasional thin bands of light-gray crystalline ls. Fauna is very early Dev., near Siluro-Dev. bdy. Treated as basal fm. of Helderbergian or Linden group. Occurs in S. part of Hardin Co. Not before described. Uncon. underlies Ross ls. (basal memb. of Olive Hill fm.) and discon. overlies Decatur ls. Max. thickness 26 ft. at Rockhouse, a hunters' clubhouse on Horse Creek, 5 mi. NW. of Lowryville, for which it is named.

†Rockingham schist.

Pre-Cambrian and Pennsylvanian (?): Southeastern New Hampshire.

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545). *Rockingham mica schist.*—Generally uncouth mica schist. Occupies principal part of Rockingham. Underlies Merrimack group.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, btw. pp. 518 and 591). *Rockingham mica schist.*—Very convenient name to designate a large mass of mica schists, with the mica often in coarse blotches and the predominant mineral, until its proper geological place is known, and therefore we cannot yet dispense with the term. Closest resemblance is to the micaceous portion of Montalban series. No difficulty in discerning relations to Merrimack group, but bdy line btw. them is not satisfactory. The fm. is better developed in Strafford than in Rockingham Co. [On a later page he gave thickness as 6,000 ft., and placed it as younger than Merrimack group and older than Kearsarge andalusite group.]

C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, No. 5, pp. 178–179). Part of *Rockingham mica schist* belongs to Huronian.

F. J. Katz, 1917 (U. S. G. S. P. P. 108 I). *Rockingham schist* of Hitchcock included Gonic fm. (Penn.?), part of Kittery qtzite (Penn.?), and part of Berwick gneiss (pre-Camb.), as mapped in this rept (on SE. N. H. and SW. Maine).

Rock Lake shale. (In Stanton limestone.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 41, 59, 156, 157). *Rock Lake sh.*—Basal 6 ft. of Scranton sh. Upper 1 to 2 ft. bluish; rest maroon; all argill. Underlies South Bend ls. and overlies Howard ls. Named for outcrop at Rock Lake, sec. 3, T. 12 N., R. 10 E., Sarpy Co., Nebr.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 13, 26, 27, 31, 32, 33, 34, 36). The *Rock Lake sh.* and overlying South Bend ls. belong in top of Stanton ls. The Rock Lake sh. rests on Stoner ls., also included in Stanton ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 135–136). *Victory Junction sh. memb.* of Kans. is possibly same as *Rock Lake sh.* of Condra in Nebr., which was originally erroneously included in Scranton sh., but which belongs in Stanton ls.

†Rockland sandstone.

Miocene (?): Eastern Texas.

E. T. Dumble, 1901 (Geology of Beaumont oil field). *Rockland ss.*—Series of hard sss. and clays [thickness not stated] underlying Lagarto beds in Beaumont oil field.

Is a ss. bed in Catahoula ss.

Named for Rockland, Tyler Co.

Rockland formation.

Cambrian or Ordovician: Central southern Maine (Rockland region).

E. S. Bastin, 1908 (U. S. G. S. Rockland folio, No. 158). *Rockland fm.*—Folded and metamorphosed sed. rocks, best developed just W. and SW. of Rockland. Includes 3 members. The upper memb. (Rockport ls. memb.) comprises major part of fm. It consists of white to purple crystalline ls., ls. cgl., and shaly ls.; its thickness is at least 400 or 500 ft. and may reach 2 or 3 times that figure. The middle memb. consists of greenish siliceous ls. (100 to 150 ft. thick). The basal memb., local, is Weskeag qtzite memb. (0 to 300 ft. thick). Conformably overlies Penobscot fm. and is overlain by surficial deposits. Is Cambro-Ord. and apparently = Stockbridge ls.

On 1933 geol. map of Maine, by A. Keith, these rocks are included in Ord. and Camb. block.

†Rockland sandstone.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, p. 610). *Rockland or National ss.*—Rockland seems to be the older name, being used in George D. Emerson's 1859 rept. But Broughton's map uses *National ss.*, from National mine, and that is more current. [The compiler is unable to find any published rept by George D. Emerson.]

Named for occurrence at Rockland, in Ontonagon Co.

Rockland formation.

Ordovician (Middle): Ontario and northern New York.

P. E. Raymond, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 348), 1916 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, pp. 255, 260), 1921 (Canada Geol. Surv. Mus. Bull. 31, p. 1). *Rockland fm.*, Ord., Ontario. Included in Trenton.

This name was used in several subsequent Canadian repts.

G. M. Kay, 1929 (A. A. P. G. Bull., vol. 13, No. 9, p. 1214), defined *Rockland ls.* in Jefferson Co., N. Y., as consisting of 40 ft. of ls. forming basal fm. of Trenton group, underlying Hull ls. and overlying Watertown ls. of Black River group. In Geol. Soc. Am. Bull., vol. 46, pp. 227, 228, 1935, Kay defined *Rockland fm.* as separable into a lower memb., in which *Doleroides gibbosus* is characteristic, and an upper memb., having abundance of *Triplecia cuspidata* at top. Max. observed thickness is 64 ft. at Dexter, N. Y. Lower memb. is 24 ft. thick at Lonsdale, Ont.

G. M. Kay, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 2+). *Rockland fm.* is 55 ft. thick W. of Watertown, N. Y., and less than 20 ft. thick 60 mi. to SE. of westernmost N. Y. exposure. Was formerly called "Triplecia beds." Overlaps onto Watertown ls. and underlies Hull fm. Type loc. is at Rockland, Ont., 30 mi. E. of Ottawa. Fossils listed. Is basal part of Trenton group.

Rockland Valley basalt.

Pliocene (middle?): Southern Idaho (Power County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Rockland Valley basalt.*—Even-bedded blue and black basalt flows, partly weathered. Contains at least one bed of clay, 15 ft. thick in Rock Creek Canyon. Thickness may be 647 ft.; 250 ft. exposed in walls of Rock Creek Canyon. Named for exposures on N. side of Rockland Valley, Power Co. Older than Raft lake beds and younger than Massacre volcanics.

Rockmart slate.

Ordovician (Middle): Northwestern Georgia.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 143) and 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 469–470, 478). North of Coosa Valley the Knox dol. is followed by the Chickamauga, a series of blue, dove-colored, and purple lss.; also at a few points S. of Coosa fault the dol. is overlain by blue ls., although in greater part of this region a strat. break, which will be described more fully later, occurs at this point; also S. of the fault the purple earthy lss. are replaced by a great thickness of black slates. They have been placed in a separate fm., the *Rockmart sl.*, although they probably represent same period of deposition as the earthy lss. farther N., but it is impracticable to separate the latter from the purer lss. beneath. Underlies Rockwood fm.

J. W. Spencer, 1893 (Ga. Geol. Surv., Paleozoic group). Chickamauga series of NW. Ga. is divided into (descending): (1) *Rockmart sl.* (semimetamorphic sl.), 1,200 ft.; (2) Deaton ore beds or series, 100 to 200 ft. of ferruginous lss.; (3) *Maclurea ls.*, 600 to 800 ft.; (4) heavy bed of breccia in ridges S. of Rockmart.

J. O. Veatch, 1909 (Ga. Geol. Surv. Bull. 18). *Rockmart sl.* is chiefly sl. but includes some ls., sh., and cgl. Thickness 2,500 to 3,000 ft. Overlies Chickamauga ls. and underlies Rockwood fm.

S. W. McCallie, 1910 (Ga. Geol. Surv. Bull. 23, pp. 51, 184). *Rockmart shales* are= upper part of Chickamauga fm., but are so well defined that they are mapped as a distinct fm.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), assigned *Rockmart sl.* to Blount group (=upper Chazy) and correlated it with Athens sh. of Tenn.

T. P. Maynard, 1912 (Ga. Geol. Surv. Bull. 27). *Rockmart shales and slates* of eastern basin are 2,500 ft. thick. They are blue to black, weather olive green and yellow, uncon. overlie 100 to 200 ft. of dark-blue and gray Chickamauga ls., and are=upper part of Chickamauga fm. of western basin. [This description was repeated by H. K. Shearer, 1918 (Ga. Geol. Surv. Bull. 34).]

A. Keith and L. La Forge, 1925 (Ga. Geol. Surv. Bull. 42, p. 7), show *Rockmart sl.* as Middle Ord. but leave indefinite the question whether it includes any Lower Ord.

R. W. Smith, 1931 (Ga. Geol. Surv. Bull. 45). *Rockmart sl.* is probably of Blount age.

Named for Rockmart, Polk Co.

Rockport shales.

Pennsylvanian: Northwestern Missouri.

C. R. Marbut, 1904 (The State of Mo., p. 69). *Rockport shales*, top fm. of coal measures of Mo.

Rockport limestone member (of Rockland formation).

Cambrian or Ordovician: Central southern Maine (Knox County).

E. S. Bastin, 1908 (U. S. G. S. Rockland folio, No. 158, pp. 3–4). *Rockport ls. memb.*—Virtually a marble, although it is either too coarse, too dark-colored, or too much fractured to be used for ornamental or building purposes. Ranges from dark purplish gray to pure white, the commonest colors being light gray and dark blue gray; banded varieties showing alternate grayish-white and dark blue-gray layers are also very common. Is top and major memb. of Rockland fm. Thickness at least 400 or 500 ft. and may reach two or three times this figure.

Named for exposures on E. shore of Rockport Harbor, Knox Co.

Rockport limestone. (In Greene formation.)

Permian: Western West Virginia.

C. E. Krebs, 1911 (W. Va. Geol. Surv. Rept. Jackson, Mason, and Putnam Counties, p. 102). *Upper Rockport ls.*, hard gray ls., 7 ft. thick; containing minute freshwater fossils; underlying Gilmore ls., and lying 30 ft. above *Middle Rockport ls.*, which is hard, gray, and also contains minute fossils. *Lower Rockport ls.* is dark gray, weathering white; lies 29 ft. below Middle Rockport ls., and overlies Nineveh ss. Named for occurrence at Rockport, Wood Co.

Rockport sandstone.

Pennsylvanian: Southwestern Indiana (Spencer County). See under †*Martha Washington ss.*

Rockport limestone.

Middle Devonian: Northeastern Michigan (Alpena County).

R. A. Smith, 1916 (Mich. Geol. and Biol. Surv. Pub. 21, geol. ser. 17, pp. 172–175). *Rockport ls.*—Thick, massive, and extremely fossiliferous bed at base of Long Lake series. At Rockport, Alpena Co., it rests directly on the soft blue Bell sh., and is 25 to 30 ft. thick. It is essentially stromatopora, coral, etc., with matrix of dark or black crystalline and very bituminous ls., and forms bluff extending from N. line of sec. 6, T. 32 N., R. 9 E., SE. along shore of Lake Huron for more than 1 mi.

W. A. VerWiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 184). *Rockport ls.*—Ls., most of it very bituminous; upper 10 ft. buff-colored and very fine-grained. Thickness 40 ft. Basal memb. of Long Lake or Lower Traverse series. Overlies Bell sh.

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526), excluded Rockport ls. from Long Lake stage and treated it as a separate fm., underlying Long Lake stage and overlying Bell sh.

Named for exposures at Rockport, Alpena Co.

Rockport formation.

C. Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 36, 61–62, 280, 301). Sss. or brownish sandy shales, 2,000 ft. thick in Utah and 1,000 ft. thick in Colo., uncon. below Bearian series and above Dakota ss. in Utah and Wyo. Composes upper fm. of Henryan series [Upper Cret.].

Named from hamlet of Rockport, Summit Co., NE. Utah.

Rockport granite.

Local quarry term for a part of Quincy granite, which has been quarried at Rockport, Essex Co., Mass.

Rock River formation.

Upper Cambrian: Quebec.

Name applied by H. W. McGerrigle (17th Rept. Vt. State Geol., pp. 182, 185, 1931) to A_1 of Logan's section of Philipsburg series of Quebec. McGerrigle mapped his *Rock River fm.* in small area in St. Albans quad., NW. Vt., stating that it extended about 4 mi. into that State. Logan described A_1 as consisting of 400 ft. of dark-gray and yellowish-white dolomites. McGerrigle gave thickness as 500 ft. (See 1931 entry under *Philipsburg series.*) Rock River rises in Quebec, but flows into Missisquoi Bay in St. Albans quad., Vt. T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 6), assigned this fm. to Upper Camb., which is where paleontologists of U. S. Geol. Survey place it.

Rock Run limestone.

Upper Ordovician (Richmond): Northeastern Illinois.

See under *Aux Sable ls.*

Rock Springs formation. (In Mesaverde group.)

Upper Cretaceous: Southwestern Wyoming (Sweetwater County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Rock Springs coal group.*—White to yellow ss., interbedded sh. and clay, with several coal beds; heaviest ss. beds near base. Thickness 600–1,400 ft. Basal fm. of Mesaverde group. Overlies Blair fm., and is separated from the younger Almond coal group by 800 to 1,000 ft. of massive white and yellowish ss., the upper third of which is conglomeratic.

J. D. Sears, 1926 (U. S. G. S. Bull. 781, p. 20, pl. 5). [See under *Almond fm.*]

Rocktown channel sandstone member (of Dakota sandstone).

Upper Cretaceous: North-central Kansas.

W. W. Rubey and N. W. Bass, 1925 (Kans. Geol. Surv. Bull. 10, pp. 16, 57–65). Occurring locally at almost any horizon from top to 125 ft. below top of Dakota ss. in Russell Co. is a series of very discontinuous, highly cross-bedded ss. strata here named *Rocktown channel ss. memb. of Dakota ss.* Thickness 15 to 100± ft. Named for excellent exposures at and near the large group of "hoodoos" or houselike blocks of ss. in NW¼ sec. 4, T. 13 S., R. 11 W., locally known as Rocktown.

Rockvale sandstone member (of Vermejo formation).

Upper Cretaceous: Eastern Colorado (Fremont County).

W. T. Lee, 1917 (U. S. G. S. P. P. 101, pp. 163–169). *Rockvale ss. memb. of Vermejo fm.*—Massive yellow to brown ss.—the ss. separating the two groups of coal-bearing beds in Vermejo fm. Contains marine invertebrate fossils [listed] of Fox Hills type, and great numbers of *Halymenites major*. Thickness 33 to 65 ft. Lies 300 to 382± ft. above Rockvale coal (basal bed of Vermejo fm.) and 30 ft. above Royal Gorge coal beds. Named for typical development near Rockvale, Fremont Co.

†Rockville sandstone.

Upper Devonian: Southwestern New York.

H. S. Williams, 1887 (U. S. G. S. Bull. 41, pp. 51 and 73), under heading "The Portage sss. and the faunas of the Chemung group," described the *stations* where these rocks had been studied. On p. 73 is subheading "Rockville, Allegany Co., N. Y.—479," and statement that at base of the section near old canal lock at Rockville is a thick ss., 6 ft. of which is visible. On pp. 78–79 he stated that the ss. (quarried) at Belmont, Allegany Co., N. Y., lies at elev. of 1,450± ft. and "represents very closely the horizon of *Rockville ss.* 479." This is the only place where the compiler has found *Rockville ss.* previous to Chadwick.

G. H. Chadwick, Nov., 1933 (Pan-Am. Geol., vol. 60, p. 200), in a chart from Olean to Genesee River, showed *Rockville ss.* as underlying Cuba ss. and overlying

Rushford ss. and as=in age Northeast sh. He stated (personal communication dated Jan. 24, 1936) that present Rockville (railway station and stores) is about 1 mi. W. of old Rockville, where occur the exposures of this ss., and that he is not author of the name, as he did not define it.

B. Willard and A. B. Cleaves, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 4, p. 780). Skaneateles fm. of eastern Pa. divided into (descending): (1) Unnamed ss. and sh.; (2) Colgate memb. (?); (3) Berwyn memb.; (4) Delphi memb.; (5) *Rockville memb.* (light-colored ss., hard, fossiliferous, present in western sections only); (6) Mottville memb., at base.

Rockville conglomerate.

Cretaceous or Tertiary: Central eastern Iowa.

W J McGee, 1891 (U. S. G. S. 11th Ann. Rept., pt. 1, p. 304). *Rockville cgl.*—Scattered bodies of either dark-brown puddingstone of well-worn quartz pebbles in matrix of earthy limonite, or obscurely stratified ferruginous ss. Thickness 0–20 ft. Seems to uncon. overlie Niagara ls. and to be composed in part of materials derived from that fm. Is littoral deposit. Provisionally assigned to Cret. and correlated with Nishnabotany ss. of SW. Iowa and Fort Dodge gyp. of west-central Iowa.

Named for Rockville, Delaware Co.

Rockville member (of Skaneateles formation).

Middle Devonian: Eastern Pennsylvania (Dauphin County).

B. Willard and A. B. Cleaves, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 4, pp. 768, 781). The 30 ft. of barren dark to olive-gray or black sh. at base of Skaneateles fm. may be Mottville memb. Overlying this is *Rockville memb.*, a name introduced for a light-colored ss. first studied at Rockville, on the Susquehanna. In Schuylkill Valley, btw. Schuylkill Haven and Auburn, it is 60 ft. of light-gray medium-grained buff to light-brown weathering, more or less cross-bedded flaggy to heavy ss. underlying the Delphi memb. The Rockville is fossiliferous, characterized by many specimens of *Stropheodonta* and *Chonetes*.

Rockville granite.

Trade name for granite quarried at Rockville, Minn.

Rockwell formation.

Mississippian: Northeastern West Virginia and western Maryland.

G. W. Stose and C. K. Swartz, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Rockwell fm.*—Soft arkosic ss., fine hard cgl., and buff hackly sh.; crumbly dark-gray carbonaceous sh. with thin coal seams near base in W. part of area. Thickness 500 to 540 ft. Basal fm. of Pocono group. Underlies Purslane ss. and overlies Catskill fm. Named for exposures in Rockwell Run, Morgan Co., W. Va.

Rockwood formation.

Silurian (Clinton and Medina): Eastern Tennessee and northwestern Georgia (?).

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 143). *Rockwood fm.*, 1,000 to 1,500 ft. thick, is of Sil. age and=Clinton or Dyestone of Smith and Safford. Underlies Dev. Chattanooga black sh. and overlies Chickamauga ls. and Rockmart sl. in NW. Ga.

C. W. Hayes, 1894 (U. S. G. S. Kingston folio, No. 4, p. 2). *Rockwood fm.*—Highest div. of Sil. in this region. Varies widely in character and thickness within limits of quad. Forms narrow strip about head of Sequatchie Valley, where it is 165 ft. thick and composed of calc. shales interbedded with blue ls. Along foot of Cumberland escarpment is about 600 ft. thick and consists of calc. and sandy shales. Still farther E., in ridge which extends from Iron Divide to Ten Mile Stand, is 850 to 1,000 ft. thick, a considerable part of which is coarse ss. interbedded with sandy shales. Toward top are sandy shales and a few calc. beds, with which is associated the iron ore that gives the fm. great economic importance. Takes its name from Rockwood, Tenn. [in Kingston quad.], where the rocks are intermediate in character btw. the western and eastern phases, and where the ore is extensively mined. Underlies Chattanooga black sh. To W. overlies Chickamauga ls.; to E. overlies Athens sh. Is=Dyestone group and White Oak Mtn ss. of Safford.

Includes rocks of Clinton and Medina ages, according to studies of E. O. Ulrich and C. Butts. As mapped in some early repts it also included, in some areas, rocks of Richmond age and also possibly rocks of Lockport age.

Named for Rockwood, Roane Co., Tenn., where, according to E. O. Ulrich, the rocks are all of Medina age.

†Rockwood sandstone.

Silurian: Northwestern Georgia.

C. W. Hayes, 1894 (U. S. G. S. Ringgold folio, No. 2, columnar section sheet). *Rockwood ss.*—White or brown ss. or cgl. forming a middle memb. of Rockwood [Red Mtn] fm. E. of Chattooga Valley.

Undesirable name, because of extended usage of *Rockwood* in broader sense.

Rockwood sandstone. (In Chester group.)

Mississippian: Southwestern Illinois (Randolph and Monroe Counties).

S. Weller, 1913 (Ill. Geol. Surv. Bull. 22, p. 31). *Rockwood ss.*—Ss., 100 ft. thick, forming topmost memb. of Birdsville fm. in Randolph and Monroe Counties. [Only use is in table.]

Probably named for Rockwood, Randolph Co. Appears to be=Palestine ss.

Rockwood oolite.

Mississippian: Northwestern Alabama (Franklin and Lawrence Counties).

W. B. Jones, 1928 (Ala. Geol. Surv. Circ. 8, pp. 13-15). *Rockwood oolite*, 0 to 55 ft. thick; much less variable in occurrence and having greater extent than Burgess oolite; beds at top and bottom carry abundance of fossils. Type loc. near Rockwood, Franklin Co., where it is 55 ft. thick and uniformly oolitic throughout. Lies 100 ft. above base of Bangor ls. and 100 ft. below Burgess oolite—all in Bangor ls. The underlying beds are blue to gray flinty fossiliferous lss. and dolomites; the overlying beds are blue fossiliferous lss.

Rocky Canyon granite.

Jurassic or Cretaceous: Northwestern Nevada (Humboldt Range).

C. P. Jenney, 1935 (Univ. Nev. Bull., vol. 29, No. 6, pp. 37-42). *Rocky Canyon granite.*—White to gray granitoid rock, spotted with many flakes of biotite and in places containing biotite segregations and bunches. Frequently weathers to coarse arkosic gravel. Outcrops over 6± sq. mi. in lower Rocky and Wright's Canyons, and elsewhere. Last of major intrusives of region. Called pre-Camb. by 40th Par. Surv., but Louderback has shown it is post-Triassic intrusive, and probably of Jura-Cret. age.

Rocky Cedar Creek limestone lentil. (In Kincaid formation.)

Eocene: Northeastern Texas (Kaufman County).

G. D. Harris, 1896 (Bull. Am. Pal., vol. 1, No. 4, p. 41), divided the Midway of Kaufman Co. into (descending) Wills Point clays and sands (upper Midway); *Rocky Cedar Creek ls.* (middle Midway); and clays W. of Rocky Cedar Creek (lower Midway). [On p. 16 he listed the fossils from 5 mi. W. of Wills Point on Rocky Cedar Creek.]

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 536, 539, 540, 541, 553). *Rocky Cedar Creek ls. lentil.*—A local thin bed of gray fossiliferous ls. similar to Tehuacana ls. lentil of Pisgah memb. of Kincaid fm., but occurring slightly lower in Pisgah memb. Thickness 12-16 ft. Typically exposed in Ola quarry, 1 mi. S. of Ola, and along Rocky Cedar Creek btw. Ola and Wills Point, Kaufman Co.

†Rocky Comfort chalk.

Upper Cretaceous (Gulf series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72, 89-95, 188). *Rocky Comfort chalk.*—Massive fossiliferous, nearly pure-white chalk, usually free from grit. Thickness 500 ft. at Rocky Comfort, where 100 ft. is exposed and 400 ft. is penetrated in wells. Is a continuation into Ark., from Tex., of fm. called *Dallas ls.* and *Austin ls.* Relations to overlying fms. in Ark. undet.

Is upper part of Annona chalk, and of same age as Pecan Gap tongue of the Annona, according to 1925 and 1926 work of L. W. Stephenson and C. H. Dane. (See C. H. Dane, U. S. G. S. Press Bull. 8823, Sept. 10, 1926; L. W. Stephenson, A. A. P. G. Bull., vol. 11, No. 1, Jan. 1927; and C. H. Dane, Ark. Geol. Surv. Bull. 1, 1929.) The Pecan Gap chalk is now treated by U. S. Geol. Survey as a memb. of Taylor marl.

Named for exposures at Rocky Comfort, Little River Co.

Rocky Gap sandstone. (In Helderberg group.)

Lower Devonian: Southwestern Virginia.

F. M. Swartz, 1929 (Pa. Acad. Sci. Proc., vol. 3, p. 80), applied *Rocky Gap ss.* to 10 to 100± ft. of sandy and cherty beds in SW. Va., extending from Tumbling Creek, near Saltsville [Saltville], to Gala, Va. He showed these beds (in section) as underlying Saltsville chert, as correlated with Shriver chert (=Becraft ls.) and the older New Scotland ls., and as having nearly their max. thickness in Rocky Gap, Va., section.

†Rocky Hill trap.

Name applied by H. B. Kümmel, 1897 (N. J. Geol. Surv. Ann. Rept. State Geol. 1896, p. 62), to a sheet of diabase that intrudes Brunswick and Lockatong fms. of Newark group (Upper Triassic) of N. J. Exposed at Rocky Hill village, Somerset Co. This local geographic name considered unnecessary, and is not used by U. S. Geol. Survey. (See U. S. G. S. Trenton folio, No. 167.)

Rocky Hill volcanics.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 74–75). *Rocky Hill basalt* [mapped in Tantalus-Roundtop dist.] overlies black ash and associated aggl. [mapped], and the 2 fms. compose Rocky Hill.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii; Div. Hydrog. Bull. 1). *Rocky Hill volcanics.*—Cinders and basalt, chiefly basalt. Mapped. Included in lower part of Honolulu volcanic series [q. v.]. Type loc. Rocky Hill.

Rocky Mound limestone member (of Graham formation).

Pennsylvanian: Central northern Texas (Young County).

Wallace Lee (Univ. Tex. Bull. soon to be published). The group of lss. outcropping conspicuously on SW. slope of Rocky Mound, 3 mi. NE. of Graham, Young Co., and erratically overlain by Avis ss. memb., is here named *Rocky Mound ls. memb. of Graham fm.* It comprises the lss. of No. 8 post-Bunger cycle, and generally consists of gray crystalline fossiliferous ls. 33 to 35 ft. thick. Lies about 250 ft. above Bunger ls.

Rocky Mountain quartzite.

Carboniferous: Alberta and British Columbia.

D. B. Dowling, 1907 (Rept. on Cascade coal basin, Alberta; Canada Geol. Surv., p. 9). *Rocky Mtn qtzite*, Carbf., Alberta.

In subsequent Canada Geol. Surv. repts (by Shimer, Allan, Daly, Adams and Dick, Kindle, and Warren) this fm. has been assigned to Penn. In 1927 Shimer assigned it to Perm. P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 300), assigned it to Penn. (?).

Rocky Mountain limestone.

Cretaceous: Alberta.

D. B. Dowling, 1915 (Canada Geol. Surv. Summ. Rept. 1914, p. 48).

Rocky Ridge sandstone member (of Pierre shale).

Upper Cretaceous: Central northern Colorado (Larimer County).

M. W. Ball, 1924 (A. A. P. G. Bull., vol. 8, No. 1, pp. 81–87). *Rocky Ridge ss.* was named and mapped [unpublished repts] by A. T. Schwennensen, E. W. Krampert, and C. H. Henley. It is 97 ft. thick; lies 163 ft. below Larimer ss. and 604 ft. above Terry ss. Forms prominent cliff around N. and E. banks of Rocky Ridge

Reservoir [about 4½ mi. SW. of Wellington, Larimer Co.] and is also prominent in cliff outlining Douglas Lake. [See also 1924 entry under *Hygiene ss. memb.*] Is included in Mesaverde fm.

K. F. Mather, J. Gilluly, and R. G. Lusk, 1928 (U. S. G. S. Bull. 796B). *Rocky Ridge ss. memb. of Pierre sh.* reaches thickness of 165 ft.; ordinarily btw. 50 and 100 ft.; but at many places it merges so gradually into the very sandy sh. which overlies and underlies it that no definite top nor bottom can be ascertained. It lies 0 to 170 ft. below Larimer ss. and 300 to 600 ft. above Terry ss.

Rocky Ridge sandstone member (of Pottsville formation).

Pennsylvanian: North-central Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14) and 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221). *Rocky Ridge ss. memb.*—Thick-bedded conglomeratic quartzose ss., 50 to 100 ft. thick. A memb. of Pottsville fm. in Cahaba field, lying about 3,000 ft. above base of Pottsville. Recognized only in Little Cahaba syncline. Lies about 900 ft. below Straven cgl. memb. and about 2,760 ft. above Chestnut ss. memb.

Named for fact it forms Rocky Ridge, E. and NE. of Cahaba pumping station, in NW. part of Vandiver quad.

Rocky Run conglomerate.

Upper Devonian: Northeastern Pennsylvania (Pike County).

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, p. 1553). *Rocky Run cgl.*—A very coarse massive ss., with large fish bones. Outcrops on Rocky Run, Montour Twp, Pike Co. In view of large number of fish beds known to exist in Chemung and Catskill series it is hazardous to identify it with other fish-bed cgls. in distant counties.

Rocky Woods conglomerate.

Carboniferous: Southeastern Massachusetts (Taunton area).

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, p. 134, table). *Rocky Woods cgl.* included in Dighton group. [On p. 185 he says: "In this northern part of the basin the several exposures of cgl. referred to the Dighton group lie in the inner or upper part of synclines. This is true of the Great Rock area in Rehoboth, whence the rocks extend eastward to 'Rocky Woods' near Taunton."]

Rod Club sandstone member (of Springer formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 12, 13). *Rod Club ss. memb.*—A sandy zone, 250 to 400 ft. thick, containing several sss. ranging up to 25 ft. in max. individual thickness. Basal memb. of Springer fm. Lies 1,000± ft. below Overbrook ss. memb.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, pp. 15–16). *Rod Club sandy memb.*—Sandy zone, usually containing 4 or more ledges, each 2 to 25 ft. thick, of rather hard greenish to buff fine- to medium-grained ss. Named for outcrops at the smaller Rod and Gun Club lake in NW¼ sec. 7, T. 4 S., R. 2 E., on SE. plunging nose of Caddo anticline.

Rodemar sand.

A subsurface sand, of Sil. age, in western Ky.

Rodeo shale. (In Monterey group.)

Miocene (middle): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Rodeo sh.*—Bituminous sh., mostly chalky and more or less stained with oxide of iron, but locally cherty. A subdivision of Monterey group. Underlies Briones ss., and overlies Hambre ss. Thickness 670 ft. Named for exposures along Rodeo Creek, in NW. part of Concord quad., Contra Costa Co.

Rodman limestone. (In Black River group.)

Middle Ordovician: Central Pennsylvania (Blair to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 525, 533, 537). *Rodman ls.*—Dark crystalline ls. weathering with rough granulated surface. Thickness 30 ft. Upper fm. of Black River group. Overlies Lowville ls. and underlies Trenton ls.

Named for exposures at Rodman Station, Blair Co.

Rogers chalk lens. (In Taylor marl.)

Upper Cretaceous (Gulf series): Northern central Texas (Bell County).

W. S. Adkins and M. B. Arick, 1930 (Univ. Tex. Bull. 3016, p. 65). *Rogers chalk lens*, in Taylor marl, is probably less than 50 ft. thick. It is a soft marly chalk, bluish gray on original exposure, dull grayish white on exposure, with mostly poor but locally platy bedding and little clay or iron segregations. Fossils. Is overlain by 424 ft. of Upper Taylor marl and underlain by 350± ft. of Lower Taylor marl. Type loc., several exposures on a small creek from about 1 mi. to 1¼ mi. S. and a little W. of Rogers. Fairly persistent in SE. Bell Co.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 270, 456), placed this chalk below Lott chalk and higher than Durango sand.

Rogers Gap division. (In Cynthiana formation.)

Middle Ordovician: Central Kentucky.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull. 17, pp. 19, 23, 42, 44). *Rogers Gap div.*—Fossiliferous strata [not described] at base of Eden in central Ky. Regarded as probably contemp. with Economy memb. of Eden.

A. F. Foerste, 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, pp. 109–145), described fauna of *Rogers Gap beds*, and included them in Cynthiana fm., stating that they were older than Eden.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2) and 1919 (Md. Geol. Surv. Camb. and Ord. vol., p. 51), and A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138, No. 121 geol. ser., chart opp. p. 58), divided Cynthiana fm. (of late Trenton age) into (descending) Rogers Gap, Gratz, Bromley, and Greendale.

Probably named for Rogers Gap, Scott Co.

Rogersian series.

A term applied by C. [R.] Keyes to upper part of the pre-Camb. rocks of Mont. and Alberta, and divided by him into *Donald qtzite* (above), 5,000 ft. thick, and *Ross qtzite* (below), 2,500 ft. thick. Derivation of names not stated. (See Pan-Am. Geol., vol. 44, 1925.)

Rogers Spring limestone.

Mississippian (lower): Southeastern Nevada (Muddy Mountains).

C. R. Longwell, 1921 (Am. Jour. Sci., 5th, vol. 1, p. 46) and 1928 (U. S. G. S. Bull. 798). *Rogers Spring ls.*—Granular lss., in part crystalline; beds regular and heavy, 1 to 20 ft. thick, dark gray or almost black to light gray; much carbonaceous matter; heavy beds of dark fine-grained qtzite and siliceous ls. in Muddy Peak and Rogers Spring horst probably belong to this fm. Madison (lower Miss.) fossils found 200 ft. above base. Thickness 600± ft. Underlies Bluepoint ls., with probable uncon., and rests on Muddy Peak ls., with probable discon. Occurs along Rogers Spring fault scarp, Clark Co.

Rogersville shale.

Middle Cambrian: Northeastern Tennessee, southwestern Virginia, and western North Carolina.

M. R. Campbell, 1894 (U. S. G. S. Estillville folio, No. 12, p. 2). *Rogersville sh.*—Blue calc. sh. 0 to 120 ft. thick, abundantly fossiliferous and remarkably persistent over large area in NE. Tenn. In Carter Valley E. of Cloud Ford the fm. becomes a dark siliceous ls. which cannot be separated from the lss. above and below. Overlies Rutledge ls. and underlies Maryville ls. [This quad. adjoins type loc.]

The foregoing is first appearance in print of *Rogersville sh.* The fm., however, was named by A. Keith, whose description of it in its type area was not published until 1896 (U. S. G. S. Morristown folio, No. 27). He described it as consisting chiefly of bright-green argill. shales with occasional beds of thin red sandy sh.; in its eastern and southern areas divided by a bed of massive blue ls.; and in its NW. outcrops contains many small beds of shaly ls. Thickness 70 to 250 ft. Overlies Rutledge ls. and underlies Maryville ls. Named for excellent exposures at and near Rogersville, Hawkins Co., Tenn.

Rogersville limestone. (In Greene formation.)

Permian: Southwestern Pennsylvania (Greene County).

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 97, 106). *Rogersville ls.*—Lies lower than Jollytown [Claysville?] ls. and higher than Pursley coal. Included in Greene fm. Is No. VIII of vol. K. Is confined to central Greene Co., where it lies 19 to 35 ft. above Ten-mile ls. Is an earthy ls.

Rogue River group.

Cretaceous: Southwestern Oregon (Rogue River Valley).

See under *Willamette group.*

Rolland granite.

Pre-Cambrian: Quebec.

F. F. Osborne, 1935 (Quebec Bur. Mines Rept. Minister Mines 1934–35, pt. E, pp. 18, 19, 24, map).

Rollins sandstone member (of Mesaverde formation).

Upper Cretaceous: Central western Colorado (Delta County region).

W. T. Lee, 1909 (U. S. G. S. Bull. 341, pp. 20, 23). *Rollins ss. memb. of Mesaverde fm.*—White cliff-making ss. containing marine invertebrates. Thickness 100± ft. Basal memb. of Mesaverde fm. in Grand Mesa coal field. Underlies Bowie sh. memb. of Mesaverde fm. Forms conspicuous cliff at Rollins mine, N. of Delta, Delta Co.

Roll Quarry limestone.

Age (?): West-central Vermont.

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., p. 283). *"Roll" Quarry ls.*—A black platy shaly ls. exhibiting slickensides and pyrite. A blue-gray massive ls. shot with calcite lies beneath the black platy ls. [All there is about it.]

Rolls Ford shale member (of McLeansboro formation).

Pennsylvanian: Central western Illinois (Springfield quadrangle).

T. E. Savage, 1915 (Ill. Geol. Surv. Bull. 20, pp. 99–107). In McLeansboro fm., btw. coals Nos. 6 and 7, are several ft. of red mottled shales which are exposed at Ralls Ford on Sangamon River, and constitute a very characteristic and easily recognized horizon throughout this region [Springfield quad.]. For convenience may be called *Ralls Ford sh. memb.* [In correlation table, pl. 12, he carried this name into Peoria section, to N.]

Some repts spell this name *Rolls Ford sh.*, and the locality is spelled *Rolls Ford* on Springfield topog. map.

Roma sandstone member (of Fayette formation).

Eocene (upper): Southern Texas (Starr County) and adjacent part of Tamaulipas, Mexico.

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1376, 1383, 1387). *Roma ss. memb. of Fayette fm.*—In lower part of Fayette fm. Exposed at Int. Bridge, San Pedro de Roma on Mexican side of Rio Grande from Roma [Starr Co.], Tex. Consists of 362 ft. of soft coarse- to medium-grained light-gray ss. with several horizons containing hard dark-brown calc. concretionary masses and others containing brown hard nodular ss. masses in very soft sandy matrix. Several gravelly and conglomeratic beds near base. A few oysters throughout the ss. and a good fossiliferous bed of small bivalves at its base. Lies 183 ft. above base of Fayette fm. in section measured along both sides of Rio Grande btw. Roma and Rio Grande City [Starr Co.], Tex.

Romaine formation.

Ordovician: Quebec (Mingan Islands).

C. Schuchert and W. H. Twenhofel, 1910 (Geol. Soc. Am. Bull., vol. 21, p. 686).

Romance arkose.

Pre-Cambrian: Northwestern Vermont (Rochester quadrangle).

W. G. Foye, 1919 (11th Rept. Vt. State Geol., p. 84, in description of Rochester quad.). *Romance arkose* is thought to form basal part of qtzite memb. of upper Mendon series, of later Algonkian age. [Probably named for Romance Mtn, in W. part of Rochester quad., in Addison Co.]

Rome formation.

Lower Cambrian: Northwestern Georgia, northern Alabama, western North Carolina, eastern Tennessee, and southwestern Virginia.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. on Cahaba coal field, p. 149), described Weisner qtzite as "interpolated in Coosa and Montevallo shales, at no definite horizon but most commonly in their lower parts." (The Montevallo is now known to be same as Rome fm.)

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 143–146) and 1892 (Ala. Geol. Surv. Bull. 4, pp. 31, 33, 34–39). *Rome ss. and Weisner qtzite.*—Sandy shales, sss., and qtzites, 2,000 to 3,500 ft. thick, overlying Coosa [Conasauga] shales and underlying Connasauga sh. At base several hundred ft. of highly indurated greenish sandy sh.; succeeded upward by great thickness of purple or reddish-brown sss. (generally thin-bedded and frequently passing into sandy shales), in which are intercalated beds of white ss. or qtzite, from a few ft. to many hundred ft. thick, called *Weisner qtzite.* Upper part of fm. consists of highly colored shales. Rome ss. and Weisner qtzite are not regarded as distinct fms. but as different lithologic types of same fm., due to local differences in condition of sedimentation.

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala. with explanatory text), excluded Weisner qtzite from †Montevallo sh. (=Rome fm.), and treated it as a distinct fm. resting on the crystalline rocks.

C. W. Hayes, 1894 (U. S. G. S. Ringgold folio, No. 2, p. 1). *Rome fm.*—Sss. and shales, 3,000 to 4,000 ft. thick, overlying Apison sh. and underlying Connasauga sh. Basal 1,500 to 2,000 ft. (consisting of alternating layers of purple, brown, and white sss. interbedded with sandy shales) called *Rome ss.* Rest of fm. consists chiefly of brown or dark olive-green shales with some thin siliceous layers. [This area adjoins, on N., Rome quad., the type loc. of the fm.]

C. W. Hayes, 1895 (U. S. G. S. 16th Ann. Rept., pt. 3, pp. 554–559), treated Weisner qtzite as a distinct fm., in places separated from overlying Rome fm. by a blue siliceous ls., which he correlated (erroneously) with †Beaver ls. of Tenn., and which is now known as *Shady dol.*, 800 to 1,200 ft. thick. (See L. LaForge, Ga. Geol. Surv. Bull. 35, 1919, pp. 43–45; also C. Butts, Ala. Geol. Surv. Spec. Rept. No. 14, 1926, p. 64.)

C. W. Hayes, 1902 (U. S. G. S. Rome folio, No. 78, p. 2). *Rome fm.*—Brilliantly colored (various shades of red, purple, green, yellow, and white) thin-bedded fine-grained sss. and sandy shales, 700 to 1,200 ft. thick. Overlies Beaver [Shady] ls. (which rests on Weisner qtzite), and underlies Conasauga fm. Basal part, thin-bedded red sss. [the *Rome ss. lentil* of many previous repts]; top characterized by rather heavy bed of white ss. Type loc. is S. of Rome, Ga. [See also description of *Conasauga sh.* in regard to drawing top bdy of Rome fm.]

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, p. 65). The *Rome fm.* (called "Montevallo or Choccolocco shales" by Ala. Geol. Surv.) is a rather heterogeneous unit, composed of red sh., green sh., reddish or chocolate ss., light-gray, rusty-weathering calc. ss., and local beds of fairly pure ls. and dol. The red sh. and rusty-weathering calc. ss. are its most characteristic features. Thickness in Ala. 700 to possibly 4,000 ft. Underlies Conasauga fm. and overlies Shady ls.

Named for exposures S. of Rome, Ga.

†Rome sandstone.

Lower Cambrian: Northwestern Georgia and southeastern Tennessee.

C. W. Hayes, 1894 (U. S. G. S. Ringgold folio, No. 2, columnar-section sheet). *Rome ss.*—Purple, brown, and white ripple-marked sss. interbedded with sandy shales and forming basal part of Rome fm.

Conflicts with Rome in broader sense.

Romney shale.

Middle Devonian: Eastern West Virginia, central and northern Virginia, western Maryland, and southern Pennsylvania.

N. H. Darton, 1892 (Am. Geol., vol. 10, pp. 13, 17). *Romney sh.*—Basal series of Dev. sediments in central Appalachian Va., consisting of dark fissile shales, in greater part black or dark brown, containing occasional thin beds of ss. and ls. Thickness 500 to 900 ft. Uncon. overlies Monterey ss. and underlies Jennings fm. Contains Hamilton fossils.

According to G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg, Pa., folio, No. 170), E. O. Ulrich, 1911 (G. S. A. Bull., vol. 22), E. M. Kindle, 1912 (U. S. G. S. Bull. 508), G. W. Stose, 1912 (Pawpaw-Hancock, Md., folio, No. 179), C. Prosser, 1915 (Jour. Geol., vol. 23), G. P. Grimsley, 1916 (W. Va. Geol. Surv. Rept. on Jefferson, Berkeley, and Morgan Counties), G. W. Stose, 1922 (Va. Geol. Surv. Bull. 23), and W. F. Prouty, 1927 (W. Va. Geol. Surv. Rept. on Hampshire and Hardy Counties) the Romney sh. included the Hamilton, Marcellus, and Onondaga, and the overlying Jennings fm. included the Genesee, Portage, and Chemung. In 1932 (Va. Geol. Surv. Bull. 34, pp. 63, 64) and 1933 (Map of Valley of Va. and accompanying text) C. Butts did not recognize the presence of any beds of unquestioned Genesee age, and divided the beds of Portage age into two parts, to the upper of which he applied the central Pa. name *Brallier sh.*, and the lower of which he included in a map unit (which he stated consisted "mainly of black sh.") which he designated *Romney sh.* Named for exposures at Romney, Hampshire Co., W. Va.

Rondout limestone. (In Cayuga group.)

Silurian: New York.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874–878). *Rondout waterlime.*—Underlies Manlius ls. and overlies Salina beds. Named for fine development in extensive cement quarries at and near Rondout. Middle fm. of Cayugan group.

E. O. Ulrich and C. Schuchert, 1901 (N. Y. State Mus. Bull. 52, pp. 650–653). *Rondout fm.* is but base of the Manlius, and former is completely transitional downward into Coralline ls. We know the Coralline ls. lies just below the Rondout at Rondout, N. Y.

C. Schuchert, 1903 (Am. Geol., vol. 31, pp. 160–175), restricted *Rondout ls.* to upper part (39 ft. at Schoharie) of strata originally apparently included under that name, and applied *Cobleskill ls.* to the 7 to 30 ft. or more of strata formerly called "Coralline ls." and apparently composing basal part of the Rondout as originally defined, since it overlies Salina fm. He stated: Clarke and Schuchert in proposing *Rondout* intended to apply this name to the "Waterlime" fm., characterized by an abundance of *Eurypterus*. It now turns out that the fm. at type loc. at Rondout, N. Y., is younger and lies above Cobleskill memb. of the Manlius, and it has therefore lost its intended significance. He also stated that the Cobleskill is inseparably connected with Rondout memb., and that it overlies Bertie fm. of the Salina. In this 1903 paper Schuchert assigned the Rondout to Cayugan, as before. This has for many years been the commonly accepted definition of Rondout ls.

C. A. Hartnagel, 1903 (Am. Geol., vol. 31, pp. 160–175), described *Rondout waterlime* as consisting of 0 to 40 ft. of sandy hydraulic ls. underlying Manlius ls. and overlying Cobleskill ls. In 1905 (N. Y. State Mus. Bull. 82) J. M. Clarke and D. D. Luther described the Rondout of Tully quad. as consisting of 40 ft. of hard dark blue-gray dolomitic ls. weathering light drab, in layers 6 in. to 2 ft. thick; overlain by Manlius ls. and underlain by Cobleskill dol. In 1906 A. W. Grabau described the Rondout of Schoharie Valley as consisting of 42 ft. of mostly lime mudrocks, but with frequent layers of more aren. texture, and at base a 6-ft. "cement bed," bluish gray, massively bedded; rests on Cobleskill ls. and is overlain by Manlius ls.

E. O. Ulrich in 1913 (Md. Geol. Surv. Lower Dev. vol., pp. 115–116) assigned the Rondout to Lower Dev., called the overlying fm. *Keyser ls.* (a name taken from W. Va. and stated by Ulrich to replace "the Manlius of the literature"), called the underlying fm. *Decker Ferry* (which he also included in Dev.), and stated that *typical* Manlius is of Sil. age, is older than Decker ls., and rests on Cobleskill ls. In same volume C. K. Swartz, C. Schuchert, and C. S. Prosser classified the Rondout of N. Y. and N. J. as Lower Dev. Geologists generally continued to place Rondout in Sil., which is where Schuchert's 1924 textbook of geol. placed it, also R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285, p. 41).

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10) and 1935 (N. Y. State Mus. Bull. 303), included *Rondout* in Sil., and placed it below Manlius ls. and above Cobleskill ls.

Ronkonkoma moraine.

Pleistocene (Wisconsin stage): Southeastern New York (Long Island).

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 766–776). *Ronkonkoma moraine*, name proposed by M. L. Fuller in manuscript discussion. Assigned to early Wisconsin. Older than Harborhill moraine, and followed Vineyard interval of uplift and erosion.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). Early part of Wisconsin stage of Mississippi Valley is represented on Long Island by Harbor Hill or inner moraine (0 to 30 ft. thick) and associated till and outwash and Ronkonkoma or outer moraine (0 to 150 ft. thick) and associated till and outwash.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). Probable equiv. of *Ronkonkoma moraine* on Cape Cod is designated as *Nantucket moraine*.

Ronkonkoma substage.

The time during which *Ronkonkoma moraine* was deposited.

Rooney chert member.

Mississippian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 14, 47, and passim). *Rooney chert memb. of Madison ls.*—Shows 3 striking differences when compared with underlying Dean Lake chert: (1) The chert is white; (2) it is usually in form of grossly vesicular nodules which break down to form angular fragments averaging 1 to 1½ in. diam.; (3) the lss. that form great bulk of the Rooney are always light-colored, in contrast to those forming part of Dean Lake memb. Rocks of entire memb. are massive, generally coarsely crystalline cream-colored lss. interbedded at irregular intervals with thin zones of calc. buff sh., and with white to white-gray chert disseminated throughout. Thickness 202 to 578 ft. Fossiliferous throughout. Forms upper part and top of higher peak of Lone Butte, where it is well exposed. Type loc. on S. slope of top of Lone Butte, in SE¼ sec. 23, T. 23 N., R. 13 W.

Roosville formation.

Pre-Cambrian: Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines Mem. 38, map 2, 114°30′ to 115°). *Roosville fm.*—Light-green and gray thin-bedded metargillite. Overlies Phillips fm. [Assigned to Middle Camb. (?), but correlated with fms. which U. S. Geol. Survey classifies as pre-Camb. Later Canadian repts assign it to *Belt series*.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 109+, table at 178). *Roosville fm.*—Chiefly thin-bedded light-green, light-gray, and greenish-gray siliceous metargillite bearing thin, more qtzitic interbeds. Weathers light gray or brownish gray. Thickness 600+ ft. No fossils. Top fm. of Galton series. Conformably overlies Phillips fm. Appears to be younger than any beds of Lewis series. May prove to be = upper div. of the Kintla or may represent westward extension of a distinct fm. Top removed by erosion. Named for post-office recently opened on Phillips Creek, at Roosville, B. C.

†Rosalie granite.

Pre-Cambrian: Central northern Colorado (Georgetown quadrangle).

S. H. Ball, 1906 (Am. Jour. Sci., 4th, vol. 21, p. 383). *Rosalie granite.*—Biotite granite; massive granular rock, whose predominant constituent is a salmon-pink microcline often showing carlsbad twinning. Forms ridge btw. Mount Evans and Mount Rosalie. Cuts the quartz monzonite and is intruded by Silver Plume granite.

T. S. Lovering, 1929 (Colo. Sci. Soc. Proc., vol. 12, pp. 69–70). "Rosalie" granite is same as Pikes Peak granite. Latter name has priority, so "Rosalie" is abandoned.

†Rosamond series.

Tertiary (Miocene?): Southeastern California (southeastern Kern County and northern Los Angeles County).

O. H. Hershey, April, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pl. 1, map). [On legend of map *Rosamond series* appears btw. Cret. shales below and Escondido series above, and is mapped to N. of Rosamond, Kern Co.]

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 349–372). *Rosamond series.*—A rhyolite series, 1,650 ft. thick, consisting of interbedded ss. and rhyolite tuff with one massive bed of dark-red lava. Uncon. underlies Barstow series. Type section near Rosamond Station.

J. C. Merriam, 1919 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, No. 5, pp. 440–448). While the name *Rosamond series* may tentatively be used for middle and late Tert. sediments of Mohave area, it has not been demonstrated that the several fms. represented are as closely related in their depositional history as they appeared in first investigations. If Barstow fm. is a memb. of Rosamond series of Hershey it is a late memb. It will be recognized as a div. of Rosamond series. It is doubtful if Rosamond series comprises sediments of the stage represented at Ricardo.

C. D. Hulin, 1925 (Calif. State Min. Bur. Bull. 95), assigned *Rosamond series* to upper Mio.

E. C. Simpson, 1934 (Calif. Dept. Nat. Res., Div. Mines, Calif. Jour. Mines and Geol., vol. 30, No. 4, p. 400). Only fossils found in *Rosamond fm.* of Elizabeth Lake quad. are reeds, calc. algae, and fragments of silicified wood, all rather useless in correlation. But abundant mammalian remains have been found in upper members of Rosamond fm. at Barstow and determined by J. C. Merriam (1919) to be upper Mio. This age may be accepted as not far wrong for the Rosamond of Elizabeth Lake quad.

C. D. Hulin, 1934 (p. 420 of book cited above under *E. C. Simpson*). Age of middle and upper phases of *Rosamond series* can be fixed as early Upper Mio. on basis of vertebrate fossils in Barstow syncline; and it appears probable base of the Rosamond is not older than Middle Mio., but this needs verification.

Rosario formation.

Cretaceous: Mexico (Baja California).

F. M. Anderson and G. D. Hanna, 1935 (Calif. Acad. Sci. Proc., 4th ser., vol. 23, No. 1, p. 7).

Rosebud beds.

Miocene (lower and early middle): Central southern South Dakota.

W. D. Matthew and J. W. Gidley, 1904 (Am. Mus. Nat. Hist. Bull., vol. 20, pp. 241–246). The lower Mio. fm. (probably the lowest stage of the lower Mio.) of southern S. Dak., for which we propose the local term *Rosebud beds*. Best exposed along Little White River and in vicinity of Rosebud Agency [Todd Co.]. Closely resembles portions of upper Olig. beds, both in character and general appearance, except that they contain a little more sand. Lithology of these river and plains deposits is so unreliable that paleontological evidence is necessary to determine horizon. Overlain uncon. by Loup Fork beds (uppermost Mio.). No traces of middle Mio. in region. Is possibly=Gering beds of Darton in NW. corner of Nebr.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 65), shows these beds as of lower and early middle Mio. age, and as=Arikaree fm. of NW. Nebr. and SE. Wyo. Arikaree has priority.

Rose Canyon shale.

Eocene: Southern California (San Diego County).

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7, pp. 187–246). *Rose Canyon sh.*—Mudstones, gray shales, fine sands, cgls., and a few thin beds of ls. The sss. are usually fine-grained and vary from light to dark brown. Lower part is cross-bedded. Thickness about 300 ft. Is upper div. of La Jolla fm. Discon. underlies Poway cgl. and grades into underlying Torrey sand. In NW. part of quad. rests with marked angular uncon. on Black Mtn volcanics. Named for exposures at big bend in Rose Canyon, La Jolla quad. Contains brackish water fauna.

Rosedale member.

Upper Ordovician: Toronto, Canada.

W. A. Parks, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 103–104).

See quotation under *Dundas fm.* Type loc. not stated.

Rosedale gas sand.

A subsurface sand, 40 to 85± ft. thick, in Pottsville fm. (Penn.) of W. Va. Believed to correspond to Guyandot ss. memb. The *Rosedale salt sand* is an older sand and believed to correspond to Sharon cgl. memb. of Pottsville fm. The sands were named for occurrence near Rosedale, Braxton Co., W. Va.

Rose Hill formation.

Silurian (Niagaran): Maryland, northern Virginia, and Pennsylvania.

C. K. Swartz, 1923 (Md. Geol. Surv. Sil. vol., see index), introduced *Rose Hill fm.* for pre-Rochester part of *Clinton group* (as he called the Clinton) of Md. Defined it as consisting of 300 to 550 ft. of fossiliferous sh. interbedded with subordinate amounts of thin argill. ss. and a few bands of ls.; the sh. being argill., thin-bedded, fissile, of drab or olive color, but with pink or reddish beds in upper part. Comprises all beds in Md. btw. top of Tuscarora fm. and base of Keefer ss., and is divisible into: (1) Upper sh. beds with some purplish bands and some thin lss.; (2) Cresaptown iron ss., 10 to 30 ft.; (3) lower sh. and ss. beds, 175 ft. Named for exposures on Rose Hill, Cumberland, Md. Correlated with pre-Rochester part of Clinton of N. Y. by its "fauna, lithology, strat. position and geographic variation." [Swartz expressed opinion that Clinton might still fittingly be retained for the beds beneath the strata containing the Rochester fauna, although "some at least of the iron ores occur in the beds assigned to the Rochester by Ulrich."]

In several subsequent repts (1930, 1931, and 1934) Swartz continued to use this name.

Rose Island arkose.

Carboniferous: Southern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 308, 380). *Rose Island arkose.*—Occurs on Rose Island [one of Newport Harbor Islands]. Probably contemp. with some part of Aquidneck sh. series. Not so thick as Conanicut arkose.

A part of Wamsutta fm. as mapped by B. K. Emerson, U. S. G. S. Bull. 597, 1917.

Rosendale limestone member (of Salina formation).

Silurian: Eastern New York.

J. Hall, 1893 (N. Y. State Mus. 46th Ann. Rept., pp. 156, 159). At Rosendale [Ulster Co.] we find most southern exposure of these high escarpments of Lower Helderberg lss. underlain by a great development of the Waterlime, which is here extensively manufactured into hydraulic cement [p. 156]. It is only those parts of Waterlime group (=*Rosendale ls.*) where these turbid sediments are not deposited, that the characteristic fauna of that horizon, the Eurypteridae, flourish. [p. 159.]

In 1894 (N. Y. State Geol. 13th Ann. Rept., pp. 15–18) James Hall included in Salina "group" the "waterlime" extensively quarried at Rosendale, Ulster Co. [8 mi. SW. of Kingston].

C. A. Hartnagel, 1905 (N. Y. State Mus. Bull. 80, pp. 342–357). *Rosendale cement.*—Lower cement bed at Rosendale and High Falls. Thickness 14 ft. Holds strat. position of Bertie waterlime of western N. Y., which is characterized by *Eurypterus* fauna. Absence of *Eurypterus* from Rosendale bed of eastern N. Y. is attributed to fact that this section of State belonged to another sea province. We therefore propose to meet this difference in the E. by introducing *Rosendale cement* for lower cement bed in Ulster and adjoining counties. Is top memb. of Salina beds. Overlain by Cobleskill ls. and underlain by Wilbur ls.

In 1913 (Md. Geol. Surv. Lower Dev. vol.) C. K. Swartz, C. Schuchert, and C. S. Prosser classified the Rosendale as Lower Dev., but later Schuchert (1924 Textbook of geology) assigned it to Sil. (Cayugan).

Is top memb. of Salina fm. in eastern N. Y., and is thus classified by N. Y. State Survey and U. S. Geol. Survey.

See also under *Bertie ls. memb.*

Rosewood shale. (In Osage group.)

Mississippian: Western and northern Kentucky and southeastern Indiana.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, p. 150). *Rosewood sh.*—Bluish-gray, unevenly fissile and siliceous sh., 190 ft. thick. Middle fm. of Osage group in Jefferson Co., Ky. Underlies Holtsclaw ss. and overlies Kenwood ss. The Riverside ss. of Ind. is represented in Rosewood sh. and probably in lower part of Holtsclaw ss. Is "Knob" sh. of early repts. Contains Keokuk fossils.

E. R. Cumings, 1922 (Hdb. Ind. Geol. pt. 4. Sep. Pub. 21, pp. 408, 489, 490). It seems very probable that *Holtsclaw ss.* is a synonym of Riverside ss., which has priority and is therefore used by writer for the ss. overlying Rosewood sh. and underlying Warsaw (Harrodsburg) ls. in Ind. The Rosewood has not been certainly identified N. of Clark Co., Ind.

P. B. Stockdale, 1931 (Ind. Dept. Cons. Div. Geol. Pub. 98, pp. 52, 111, 124). Above Kenwood ss. of Butts (1915, pp. 150–151), which is here included in New Providence fm., is a very fine-grained siltstone, 125± ft. thick in Floyd Co., Ind., which weathers to a decided shaly appearance. This siltstone, which is [in part] the Rosewood sh. of Butts, is here named *Locust Point fm.* The rest of Rosewood sh. of Butts and his overlying thin Holtsclaw ss. are here included in Carwood fm. Writer concludes, from great number of observations in Ind. and adjacent Ky., that upper part of Butts' "Rosewood" cannot be differentiated lithologically from Butts' "Holtsclaw ss." where exposures with same degree of weathering are compared. Butts apparently based his subdivisions "Rosewood sh." and "Holtsclaw ss." partly upon faunal characteristics, believing that certain large brachiopods were restricted to "Holtsclaw ss." Butts' list of "Rosewood sh." fauna did not include *Orthotetes keokuk* or *Syringothyris textus*, but writer found former fossil well down in "Rosewood sh." In numerous Ind. exposures "typical Holtsclaw fossils" occur 125 ft. below top of Holtsclaw ss. Type loc. of "Rosewood sh." is also objectionable. Instead of village of Rosewood, Harrison Co., Ind., "being located on the outcrop of the sh.," as stated by Butts (1915, p. 150), it is situated on the alluvium of Ohio River, and lies much higher than the rock to which Butts applied the name "Rosewood" in Jefferson Co., Ky. The base of bluff nearest village of Rosewood is about 125 ft. above base of Butts' "Rosewood sh." As the rocks in lower part of bluff are covered, but little exposure of rock can be found that belongs to the 190-foot strat. interval of the Jefferson Co., Ky., "Rosewood sh." These facts all indicate that the term "Rosewood" is unsuitable and confusing. The misapplication of "Holtsclaw" in Ind. has also added to the confusion [see p. 125 of book cited]. All facts oppose placing dividing plane at position given by Butts and call for a resubdivision and renaming of the rocks. [See also under *Carwood fm.* and *Locust Point fm.*]

Rosiclare sandstone member (of Ste. Genevieve limestone).

Mississippian: Western Kentucky and southern Illinois.

E. O. Ulrich and W. S. T. Smith, 1905 (U. S. G. S. P. P. 36, pp. 24, 40). *Rosiclare ss.*—Highly calc. ss., laminated, soft, and porous; 1 to 25 ft. thick; of light-red or reddish-brown color in natural exposures. Middle memb. of Ste. Genevieve ls. Underlies Ohara ls. memb. and overlies Fredonia ls. memb.

Named for Rosiclare, Hardin Co., Ill. Typical development in Ohio River bluff just below town.

Rosita andesite.

Tertiary (Eocene): Central southern Colorado (Silver Cliff-Rosita region, Custer County).

W. Cross, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 285). *Rosita andesite tuff and breccia.*—Massive andesite, breccia, and tuff. Chief occurrence is beneath and about town of Rosita, "whence the local name."

Roslyn formation.

Eocene: Central Washington (Mount Stuart and Snoqualmie quadrangles).

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137, map). *Roslyn ss.*—Thick-bedded light-colored ss. at top and base; rest of fm. shales and coals, latter mined at Roslyn; locally includes a sheet of Columbia [River] basalt resting on 100 to 150 ft. of tuff. Total thickness of fm. 200 to 3,500± ft. Separated from overlying Ellensburg ss. by several later sheets of Columbia [River] lava and associated tuffs. Overlies lowest sheet of Columbia [River] lava. Fossil plants assigned to Eo. by F. H. Knowlton.

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Roslyn fm.* (Eo.) rests on Teanaway basalt (Eo.). [See also U. S. G. S. Mount Stuart folio, No. 106, 1904, and Snoqualmie folio, No. 139, 1906, both by G. O. Smith.]

Ross limestone member (of Olive Hill formation).

Lower Devonian (Helderbergian): Western Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 579, 685). [See explanation in 1903 item under *Pyburn ls.*]

C. O. Dunbar, 1918 (Am. Jour. Sci., 4th, vol. 46, p. 739). *Ross ls. memb.*—Impure dense fine-grained thin-bedded cherty ls. in layers 2 to 5 in. thick; hard and compact when fresh; weathers to soft, porous shaly ss. of rusty-brown color. Thickness 0 to 80± ft. Heretofore regarded as oldest Dev. bed in Tenn. Basal memb. of Olive Hill fm. Uncon. overlies Rockhouse sh. (basal Dev.) to S., but to N. rests on Decatur ls.

Named for exposures on Ross farm, near Sulphur Spring, Hardin Co.

Ross quartzite.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 137). Included in Beltian series.

†Ross limestone. (Lower Triassic.)

See *Ross Fork ls.*, the approved name.

Ross Brook formation.

Silurian: Nova Scotia.

M. Y. Williams, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 240).

Ross Fork limestone. (Of Thaynes group.)

Lower Triassic: Southeastern Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492) and 1916 (Wash. Acad. Sci. Jour., vol. 6, Jan., 1916, pp. 33, 35). *Ross ls.*—Consists of (descending): (1) 500± ft. of dense calc. sh., gray to olive greenish, weathering brown to yellow; (2) 800± ft. of massively bedded and thin-bedded gray to brown lss. with large numbers of small brachiopods and pelecypods, with intervening shales; (3) *Meekoceras* zone, consisting of 50 ft. of gray to reddish-brown lss. Thickness of fm. 1,350± ft. Is basal fm. of Thaynes group in Fort Hall Ind. Res. Conformably underlies Fort Hall fm. and conformably overlies Woodside sh. Named for Ross Fork Creek, in upper waters of which it is well exposed.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713, p. 46, and Bull. 716, p. 128). *Ross Fork ls.*, previously described under name *Ross ls.* [preoccupied by a Lower Dev. ls. in Tenn.].

Rossian series.

A term employed by C. [R.] Keyes to cover rocks of Cordilleran region interpreted by him as formed during Keweenawan epoch. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.) Probably covers Ross qtzite of Daly.

Rossie intrusive complex.

Pre-Cambrian: Northwestern New York (St. Lawrence County).

A. F. Buddington, 1929 (N. Y. State Mus. Bull. 281, pp. 81–86, 89). *Rossie intrusive complex*, mapped in Hammond quad., near Rossie. Intrudes Grenville series. Consists of gabbro, diorite, quartz diorite, etc. [According to p. 52 the Rossie phacolith belongs to his Hermon type of granite.]

See also Buddington, 1934 (N. Y. State Mus. Bull. 296, pp. 105–108, 149, etc.).

Ross Lake shale member (of Ptarmigan formation).

Middle Cambrian: Alberta and British Columbia.

C. D. Walcott, 1917 (Smithsonian Misc. Coll., vol. 67, No. 1, Pub. 2444, pp. 1-5). *Ross Lake sh. memb. of Ptarmigan fm.* is name proposed for the 7 to 11 ft. of dark-gray fine siliceous sh. with local fillets and thin layers of gray ls., carrying *Albertella* fauna and lying about 100 ft. below top of Ptarmigan fm. Type loc. is cliffs above Ross Lake, 1 mi. S.-SW. of Stephen Station on Continental Divide and S. of Canadian Pacific Ry. [Fauna listed.] It may be an error to include Ross Lake sh., with its *Albertella* fauna, in Ptarmigan fm. That is problem for future worker in field to determine.

Rossland volcanic group.

Age? (Carboniferous?, Triassic?, Jurassic?): Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, maps 7, 8, 9, 117° to 118°30'). *Rossland volcanic fm.*—Flows and pyroclastic deposits of latites, andesites, and basalt. [Mapped at and around Rossland, B. C., just N. of Int. Bdy. Assigned to *Carbf. to Cret.* (?).]

O. E. LeRoy, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 143). [Assigned to *Carbf. and post-Carbf.*]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 323, 385, etc.). If in future *Rossland volcanic group* can be analyzed with sufficient accuracy to permit of its subdivision on the map, it would be appropriate to reserve the name for the latitic lavas and associated pyroclastics, for these seem to be the dominant extrusives of the area.

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, pp. 47-49). *Rossland volcanic series.*—Voluminous series of lavas and tuffs. Extends along Int. Bdy for distance of one-half width of Stevens Co., Wash. Has been referred to Triassic and Jurassic but may include also lavas of Tert. age. Overlies Pend Oreille group.

R. W. Goranson, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 69). *Rossland group* is Triassic.

Rossland monzonite.

Mesozoic: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 8, 117°30' to 118°). *Rossland monzonite (stock)*, Mesozoic.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 337). *Rossland monzonite.*—Shonkinitic rocks; hornblendite at Columbia River. Underlies city of Rossland [B. C., just N. of Int. Bdy]. Assigned to Mesozoic. Dr. Young has suggested possible Jurassic age for this monzonite.

Rossland alkali granite.

O. E. Le Roy, 1913 (12th Int. Geol. Cong. Guidebook 9, p. 62). Tertiary, British Columbia.

Rossland Mountain group.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 319). *Rossland Mtn group,* Wash. and B. C. [Apparently same as Rossland volcanic group.]

Rossville shales and sandstone.

Pennsylvanian: Northeastern Kansas.

J. W. Beede, 1898 (Kans. Acad. Sci., Trans., vol. 15, p. 31). *Rossville shales and ss.*—Nearly unfossiliferous shales and soft sss. of various colors, with occasional streaks of ls. Thickness about 100 ft. [From statement on p. 28 appear to constitute topmost part of Upper Coal Measures in Shawnee Co. and to overlie Dover ls.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 235, 255), discarded this term but did not explain its limits.

Apparently named for Rossville, Shawnee Co.

†Rotten limestone.

Upper Cretaceous: Alabama, western Tennessee, and Mississippi.

A. Winchell, 1857 (Am. Ass. Adv. Sci. Proc., vol. 10, pt. 2, p. 91), appears to have been the first to use "Rotten ls." in a titular sense although M. Tuomey, 1850 (Geol. Ala., 1st Rept.), and perhaps earlier repts, divided the Cret. rocks of Ala. into *rotten ls.* above and *marls, etc.* below. The first geographic name introduced to replace this descriptive term was "Tombigbee chalk" (preoccupied). The second geographic name appears to be "Demopolis." The third geographic name was "Selma chalk," by which name "Rotten ls." has been known since 1894.

Roubidoux formation.

Lower Ordovician (Beekmantown): Eastern and central Missouri.

F. L. Nason, 1892 (Mo. Geol. Surv. vol. 2, pp. vii, 12, 93, 114–115). *Roubidoux ss.*—Fossiliferous sss. overspreading Ozark region from Cabool to Gasconade City and from Salem to Doniphan, embracing much, if not all, of what has been called Second ss., and will undoubtedly include the areas of so-called First ss. as well, which is believed to be same as Second ss. The Roubidoux is upper fm. of Ozark series. Overlies Gasconade ls., the lower fm. of Ozark series.

C. R. Keyes, 1894 (Mo. Geol. Surv. vol. 4). *Roubidoux ss.*, 0 to 75 ft. thick, underlies First Mag. ls. and uncon. overlies Second Mag. ls. Is=First or Saccharoidal ss. and not believed=St. Peter ss.

A. Winslow, 1894 (Mo. Geol. Surv. vols. 6 and 7), and 1895 (Am. Geol., vol. 15, pp. 81–89). *Roubidoux or Saccharoidal ss.* overlies Jefferson City ls., and is=Joachim ls. and Crystal City ss.

C. F. Marbut, 1904 (The State of Mo., pp. 63–70). *Roubidoux ss.* underlies Jefferson City ls. and overlies Gasconade ls.

E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, pp. 41–42). *Roubidoux ss.*, 100 ft. thick, underlies Jefferson City ls., overlies Gasconade ls., and is=Moreau ss. and St. Elizabeth in part.

E. R. Buckley, 1905 (Mo. Bur. Geol. and Mines vol. 3, 2d ser., pp. 3–9). *Roubidoux ss.* of Nason, Winslow, and Marbut is=Bolin Creek ss., upper part of St. Elizabeth fm.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 267). *Roubidoux fm.*—A complex of ss., chert, qtzite, dol., and sh., of uncertain thickness and areal extent. Thickness 70 to 225+ ft. Underlies Jefferson City ls. and overlies Gasconade ls. Includes Bolin Creek ss. memb. Is=Second ss., Moreau ss., St. Elizabeth fm., and doubtfully Marshfield ss. and Bolivar ss. [This is commonly accepted definition of Roubidoux fm.]

C. L. Dake, 1922. (See under *Bolin ss. memb.*)

Named for Roubidoux Creek, Mo. (in Texas and Pulaski Counties).

Rough Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374–383). *Rough Creek bed.*—In descending order: 25 to 40 ft. of ss., partly massive; 50 ft. of blue sandy clay; and 150 ft. of sss., usually massive and containing considerable cgl., especially at top. Memb. of Strawn div. Underlies Buffalo Creek bed and overlies Hanna Valley bed.

Named for Rough Creek, Mills Co.

†Rough Creek shale member (of Tesnus formation).

Pennsylvanian: Western Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 45). *Rough Creek sh. memb.*—Hard, compact, and brittle dark-green, occasionally black sh., 865 ft. thick. Basal memb. of Tesnus fm. Probably disappears in E. part of Marathon region. [Type loc. not stated.]

Because of prior use of *Rough Creek* for a Penn. deposit in central Tex. the U. S. Geol. Survey has discarded this name and calls the bed *lower sh. memb. of Tesnus fm.*

Named for exposures on Rough Creek, in Dove Mtn quad.

Roulet conglomerate.

Upper Devonian: Central northern Pennsylvania (Potter County).

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. G_3, pp. 97–104). *Roulet cgl.* is name given to Mr. Sherwood's Chemung cgl., supposed by him to be represented by scattered blocks in vicinity of Roulet [Potter Co.]. From position of the scattered masses at Hebron I think it more than probable that they have descended from the stratum which may form top of Oswayo Mtns at the road crossing. In other words the exposure of Mr. Sherwood's typical Chemung cgl. would be above the exposure of his typical Pocono.

Apparently named for *Roulette* (Potter Co.), the spelling adopted by U. S. Geog. Bd. and U. S. Postal Guide.

Roulette conglomerate. (See above.)

Round Knob horizon (also shale member). (In Conemaugh formation.)

Pennsylvanian: Eastern Ohio and western Pennsylvania.

D. D. Condit, 1912 (Ohio Geol. Surv., 4th ser., Bull. 17, p. 35). *Round Knob horizon.*—Purple-red clay to deep-red even-bedded sh., 34 ft. thick, designated "Pittsburg red sh." by I. C. White. In many places entirely replaced by cross-bedded ss., the Saltsburg ss. of Stevenson. Underlies Harlem coal and overlies Barton coal. A memb. of Conemaugh fm.

W. Stout and R. E. Lamborn, 1924 (Ohio Geol. Surv., 4th ser., Bull. 28, p. 342), called these beds *Round Knob sh. memb.* and gave their thickness as 0 to 80 ft. "Normal position is btw. Harlem and Barton coals, but locally it extends up to Ames ls. and down to Anderson coal. Is usually red, but also gray, yellow, and buff."

Named for Round Knob, a hill in Madison Twp, Columbiana Co., Ohio.

Round Mountain silt.

Miocene: Southern California (Kern County).

A. Diepenbrock, 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, pp. 14, 16, pl. 2). *Upper Temblor (Round Mtn silt).*—In wells in Round Mtn and Mount Poso oil fields, NE. of Bakersfield, Kern Co. Consists, in Mount Poso field, of 220 ft. of gray and brown siltstone including a 50-ft. bed of diatomite 70 ft. below top, and 57 ft. of gray silty sand 3 ft. above base. Overlies Middle Temblor (Olcese sand).

Round Rock member (of Esmeralda formation).

Miocene (upper): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Round Rock memb.*—Chiefly rhyolitic breccia, tuffs, and rhyolite; contains a little bedded material, including some lenses of ss. Lithologically similar to Fraction breccia of Tonopah dist. and believed equiv. to the Fraction. Thickness 800 ft. Separated from overlying Diamond King memb. by 0 to 80 ft. of thin-bedded quartzose ss., which, for convenience, is mapped with the Round Rock memb. Overlies Hedwig breccia memb. Exposed in vicinity of Round Rock, about 1 mi. N. of Manhattan.

Rouzer sand.

A subsurface sand in Big lime of W. Va.

Rove slate.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Vermilion district) and western Ontario.

J. M. Clements, 1903 (U. S. G. S. Mon. 45, index). *Rove sl.*—Chiefly black carbonaceous sl., with graywacke, some quite slaty, others very massive; some qtzite. Thickness 2,600± ft. Overlies Gunflint fm. Uncon. below Duluth gabbro. Named for Rove Lake, just N. of Int. Bdy.

Rowan County stone.

Trade name for Berea ss. in Rowan Co., Ky. (See J. B. Hoeing, Ky. Geol. Surv. Bull. 1, 1905.)

Rowe schist.

Lower Cambrian (?): Western Massachusetts and southwestern and southeastern Vermont.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Rowe schist.*—Sericite schist, with amphibolite beds. Underlies Chester amphibolite and overlies Hoosac schist.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 76–78, 158, pl. 34). *Rowe schist.*—Quartzose sericite or hydromica schist with amphibolite beds. Thickness 4,000 (?) ft. Grades into underlying Hoosac schist, and to S. is indistinguishable from the Hoosac. Underlies Chester amphibolite. [See also U. S. G. S. Bull. 597, p. 41, and map, where it is assigned to Ord.]

Named for occurrence at town of Rowe, Mass.

Age changed to Lower Camb. (?) in 1932, because L. M. Prindle and E. B. Knopf, who have studied and mapped the fm., consider it to be Lower Camb. or older. (Am. Jour. Sci., 5th, vol. 24, Oct. 1932.)

Rowes vent-agglomerate.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series*. Is ½ mi. wide on Rowes Hill.

Rowlandville granite.

Age (?): Northeastern Maryland.

G. P. Grimsley, 1894 (Cincinnati Soc. Nat. Hist. Jour., vol. 17, pp. 79, 81, 88). *Rowlandville granite.*—Eruptive granite at Rowlandville, Cecil Co. Originally a normal granitite or biotite granite. May be much younger than Port Deposit granite gneiss.

Rowlesburg sandstone. (In Chemung formation.)

Upper Devonian: Northern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Preston Co., pp. 97, 194). *Rowlesburg ss.*—Bluish-gray hard fine-grained micaceous ss. with numerous fossil plants and strong odor of oil. Thickness 18 ft. Long quarried at Rowlesburg, Preston Co., where it lies 737 ft. below top of Chemung.

Rowley Creek slate.

Pre-Cambrian: Central southern Wisconsin (Sauk County).

A. Leith, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 216, pp. 329–330). *Rowley Creek sl.*—This sl. does not outcrop and is known only by drill records of 8 holes in E. part of Baraboo dist., all of which passed through Camb. ss., Rowley Creek sl., and underlying Dake qtzite. Occupies middle of synclinal trough where found but is apparently absent over most of dist. Thickness 40 to 149 ft. Gray on fresh surface but oxidized to red along some bedding and cleavage surfaces. Dominantly sericitic. Contains some chlorite and quartz. Is folded; bedding inclined from 20° to 60°. Named for small creek that flows through E. part of Baraboo syncline immediately above the known occurrence of the sl. Assigned to Algonkian.

Roxbury conglomerate.

Devonian or Carboniferous: Eastern Massachusetts (Boston Basin).

E. Hitchcock, 1861 (Am. Jour. Sci., 2d, vol. 31, p. 377). [See first entry under †*Newport cgl.*]

N. S. Shaler, 1871 (Boston Soc. Nat. Hist. Proc., vol. 13, pp. 173–175). *Roxbury cgl.*—Mass of stratified pebbles with intercalated sss. and grits, the whole capped by a series of ripple-marked sss., about 100 ft. thick, and at certain points overlain by masses of amygdaloidal trap. Thickness can not be less than 1,200 to 2,000 ft. and may be 4,000 ft. Assumed to belong to same great series of beds as Cambridge slates.

J. B. Woodworth, 1895 (Boston Soc. Nat. Hist. Proc., vol. 26, pp. 125–126). *Roxbury cgl.* underlies Cambridge sl.

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, geol. ser. vol. 8, No. 4, pp. 94–260). *Roxbury cgl.*—A series of ancient sediments which occupy large part of so-called Boston Basin. Consists of arkoses and coarse and fine cgls. interbedded with sss. and shales or slates. One of conglomeratic members is well developed and exposed in Roxbury, where it has long been known as "Roxbury Pudding-Stone." Since this rock is, on the whole, one of the most important and characteristic members of the series, its name has been extended to include the entire fm. Accompanying the Roxbury cgl. are contemp. intrusions or outflows of basic lava that are intimately related to the sed. series. The true northern bdy of Roxbury cgl. series is enveloped in some obscurity on account of uncertainty regarding age and strat. position of Cambridge and Somerville slates, which have been variously considered as underlying the cgl., as overlying the cgl., and as forming part of the cgl.

R. W. Sayles and L. LaForge, 1910 (Sci., n. s., vol. 32, pp. 723–724). *Roxbury cgl.* underlies Cambridge sl. Is of glacial origin. Upper part consists of 60 ft. of stratified cgl., ss., and interbedded sl., underlain by 500 to 600 ft. of tillite. [Lower part of fm. not described.]

R. W. Sayles, 1914 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, p. 164). *Roxbury series* consists of *Roxbury cgl. proper*, Squantum tillite, and Cambridge sl. [Diagram on p. 157 shows a *lower sl.* [Dorchester sl. memb.] btw. Roxbury cgl. and Squantum tillite.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 56–57). *Roxbury cgl.*—Thick cgl. and some ss. and sl. In S. part at least of Boston Basin it can be divided into 3 members (descending), Squantum tillite, Dorchester sl., and Brookline cgl. Underlies Cambridge sl. and overlies rocks belonging to Mattapan volcanic complex, but the later flows of Mattapan volcanic complex, chiefly amygdaloidal melaphyr, are at several places interstratified with the Brookline and Dorchester members. [L. LaForge (U. S. G. S. Bull. 839, 1932) separated these so-called "later flows of Mattapan volcanic complex" as a distinct fm., called *Brighton melaphyr*, which he mapped separately.]

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 97–134), treated Squantum tillite as a distinct fm.; separated as a distinct fm. (called *Milton qtzite*) 450 to 500 ft. of coarse greenish qtzite or grit, which he stated had formerly been included in Roxbury cgl. but which he considered to probably be of Camb. age; and assigned *Roxbury cgl.*, Squantum tillite, and overlying fms. to Perm.

L. LaForge, 1932 (U. S. G. S. Bull. 839), included Squantum tillite in Roxbury cgl.; did not mention Milton qtzite of Billings; stated that the 3 members of Roxbury cgl. (Squantum tillite, Dorchester sl., and Brookline cgl.) do not persist throughout Boston area; separated the so-called "later flows of Mattapan volcanic complex" as a distinct fm., called *Brighton melaphyr;* and assembled Roxbury cgl., Brighton melaphyr, and Cambridge sl. into Boston Bay group, which he assigned to Dev. or Carbf.

Roxbury puddingstone.

A name applied in some early repts (see W. W. Dodge, 1881, Boston Soc. Nat. Hist. Proc., vol. 21, pp. 201–205) to Roxbury cgl. of present nomenclature, and also probably applied to Brookline cgl. memb. of Roxbury cgl. (see G. R. Mansfield, 1906, Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, p. 95).

†Roxbury conglomerate proper.

A term applied by R. W. Sayles (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, pp. 164, 165, 1914) to basal memb. (Brookline cgl. memb.) of Roxbury cgl. of present nomenclature.

†Roxbury conglomerate series.

†Roxbury series.

Terms that have been used in some repts to include Cambridge sl. and Roxbury cgl. of present accepted nomenclature. R. W. Sayles, 1914 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, No. 2, p. 164), stated that *Roxbury series* consists of *Roxbury cgl. proper* [Brookline cgl. memb.], Squantum tillite, and Cambridge sl. His diagram on p. 157 shows a *lower sl.* [Dorchester sl. memb. of present nomenclature] btw. his Roxbury cgl. and Squantum tillite.

†Roxton beds.

Upper Cretaceous (Gulf series): Northeastern Texas and southwestern Arkansas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 114, 340). *Roxton beds.*—Glauconitic calc. stone outcropping near Roxton [Lamar Co.] and Honey Grove, Tex., and at base of White Cliff section on Little River, Ark. Memb. of Navarro fm. Overlies Brownstown beds and underlies Anona chalk.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Is a part of Gober tongue of Austin chalk in Tex., as now interpreted by L. W. Stephenson. In Ark. the beds btw. Brownstown marl and Annona chalk are now known as *Ozan fm.*

Royal formation.

Pennsylvanian: Southern West Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, pp. 487, 490). *Royal fm.*—Lower 150 to 200 ft. red and green shales and argill. sss., which lithologically clearly belong to Hinton fm.; upper part typical coal-bearing strata, which, according to David White, contain a true Pottsville flora. Natural line btw. lower Carbf. and Pottsville series seems to be at top of red shales, but geologists have generally regarded that horizon as variable and unsatisfactory. The practical difficulties in mapping the red shales which lie above Princeton cgl. are so great that present writers prefer to group them with the coal-bearing rocks above, although they are lithologically different and may belong to another series. Above this soft basal portion occurs a band of prevailingly aren. strata 400 to 500 ft. thick, chiefly beds of ss., usually coarse, heavy-bedded, and frequently conglomeratic; associated shales generally sandy; no workable coals, but thin coal seams at several horizons. The remaining beds are more argill. and valuable commercially because they include the Quinnimont-Fire Creek coal; also include at least one heavy ss., 50 or 60 ft. below Raleigh ss. Overlies Princeton cgl. and underlies Raleigh ss. along New and Kanawha Rivers, W. Va. [In U. S. G. S. Pocahontas folio (No. 26) the rocks btw. Princeton cgl. and Raleigh ss. are divided into following fms., descending order: Quinnimont sh., Clark fm., Pocahontas fm., and Bluestone fm.]

Named for Royal (P. O. Prince), Fayette Co.

Royal shale. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western Mercer and Summers Counties, p. 366). *Royal sh.*—Buff sandy sh. containing marine fossils. Thickness 2 to 4 ft. Lies 0 to 40 ft. below Pierpont ss. and overlies Pocahontas No. 6 coal. Occurs at Royal, Raleigh Co.

†Royalton formation.

Mississippian: Northeastern Ohio.

C. S. Prosser, 1912 (Ohio Geol. Surv., 4th ser., Bull. 15, pp. 33, 72, 144, 493). *Royalton fm.*—Blue argill. shales, with thin layers of ss. and ls.; 12 to 250 ft. thick; composing upper part of Cuyahoga terrane in Cuyahoga Valley, NE. Ohio. Underlain by Orangeville fm. and overlain by Sharon cgl. Includes Sharpsville sss.

Replaced by Meadville sh. and Sharpsville ss. (See U. S. G. S. Bull. 818, 1931.)

Named for exposures in Royalton Twp, Cuyahoga Co.

Royer marble.

Upper Cambrian: Central southern Oklahoma (Arbuckle Mountains).

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 28). Marine deposition in Arbuckle uplift began with Reagan ss., an Upper Camb. fm. with abundant fauna. Over this comes *Royer marble*, a previously unnamed Lower Ozarkian fm., about 500 ft. thick, that was included by Taff in basal part of his great Arbuckle ls. The fauna found in this fm. invaded from W. of Rocky Mtns by way of Marathon Basin of western Tex. Neither Middle nor Upper Ozarkian deposits occur in Okla. The remainder of Taff's Arbuckle ls. is assigned to Canadian period. It includes Lower, Middle, and Upper Canadian.

E. O. Ulrich, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 742+). In Wichita Mtns, Okla, the Signal Mtn fm. is everywhere underlain by Fort Sill fm. In Arbuckle Mtns the *Royer marble*, 100 to 600 ft. thick, wedges in btw. Signal Mtn and Fort Sill fms. The *Royer fm.* consists of massive dolomitic marbles with intercalations of thinner-bedded pure ls. Along Honey Creek, sec. 1, T. 2 S., R. 1 E., Okla., the Royer rests uncon. on Honey Creek fm., which in Wichita Mtns uncon. underlies Fort Sill fm. Named for old Royer ranch, near East Timbered Hills, along Ardmore-Davis highway, Arbuckle Mtns, where a good section is exposed.

Royston formation.

Permian: Central northern Texas (Fisher County).

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, p. 26, pl. 1). *Royston fm.*—A series of about 100 ft. of red shales, gyp., thin dolomites, and white calc. shales in Double Mtn group. Type loc. at Royston, Fisher Co. Older than Eskota dol. and younger than Aspermont dol.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 177). *Royston fm.* (Cheney, 1929) is probably basal part of Peacock fm. as defined by Patton and is probably chiefly within the Whitehorse as mapped by Lloyd and Thompson (Univ. Tex. Bull. 2913, 1929).

Royston gypsum.

A name that has been applied (W. E. Hubbard and R. W. Fischer, Tex. Bur. Econ. Geol. geol. map of King Co., central northern Tex., 1930) to 8± ft. of gyp. that lies within Royston fm. of Cheney, 1929.

Roystone coquinite member.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 61, 97). *Roystone coquinite memb.* (also *zone*).—Massive coquinite zone in lower part of Oswayo sh. memb. While coquinite layers are common throughout the Oswayo, this basal zone is so persistent in NW. Pa. that it seems worthy of memb. designation. Is of great correlation value. Well developed along Kinzua Creek, McKean Co.; exposed on Roosevelt Highway btw. Roystone and Ludlow, McKean Co., and on Wild Cat Creek at Ludlow, also on highway to Olean Rock City from Olean, N. Y., at the side road going W. to former trolley stop known as Flat Iron Station. Has frequently been mistaken for the younger Marvin Creek ls. Replaces Wild Cat coquinite (preoccupied), proposed by writer in 1933.

Rubio shale.

Cretaceous: Mexico.

E. Ordóñez, 1908 (Min. and Sci. Press, vol. 96, p. 363).

Rubio diorite and metadiorite.

Pre-Cretaceous (pre-Cambrian?): Southern California (San Gabriel Mountains).

W. J. Miller, 1934 (Univ. Calif. at Los Angeles Pub. Math. and Phys. Sci., vol. 1, No. 1, pp. 7–12, 49–65, 83, map). *Rubio diorite and metadiorite.*—About 30 bodies occur in western San Gabriel Mtns. Name *Rubio diorite* is here proposed because of its typical occurrence in large area extending from Rubio Canyon into Eaton Canyon. The rock varies to metadiorite on top of ridge 1¼ mi. NW. of top of Mount Wilson. Almost certainly younger than Placerita fm., which it cuts; is cut by Echo granite; is intimately associated with San Gabriel fm.; and is assigned to pre-Cret. [On map part of it is called *pre-Camb.* (?).]

†Ruby formation.

Eocene: Western Colorado (Gunnison County).

W. Cross, 1892 (Am. Jour. Sci., 3d, vol. 44, pp. 21–23). *Ruby beds.*—Cgls., sands, and shales, composed almost entirely of debris of volcanic rocks of andesitic character, much hardened and metamorphosed by later eruptive rocks, which pierce them in numerous dikes. At base a cgl. of small pebbles, some of which contain crinoid stems of identical character to those in Ohio Creek beds. These facts suggest that the chert pebbles of *Ruby cgl.* may be the residuum from destruction of Ohio Creek beds formerly existing to N. of Anthracite Range. Thickness of Ruby beds 300 to 2,000+ ft. Rest uncon. on Laramie fm. on Grand River, Gunnison Co. To N. there are soft yellowish sss. btw. the firm gray sss. of Laramie coal measures and Ruby cgl., which Hills suggests may possibly correlate with Ohio Creek beds. Underlie Wasatch fm., which consists of shales and brownish sss. No fossils except carbonized plants. Lithologic and strat. evidence suggests Ruby beds may = Denver fm. Named for Ruby Peak, near Irwin, Gunnison Co., where they are more than 2,000 ft. thick.

W. T. Lee, 1912 (U. S. G. S. Bull. 510, p. 51). G. H. Eldridge says (U. S. G. S. Anthracite-Crested Butte folio, No. 9, 1894) that "Ruby" fm. extends W. from Ruby Range and disappears beneath Wasatch fm. Present investigation shows his "Ruby" fm. is probably identical with that mapped as Wasatch in Grand Mesa region by geologists of Hayden Survey. No fossils found by Eldridge in his "Ruby" of Anthracite-Crested Butte region, nor did writer find any in this region or in Grand Mesa field, but in Book Cliffs, W. of Grand Mesa, G. B. Richardson found Wasatch fossils in variegated beds that are apparently identical with those of Grand Mesa. R. C. Hills states "Ruby" fm. extends N. to and beyond Grand River, and H. S. Gale and A. L. Beekly have traced a fm. that is apparently the same into the characteristic Wasatch of southern Wyo. For these reasons "Ruby" fm. is here referred to Wasatch.

Ruby limestone and gneiss.

Pre-Cambrian: Southwestern Montana (east of Dillon).

E. Douglass, 1905 (Carnegie Mus. Annals, vol. 3, pp. 407–428). Crystalline ls. and gneiss exposed in Ruby Canyon, W. of Old Baldy, and on E. slope of Ruby Mtns [Dillon quad.]. Probably are=Cherry Creek fm. of Peale, but to avoid possible confusion I will call these for the present the *Ruby crystalline ls. and gneiss.*

Rubyan series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53) and 1924 (Pan-Am. Geol., vol. 41, pp. 38, 78), to upper 1,100 ft. of Eldorado ls. (Middle Camb.) of Nev. ("well displayed on Ruby Hill at Eureka"), and to Bloomington fm. (Middle Camb.) of Utah.

Rudolph quartzite.

Pre-Cambrian (middle Huronian): Central northern Wisconsin (Wood County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16). [*Qtzite at Rudolph* (in heading), but on later pp. he calls the fm. *Rudolph qtzite.*]—Largest area is immediately E. of Rudolph, Wood Co. Probably 300 to 400 ft. thick. May be same as Junction City qtzite. Assigned to lower Huronian (?).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pl. opp. p. 598), assigned the qtzites of this area to middle Huronian.

Ruffner fire clay. (In Allegheny formation.)

Pennsylvanian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., p. 202). *Ruffner fire clay.*—Bluish-buff clay, 5 to 7 ft. thick, underlying Lower Freeport coal. Named for Ruffner, 2 mi. E. of Charleston, Kanawha Co.

Rugg Brook dolomite conglomerate.

Middle (?) Cambrian: Northwestern Vermont (Franklin County).

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 356, 359, 365, 366, 368, etc.). The Middle Camb. of NW. Vt. consists of St. Albans sl. and its basal *Rugg Brook dol. cgl.*, which Keith thinks should be regarded as a separate fm. Thickness of the cgl. is 0 to 20 ft. It uncon. overlies Parker sl. (Lower Camb.). The St. Albans sl. is underlain basally in at least 3 places by the Rugg Brook dol. cgl., which weathers salmon yellow and is usually less than 20 ft. thick. These 3 localities are on Rugg Brook, on Conner's farm, and near Rockledge. Type loc. is on Rugg Brook, less than 3 mi. SW. of St. Albans. The dol. blocks, up to 2 ft. across, are out of either the Parker or the Mallett fm., and rarely there are also pieces of Winooski red dol. The paste is the usual round-grained sand cemented by dol. No fossils known in Rugg Brook cgl. but St. Albans sl. contains Middle Camb. fossils.

Keith correlated his Clarendon Springs dol. (Lower Camb.) with his so-called Milton dol., which Schuchert has renamed *Rugg Brook dol. cgl.* and assigned to Middle Camb. If this correlation is correct, the Rugg Brook cgl. may be Lower Camb. or the Clarendon Springs dol. may be Middle Camb.

Ruin granite.

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Ruin granite.*—Granitite or biotite granite. Intrudes Pinal schist, which is overlain by Apache group. Is frequently found overlain by basal cgl. of Apache group. Occurs in Ruin Basin, Globe quad.

Rulo limestone. (In Scranton shale.)

Pennsylvanian: Southeastern Nebraska and eastern Kansas.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 8, 14, 26). *Rulo ls.*—Light-colored hard massive ls., 12 to 20 in. thick, lying 8 to 12 ft. below Burlingame ls. and overlying City Bluffs (Scranton) shales. Type loc. 2½ mi. N. of Rulo, Richardson Co., Nebr.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 41, 58, 105, 106), included in Scranton sh. his *Rulo ls.* and the sh. (named *Silver Lake sh.*) separating it from overlying Burlingame ls.; and this classification was adopted by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans. Condra's 1927 publication stated that Elmo-Silver Lake coal is just below Rulo ls.

G. E. Condra in 1930 named the sh. bed underlying Rulo ls. the *Cedarvale sh.*, and his 1935 classification adheres to that nomenclature.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), discarded Scranton sh. and treated Rulo ls. as a fm. in his redefined Wabaunsee group.

†Ruma formation. (In Chester group.)

Mississippian: Southwestern Illinois.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 126). *Ruma fm.*—Series of variegated shales and thin-bedded sss., 40 to 50 ft. thick, shales predominating. Underlies Okaw fm. and overlies Paint Creek fm.

Later work by S. Weller revealed fact that upper part of Ruma consisted of Cypress ss. and that lower part "properly belongs with Paint Creek fm." The name "Ruma fm." has therefore been abandoned. (See Jour. Geol., vol. 28, No. 4, 1920, pp. 281-290, and No. 5, pp. 395-416; also Ill. Geol. Surv. Bull. 41, 1920.)

Named for Ruma, Randolph Co. Typically exposed in some tributaries of Horse Creek, near Ruma.

Rundle limestone.

Pennsylvanian: British Columbia.

E. M. Kindle, 1924 (Pan-Am. Geol., vol. 42, pp. 115-123).

Later repts, by other geologists, assign Rundle ls. of *Alberta* to Penn. and Miss.; to Miss. (?) and Penn.; to Dev.; to Miss.; to Carbf.; and to Penn.

Rundlian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, pp. 285-288). Lss., 2,300 ft. thick, lying stratigraphically and uncon. below Weberian (?) series and stratigraphically and uncon. above Kinderhookian series in Banff, Alberta. Should the Rundle ls. prove to be a valid series the terrane should be given a serial ending to indicate its proper taxonomic rank; otherwise it shall have to be restricted or abandoned.

Rupert formation.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 222).

Rush member (of Tully limestone).

Upper Devonian: Central Pennsylvania (Northumberland County).

B. Willard, 1934 (Pa. Acad. Sci. Proc., vol. 8, pp. 57-62). *Rush memb. of Tully ls.* proposed for 10 ft. of more or less shaly to compact, dark ls. that weathers brown, exposed in road cut E. of small brook ½ mi. from railway station at South Danville (Riverside), in Rush Twp, Northumberland Co. Carries diagnostic Tully fossil *Hypothyridina venustula*, the first known occurrence of this fossil in Pa. Overlain by 13 ft. of gray sh. considered to be basal part of Genesee sh., and underlain by 21 ft. of dark limy sh. with pyrite nodules, which has strong Hamilton affinities and is here classed as Hamilton. [See further statement under *Tully ls.*, 1934 entry.]

See also *Rush fm.*

Rush formation.

Upper Devonian: Central Pennsylvania.

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1199 et seq). *Rush fm.*—Lower fm. of Portage group. Includes Burket memb. and underlying Tully memb. The name was originally used by writer for Tully ls. memb. where first recognized in Pa. It is now raised to formational rank. [The Burket memb. as defined by C. Butts, its namer, was included in Harrell sh., of Portage age. Willard stated it is of nearly equal distribution to Harrell, and that it replaces Genesee of his 1934 paper, which he defined as overlying his Rush memb. of Tully ls.] Named for Rush Twp, Northumberland Co. The intergradation of Burket and underlying Tully members and lack of intergradation of Burket and overlying Harrell memb. [restricted] have influenced the decision for grouping them into a single fm. Is separated from Harrell memb. by sharp lithologic change (practically a break) accompanied by appearance of a plentiful Naples fauna. Is discon. on Hamilton and is overlain by Fort Littleton fm., of Portage group. [The typical Tully ls. of N. Y. underlies Genesee sh., which is overlain by Portage group.]

Rushford sandstones.

Upper Devonian: Western New York.

D. D. Luther, 1902 (N. Y. State Mus. Bull. 52, p. 619). The Wiscoy shales (top fm. of Portage or Nunda group in Genesee River section) are overlain by band of flags and thin sss. that form "Long Beards riffs" and carry Chemung fossils. which are succeeded by nearly 300 ft. of shales and flags carrying Chemung fossils and overlain by the heavy *Rushford sss.* exposed in hills W. of Caneadea.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), showed Cuba ss. and Gowanda beds of Allegany Co. separated by *"Chemung," "Rushford ss."*

C. A. Hartnagel, 1927 (letter dated Sept. 13, 1927). These heavy sss. at Rushford appear to lie at least 450 ft. above base of Chemung. Until more field work is done it will be impossible to say whether the Rushford sss. correlate with any known fms. to E. or W. of Genesee River section.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, p. 862). *Rushford*=Shumla, Westfield, and Laona; is younger than Gowanda and older than Machias.

Rush Lake moraine (also **morainic system**).

Pleistocene (Wisconsin stage): Southeastern Wisconsin and southern Minnesota. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for development at S. end of Rush Lake, Winnebago Co., Wis. Also described in U. S. G. S. P. P. 161, 1932, where it is called, in Minn., *Rush Lake morainic system*, and divided into Pine City, Cambridge, Isanti, and Harris moraines, named in order from oldest to youngest.

Rush Run sandstone. (In Greene formation.)

Permian: Northern West Virginia.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel, and Tyler Counties, p. 191). *Rush Run ss.*—Massive ss., resembling in color and structure the Fish Creek ss. above. Thickness 10 to 25 ft. Lies 30 to 40 ft. below Fish Creek coal and a few in. to 20 ft. above Dunkard coal. Named for Rush Run, which empties into Fish Creek ¾ mi. SE. of Hundred, Wetzel Co. [Later repts give max. thickness 50 ft.]

Rush Springs member (of Whitehorse sandstone).

Permian: Southwestern Oklahoma (Wichita Mountains region).

R. W. Sawyer, 1929 (Okla. Geol. Surv. Bull. 40HH). Two divisions of Whitehorse ss. can be recognized in Kiowa and Washita Counties. The lower (Marlow memb.) consists of red even-bedded sss. and red shales, with some regular bands of fine white sand and much disseminated gyp.; the upper (*Rush Springs memb.*) consists almost entirely of red cross-bedded ss. and has little or no sh. or gyp. in this area. The Rush Springs memb. is Whitehorse ss. of Reeves. In Grady Co. the Marlow memb. is 110 ft. thick and Rush Springs memb. 240 to 280 ft. thick. The Greenfield dol. is near bdy btw. Marlow and Rush Springs members. In Kiowa and Washita Counties Whitehorse ss. is overlain by Cloud Chief fm.

C. M. Becker, 1930 (A. A. P. G. Bull., vol. 14, pp. 48, 50). The name *Marlow* (for basal Whitehorse ss., 110 to 135 ft. thick) and *Rush Springs* (for upper

Whitehorse ss., 250 to 300 ft. thick) are suggested by R. W. Sawyer and F. C. Greene. The upper Whitehorse or Rush Springs seems to be nearly all wind-blown sand, although local clay and gyp. deposits indicate presence of shallow ponds and small lakes within area of the Perm. desert. [Derivation of name not stated.]

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 408, 415–431). The top of *Rush Springs* is base of the Cloud Chief. The *Rush Springs* is "Whitehorse" of Reeves' rept on Cement field, Okla. (U. S. G. S. Bull. 726B, 1921). (See also under *Marlow fm.*)

S. Buckstaff, 1931 (A. A. P. G. Bull., vol. 15, No. 4, pp. 434–437). Evans' grouping of Marlow, Rush Springs, and Cloud Chief in a single unit is a logical step, but his separation and correlation of the members within that group is open to serious question. [Long discussion.]

F. C. Greene, 1932 (Tulsa Geol. Soc. Summ. and Abstracts, 1932, Tulsa Daily World), stated that *Rush Springs memb. of Whitehorse ss.* overlies Marlow memb. of the Whitehorse and underlies Weatherford dol.

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1454–1475). *Rush Springs ss.* is given fm. rank, because of uncon. at its base and at its top. It underlies Quartermaster fm. and overlies Marlow fm.

Apparently named for Rush Springs, Grady Co.

Rushville group.

Mississippian: Central Ohio.

E. B. Andrews, 1879 (Am. Jour. Sci., 3d, vol. 18, p. 137). *Rushville group.*—About 50 ft. of fossiliferous Lower Carbf. clay sh., with thin ls. in lower part and coarse ss. at top, underlying Maxville ls. (approx. Chester group of Ill.) and overlying the Waverly (=Kinderhook of Ill.) in Perry Co.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 771–779). The *Rushville group* of Andrews, 22½ ft. thick, possibly should be a 4th memb. of Logan fm., overlying Vinton memb.

Probably named for Rushville, near E. border of Fairfield Co.

†Russell formation.

Lower and Middle Cambrian: Southwestern Virginia and southeastern Kentucky.

M. R. Campbell, 1894 (U. S. G. S. Estillville folio, No. 12, p. 2). *Russell fm.*—Alternating sh., ss., and impure ls., more than 1,000 ft. thick (base not exposed). Top usually brown argill. sh., growing more sandy below, and varying in thickness from 200 to 600 ft. Oldest fm. known in this region. Underlies Rutledge ls. [In a later folio (Bristol, No. 59, 1899), which covers a large part of Russell Co., the type loc., the Russell is described as consisting, N. of Clinch Mtn, of 1,000 ft. of shales, sss., and impure lss. of various colors, green and red predominating, with thick bed of brown, slightly calc. sh. at top, overlain by Rutledge ls.; and S. of Clinch Mtn as consisting of more than 400 ft. of red and green shales and thin-bedded sss. and lss. of Lower Camb. age, overlying [uncon.] more than 600 ft. of sandy sh. of Lower Camb. age called *Hampton sh.*, and underlying Honaker ls., the equiv. of Rutledge ls. and two overlying fms. N. of Clinch Mtn.]

Same as Rome fm., and discarded.

Named for Russell Co., Va.

†Russell formation.

Upper Cretaceous: Central and western Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 49). *Russell fm.*—Alternating lss. and bluish carbonaceous to light-gray calc. shales, constituting lower fm. of Benton div. in Kans. Underlies Victoria clays, or upper fm. of Benton. Includes Downs or Fence-post ls. and *Globigerina bulloides* "Lincoln marble."

Same as Greenhorn ls. plus Fairport chalky sh. memb. of Carlile sh.

Named for exposures at Russell, Russell Co.

Russell serpentine.

A name loosely applied by B. K. Emerson (U. S. G. S. Mon. 29, p. 90, 1898) to a bed of serpentine exposed in Russell, Old Hampshire Co., Mass.

Russell Street Road moraine.

Pleistocene (Wisconsin stage): Northeastern New York (Essex County).

Named for road. See N. Y. State Mus. Bull. 187, 1916.

Russellville shale. (In Atoka formation.)

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Russellville shales.*—Shales, 500 to 600 ft. thick, underlying Cross Plains ss. and overlying Washburn sss. Middle memb. of Appleton stage.

Probably named for Russellville, Pope Co., Ark.

Rustler formation.

Rustler limestone.

Permian: Western Texas and Pecos Valley of southeastern New Mexico.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 44). *Rustler fm.*—Fine-textured white mag. ls. and less abundant ss. Thickness 200 ft. In southern outcrops there is no ss. and hills are capped by 150 ft. of massive gray ls. In Horseshoe Draw the fm. consists of 100 ft. of calc. buff ss. overlain by 50 ft. of ls. Overlies Castile gyp. and is clearly older than "Red Beds" but may be contemp. with part of Capitan ls. [Now considered to be much younger than Capitan. See 1931 entry under *Castile gyp.*]

In Delaware Basin of SE. N. Mex. and western Tex. there occurs, btw. the Rustler ls. and Castile gyp. of Richardson, an unexposed series of salt beds (1,400 ft. thick in well borings) known as upper salt series, in contradistinction to lower salt series or Castile fm. To these unexposed rocks W. B. Lang in 1935 (A. A. P. G. Bull., vol. 19, No. 2) applied the name *Salado halite*. Neither the Castile nor the Rustler fm. is restricted by the introduction of Salado, because in all surface exposures the Rustler rests upon the Castile. (See under *Salado halite*.) Lang also applied *Pierce Canyon redbeds* to the fm. overlying the Rustler.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7), discriminated *Rustler fm.* much farther N. in Pecos Valley of SE. N. Mex., where it also rests on Salado halite and is overlain by Pierce Canyon redbeds.

Named for exposures in Rustler Hills, Culberson Co., Tex.

†Rustler Springs formation.

Permian: Western Texas.

J. A. Udden, 1915 (Am. Jour. Sci., 4th, vol. 40, pp. 151–155). *Rustler Springs fm.*—Same as Richardson's Rustler fm. Named for Rustler Springs, Culberson Co.

rusty beds.

See under *Thermopolis sh.*

†Ruth limestone.

Pennsylvanian: Eastern Nevada (Ely region).

A. C. Lawson, 1906 (Univ. Calif. Pub., Bull. Dept. Geol., vol. 4, No. 14, p. 292). *Ruth ls.*—Heavy but distinctly bedded blue-gray ls. carrying fossils identified by G. H. Girty as Upper Carbf. Characterized by abundance of flint or chert nodules. Thickness 500 ft. Overlies Arcturus ls. Named for Ruth mine, Robinson mining dist., Egan Range, White Pine Co. [This dist. is in Ely quad.]

A. C. Spencer, 1917 (U. S. G. S. P. P. 96, pp. 26, 28). "Ruth" ls. of Lawson is same as Ely ls. [See explanation in 1917 entry under *Ely ls.*]

Ruth argillite.

Carboniferous: British Columbia.

S. J. Schofield, 1920 (Canada Geol. Surv. Mem. 117, p. 16).

Rutland dolomite.

Lower Cambrian: Southwestern Vermont (Rutland County).

J. E. Wolff, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 331–338). *Rutland ls.* [long in use as a commercial term] is Lower Camb. and overlies Pine Hill qtzite. [Pine Hill is a short distance NW. of Rutland, in Castleton quad.]

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 128). *Rutland dol.*—Mainly dol.; generally gray; beds of dark bluish-gray dol. numerous in lower and upper parts of fm., while light- and dark-gray layers occur throughout its thickness. In upper part just N. of Rutland occur a few beds of light-buff, almost white ls.; a few layers of blue ls. are scattered at various horizons through the fm. At base are interbedded sss., but such beds are rare at other horizons. Mostly fine-grained, but here and there are beds of medium-grained dol., and a few coarse layers occur. Here and there are small scattered nodules or geodes of vein quartz. The fm. is=combined Winooski marble and Mallett dol. of central sequence. Thickness 1,000± ft. There are no continuous sections of the fm., and its full content has to be built up from scattered sections. Underlies Danby fm. and overlies Cheshire qtzite. Contains Lower Camb. fossils. Well developed in valley around Rutland, for which it is named.

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., p. 284). *Rutland dol.* is a light-brown and white rock 4,500 ft. thick.

F. A. Burt, 1931 (17th Rept. Vt. State Geol., p. 118), included *Rutland dol.* in Stockbridge ls.

†Rutledge limestone. (In Midway group.)

Eocene (basal): Southern Alabama.

E. A. Smith, 1892 (Sketch of geology of Ala., Birmingham, Ala., Roberts & Son, pam. of 36 pp.). *Clayton or Rutledge ls.*—Thin to W.; 200 ft. thick on Chattahoochee River. Impure ls. formerly known as Midway group. [The name *Rutledge* appears only in the table.]

Same as Clayton fm., the earlier and established name.

Probably named for exposures at Rutledge, Crenshaw Co.

Rutledge limestone.

Middle Cambrian: Northeastern Tennessee, southwestern Virginia, and western North Carolina.

A. Keith, 1896 (U. S. G. S. Morristown folio, No. 27, p. 2). *Rutledge ls.*—As a whole the strata are ls., but there are many beds of green and yellow calc. sh. toward base, which form a passage into underlying Rome fm. The lss. are massive and range in color from blue to dark blue, black, and gray. Thickness 250 to 500 ft. Underlies Rogersville sh.

Foregoing is original definition at type loc. The name, however, first appeared in print in 1894, in U. S. G. S. Estillville folio (No. 12), by M. R. Campbell, who accepted Keith's name, correlating the rocks of Estillville quad. with those of Morristown quad. He described the fm. as consisting of 200 to 240 ft. of very dark impure mag ls. at top, its base being quite siliceous and containing many thin beds of sandy sh., and as overlying Russell fm. and underlying Rogersville sh. Keith also published the name in 1895, in U. S. G. S. Knoxville folio (No. 16), in which area the fm. is described as 350 to 450 ft. thick, with same lithology as in Morristown quad., and as overlying Rome fm. and underlying Rutledge ls.

Named for exposures in valley of Rutledge, Grainger Co., Tenn.

Ryan sandstone.

Pennsylvanian: Central southern Oklahoma (Jefferson County).

J. R. Bunn, 1930 (Okla. Geol. Surv. Bull. 40PP, pp. 10+). *Ryan ss.*—A ss. having same general description and occurring in approx. same strat. position as Asphaltum ss. Typically exposed in scarps SE. and NW. of town of Ryan, Jefferson

Co., where it usually consists of one massive to thin-bedded memb. 17 to 28 ft. thick. In bluffs bordering "Dead Man's Gulch" it consists of at least 3 distinct members aggregating 60 ft. Underlies Claypool fm., and top lies 100 to 125 ft. higher than Oscar ss., the interval consisting largely of brown sh. with occasional thin sandy streaks.

Ryans Ford limestone. (In McLeansboro formation.)

Pennsylvanian: Central eastern Illinois (Coles and Cumberland Counties).

See 1934 entry under *LaSalle ls. memb.*, the only known use of name. Derivation unknown.

Rye gneiss.

Pre-Cambrian (?): Southeastern New Hampshire and southwestern Maine.

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, pp. 141, 143–144). *Rye gneiss.*—The Algonkian complex of Katz. [Katz used Algonkian (?).] Most northerly outcrops occur on Gerrish's Island, Kittery, Maine. Has been traced S. and SW. into Portsmouth, Rye, North Hampton, and Hampton, N. H. At type loc. is well banded, consisting of alternations of light feldspathic layers, which become pegmatitic, with dark fine biotite-rich schistose bands. On Gerrish's Island the rock is fine-grained, but banding is absent. As narrow stringers of feldspathic material penetrate the rock it loses its sedimentary habit. A number of dikes cut the gneisses. Grouped with these gneisses are some rocks which suggest altered basic volcanic flows. [According to Katz's map (U. S. G. S. P. P. 108, pl. 61, 1917) this complex is throughout its area overlain by Kittery qtzite.]

Named for development in Rye Twp, Rockingham Co., N. H.

Ryegate granite.

Devonian: Northeastern Vermont (Caledonia County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of eastern Vt., but without definition. Quarried in NE. part of Ryegate Twp, Caledonia Co.

Ryegrass sandstone. (In Bearpaw shale.)

Upper Cretaceous: Southern Alberta (Lethbridge region).

T. A. Link and A. J. Childerhose, 1931 (A. A. P. G. Bull., vol. 15, No. 10, pp. 1232, 1237). *Ryegrass ss.*—That part of Bearpaw sh. above Kipp ss. memb. shows considerable amounts of fine-grained laminated ss. interbedded with sh., so that it is difficult to decide whether the beds are shaly ss. or sandy sh., but the sh. does predominate. However, one conspicuous light greenish-blue bentonitic ss., with a dark-blue 4-ft. sh. break, emerges 30 ft. above water level on E. bank of Oldman River, just above its junction with Belly River, in form of a sharp fold. About 30 ft. of this ss. is exposed during low water, but diamond-drill holes reveal a section at 90 ft. which is dominantly ss. This ss. was seemingly mistaken for part of Fox Hills ss. by Dowling. Locally it is very coarse, cross-bedded, and ripple-marked. Its top is 642 ft. above base and 84 ft. below top of Bearpaw sh. Its base lies 150± ft. above Kipp ss. Named for proximity of outcrop to Ryegrass Flats.

Rykert granite.

Jurassic (?): British Columbia, Washington, and northern Idaho.

R. A. Daly, 1912 (Canada Dept. Mines Mem. 38, p. 284).

Rysedorph conglomerate.

Middle Ordovician (lower Trenton): Eastern New York.

R. Ruedemann in defining Normanskill sh. (N. Y. State Mus. Bull. 42, 1901) included in it the *lower Trenton ls. cgl. of Rysedorph Hill*. In N. Y. State Mus. Bull. 49, 1901, Ruedemann described *Trenton cgl. of Rysedorph Hill* as an intraformational ls. cgl., containing pebbles of Lower Cambric ls., probably of Potsdam ss., of Beekmantown ls., Chazy ls., Lowville ls., and lower or lowest Trenton ls. He frequently called it *Rysedorph Hill cgl.*, and stated that it is intercalated in Normanskill sh.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 17 and chart). Normanskill sh. of eastern N. Y. is underlain by Rysedorph cgl., of Trenton age.

In 1912 (N. Y. State Mus. Hdb. 19, p. 35) C. A. Hartnagel stated that "*Rysedorph cgl.* (1901 Ruedemann)" is intercalated in or overlies Normanskill sh., and on his chart stated that Normanskill sh. includes at top Rysedorph cgl.

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 66-99). [See 4th item under *Normanskill sh.*]

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, pp. 412, 414) and 1930 (N. Y. State Mus. Bull. 285, pp. 103-104), transferred *Rysedorph cgl.* to Middle Ord. (stating that its pebbles contain fossils ranging in age from Lower Camb. to lower Trenton); excluded it from *Normanskill sh.* (which he assigned to Lower Ord. (Chazy) and possibly Middle Ord. (Lowville)); and showed Rysedorph as lying uncon. on Normanskill sh. This is present accepted classification of Normanskill and Rysedorph. He also showed (pp. 27 and 72) *Tackawasick ls. and sh.* as younger than Rysedorph cgl. but on p. 25 the Rysedorph is placed above Tackawasick. In one place in this paper Ruedemann stated that Rysedorph cgl. is "probably on the Normanskill, though at most places inclosed in it by close folding."

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 279-281). ***Rysedorph cgl.*** occurs in Rysedorph Hill (locally called Pinnacle or Sugar Loaf Hill), 2 mi. SE. of Rensselaer (across river from Albany), and overlies Normanskill sh. Contains pebbles of Lower Camb. to Trenton age. At type loc. it is 2½ ft. thick, but elsewhere it varies in thickness up to 50 ft. (Moordener kill, near Castleton).

†Rysedorph Hill conglomerate.

Same as *Rysedorph cgl.*

Saanich granodiorite.

Jurassic: British Columbia.

J. A. Allan, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 99). Upper Jurassic (?). [Later Canada repts assign this fm. to Jurassic.]

Saanich formation.

Pleistocene: Northwestern Washington and British Columbia (Vancouver Island); also western Oregon.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 565-595). *Saanich fm.*—Raised-beach deposit. Benches Olig. and glacial deposits at Alki Point and Bainbridge Island in Puget Sound; fills glacial depressions at various points N. of Victoria on Saanich Peninsula, Vancouver Island, and terraces length and breadth of Straits of Georgia, notably Sucia Islands. Tentatively includes widespread raised beaches on W. coast of Oreg. and Wash. containing marine shells at Cape Blanco, Bandon, and Newport, Oreg., and at Bay Center, Wash.

Sabattisville moraine.

Pleistocene (Wisconsin): Southwestern Maine.

G. H. Stone, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 380). *Sabattisville moraine.*—A terminal moraine of till, named for occurrence a short distance S. of bridge at Sabattisville, Androscoggin Co.

Sabetha limestone. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 232, 234). *Sabetha ls.*, about 12 ft. thick, underlies Speiser sh. and overlies Easly Creek sh. Consists of (descending): (1) Fossiliferous gray ls., weathering gray or yellowish brown, 3 to 4 ft.; (2) bluish-gray calc. sh. with limy nodules, 6 to 7 ft.; (3) gray ls., 2 to 3 ft., fossiliferous. Named for exposures on Omaha-Tulsa highway 1 mi. N. of Sabetha, Kans.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 21). Investigation shows that "Sabetha ls." is correlative with Crouse ls., which has about 10 yrs. priority, and is here used instead of "Sabetha."

†Sabine formation.

Eocene (lower): Eastern Texas, Louisiana, Arkansas, and Alabama.

A. C. Veatch, 1905 (La. Geol. Surv. Bull. 1, pt. 2, Rept. 1905, pp. 84, 85, 88, letter of transmittal of La. Director to Governor dated Dec. 9, 1904; U. S. G. S. W. S. P. 114, on La. and southern Ark., pp. 180, 184–185, ms. sent to Govt Ptg Office Aug. 2, 1904). *Sabine (Lignitic) sand* (also *Sabine group*).—Name adopted to supplant nongeographic name *Lignitic*. Under this head is classed not a single well-defined horizon, like Nacatoch, or Bingen, or other Cret. horizons, but a number of somewhat irregular water sands occurring throughout a fm. which in W. part of this area [NW. La. and SW. Ark.] attains thickness of perhaps 1,000 ft. The lowest of these sands is about 700 ft. above the Nacatoch, and like it is very nearly horizontal over considerable area. Eastward and southward this bed dips gently toward Mississippi Valley and the coast. Other sand beds occur in the fm. above this one, at varying distances from each other and of varying thicknesses. Underlies Lower Claiborne and overlies Midway. Named for typical fossiliferous development on Sabine River in Sabine Co., Tex., and Sabine Parish, La.

E. C. Eckel, 1905 (Iron ores of NE. Tex., U. S. G. S. Bull. 260, pp. 349–350; ms. sent to Govt Ptg Office Mar. 10, 1905). Underlying the Claiborne and overlying the Wills Point clays is *Sabine fm.*, a thick series of chocolate-colored clays and various colored sands, with occasional beds of lignite or brown coal. White and reddish clays occur in places, being particularly well exposed near Queen City, Marshall Co.

On Mar. 23, 1905, the U. S. Geol. Survey, in connection with repts then in preparation on geol. and underground-water resources of Miss. (under supervision of E. C. Eckel) and Ala. (by E. A. Smith), formally adopted *Wilcox* as geographic name to replace the nongeographic term *Lignitic* in this, its typical region. This name was selected after correspondence (by E. C. Eckel) with State Geologist E. A. Smith of Ala., and type loc. was specifically stated in the records to be Wilcox Co., Ala., "which affords good exposures of the entire 'Lignitic' section." At the time *Wilcox* was adopted, the Survey also had in course of preparation (by A. C. Veatch) a rept (U. S. G. S. P. P. 46) on geol. and underground water resources of La. and northern Ark., and it was decided that if author of that rept was unwilling to correlate the Lignitic of that area with typical Lignitic of Ala., the name *Sabine* would be acceptable W. of Miss. River. The repts on Miss. (U. S. G. S. W. S. P. 159 and U. S. G. S. Bull. 283) were published Aug. 20, 1906, and Sept. 25, 1906, respectively.

A. C. Veatch, 1906 (Geology and underground-water resources of northern La., with notes on adjoining districts: La. Geol. Surv. Bull. 4, pp. 14, 26–29, map, etc.; letter of transmittal of W. R. Dodson, La. Director, to the Governor, dated Aug. 1, 1906). *Sabine fm.*—Overlies Midway lss. and calc. clays and underlies Claiborne beds. In Ala. this fm., which has long been called the Lignitic, contains several fossiliferous horizons that are closely related from a paleontologic standpoint, but show faunal differences which have led to recognition of 4 substages, named (ascending) Nanafalia, Bells and Greggs Landing (Tuscahoma), Woods Bluff, and Hatchetigbee. No distinctive marine fossils have yet been found in the lignitiferous time equivalents of this fm. in Miss., Ark., and upper embayment region, but along Sabine River in La. and Tex., in the same position relative to the embayment as the Ala. deposits, are developed fossiliferous beds showing same facies. *Ostrea thirsae*, an oyster common in Nanafalia horizon in Ala., occurs in abundance at Marthaville, La., and the fossils from Pendleton and Sabinetown bluffs on Sabine River, Sabine Co., Tex., show very close affinities to Greggs Landing and Woods Bluff horizons of Ala. These beds are limited above by a well-preserved and abundant lower Claiborne fauna, and below by the Midway (Wills Point) fossiliferous clays and lss. The name *Sabine fm.* is adopted to replace *Lignitic fm.* (nongeographic), *Chickasaw fm.* (inappropriate), *Lagrange* [more inclusive], and *Mansfield group* and *Camden group* (both of doubtful definition and without marine fossils at type localities). Named for typical development of fm. along Sabine River, Sabine Co., Tex., and Sabine Parish, La., and from noteworthy exposures at Sabinetown Bluff. The Sabine fm. and its equiv. beds in the undiff. Eocene underlie whole of La. except the limited areas occupied by the outcrops of the Cret. and Midway domes, and all of Ark. S. and E. of the Cret. and Midway outcrops. Thickness ranges from 300 ft. in northern Bossier Parish to 800 to 900 ft. near Natchitoches and on Sabine River.

A. C. Veatch, 1906 (U. S. G. S. P. P. 46, p. 34). [Same description as in La. Geol. Surv. Bull. 4, summarized above.]

Other users of *Sabine fm.* in La. and Tex. are G. D. Harris (La. Geol. Surv. Bull. 5, p. 21, 1907, and Econ. Geol., vol. 4, p. 15, 1909); E. T. Dumble (Tex. Univ. Bull. 1869, p. 38, 1920); H. V. Howe, 1933 (A. A. P. G. Bull., vol. 17, No. 6, pp. 617–621).

On Jan. 15, 1910, the U. S. Geol. Survey decided to use *Wilcox fm.*, instead of *Sabine fm.*, in the rept by A. Deussen entitled "Geology and underground-water resources of Texas Coastal Plain east of Brazos River" (which was published in 1914 as U. S. G. S. W. S. P. 335), and to abandon the admittedly synonymous term *Sabine fm.* Since that time *Wilcox* has been the generally accepted name for the Eocene deposits underlying Claiborne group and overlying Midway group in Gulf Coastal Plain, and it has been employed in more than 100 repts on Ala., Ga., Miss., Tenn., Ky., Ill., Ark., La., Tex., and Mexico.

†Sabine phase of Wilcox formation.

A term applied in some Tex. repts to upper part of so-called Wilcox fm., the lower part being called "Lignitic phase of Wilcox." Later work showed that the "Sabine phase" is of Claiborne age and that the "Lignitic phase" is in part of Claiborne age.

E. T. Dumble, 1920 (Univ. Tex. Bull. 1869). *Sabine phase of Wilcox fm.*—The exposures along Sabine River described by Harris and Veatch seem to correspond in large measure to the Ala. section and show an interbedding of the lignitic and marine phases. The Sabine phase succeeded the Lignitic phase of the Wilcox.

Sabine formation.

Upper Cambrian: Alberta and British Columbia.

S. J. Schofield, 1921 (Roy. Soc. Canada Trans., 3d ser., vol. 14, sec. 4, p. 76). *Sabine fm.*, Cambrian, B. C.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 75, p. 49), and 1928 (ditto, p. 227). *Sabine fm.*, Camb., B. C.

E. M. Kindle, 1924 (Pan-Am. Geol., vol. 42, p. 117). *Sabine fm.*, Camb., B. C.

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 300–307). Fauna of *Sabine fm.* is Upper Camb. Underlies Mons fm., which as restricted by Walcott in 1928 is Lower Ord. (Beekmantown).

†Sabine River beds.

Eocene: Eastern Texas.

E. T. Dumble and R. A. F. Penrose, Jr., 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. xxxvi, 17, 22). [See under *†Timber Belt beds*. Included Wilcox group and part of Claiborne group.]

Named for Sabine River, eastern Texas.

Sabinetown formation. (In Wilcox group.)

Eocene (lower): Eastern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 574, 601, 634). *Sabinetown fm.*—Top fm. of Wilcox group in eastern Tex. Underlies (uncon.?) Carrizo sand (of Claiborne group) and uncon. overlies Rockdale fm. Contains marine fossils of upper Wilcox age. Outcrops as remnants. Occurs at Sabinetown, on Sabine River, Sabine Co., and other places. Thickness 40 to 100 ft. Absence in many places may be due to erosion before deposition of Carrizo sand. Consists of near-shore and shallow-water deposits of thinly laminated light-gray sand, lentils and thin beds of blue sandy clay containing thin partings of impure sand and numerous large, somewhat flat and smooth-surfaced ferruginous concretions. In some places base is a layer of cgl., in other places a layer of glauconitic sand. Distinguished from Carrizo by its finer sand grains, its smooth ferruginous and in places fossiliferous concretions, and by its fossils (listed). Correlated with Bashi of Ala.

Sabula dolomite.

Silurian (Niagaran): Central eastern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 149, 150). *Sabula terrane.*—Dol., 50 ft. thick, composing bottom fm. of Niagaran series. Underlies Colesburg dol. of Niagaran series, and overlies Maquoketan series. Separated from Colesburg dol. by its fauna.

Named for Sabula, or Sabula Junction, Jackson Co.

Sac limestone.

Lower Ordovician (Beekmantown): Southwestern Missouri.

E. M. Shepard, 1898 (Mo. Geol. Surv. vol. 12, pt. 1, pp. 49, 74–77). *Sac ls.*—Massive purplish, gray, or drab-colored mag. ls. 1 to 18 ft. thick, uncon. underlying Phelps ss. and overlying King ls. All included in Hamilton stage of Dev.

Later repts by S. Weller (1901) and other geologists assigned this ls. to Kinderhook group.

R. C. Moore, 1928. [See 1928 entry under *King ls.*]

The Sac ls. belongs to Powell ls. (which uncon. underlies Sylamore ss. in SW. Mo.), according to J. Bridge (1937 personal communication).

Named for outcrops on Sac River, Greene Co.

Sacajawea formation.

Mississippian: Wyoming.

C. C. Branson, 1936 (Geol. Soc. Am. Proc. 1935, p. 391). Lower part of Amsden fm. of Darton is Miss., and is here designated *Sacajawea fm.*, with type section on Bull Lake Creek. Upper part of Amsden is Penn., and is not separable stratigraphically or faunally from rest of the Tensleep.

Sacandaga quartzite.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199, pp. 94, 121). *Sacandaga qtzite.*—Thickness 70 ft. Included in Grenville series. Underlies Johnsburg ls. Type loc. Sacandaga River, Sacandaga mine, Day Twp, Saratoga Co.

†Saccharoidal sandstone.

A descriptive term applied, in a titular sense, in early Mo. repts to ss. now called *St. Peter ss.* and the underlying Everton ls., the lower part of which is sandy. So called because when struck with hammer it crumbles into fine white sand resembling granulated sugar.

Sac-Fox subgroup.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 4, 5, 10–11). *Sac-Fox subgroup* (of Wabaunsee group) hereby named from Iowa-Sac-Fox Indian Res. in SE. Nebr. and NE. Kans. Includes (descending) Scranton sh. fm., Howard ls. fm., and Severy sh. fm. Type loc. in Mo. River blufflands, btw. mouth of Big Nemaha and Iowa Point, Kans.

Sachuest arkose.

Carboniferous: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 284–288, 379). *Sachuest arkose.*—Arkose interbedded with more or less coaly sh. Thickness 200± ft. Composes W. and S. shores of Sachuest Neck, N. shore at Flint Point, and a small exposure offshore at a headland ¼ mi. S. of Flint Point. Believed to rest on Camb. cgl. and sh.

A part of Wamsutta fm., as mapped by B. K. Emerson, U. S. G. S. Bull. 597, 1917.

Saclin formation.

Quaternary: Nicaragua.

O. H. Hershey, 1912 (Geol. Soc. Am. Bull., vol. 23, p. 507).

Sacramento porphyry (also porphyrite).

Eocene: Leadville region, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230), 1883 (U. S. G. S. Leadville Atlas, cross section sheet), and 1886 (U. S. G. S. Mon. 12, p. 81). Dark-gray granular, rather even-grained rock, of same general appearance as the variety of Lincoln porphyry which has no large crystals. [On p. 341 of Mon. 12 Whitman Cross described the rock as *Sacramento porphyrite*.]

In U. S. G. S. P. P. 148, pl. 2, 1927, this rock was mapped with the other masses of Gray porphyry, without a distinctive name.

Named for occurrence under Gemini Peaks, btw. heads of Big and Little Sacramento Gulches, vicinity of Leadville.

†Sacramento formation.

Middle Devonian: Northern California (Redding region).

J. P. Smith, 1894 (Jour. Geol., vol. 2, pp. 591 and 592). [In heading and table *Sacramento fm.* is used to cover *Kennett lss. and shales*, and is credited, in footnote, to H. W. Fairbanks ms. A later (1916) publication by J. P. Smith (Calif. State Min. Bur. Bull. 72) stated that the Middle Dev. lss. of Kennett and Lower Soda Springs occur in Sacramento Canyon.]

Same as Kennett fm.

Saddleback series.

Pre-Cambrian: British Columbia.

C. W. Drysdale, 1917 (Canada Geol. Surv. Summ. Rept. 1916, p. 59).

Saddle Creek limestone member (of Harpersville formation).

Pennsylvanian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 416). *Saddle Creek bed.*—Ls., usually massive, light gray, 6 to 12 ft. thick. Underlies Camp Creek bed and overlies Waldrip bed in Colorado coal field of Tex. Is memb. of Cisco div.

N. F. Drake, 1917 (Univ. Tex. Bull. 1755). *Saddle Creek bed* is finely exposed 1 to 2 mi. S. of mouth of Saddle Creek [McCulloch Co.]. On N. side of Colorado River it remains N. of the river from N. of mouth of Saddle Creek to NW. of Waldrip.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, p. 136). *Saddle Creek* of Drake immediately underlies Pueblo fm.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132). *Saddle Creek ls.* (=Saddle Creek bed of Drake) is top memb. of Harpersville fm. [Many details.]

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 18–42). *Saddle Creek ls.* (top memb. of Harpersville fm.) consists of 2 or 3 beds 1 to 3 ft. thick separated by sh. To N. the Saddle Creek bed changes to calc. ss.

Saddlehorse gypsum lentil (of Quartermaster formation).

Permian: Panhandle of Texas.

C. N. Gould, 1907 (U. S. G. S. W. S. P. 191, pp. 16–20). *Saddlehorse gyp. lentil.*—One to three ledges of massive white gyp. interstratified with red shales. Total thickness 10 ft. Local lentil in Quartermaster fm., 60 to 80 ft. above base. Separated from overlying Alibates dol. memb. of Quartermaster fm. by 50 to 60 ft. of red sh. with white bands and ledges of soft ss.

C. N. Gould and F. E. Lewis, 1926 (Okla. Geol. Surv. Circ. 13, pp. 14–15). Day Creek (Alibates) dol. of Carson Co., Tex., is separated from underlying Blaine gyp. by 300 or 400 ft. of red sands, red shales, and occasionally a thin bed of gyp. or lime and probably anhydrite. The most prominent of gyp. lenses is *Saddlehorse gyp.* [Day Creek dol. is much older than Quartermaster fm., from which it is separated by Cloud Chief gyp.; and Saddlehorse gyp. is older than Alibates dol.]

W. W. Rubey, 1926 (personal memo.). Gould now thinks Quartermaster fm.=the supposedly underlying Woodward group. This new interpretation is based upon lithologic similarity, tracing of outcrops, and well-log correlations, and makes Alibates dol.=Day Creek dol. and underlying beds=Whitehorse ss. of Kans. and Okla. This revised correlation has been concurred in by Messrs. Trager, McCoy, and Howell, geologists of Marland Oil Co.

C. N. Gould and R. Willis, 1927 (Geol. Soc. Am. Bull., vol. 38, No. 3, pp. 431–438), correlated Alibates dol. with Day Creek dol.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 167, 243), placed Alibates dol. and Saddlehorse gyp. in Quartermaster fm., stating that the Alibates is in upper part of the Quartermaster and the Saddlehorse 60 to 80 ft. above base of Quartermaster.

Named for Saddlehorse Creek, Potter Co.

Saddle Mountain porphyry.

Pre-Cambrian: Southwestern Oklahoma (Wichita Mountains).

H. F. Bain, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 135, 136). [See 1st entry under *Carlton porphyry*.]

M. G. Hoffman, 1930 (Okla. Geol. Surv. Bull. 52, pp. 40–48). *Saddle Mtn granophyre.*—Very dark-gray dense and porphyritic granophyre. Red orthoclase crystals, 1 to 4 mm. long, are set in groundmass and compose about 20 percent of the rock. Occurs near Saddle Mtn and centers in and around sec. 36, T. 5 N., R. 15 W. Intrudes Meers qtzite. Considered older than Davidson granophyre. Is intruded by Lugert granophyre.

Sadlerochit sandstone.

Permian: Northern Alaska (Canning River region).

E. D. Leffingwell, 1919 (U. S. G. S. P. P. 109, pp. 103, 113, map). *Sadlerochit ss.*—About 300 ft. of light ss. or dark qtzite, conformably overlying Lisburne ls. (Miss.) and underlying (probably conformably) Shublik fm. (Upper Triassic). In Sadlerochit Mtns it is light-colored heavy-bedded fine ss. that weathers dark brown. Is very fossiliferous. Fauna is Penn.

Saegerstown shale.

Devonian or Carboniferous: Northwestern Pennsylvania (Erie County).

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 457–464). [See definition under *Woodcock ss*. Outcrops mentioned. Fossils. Included in Bradfordian and also treated as a memb. of Chagrin fm., which U. S. Geol. Survey classifies as Upper Dev.]

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Saegerstown sh. memb.* included in Cattaraugus fm., of Dev. age. Underlies Woodcock ss. memb. and overlies Millers ss. memb. [The U. S. Geol. Survey classifies Cattaraugus fm. as *Dev. or Carbf.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 89), stated that Millers ss. of Chadwick is same as Salamanca cgl. memb. of Butts and Glenn, which he assigned to Dev. He also stated that Saegerstown sh. of Chadwick was named for exposures along French Creek, in village of Saegerstown, Crawford Co.

Sagamore sandstone lentil (in Bedford shale).

Devonian or Mississippian: Northeastern Ohio.

C. S. Prosser, 1912 (Ohio Geol. Surv., 4th ser., Bull. 15, pp. 26, 86, 88). *Sagamore ss. lentil.*—Bluish fine-grained sss., with sh. partings; 23 ft. thick; forming lentil in upper part of Bedford sh. Separated from underlying Euclid ss. memb. of Bedford by 14 ft. of bluish shales; overlain by bluish-gray to bluish shales alternating with thin sss. forming topmost part of Bedford.

Named for Sagamore Creek, Bedford Twp.

Saganaga granite.

Pre-Cambrian (Laurentian): Northeastern Minnesota (Vermilion district).

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept.). *Saganaga granite* (Laurentian) occupies all shores and islands of ˊaganaga Lake except NW. shore.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 128). The *granite of Saganaga Lake*, locally known as "Saganaga Lake granite," is intrusive granite of Laurentian age, and same as granite of Basswood Lake.

Saganaga syenite.

Pre-Cambrian (Keewatin): Northeastern Minnesota.

A. Winchell, 1891 (Am. Jour. Sci., 3d, vol. 41, p. 386). Included in Keewatin.

†Saganaga Lake granite.

The Laurentian granite of Saganaga Lake, NE. Minn., is locally known as "Saganaga Lake granite."

Sagean series.

Term applied by C. [R.] Keyes to 300 ft. of undescribed Eo. beds in Mont., which probably correspond to Sage Creek fm. of Douglass and other geologists.

Sage Breaks shale member (of Niobrara formation).

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Sage Breaks sh. memb.*—Gray noncalc. mudstone and sh. with many large light-gray calc. septarian concretions. Fossils scarce, but a few marine species found. Commonly forms scarps and buttes. Thickness 250 to 325 ft. Is lower memb. of Niobrara fm. Underlies Beaver Creek chalky memb. and overlies Turner sandy memb. of Carlile sh. In previous repts on NE. Wyo. and SE. Mont. included in Carlile sh. Named for exposures in the Sage Breaks, in T. 46 N., R. 63 W., Weston Co., Wyo.

Sage Creek formation.

Eocene (upper?): Southwestern Montana (Beaverhead County).

E. Douglass, 1903 (Carnegie Mus. Annals, vol. 2, pp. 145–146). *Sage Creek beds* (*Eocene?*).—A fm. that occurs N. of Sage Creek, about 7 mi. NE. of Lima, Beaverhead Co. [Fossils listed, but lithology and thickness not given.]

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 98). Deposits on Sage Creek, Mont., are probably *Eobasileus* zone (upper Eocene).

H. E. Wood, 2d, 1934 (Am. Mus. Nat. Hist. Bull., vol. 67, art. 5, pp. 253, 255, 277). *Sage Creek fm.* is Eocene and apparently of either Lower Uinta or Upper Bridger age, based on emended identifications of Douglass' fossils. Type loc. of Sage Creek fm. was finally located by F. D. and H. E. Wood, June 30–July 5, 1933, NW. of loc. No. 3 on map (fig. 51) about at bdy btw. secs. 29 and 30. This loc. (our No. 8) is 8 mi. N. by W. of Lima, instead of 7 mi. NE., but agrees perfectly otherwise with Douglass' description, and is the only loc. in region that does. The Sage Creek is a unit fm., and there is no reason to believe that it covers any large passage of time. It consists of regularly bedded fine-grained greenish-gray sss., with interspersed coarse cross-bedded channel sss., ranging into cgls. in places. The beds dip northeasterly and are separated from underlying Lower Eocene (?) salmon-colored beds by a marked erosional uncon. Upper surface of the beds is strongly eroded, and is overlain by the beds here named *Cook Ranch fm.*, which contain a Middle Olig. fauna that clearly has nothing to do with Douglass' Sage Creek, which term must be restricted to the Eocene beds.

Sage Creek white layer.

Eocene (middle): Southwestern Wyoming (Bridger Basin).

W. D. Matthew, 1909 (Am. Mus. Nat. Hist. Mem., vol. 9, pp. 295–297). Horizon C of Bridger fm. of Bridger Basin is defined inferiorly by a heavy and persistent calc. stratum, the *Sage Creek white layer*, shown at Sage Creek Spring.

Sage Hen limestone member (of Colorado shale).

Upper Cretaceous: Central northern Montana (Little Rocky Mountains region).

C. T. Lupton and Wallace Lee, 1921 (A. A. P. G. Bull., vol. 5, pp. 264, 266). *Sage Hen sandy ls.* (in Colorado sh. of Cat Creek field) lies 335 ft. above Mosby ss. memb. of the Colorado. Is named for conspicuous exposures in Sage Hen Creek. Is a fine-grained ss. cemented with the lime and when fresh shows no indication of its sandy character. When weathered becomes rotten and is easily crumbled with the fingers. Thickness 10 to 20 inches. Occurs at top of a zone of calc. concretions 130± ft. thick. At top of Sage Hen ls. there is distinct change in sedimentation. The beds overlying it are conspicuously argill., and ascending in the section become somewhat calc., though there are no limy beds in first 200 ft.

151627°—38——40

Saginaw formation.

Pennsylvanian (late Pottsville): Michigan (Lower Peninsula).

A. C. Lane, 1901 (Mich. Miner, vol. 3, No. 1, p. 9). We are considering replacing *Jackson* (preoccupied) by *Saginaw*, a characteristic Michigan name, the Saginaw Valley occupying a large part of the coal basin and Saginaw Co. at present containing the most important coal mines.

A. C. Lane, 1902 (Mich. Geol. Surv., vol. 8, pt. 2, map at end). *Saginaw fm.*—Coal, paving brick clays and shales, ss., etc. Overlies Grand Rapids [group]. Is of Pottsville age. [In some early repts the Parma ss. was included in †Jackson or Saginaw fm. The generally accepted definition, however, treats Parma ss. as a distinct fm. lying btw. Saginaw fm. and Grand Rapids group.]

Saginaw sand.

Middle Devonian: Eastern Michigan (Saginaw region).

C. G. Carlson, 1927 (A. A. P. G. Bull., vol. 11, pp. 962+). *"Saginaw sand."*—A dolomitic lime near top of Traverse fm. Produces oil at Saginaw, near Bristol St. Bridge.

†Saginaw moraine.

A name used by F. B. Taylor in early repts for main moraine of Port Huron morainic system in Saginaw Valley, Mich. But he later (U. S. G. S. Mon. 53, 1915) discarded the name.

Saginaw.

Name applied to two glacial lakes, of Pleist. age, in Great Lakes region.

Saguenay formation.

Pre-Cambrian: Quebec.

J. A. Dresser, 1916 (Roy. Soc. Canada Trans., 3d ser., vol. 10, p. 126; Canada Geol. Surv. Mem. 92, p. 25).

Sailor Canyon formation.

Lower Jurassic: Northern California (Colfax region).

H. W. Turner, 1894 (Am. Geol., vol. 13, p. 232). *Sailor Canyon beds.*—At Sailor Canyon, which drains into American River about 6 mi. SE. of Cisco, are a series of beds from which Mr. Lindgren and Dr. Cooper Curtice have collected fossils regarded by Hyatt as of Liassic [Lower Jurassic] age. Considered older than Milton and younger than Cedar fm.

W. Lindgren, 1900 (U. S. G. S. Colfax folio, No. 66). *Sailor Canyon fm.*—Calc. clay slates with some ls. and a contact-metamorphic facies consisting chiefly of mica schist and hornfels. Younger than Calaveras fm. and older than Mariposa sl.

The Sailor Canyon fm. has an estimated thickness of 6,000 ft.

St. Alban formation.

Devonian: Quebec.

J. M. Clarke and C. Schuchert, 1900 (N. Y. State Mus. Mem. 3, vol. 3, p. 81).

St. Albans slate.

Middle Cambrian: Northwestern Vermont (Franklin County, St. Albans region).

J. Marcou, 1862 (Boston Soc. Nat. Hist. Proc., vol. 8, pp. 239–253). *St. Albans group.*—Green, brown, and reddish slates, containing lenticular masses of very hard whitish ls. Thickness 2,500 to 3,000 ft. Underlies Georgia slates [restricted to "gray and black sandy slates passing into true yellowish ss."] and overlies Lower Taconic system, which consists of 10,000 ft. of qtzite, cgls., talcose slates, clay slates, mica schist, and gneiss, with intercalated masses of crystalline ls.

C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, No. 5, pp. 176–178), recognized *St. Albans slates* as underlying *Georgia schists*.

C. D. Walcott, 1910 (Smithsonian Misc. Coll., vol. 53, No. 6, p. 254). A specimen of cephalon of *Paradoxides* was found by Mr. Geo. Edson (1907), of St. Albans, Vt., in the St. Albans shales just W. of city of St. Albans. The *St. Albans shales* are argillaceo-aren. and carry lentils of ls. that are more or less fossiliferous. The *Paradoxides* occurs in the sh. and in a ls. lentil.

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 112). Edson reported discovery of *Paradoxides* in shales in town of St. Albans, which indicates strongly that Middle Camb. is present there. He also reported finding *Agnostus* in same place, thus indicating Middle Camb. or later beds. It is thus possible some of sh. here named *Colchester* (Lower Camb.) is of Middle Camb. age, but it has not yet been practicable to distinguish such beds as a fm. If Middle Camb. shales are present, they can only extend a few mi. to N. and S., being cut out by Milton dol. This possibility is strengthened through the finding, by B. F. Howell, at same locality, in 1922, of apparent Middle Camb. fossils.

B. F. Howell, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 236). A small fossil, which appears to be possibly a fish plate, was found during past summer by Prof. C. Schuchert and writer in *St. Albans sh.*, a Camb. fm. containing *Paradoxides* and other marine fossils of a *Paradoxides* fauna just S. of town of St. Albans, Franklin Co., NW. Vt. The fossil will be of great interest if it can be proved to be a fish plate, as it will be the first evidence of existence of fish or fishlike creatures in the Camb. [On p. 242 Howell stated:] Paradoxidian fossils were reported from Franklin Co., Vt., by Edson, Perkins, and Walcott some 15 yrs ago, but not much was then known about the beds from which they came. During past 4 yrs the field work of Raymond, Prindle, Dunbar, Sayles, and especially Keith, Schuchert, and writer, has added much to our knowledge of the strat. and areal extent of these *Paradoxides* beds and character and relationships of fossils. The beds are dark shales, named *St. Albans fm.*, which, although they outcrop at only a few places and are known to be fossiliferous in only 4 of their outcrops, are believed to underlie mantle of glacial deposits in a continuous or nearly continuous band varying from a few yds. to ¼ mi. in width and extending from vicinity of West Georgia NE. for about 16 mi., to near Highgate.

B. F. Howell, 1929 (16th Rept. Vt. State Geol., pp. 255, 263, 265–269). In 1881 Marcou described and mapped the rocks in and about St. Albans. The area which he mapped as underlain by the rocks of his St. Albans group—a strip running N. from Georgia through St. Albans and Highgate Falls to and across Canadian bdy—is now known to contain beds of Paradoxidian age. Keith (1923) tentatively included the *Paradoxides* beds in the fm. which he called *Highgate sl.*, which he described as resting on Milton dol. The present writer in 1926 proposed that the old name *St. Albans* be restricted to the *Paradoxides* beds of Franklin Co. and used as a regular fm. name, with a definite meaning. It has been used before in a larger sense, but only a few times; and it is the most logical—almost the only appropriate—name available for those beds. It is used in that sense in this paper. The *St. Albans sh.* is, as its name implies, composed chiefly of mudstones. Many of its beds are, however, so limy as to deserve the name of *lss.*; and thin layers and lenses of ss. occur here and there throughout the fm. Some of beds are fine-grained black shales, but majority are dark-gray and coarser-grained, sometimes so micaceous as to be of golden-brown color, and sometimes sandy. The more limy strata tend to blue-gray color and vary from limy shales to impure lss., which are always mere lenses—never beds. Matrix of the ss. layers is also frequently limy. Whole fm. seems to have been thin-bedded and was at least in part banded, but cleavage has destroyed evidence of original bedding and banding. No evidence of cross-bedding on any considerable scale was seen in main body of fm. The St. Albans overlies Milton dol. [not true Milton and later renamed *Rugg Brook cgl.* by Schuchert], probably with discon., and underlies Mill River cgl., apparently with uncon. Thickness approx. 200 ft. The St. Albans closely resembles the younger Highgate sh. and also parts of the older Colchester fm., but is usually of a little lighter gray color, less distinctly banded, and coarser-grained and heavier-bedded than the Highgate, and is finer-grained and less heavy-bedded than the shales of Colchester fm. These distinctions do not always hold, however, and since the Milton, Mill River, and Swanton fms. are also frequently difficult to distinguish in the field, it is necessary for one to find fossils of a *Paradoxides* fauna in his shales if he is to feel certain that he has the St. Albans fm.

H. W. McGerrigle, 1931 (17th Rept. Vt. State Geol., pp. 179–191), compiled a table showing the superposition of the Camb. fms. beneath the Georgia sl. (Ord.) at Burlington, St. Albans, Highgate Springs, and Int. Bdy, in which he listed *St. Albans sh.*, 200 (?) ft. thick, uncon. underlying Mill River cgl. (Upper Camb.) and uncon. overlying Milton dol. [not true Milton and later renamed *Rugg Brook cgl.* by Schuchert].

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 374). After thorough search Middle Camb. fossils were found by Howell in *St. Albans sl.* at W. border of city of St. Albans and at several other localities. These beds have been traced by writer into W. part of Milton Twp. They are cut out a few mi. S. of Highgate Center btw. Milton dol. below and Highgate sl. above. There is fair prospect they can be identified in one of beds of sl. that is exposed only at low water below Highgate Falls. The St. Albans contains only sl., dark gray, locally banded, and, like the older Parker sl., micaceous.

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 353–381). *St. Albans sl.* is 0 to 250 ft. thick; contains 20 sp. of Middle Camb. fossils; is uncon. overlain by Mill River ls. cgl. and rests on a nonfossiliferous basal cgl. (0 to 20 ft. thick and apparently of Middle Camb. age, as it rests uncon. on underlying Parker sl.), here named *Rugg Brook dol. cgl.* In previous repts the Rugg Brook cgl. has been called *Milton dol.*, but the typical Milton dol. lies higher in the section and is Upper Camb., hence the new name *Rugg Brook.*

†St. Albans group.

A name applied in Hitchcock's early repts to include rocks ranging in age from Lower Camb. to Lower Ord. and now divided into Georgia sl., Swanton cgl., and Highgate sl.

St. Albans limestones.

Lower Devonian: Quebec (Gaspe Peninsula).

J. M. Clarke, 1900 (N. Y. State Mus. Mem. 3, vol. 3, pp. 80–81). Mr. Charles Schuchert and writer have thought that beds 1 and 2 of Sir Wm. Logan's 1844 subdivisions, which carry Helderbergian fauna and are exposed at base of Mount St. *Alban* along shore of Cape Rosier cove on gulf of St. Lawrence, may be called *St. Albans lss.*

St. Anna moraine.

Pleistocene (Wisconsin stage): Southeastern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for development 1 mi. W. of St. Anna, Sheboygan Co.

St. Anthony sandstone.

Name applied by T. C. Hopkins (Ind. Dept. Geol. and Nat. Res. 20th Ann. Rept., 1895, p. 312, 1896) to ss. quarried at St. Anthony, Dubois Co., Ind.

St. Armand limestone.

Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 6).

St. Bartholomew limestone.

Eocene: West Indies.

T. W. Vaughan, 1918 (Wash. Acad. Sci. Jour., vol. 8, p. 271) and 1924 (Geol. Soc. Am. Bull., vol. 35, p. 726).

St. Charles limestone.

Upper Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, p. 6). *St. Charles fm.*—Bluish-gray to gray aren. lss. with some cherty and concretionary layers, passing at base into thin-bedded gray to brown sss. Thickness 1,225 ft. in Blacksmith Fork Canyon, E. of Hyrum, Cache Co., Utah, the most accessible locality for study, and 1,197 ft. W. of Liberty, Bear Lake Co., Idaho. Type loc. is W. of St. Charles, Bear Lake Co., Idaho. The stream flowing through St. Charles passes over the fm. Contains Upper Camb. fossils, passing at top into Ord. [Garden City ls.]. Overlies Nounan fm.

St. Clair limestone.

Silurian: Northern Arkansas and central eastern Oklahoma.

R. A. F. Penrose, Jr., 1891 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 1, pp. 102–103, 112–114, 124–128, 166–174). *St. Clair ls.*—Highly crystalline granular fossiliferous ls., of light-gray, pink, chocolate-brown, or purplish-black color. Contains nodules and interbedded layers of oxides of manganese and is source of the manganese ores, as they are now found in a residual clay. Thickness 0 to more than 150 ft. In some places underlies Sylamore ss.; in other places is separated from overlying Boone chert by dark-brown or black earthy siliceous deposit, 1 to 40 ft. thick, underlain by residual clay, the product of decomposition in situ of St. Clair ls. Overlies Izard ls.

H. S. Williams, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 325–331). St. Clair ls. of Penrose includes beds ranging in age from Cincinnati to Niagara, and should be divided into three fms., here named (descending) Cason ls. (containing Clinton-Niagara fauna); Cason sh. (the manganese-bearing shales); and St. Clair ls. (containing Ord. fauna); the latter two fms. separated by erosion uncon.

H. S. Williams, 1900 (Ark. Geol. Surv. Ann. Rept. 1892, vol. 5, pp. 277–301). Cason ls. is abandoned and *St. Clair ls.* restricted to Sil. ls. overlying Cason sh., which outcrops at St. Clair Springs. For the Cincinnati memb. of Penrose's St. Clair ls., which does not outcrop in region of St. Clair Springs, Branner's suggested name *Polk Bayou ls.* is adopted.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28, pp. 421, 486, 558, 559), restricted *St. Clair ls.* to beds of pre-Rochester Clinton age, or to the ls. actually present at St. Clair Springs, the beds of Medina age being westward extension of Brassfield ls. of western Tenn., and therefore excluded.

H. D. Miser, 1920 (U. S. G. S. Bull. 715G, p. 98). In Batesville, Ark., dist. the true St. Clair ls. is locally overlain by a hitherto undiscovered fm. of late Sil. (probably late Niagaran) age named *Lafferty ls.*, and it is underlain by Brassfield ls. (in one place in Batesville dist.). The Brassfield ls. is not present at type loc. of St. Clair ls.

I. H. Cram, 1930 (Okla. Geol. Surv. Bull. 40QQ). Fauna collected by Taff from upper part of St. Clair near Marble [Sequoyah Co., Okla.] is of Niagaran age according to Ulrich. The typical St. Clair fauna is present in pink crinoidal bed [top memb.] of Chimneyhill ls. Base of St. Clair is not exposed in Okla.

Adopted for ls. uncon. overlying Brassfield ls. and in Ark. locally underlying Lafferty ls. (of Sil. age), or, in its absence, Sylamore ss. memb. of Chattanooga sh. Contains fossils of Rochester age, according to E. O. Ulrich. In Okla. it is locally overlain by a ls. of late Oriskany age.

Named for St. Clair Springs, 8 mi. NE. of Batesville, Independence Co., Ark.

†St. Clair shale.

Upper Devonian: Michigan (Lower Peninsula).

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. 1891 and 1892, p. 66). *St. Clair shales*, 150 to 300 ft. thick, underlie Richmondville or Berea ss. and overlie Traverse group.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2, btw. pp. 1 and 31). *St. Clair black shales* are 145 to 300 ft. thick. Underlie Richmondville or Berea ss. and overlie Traverse group.

A. C. Lane, 1901 (Mich. Miner, vol. 3, No. 1, p. 9). We are considering replacing *St. Clair* (preoccupied) by Antrim.

Replaced by Antrim sh. in 1902.

Named for exposures along St. Clair River, St. Clair Co.

St. Cloud sandstone. (In Greene formation.)

Permian: Northern West Virginia.

R. V. Hennen and D. B. Reger, 1913 (W. Va. Geol. Surv. Rept. Marion, Monongalia, and Taylor Counties, p. 171). *St. Cloud ss.*—Massive micaceous medium-grained ss., 15 to 20 ft. thick in Monongalia and Marion Counties. Underlies Lower Proctor ss. and lies 4 to 5 ft. above Windy Gap coal, the Windy Gap ls. not being seen in area. Named for St. Cloud P. O., Monongalia Co.

St. Cloud granite.

Name applied by C. C. Wang (Geol. Soc. China Bull., vol. 11, No. 4, pp. 426–428, 1932) to a pre-Camb. intrusive granite in Wis. (area not stated).

†St. Croix formation.
†St. Croix sandstone.
†St. Croix series.
†St. Croix shales.

Upper Cambrian: Eastern Minnesota and western Wisconsin.

N. H. Winchell, 1873 (Minn. Geol. and Nat. Hist. Surv. 1st Ann. Rept., for 1872, pp. 68–80). *St. Croix ss.*—White or buff-colored heavy- or massive-bedded quartzose sss. with intercalated beds of sh. Thickness 600 ft. Underlies Lower Magnesian ls. [which included all beds btw. St. Peter ss. and his St. Croix ss.] and uncon. overlies [so-called] Potsdam ss. (hard vitreous red sss. with partings of red sh.). Named for occurrence in St. Croix Valley.

N. H. Winchell, 1874 (Minn. Geol. Nat. Hist. Surv. 2d Ann. Rept), designated basal fm. of †Lower Magnesian as *St. Lawrence ls.*, and applied "St. Croix ss." to the beds beneath the St. Lawrence and above his so-called Potsdam ss. This definition was followed by him in several succeeding repts.

N. H. Winchell, 1886 (Minn. Geol. Nat. Hist. Surv. 14th Ann. Rept., pp. 334–337), included Jordan ss. and St. Lawrence ls. in his St. Croix fm., and followed this definition of "St. Croix ss." in his 1888 rept.

C. W. Hall, 1889 (Minn. Acad. Nat. Sci. Bull., vol. 3, pp. 125–136), applied "St. Croix series" to the rocks beneath St. Lawrence fm. and above the red so-called Potsdam ss., and divided this "series" into Dresbach ss. or upper St. Croix, St. Croix shales or middle St. Croix, and St. Croix sss. or lower St. Croix.

N. H. Winchell, 1900 (Geol. map of Minn.). *St. Croix series.*—Includes Jordan, St. Lawrence, and Dresbach, and overlies Hinckley ss.

Some authors have applied "St. Croix shales" to the sh. underlying Dresbach ss. and "St. Croix sss." to the sss. underlying those shales.

St. Croix morainic system.

Pleistocene (Wisconsin stage): Northeastern Minnesota and northern Wisconsin.

C. P. Berkey, 1897 (Am. Geol., vol. 20, p. 360). Passes a short distance E. of village of St. Croix Falls, Wis., and follows almost parallel with and at certain points encroaches upon River St. Croix.

See also Jour. Geol., vol. 13, pp. 242–256, 1905, and F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 40–45). The members are unnamed.

St. Croix formation.

Miocene and Oligocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in Geol., No. 7, pp. 48–49).

St. Croixan epoch (or **series**).

Geographic name for Upper Cambrian. Proposed by C. D. Walcott (Smithsonian Misc. Coll., vol. 57, No. 10, pp. 306–307, 1912). Replaces †Saratogan. See U. S. G. S. Bull. 769, pp. 97–98.

St. David shale and limestone. (In Carbondale formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *St. David sh. and ls.* to that part of Carbondale fm. overlying Springfield (No. 5) coal and underlying his Canton sh. in Fulton Co. Derivation of name not stated, but probably is the town in Fulton Co.

H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 804), showed *St. David ls.*, 0 to 5± ft. thick, resting on coal No. 5.

St. David cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to an upper portion of Carbondale fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 5 and St. David ls. Derivation of name not stated.

St. Edmund dolomite lentille (of Cabot Head shale member).

Silurian (early): Ontario (Bruce Peninsula and Manitoulin Island).

M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111, No. 91 geol. ser., p. 37 and chart opp. p. 18). *St. Edmund dol. lentille.*—Fine-grained light-buff weathering dol. and mag. calcilutite. Thickness 8+ ft. Occurs near top of Cabot Head sh. memb. on Bruce Peninsula and Manitoulin Island. Is younger than Dyer Bay dol. lentille of Cabot Head sh. memb. Type loc. along shore 3 mi. W. of Cabot Head, on lots 3 and 4, concession XIV, St. Edmund Twp, Bruce Peninsula.

St. Elias schist.

Age (?): Southeastern Alaska (St. Elias region).

I. C. Russell, 1891 (Nat. Geog. Mag., vol. 3, pp. 167–175). *St. Elias schist.*—The metamorphic rocks of main St. Elias Range are a schist in which bedding planes are preserved. Forms several thousand ft. of upper part of the range. Overthrust on Yakutat system.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, p. 212). *St. Elias schist of Russell* is a metamorphic terrane of unknown age. It may represent same horizon as Wales series.

†St. Elizabeth formation.

Lower Ordovician (Beekmantown): Central Missouri.

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser., p. 50). *St. Elizabeth fm.*—A complex of ss., chert, qtzites, dol., and sh., 70 to 160 ft. thick, overlying Gasconade ls. and underlying Jefferson City fm. in Miller Co.

Same as Roubidoux fm., older name.

Named for St. Elizabeth, Miller Co.

St. Eugene silts.

St. Eugene interglacial epoch.

Pleistocene: British Columbia.

S. J. Schofield, 1915 (Canada Geol. Surv. Mem. 76, p. 85).

St. Francisville sand.

A subsurface sand in Chester group (Miss.) of Lawrence Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

†St. Francois limestone.

Upper Cambrian: Eastern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv., vol. 6, pp. 331, 346, 349–354). *St. Francois ls.*—Great body of mag. ls., 600 ft. thick, lying btw. La Motte ss. below and Crystal City [St. Peter] ss. above in SE. Mo. Includes Potosi ls. and St. Joseph ls.

Named for St. Francois Co.

†Ste. Genevieve marble.

Mississippian: Central eastern Missouri.

G. C. Swallow, 1855 (Mo. Geol. Surv. 2d Ann. Rept., pt. 1, p. 96). The well-known oolite found at Ste. Genevieve, called *Ste. Genevieve marble*, belongs to Archimedes ls.; it is a very superior building stone. [According to B. F. Shumard (St. Louis Acad. Sci. Trans., vol. 1, p. 407, 1857) the white, highly oolitic ls. extensively quarried near Ste. Genevieve is basal memb. of St. Louis ls. and older than fm. near Ste. Genevieve which he named *Ste. Genevieve ls.*]

Ste. Genevieve limestone. (In Meramec group.)

Mississippian: Eastern Missouri, southern Illinois and Indiana, Iowa, Kentucky, Tennessee, northern Alabama, and northeastern Mississippi.

B. F. Shumard, 1860 (St. Louis Acad. Sci. Trans., vol. 1, p. 406, in a description of the rocks of Ste. Genevieve Co., Mo., read June 6, 1859). *Ste. Genevieve ls.*—A second Archimedes ls., very analogous in lithologic features to upper Archimedes ls. [described by Shumard as thin beds of gray ls. and bluish marl highly charged with fossils], occurring, however, in thick beds. Inferior part shades almost imperceptibly down into St. Louis ls. Underlies Ferruginous ss. [Aux Vases ss.] and overlies St. Louis ls.

In subsequent repts the use of *Ste. Genevieve ls.* was for many years confined to Mo., where the beds, usually not specifically named, were included in St. Louis ls., the †Ferruginous ss. (Aux Vases ss.) being treated as basal fm. of overlying Chester group. J. A. Gallaher, however, in 1898 (5th Bien. Rept. Mo. Bur. Geol. and Mines) and 1900 (Mo. Geol. Surv. vol. 13) deviated from this definition of St. Louis ls. by treating the Ste. Genevieve as a fm. distinct from the St. Louis and from the overlying rocks of Chester age, as did E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, pp. 41–42).

In early Ill. repts the beds later distinguished as *Ste. Genevieve ls.* were usually included, without a name, in St. Louis ls. According to Bain, however (U. S. G. S. Bull. 255, p. 22), the upper beds (later named *Rosiclare* and *Ohara* members of the Ste. Genevieve) were in some early Ill. repts included in Chester group.

In early repts on western Ky. the †Big Clifty ss. was treated as basal fm. of Chester group, and the beds now designated *Ste. Genevieve ls.* were included, without a name, in St. Louis ls. or "group." The typical Big Clifty is now generally considered to be same as true Cypress ss., the prior name, and "Big Clifty" has been discarded. In 1903 (U. S. G. S. Bull. 213, pp. 207–208) E. O. Ulrich separated, as a distinct fm., the upper 200 to 250 ft. of St. Louis ls. of western Ky. and named it "Princeton ls." He excluded his Princeton ls. from overlying Chester group.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., pp. 109–111, by E. R. Buckley and H. A. Buehler; U. S. G. S. Bull. 225, pp. 507–508, by H. F. Bain, relating to lead and zinc deposits of southern Ill. and western Ky.) and 1905 (U. S. G. S. Bull. 255, pp. 17–27, by H. F. Bain; and U. S. G. S. P. P. 36, by E. O. Ulrich and W. S. T. Smith; both relating to southern Ill. and western Ky.), included Ste. Genevieve ls. of western Ky. and southern Ill. in Chester group; divided the Ste. Genevieve into 3 members, named (descending) Ohara ls., Rosiclare ss., and Fredonia ls.; called the overlying ss. *Cypress ss.*, and correlated this ss. with Aux Vases ss. of Mo. and with Big Clifty ss. of Ky.

In 1907 (geol. map of Ill. and Ill. Geol. Surv. Bull. 6) S. Weller excluded Ste. Genevieve from the Chester; stated that it had not usually been distinguished from the St. Louis; that lithologically it closely resembles the St. Louis, although it contains oolitic beds, which the St. Louis does not; and that it is perhaps less cherty than the St. Louis; also that main distinction btw. Ste. Genevieve and St. Louis is faunal, the Ste. Genevieve containing recurrent Salem (Spergen) forms, which are older than St. Louis and which are absent from the St. Louis. He also reported an uncon. btw. the Ste. Genevieve and the overlying ss. (*Cypress*, as he then called it). In some subsequent Ill. Geol. Surv. repts Ste. Genevieve ls. and Cypress ss. were both excluded from Chester group, and also treated as distinct from Meramec group. The Ste. Genevieve was treated as distinct from both Chester group and Meramec group in Ill. repts until 1920, when S. Weller (Ill. Geol. Surv. Bull. 41) definitely included it in Meramec group.

In recent years a voluminous literature has appeared on the strat. subdivisions of Chester group in Miss. Valley region and their correlation, and on the subdivisions and proper classification of Ste. Genevieve ls. Detailed work has proved, to the satisfaction of most if not all geologists, that true Cypress ss. is not same as Aux Vases ss., but is a younger ss. in Chester group of Ill. and Ky., and that it is same as Big Clifty ss. of Ky., which is now discarded. But the limits of Ohara ls. and the classification of Ste. Genevieve ls. (i. e., whether it properly belongs in Chester group or in Meramec group) are matters about which there has long been considerable difference of opinion. It seems to be agreed that the typical Ste. Genevieve is uncon. overlain by Aux Vases ss. and uncon. underlain by St. Louis ls. In western Ky., however, the ss. overlying the Ste. Genevieve and formerly called "Cypress ss.," also "Big Clifty ss.," is now known to be older than true Cypress (=type Big Clifty) and is called *Bethel ss.* by Ulrich and Butts, who consider it is same as typical Aux Vases ss. of Mo., but which S. Weller contended is a younger ss. and=his Yankeetown chert of eastern Mo. and southern Ill. Weller also contended that upper part of Ohara ls. is=Renault fm. of Ste. Genevieve Co., Mo., which is much younger than typical Ste. Genevieve ls. The Ste. Genevieve ls. of S. Weller includes only lower part of Ohara ls. memb., and the Rosiclare ss. and Fredonia oolite members of Ulrich. The interpretation of Ulrich and Butts is that all of Ohara ls. memb. is present at its type loc. and that the upper part of type Ohara ls. memb. underlies a ss. (Bethel) that they consider to be=Aux Vases ss. of Mo., which overlies typical Ste. Genevieve ls. They also consider the Ste. Genevieve fauna to be more closely related to overlying Chester faunas than to underlying St. Louis fauna; and they consider the uncon. (present everywhere) at base of Ste. Genevieve to be of greater value than the uncon. (present in places only) at top of the Ste. Genevieve.

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430–442), adhered to correlation of upper part of Ohara ls. memb. with Renault fm., and introduced *Levias* for the lower part of the Ohara, which they treated as top memb. of Ste. Genevieve ls.

The U. S. Geol. Survey formerly included Ste. Genevieve ls. in Chester group, but in May 1937 it transferred so-called "Upper Ohara" of repts to Renault fm. of Chester group and transferred the remainder of Ste. Genevieve ls. to Meramec group.

Named for outcrops in Miss. River bluffs 1 or 2 mi. below Ste. Genevieve, Ste. Genevieve Co., Mo.

†Ste. Genevieve sandstone. (In Chester group.)

Mississippian: Central eastern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., p. 37) and 1900 (Mo. Geol. Surv. vol. 13, p. 168). *Ste. Genevieve ss.*—Massive yellow-brown ss., quarried 4 mi. below Ste. Genevieve and used in construction of Eads Bridge at St. Louis. Underlies Kaskaskia ls. and overlies St. Louis ls.

Same as Aux Vases ss., older name.

Named for exposures at Ste. Genevieve, Ste. Genevieve Co.

†Ste. Genevieve group.

Mississippian: Missouri, Illinois, western Kentucky.

C. R. Eastman, 1903 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 39, No. 7, p. 195), used *Ste. Genevieve group or stage* to include Chester, St. Louis, and Warsaw in Miss. Valley.

†Ste. Genevieve group.

Mississippian: Missouri, Illinois, and Iowa.

H. S. Williams, 1922 (Pan-Am. Geol., vol. 37, No. 1, pp. 39–40; posthumous paper; written for publication in Bull. 3 of Mo. Geol. Surv. (which was published in

1890), but withdrawn from page proof and suppressed). *Ste. Genevieve group.*—Name and classification proposed to include the fms. whose faunas have been described under the names *Warsaw* (in part), *St. Louis*, *Chester*, *Kaskaskia*, *upper Archimedes*, *Ferruginous ss.*, and their equivalents in Mo., Ill., and Iowa; and particularly defined, under the name "Archimedes group," by B. F. Shumard in his rept. on geol. of Ste. Genevieve Co., Mo.

Preoccupied by *Ste. Genevieve ls.* Replaced by Chester group and Meramec group.

Apparently named for Ste. Genevieve Co., Mo.

St. George formation.

Pliocene (?): Northwestern California (Del Norte County).

J. H. Maxson, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, p. 135 and map). *St. George fm.*—Northeasterly dipping marine fm. of sss. and shales carrying abundant invertebrate fauna. Thickness exposed near Point St. George, on W. coast of Del Norte Co., somewhat under 100 ft., but is presumably considerably thicker. Lies noncon. on Dothan fm. (Jurassic) and is noncon. overlain by Battery fm. (Pleist.).

St. George series.

Lower Ordovician: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, pp. 24, 46, 99).

St. Helena rhyolite.

Pliocene: Northern California (Sonoma County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 59–87). *St. Helena rhyolite.*—Of varying thickness up to 2,000 ft. Rests conformably on Sonoma tuff.

Apparently named for occurrence on Mount St. Helena, Sonoma Co.

St. James morainic system.

Pleistocene (Wisconsin stage): Southwestern Minnesota.

F. Leverett, 1932 (U. S. G. S. P. P. 161, pp. 94–99). Members not named. Village of St. James, Watonwan Co. stands on it.

St. Jean group.

Middle Cambrian: New Brunswick.

L. W. Bailey and G. F. Matthew, 1872 (Canada Geol. Surv. Rept. 1870–71, pp. 138–148). *St. Jean (John) group*, Lower Sil. Exact synonym of Acadian group [now classified as Middle Camb.].

St. Joe limestone member (of Boone limestone).

Mississippian (Fern Glen): Northern Arkansas, eastern Oklahoma, and southwestern Missouri.

T. C. Hopkins, 1893 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 4, pp. 10, 212, 253–349, pl. 10). *St. Joe ls.*—Prominent bed of fossiliferous red chertless ls., forming basal part of Boone chert and in places merging into overlying gray ls. of the Boone. Body of rock varies from light pink to dark chocolate color, interspersed with white, gray, or pea-green spots. Thickness 0 to 100 ft. Overlies Eureka [Chattanooga] sh., or, in its absence, the Sylamore ss. or still older (Lower Sil.) rocks.

Named for exposures at St. Joe, Searcy Co., Ark.

†St. Joe limestone. (In Shawnee formation.)

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., pp. 52–53). *St. Joe ls.*—Rough and many-bedded ls. resting on coal No. 7 and separated from overlying coal No. 8 by 3 in. to 100 ft. of clay sh.

Preoccupied. Probably same as Lecompton ls. memb.

Named for exposures near St. Joseph, Buchanan Co., and because it has contributed more building material to St. Joseph than any other native rock.

St. John group.

Middle Cambrian: New Brunswick.

J. M. Dawson, 1863 (Am. Jour. Sci., 2d, vol. 35, pp. 314-319). Includes St. John shales. Assigned to Dev.

G. F. Matthew, 1863 (Canadian Nat., vol. 8, pp. 241, 247-251). St. John group of New Brunswick is Camb.

Seems now to be classified as Middle Camb.

St. John formation.

Cretaceous: Alberta.

F. H. McLearn, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 16). [Assigned to Cret.; Williams and Bocock, 1932 (Roy. Soc. Canada Trans., 3d ser., vol. 26, sec. 4, p. 210) and Allan and Rutherford, 1934 (Alberta Research Coun. Rept. No. 30, p. 13), assigned this fm. to Lower Cret.

St. Johns slate.

Cambrian: Newfoundland.

J. B. Jukes, 1839 (Rept. on geol. Newfoundland, p. 3); 1840 (Edinburgh New Phil. Jour., vol. 29, p. 107). [No age given.]

J. B. Jukes, 1843 (Gen. rept. geol. Newfoundland, pp. 51+). St. Johns sl. is Camb. (?).

St. Johns shales.

Middle Cambrian: New Brunswick and Newfoundland.

J. W. Dawson, 1863 (Am. Jour. Sci., 2d, vol. 35, pp. 314-319). Included in St. John group [which is now classified as Middle Camb.].

St. Johns moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. (Not same as St. Johns moraine of Winchell (1872), who applied name to the moraine in Ind. and Ohio later named *Salamonie* by Leverett. See U. S. G. S. Mon. 41, p. 509.)

†St. Joseph limestone.

Upper Cambrian: Eastern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 347). *St. Joseph ls.*—Massive ls., 200 or more ft. thick, forming lower part of St. Francois ls. in SE. Mo. Underlies Potosi ls. and overlies La Motte ss.

Includes Elvins fm. and Bonneterre ls.

Named for mines of St. Joseph Lead Co. near Fredericktown.

†St. Joseph formation.

Mississippian: Southeastern Indiana.

P. B. Stockdale, 1929 (Ohio Jour. Sci., vol. 29, No. 4, p. 170). [See under *Borden group*.]

Probably named for St. Joseph, Clark Co.

Replaced by *Locust Point fm.*

St. Kitts gravels.

Age (?): West Indies.

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 537).

St. Landry marble.

Cretaceous (?): Southwestern Louisiana.

E. W. Hilgard, 1873 (Suppl. and Final Rept. Geol. Reconn. La., 1869, p. 12). Remarkably pure ls., of peculiar horizontally banded and fissured structure (whence it has received name of "St. Landry marble") and of fetid bituminous odor when struck. Weathered surfaces show horizontal structure and granular concretionary texture. Thickness of about 8 ft. is visible in pits about 1/4 mi. apart in bed of Nezpique and Boggy Bayou. No fossils found, but assigned to Cret.

Above is only known use of this name. On early maps Nezpique Bayou formed SW. bdy of St. Landry Co. and W. bdy of Acadia Co., but present maps show St. Landry Co. has been divided into Evangeline Co. to W. and St. Landry Co. to E.

St. Laurent limestone.

Middle Devonian (Hamilton): Eastern Missouri (Ste. Genevieve and Perry Counties).

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser., pp. 88, 175). *St. Lorenz*.—Ls. with a few thin ss. layers. Underlies Chattanooga sh. and overlies Beauvais ss.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser., p. 51). *St. Laurent ls.*—Named by [S.] Weller, in unpublished ms. of Mo. Bur. Geol. and Mines. Dominantly lss., but contains some highly aren. layers and some thin seams of pure ss. Overlies Beauvais ss. and is highest Middle Dev. in this area.

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., p. 151). *St. Laurent fm.*—Dominantly ls., but some notable aren. beds are included. Named for exposures along St. Laurent Creek, Perry Co., 3 mi. S. of St. Marys [in Ste. Genevieve Co.], where 275 ft. of these beds are exposed. Overlies Beauvais ss., possibly uncon. Is uncon. overlain by Lower Miss. (Burlington ls.). Carries Hamilton fauna.

St. Lawrence formation.

Upper Cambrian: Southern Minnesota, and Wisconsin, Iowa, and northern Illinois.

N. H. Winchell, 1874 (Minn. Geol. Nat. Hist. Surv. 2d Ann. Rept., pp. 86, 132, 138–157), divided the Paleozoic rocks of Minn. Valley into (descending): Trenton lss. and shales; St. Peter ss.; Lower Magnesian series (including Shakopee ls., Jordan ss., and *St. Lawrence ls.*); and St. Croix ss. The ss. underlying the Shakopee was in this rept miscorrelated with Jordan ss., and the rocks below the ss. were miscorrelated with the ls. at St. Lawrence, Minn., so that St. Lawrence ls. as here *defined* was applied to Oneota dol. of later repts. Winchell herein described the St. Lawrence as a heavy calc. fm. underlying the Jordan ss., and stated that only 14½ ft. of it was exposed at St. Lawrence, the type loc. He also, in another place in same rept, described it as "a great limestone formation which, while it differs considerably from the Shakopee stone, is still a magnesian limestone, and belongs to the same great series. It is harder than the Shakopee limestone, evenly bedded, quartzose, and specked with green. These green specks have somewhat the appearance of coming from metamorphism, yet they are caused by little rounded masses, which, if harder, would seem to have been water-worn and deposited with the sedimentation. They are, however, rather soft, cutting like talc. They exactly fill the cavities in which they lie. In some small portions they almost make up the bulk of the rock, which then has a green compact appearance, as if hornblendic. While the rock is evidently calcareous and magnesian in some parts, and almost destitute of these green specks, it is also siliceous and sharply crystalline." "The thickness of the next member [St. Lawrence ls.] of the Lower Magnesian has not yet been made out. It is visible at St. Lawrence, in Scott County, and at Judson, in Blue Earth County."

N. H. Winchell, 1876 (Minn. Acad. Nat. Sci. Bull. for 1875, pp. 153–155, and Minn. Geol. and Nat. Hist. Surv. 4th Ann. Rept., pp. 30–67), described *St. Lawrence ls.* as consisting of 200 ft. of dolomitic ls. with some distinctly aren. layers and stained with green sand, and as overlain by Jordan ss. and underlain by St. Croix ss., the latter 500 ft. thick. He also stated: "In Fillmore County [Minn.] the St. Lawrence limestone contains near its base a Trilobite bed as described in the Mendota limestone by Irving and which amounts to more than the total thickness of all the members at Madison."

N. H. Winchell, 1886 (Minn. Geol. and Nat. Hist. Surv. 14th Ann. Rept., pp. 334–337) and 1888 (Minn. Geol. and Nat. Hist. Surv. Final Rept., vol. 2, pp. xxi–xxii), from Winona, Minn., to Minnesota Valley, Minn., used the following classification:

Shakopee ls. 20–40.

White ss. 0–40. Has been erroneously described as Jordan ss. Is=New Richmond beds of Wooster.

Magnesian ls. 75–175.

Jordan ss. 75–100.

St. Lawrence ls. (shaly) 0–30. "If the shaly beds [see next item below] with which it is associated, and into which it seems to graduate, be included under this term, it will include beds to the amount of nearly 200 ft."

Sands and sandy shales at least 200.

Dresbach ss.

In several papers published in 1888 N. H. Winchell avoided the use of *St. Lawrence* as a fm. name, but applied it as a memb. under either St. Croix or Mendota. All other geologists down to 1924 applied the name to whole interval btw. Jordan ss. and the ss. variously called St. Croix, Dresbach, and Franconia.

E. O. Ulrich in 1924 (Wis. Acad. Sci., Arts and Lett., vol. 21, pp. 72–84) restricted the name *St. Lawrence* to 20 to 25 ft. of ls. or dol. that forms a part only of the St. Lawrence of previous usage, and treated this restricted St. Lawrence as a memb. of his Trempealeau fm., which had essentially the same limits as St. Lawrence fm. of most repts, but with the addition, at top, of Norwalk ss. memb., the fossiliferous part of the Jordan ss. as usually defined.

C. R. Stauffer, 1925 (Jour. Geol., vol. 33, pp. 699–713), followed the established definition of *St. Lawrence fm*, applying the name to the beds btw. Jordan ss. above and Franconia ss. below, and excluding from it Norwalk ss., which is all of Jordan ss. present at Jordan type loc.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 21–79). *St. Lawrence fm.* should continue to be used to include (descending) Lodi sh. memb., Black Earth dol. memb., and the thin unnamed sh. and ls. locally present at base. The Norwalk ss. is all of overlying Jordan ss. that is present at Jordan type loc. and should be included in Jordan ss. The Mazomanie ss. is same as Franconia ss., which underlies St. Lawrence fm. Trempealeau fm. should be discarded, as it includes all of St. Lawrence fm. and part of Jordan ss.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 6, 21–25). *Trempealeau fm.* includes (descending) Jordan ss. memb., Lodi sh. memb., *St. Lawrence* (Mendota or Black Earth) *dol.*, and a basal greensand and greensand cgl. memb. (0 to 15 ft. thick). It rests (probably with discon.) on Franconia fm. and is overlain by Madison fm. All evidence indicates that the Black Earth, Mendota, and St. Lawrence [restricted] are different expressions of same dol.

The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, adopted, for Ill., Iowa, Wis., and Minn., Trempealeau fm. (expanded to include at top Madison ss. and all of Jordan ss.), and *St. Lawrence memb.* (redefined to include basal unnamed memb. of previous repts) for beds beneath Lodi memb.

W. H. Twenhofel, G. O. Raasch, and F. T. Thwaites, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, pp. 1687–1744). Trempealeau fm. divided into (descending) Madison memb., Jordan memb., Lodi memb., St. Lawrence memb., and Basal greensand and cgl. memb.

The U. S. Geol. Survey at present defines *St. Lawrence fm.* as underlying Jordan ss. (including Norwalk ss. memb. of Ulrich) and overlying Franconia ss., and divides it into (descending) Lodi sh. memb., Mendota dol. memb., and an unnamed basal memb. of sh. and cgl.

Named for exposures of part of fm. at St. Lawrence, Scott Co., Minn.

St. Lawrence stage.

Pleistocene.

W. Upham, 1895 (Am. Geol., vol. 16, p. 106). Included in Champlain epoch.

†St. Lawrence limestone or dolomite member.

Upper Cambrian: Southern Minnesota and southern Wisconsin.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, p. 547). *St. Lawrence or Black Earth dol.*—Almost exactly like the Mendota. Name proposed by E. O. Ulrich for a memb. of his Trempealeau fm., underlying Lodi dol. or sh. memb. Rests on sandy dolomitic shales of local distribution.

E. O. Ulrich, 1924 (Wis. Acad. Sci., Arts, and Lett. Trans., vol. 21, pp. 83, 84, 87–90). *St. Lawrence ls.* is proposed for a memb. of Trempealeau fm., 20 to 25 ft. thick, overlain by Lodi sh. memb. and underlain by either the local basal sh. memb. of Trempealeau fm., or, where that is absent, by Mazomanie ss. or Franconia ss. Is the rock exposed at St. Lawrence, Scott Co., Minn.

Same as Mendota dol. memb. of St. Lawrence fm. of U. S. Geol. Surv. classification.

A. C. Trowbridge, W. H. Twenhofel, F. T. Thwaites, and G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc.), expanded the definition of this St. Lawrence restricted memb. by including in it the basal unnamed memb. of Trempealeau fm. of previous repts. But Twenhofel, Raasch, and Thwaites 1935 (Geol. Soc. Am. Bull., vol. 46, No. 11, pp. 1687–1744) recognized a *basal greensand and cgl. memb.* btw. their St. Lawrence memb. and underlying Franconia fm., and stated that in places this basal memb. is separated from overlying St. Lawrence dol. memb. by as much as 15 ft. of glauconitic ss.

†St. Lawrencian terrane.

Pleistocene: New York, New England, and adjacent parts of Canada.

C. H. Hitchcock, 1890 (Am. Geol., vol. 5, pp. 197–200). In Jan. number of Am. Geol. Mr. Jos. F. James endeavors to persuade geologists to use *Laurentian* for the marine Quat. terrane for which Champlain is commonly employed. His reason is that Laurentian (in distinction from Lawrencian) was applied to this terrane by E. Desor "about beginning of year 1851" and before the same name had been suggested for the great fundamental crystalline system of rocks by W. E. Logan. Mr. Desor intended to name the terrane after the valley of St. Lawrence River. The English form is Lawrencian, while the French is Laurentian. Prof. Dana used Laurentian for the Quat. terrane in his presidential address before the A. A. A. S. in 1855, but later, in his Manual of Geol. and elsewhere, used the same word for the crystallines and Champlain for the clays. Now it was evidently intended to name this terrane after the St. Lawrence Valley. Should it not therefore be more correctly written the *St. Lawrencian terrane?* The river is not the Lawrence River, whether written in French or English, and therefore the *St.* should be prefixed. It need hardly be added that with such correct rendering there would never be any conflict with *Laurentian* as applied to the crystalline system. *The term Champlain has been in use for many years to embrace both the littoral and marine deposits now referred to the Columbia.*

St. Leon formation.

Silurian: Quebec (Matapedia Valley).

G. W. Crickmay, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 368–385). *St. Leon fm.*—Fine-grained, argill. sss. or siltstones of a gray or greenish gray color. About 1,000 ft. from base is a ls. cgl. at least 100 ft. thick, abundantly fossiliferous. Minimum thickness estimated at 2,500 ft. Basal part of fm. contains ls. lenses indicating transition from Sayabec fm. Underlies (conformably) Causapscal fm. Typically exposed in Amqui River Valley N. of village of St. Leon. Fossils (listed).

†St. Lorenz limestone.

Same as *St. Laurent ls.*, the approved spelling.

St. Louis limestone. (In Meramec group.)

Mississippian: Illinois, southern Indiana, Iowa, Missouri, Kentucky, Tennessee, northern Alabama, and southwestern Virginia.

G. Engelmann, 1847 (Am. Jour. Sci., 2d, vol. 3, pp. 119–120). *St. Louis ls.*—Hard light-yellowish or grayish rock, mostly pure carbonate of lime, in some strata mixed with sand, in others including irregular siliceous masses of a dark color, or light-colored thin siliceous strata; some strata compact and fine-grained; other strata coarser and even completely crystalline. Thickness 200 to 300 ft. Uppermost bed of carboniferous or mountain ls. in eastern Mo. and southern Ill. Overlain by coal-bearing strata. Rests on 50 to 100 ft. of soft, friable light-yellowish ss. with thin coal bed at top.

G. C. Swallow, 1855 (Mo. Geol. Surv. 2d Ann. Rept., pp. 93, 174). *St. Louis ls.*—Hard crystalline gray and bluish-gray cherty ls. with thin layers of argill. sh.: some strata are impure silico-mag. ls., earthy fracture, others compact silico-argill., drab or yellowish gray, conchoidal. Thickness 250 ft. Underlies Ferruginous ss. [Aux Vases] and overlies Archimedes ls. [Warsaw ls.].

B. F. Shumard, 1860 (St. Louis Acad. Sci. Trans., vol. 1, p. 406). *St. Louis ls.* [restricted] is conformably overlain by Ste. Genevieve ls. [new name] and underlain by Third Archimedes ls. [Warsaw ls.] in Ste. Genevieve Co., Mo. It is 60 to 200 ft. thick. Upper 50 ft. cherty; middle 60 ft. light-gray sandy ls.; lower 20 ft. white, highly oolitic ls. [Spergen ls.].

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines, 2d ser., vol. 2) and 1905 (U. S. G. S. P. P. 36). *St. Louis ls.* [restricted] overlies Spergen ls. (heretofore included in St. Louis ls.) and underlies Ste. Genevieve ls. [This is present commonly accepted definition of St. Louis ls.]

Named for exposures at St. Louis, Mo.

†St. Louis group.

Mississippian: Illinois, Iowa, Missouri, and western Kentucky and Tennessee.

A. H. Worthen, 1866 (Ill. Geol. Surv. vol. 1, pp. 41–43, 83–89). *St. Louis group.*—Fossiliferous lss., 50 to 200 ft. thick, underlying Chester group and overlying Keokuk group (which includes geode bed at top). Includes even-bedded lss. of Alton and St. Louis; concretionary and brecciated lss. of Alton; oolitic ls. 3 mi. above Alton and equiv. beds at Bloomington and Spergen Hill, Ind.; also the faunally related blue calcareo-argill. shales and mag. and aren. lss. at Warsaw, Hancock Co., Ill. Overlain by Ferruginous ss.

Preoccupied by St. Louis ls. Replaced by *Meramec group.*

Named for St. Louis, Mo.

†St. Louis slate.

A name applied in some early repts (see R. D. Irving, U. S. G. S. 7th Ann. Rept., pp. 440–441, 1888) to St. Louis River sl. of NE. Minn. (later replaced by Virginia sl.), of upper Huronian age.

†St. Louis gabbro.

A name applied in some early repts to † St. Louis River gabbro (=Duluth gabbro) of NE. Minn.

†St. Louis conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 79, 83). *Bohemia cgl.*, of Keweenaw series, is same as St. Louis cgl.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 33, 371, 400, 932). St. Louis cgl. is same as Bohemia cgl., top fm. of Bohemian Range group. Occurs on the St. Louis property, Houghton Co.

†St. Louis marls.

A term applied by H. Hinds (Iowa Geol. Surv. vol. 19, p. 339, 1909) to upper part of Miss. rocks in Des Moines Co., Iowa, which he described as resting on St. Louis ls.

†St. Louis amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in lower part of Central Mine group. The mineralized part is the St. Louis lode.

†St. Louis flow.

Includes †St. Louis amygdaloid and underlying trap.

†St. Louis River slate.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (St. Louis and Carlton Counties).

R. D. Irving, 1883 (U. S. G. S. Mon. 5, p. 384). *St. Louis River slates* are plainly same as Thunder Bay slates, and both are Animikie slates.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pl. 14), mapped these slates as Virginia sl., the approved name.

Named for exposures on St. Louis River, St. Louis and Carlton Counties.

†St. Louis River gabbro.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 14, pp. 143–146; also U. S. G. S. Mon. 5). *St. Louis River gabbro*.—Chiefly coarse orthoclase gabbro, but including also orthoclase-free gabbros and very fine-grained diabase beds. Thickness of gabbro and associated granitic porphyry 6,000± ft. Underlies Duluth group. Included in Keweenawan series. Exposed along N. shore of St. Louis River to Duluth.

Same as Duluth gabbro.

St. Marc limestone.

Middle Ordovician (Trenton): Quebec (Deschambault region).

M. F. Goudge, 1933 (Dept. Mines Ottawa, Mines Branch Pub. 733, pp. 38–54).

A. J. W. Laverdiere, 1935 (Quebec Bur. Mines, Rept. Minister Mines 1934–35, pt. D, pp. 55–58).

Ste. Marie sandstone.

Upper Cambrian: Northern Michigan (Sault Ste. Marie region).

W. E. Logan, 1863 (Canada Geol. Surv. Rept. Prog. to 1863, p. 196), described the ss. at Sault Ste. Marie as *Ste. Marie ss.*

See also *Sault St. Mary sss.*

†St. Mary formation.

Tertiary? (Eocene?): Northwestern Montana and southwestern Alberta.

An abbreviated form of *St. Mary River fm.* that has been used by some geologists.

St. Mary River formation.

Upper Cretaceous: Northwestern Montana and southwestern Alberta, Canada.

G. M. Dawson, 1883 (Canada Geol. Surv. Rept. 1880–82, pp. 3B–6B). *St. Mary River series*.—Exposed for many mi. on St. Mary River [SW. Alberta]. Consists of sss., shales, and clays of general grayish or greenish colors. Underlies Willow Creek beds and overlies yellowish sss. and shaly beds with mingled fresh-water and brackish or marine mollusks.

E. Stebinger, 1914 (U. S. G. S. Bull. 540, pp. 330, 332). *St. Mary River fm.* was named by geologists of Canadian Geol. Surv., who first studied the fm. on banks of St. Mary River, Alberta, a few mi. N. of Blackfeet Indian Res. It consists essentially of an irregularly bedded mass of light-gray fresh- and brackish-water clays and sss., the clays making up two-thirds of bulk of fm.; the sss. are in places only partly indurated and not persistent, commonly thinning out and merging into clays within a short distance; some red and variegated clays are present in upper part. Thickness along Little Rocky Coulee, T. 35 N., R. 9 W., and T. 36 N., R. 10 W., is 990 ft. In Blackfeet Indian Res. it is separated from underlying Bearpaw sh. by 360 ft. of magnetite-bearing ss. [now known as *Horsethief ss.*], and is overlain by Willow Creek fm. [of dominantly red color].

St. Marys sandstone.

Upper Cambrian: Michigan (Upper Peninsula) and northeastern Wisconsin.

C. Rominger, R. Pumpelly, and T. B. Brooks, 1873 (Mich. Geol. Surv. Atlas, map of Upper Peninsula), showed *Potsdam or St. Marys* beneath *Calciferous*.

T. B. Brooks, 1880 (Geol. Wis., vol. 3, table opp. p. 450). *The Lower Sil. (St. Mary's) ss.* horizontally caps the highest hills, resting noncon. on Huronian and Laurentian in Menominee iron region, Mich. and Wis. [This ss. is shown in table as overlying Keweenawan copper series. On another page he called it *Potsdam ss.*]

Mich. Geol. Surv. 1916 geol. map of Mich. mapped this ss. as *Lake Superior ss.*

Named for exposures on St. Marys River, E. end of Upper Peninsula of Mich.

†St. Marys epidote.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, p. 25), used *"Epidote Lode," St. Mary's.* In detailed section (pp. 84–85) of St. Mary's mine (sec. 18, T. 55, R. 33, Houghton Co.) he used simply *"Epidote lode."*

According to A. C. Lane (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 431, 490, 1911) this rock is same as †Mesnard epidote, and belongs to Ashbed group.

St. Marys formation.

Miocene: Eastern Maryland and Virginia.

G. B. Shattuck, 1902 (Sci., n. s. vol. 15, p. 906). Chesapeake group is differentiated into 3 well-defined lithologic fms., named (ascending) Calvert, Choptank, and *St. Mary's* fms. An uncon. exists btw. the Calvert and the Choptank. These have been mapped in great detail throughout southern and eastern Md. Each has a clearly defined fauna.

W. B. Clark, 1903 (Md. Geol. Surv. St. Marys Co. Atlas). *St. Marys fm.*—Fossiliferous sandy clay, clay, and marl, 140 ft. thick. Top fm. of Chesapeake group. Overlies Choptank fm.

Named for development in St. Marys Co. and on St. Marys River, Md.

†St. Marys moraine.

Pleistocene (Wisconsin stage). Name applied by G. K. Gilbert to moraine later named *Fort Wayne*, from its relation to St. Marys River, Ohio, "whose course it governs for about 60 mi." But as town of St. Marys, Ohio, is on an earlier moraine, the name has led to some confusion, and is now replaced by *Fort Wayne.* (See U. S. G. S. Mon. 41, p. 566.)

St. Marys sands.

A. W. Grabau (Jour. Geol., vol. 17, p. 211, 1909) casually alluded, in one place, in parentheses, to the basal sands of the Beekmantown of Lake Ontario region as *St. Marys sands.* This is only record of this name.

St. Maurice sand.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 225).

†St. Maurice formation. (In Claiborne group.)

Eocene (middle): Northwestern Louisiana and southwestern Arkansas.

G. D. Harris, 1910 (Sci., n. s., vol. 31, p. 502). In preparing ms. for publication on lower Tertiaries of La., it has seemed desirable to have a formation name for that portion of the Eocene usually styled in our former publications "Lower Claiborne." The geographic name *St. Maurice fm.* is here proposed for these well-known Mississippi embayment marine beds.

The St. Maurice as defined in subsequent repts was treated as lower fm. of Claiborne group in NW. La. and SW. Ark., and was described as consisting of 200 to 550 ft. of argill. lss., calc. clays, calc. glauconite, with a large amount of ferruginous matter, and as underlying Yegua (†Cockfield) fm. (the upper fm. of Claiborne group) and overlying Wilcox group. More recent work resulted in dividing these deposits into 3 fms., in descending order, Cook Mtn fm., Sparta sand, and Cane River fm. The Cook Mtn fm. has also been called *St. Maurice fm.* (by Spooner), *Minden fm.* (by Campbell), and *Mount Lebanon fm.* (by Shearer): but the U. S. Geol. Survey has adopted the older name, *Cook Mtn fm.*, and discarded the more recent names that have been applied to these beds.

Named for exposures at St. Maurice, Winn Co., La.

†St. Maurice formation (restricted).

Eocene (middle): Northwestern Louisiana.

W. C. Spooner, 1926 (A. A. P. G. Bull., vol. 10, No. 1, p. 7, No. 3, pp. 234-237). St. Maurice fm. of Harris and later writers is here divided into three fms., named (descending) *St. Maurice beds* [restricted], Sparta sand [restricted], and Cane River beds. St. Maurice [restricted] includes the beds above Sparta sand and below Yegua fm., ranges in thickness from 100 to 150 ft., and consists of alternating beds of sands and clays, the sands predominating and ranging in color from light gray to red and brown. The sands are massive, cross-bedded, and laminated, and contain considerably more ferruginous ss. than is present in underlying Sparta sand. The clays are gray, green, red, and brown. The glauconitic beds are usually massive, but the sandier clays and lignitic clays are often laminated. Basal and upper beds are fossiliferous and at least one other fossiliferous horizon occurs btw. these two horizons.

These beds in La. have been called *Minden beds* by Campbell and Miller (1928), *Mount Lebanon fm.* by Shearer (1930), *Crockett* by Ellisor (1929), and *Cook Mtn fm.* They are same as Cook Mtn fm. of Tex., which has priority, and are now known by that name. For a short time the Sparta sand was treated as a memb. of Cook Mtn fm., but that usage is now discontinued, and the Sparta is treated as a distinct fm. by U. S. Geol. Survey.

St. Patrick limestone.

Miners' local name for an ore-bearing ls., 14 ft. thick, in lower part of Oquirrh fm. (Penn.), Stockton dist., central northern Utah. Lies 150 ft. below Hercules ls. of miners and 140 ft. above their North Ada ls. Exposed in St. Patrick claim. (See U. S. G. S. P. P. 173, 1932.)

St. Paul sand.

A subsurface sand, about 30 ft. thick, occurring toward top of Santa Margarita fm. in Coalinga dist., in "vicinity of California Oilfields property, sec. 27, No. 20, and extending down into N. part of sec. 34." Lies about 830 ft. above base of Big Blue serpentinous memb. and from 150 to 600 ft. beneath the surface.

St. Peter sandstone.

Lower Ordovician: Minnesota, Wisconsin, Michigan, Iowa, Illinois, Missouri, Indiana, Ohio, western Kentucky, Kansas, northern Arkansas, and Oklahoma.

D. D. Owen, 1847 (Prel. Rept. Prog. Geol. Surv. Wis. and Iowa, U. S. Gen. Land Office Rept. 1847, pp. 169, 170). Soft white ss. [called *St. Peters soft white ss.* on p. 170] near Lake St. Croix, capped with shell lss. such as form upper portions of hills on Wisconsin River near Prairie du Chien and constitute whole of escarpment of St. Peters Falls as well as bluffs on both sides of the Mississippi, from thence to Carvers Cave and St. Pauls, and therefore sometimes alluded to by us under the local name *St. Peters fm.*

In Upper Miss. Valley region the St. Peter ss. uncon. overlies Shakopee dol. and underlies Platteville ls. In northern Ark. the name *St. Peter ss.* has been misapplied to several sss., the upper of which (called "Upper St. Peter" by E. O. Ulrich) is now considered to be true St. Peter ss.

This upper ss. is overlain by Joachim ls. and is separated from the older Everton ls. (which includes 2 sss. formerly miscalled *St. Peter ss.*) by Jasper ls. The Lower St. Peter of Ulrich in Ark. has been named *Kings River ss. memb. of Everton ls.* (See E. T. McKnight, U. S. G. S. Bull. 853, 1935.) The beds in northern Ark. extending from top of upper or true St. Peter ss. down to top of Powell dol. were called *St. Peter group* by C. L. Dake in 1921.

C. R. Stauffer, 1934 (Jour. Geol., vol. 42, No. 4, p. 352). Minn. River was formerly called *St. Peter's*, and from outcrops near its mouth the St. Peter ss. was named. Type loc. is at Fort Snelling, and type section is that at bluff where Minn. River joins Miss. River. [On p. 354 is a detailed section of the St. Peter at Fort Snelling, footing 163 ft., resting on Shakopee dol. and overlain by 3 ft. of Glenwood beds, succeeded by 25 ft. of Platteville ls.]

F. C. Edson, 1935 (A. A. P. G. Bull., vol. 19, No. 8, pp. 1110, 1119, etc.). In Minn. and in Ozark region the beds overlying St. Peter series were formerly correlated with Stones River group, but are now known to be Black River in age. In both regions strata of Beekmantown age underlie the St. Peter series. In the east the Black River and Chazyan groups are present, but St. Peter series is absent. In these 3 type outcrop regions there is no evidence to support the generally accepted belief that the St. Peter-Buffalo River ss. series is pre-Chazyan in age. Work up to present indicates that when studies are completed the St. Peter series will be found in Okla. beneath beds of known Black River age, *and above beds of known Chazyan age*. Writer doubts presence of true St. Peter ss. in Ky. and Ohio.

Named for exposures on St. Peter River [see map in D. D. Owen's 1852 Rept.], now called *Minnesota River*, southern Minn.

†St. Peter group.

Lower Ordovician: Missouri.

C. L. Dake, 1918 (Mo. Bur. Geol. and Mines vol. 15, 2d ser.). Until recently *Everton* was included in St. Peter ss. North of Cedar Hill and S. of Brewerville, Perry Co., the dol. layers of Everton fm. disappear and underlying Everton and St. Peter ss. come together to form a single ss., 75 to 100 ft. thick. Where the lss. are absent it is nearly impossible to separate St. Peter and Everton.

C. L. Dake, 1921 (Univ. Mo. School Mines and Met. vol. 6, No. 1). *St. Peter group.*—In southern Mo. and Ark. the St. Peter fm. rests on Everton dol., except locally. Farther N., where the Everton thins out and disappears, the two sss. [St. Peter ss. and basal sandy beds of Everton ls.] come together and are wholly indistinguishable. In this area it is not practicable to attempt any separation, and while it is certain that the equivalents of both fms. are present, the term St. Peter is still used to refer to both, and includes all beds below Plattin ls. and above Powell dol., which are correlated with St. Peter ss. of Wis.

St. Peters sandstone.

Same as *St. Peter ss.*, the present approved spelling.

†St. Peter's shell limestone.

A name applied by D. D. Owen in 1848 (Rept. geol. reconn. Chippewa land dist. of Wis., etc.) and 1852 (Rept. Geol. Surv. Wis., Iowa, and Minn.) to the Platteville ls. of current nomenclature.

St. Piran sandstone.

Lower Cambrian: Alberta and British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 4). *St. Piran fm.*—Mainly gray qtzitic sss. with a few bands of siliceous sh. Thickness at Mount St. Piran 2,640 ft.; 300+ ft. at Mount Bosworth, B. C., and 500+ ft. at Castle Mtn. Alberta. Type loc. on SE. slope of Mount St. Piran. Lower Camb. fossils in upper part. Underlies Mount Whyte fm. and overlies Lake Louise fm.

St. Regis formation. (Of Ravalli group.)

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and northwestern Montana.

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, pp. 277-285). *St. Regis fm.*—Shallow-water sss.; generally flaggy or shaly; usually fine-grained and much indurated;

mostly green and purple. Thickness 800± ft. Underlies Wallace fm. and overlies Burke fm. Description of general geology of region is based almost wholly on work of F. C. Calkins. Named for exposures in vicinity of St. Regis Pass, SE. part of Coeur d'Alene dist., Idaho.

†St. Stephens division.

†St. Stephens formation.

†St. Stephens group.

†St. Stephens limestone.

Oligocene and upper Eocene: Southern Alabama.

T. A. Conrad, 1856 (Phila. Acad. Nat. Sci. Proc., vol. 7, pp. 257–258). [This rept lists "groups of characteristic fossils" from "Newer Eocene" and "Older Eocene" of Miss. The upper two fossil groups (8 and 7) are designated *Vicksburg group*. Of fossil group No. 6 author says: "*Pecten poulsoni, Orbitolites mantelli.* Is probably synchronous with Orbitolite ls. of St. Stephens, Ala., as its two most prominent fossils are very abundant in this stratum at Vicksburg. Convenient to designate this *St. Stephens group*." Of fossil group No. 5, which he makes basal group of his "Newer Eocene," he says: "*Ostrea georgiana* (?). Lowest bed exposed in bank of Mississippi River at Vicksburg." The ls. is more fully described in Ala. Geol. Surv. Rept. on Coastal Plain, pp. 107–122, 1894.]

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala. with explanatory text), defined *St. Stephens (White ls.)* as including Vicksburg and Jackson, as consisting of 150 ft. of soft white ls. underlain by 50 ft. of argill. lss. containing *Zeuglodon* bones, and as overlying Claiborne group and underlying Grand Gulf fm. In subsequent repts (58th Cong., 1st sess., S. Ex. Doc. 19, 1903, pp. 12–20; U. S. G. S. Bull. 225, 1904, pp. 434–447; U. S. G. S. Bull. 243, 1905, pp. 71–81) he divided *St. Stephens ls. or white ls.* into (descending): (1) Upper or Salt Mtn div., (2) middle or *St. Stephens div.*, and (3) lower or Jackson div.

J. E. Brantly, 1920 (Ala. Geol. Surv. Bull. 22). *St. Stephens group*.—Consists of (descending): (1) Coral or Salt Mtn ls., hard white ls. 150 ft. thick, exposed at Salt Mtn, Clarke Co.; (2) Vicksburg fm., hard crystalline to soft white pulverulent ls., 140± ft. thick; and (3) Jackson fm., soft impure ls. with thin strata of harder ls. and thin beds of clay, 60 to 1,200 ft. thick. Overlies Gosport greensand and underlies Catahoula fm.

The rocks in SW. Ala. (the type region) to which *St. Stephens* has been applied are now divided into:

Vicksburg group	Byram marl 0 to 35 ft. Glendon fm. 0 to 100 ft. Marianna ls. 0 to 90± ft. Red Bluff clay 0 to 40 ft.
Jackson fm.	Yazoo clay memb. 16 to 65 ft. Cocoa sand memb. 6 to 70 ft. Calc. clay 30 to 50 ft. *Periarchus*-bearing bed 1 to 10 ft.

Named for exposures in bluff at St. Stephens, Washington Co.

†St. Thomas sandstone.

Lower Ordovician: Central Missouri (Cole County).

J. A. Gallaher, 1900 (Mo. Geol. Surv. vol. 13, p. 124). *St. Thomas ss.*—Generally massive qtzite, having in places oolitic structure. Underlies Second Calciferous [of Gallaher] and overlies First Calciferous [of Gallaher].

The 1922 geol. map of Mo. shows that rocks at and near St. Thomas are Roubidoux fm. and Jefferson City dol.

J. Bridge, 1930 (personal communication), states that St. Thomas ss. of Gallaher is Roubidoux fm.

Named for St. Thomas, Cole Co.

St. Wendell sandstone.

Pennsylvanian: Southwestern Indiana (Knox County) and adjacent parts of Illinois.

M. M. Fidlar, 1933 (Ind. Acad. Sci. Proc., vol. 42, p. 137). [See under *Parker fm., Fidlar, 1933.*]

M. A. Harrell, 1935 (Ind. Dept. Cons. Pub. No. 133), gave a table in which he showed (but did not define the units) the following subdivisions of the *Wabash* in Ind. (downward): New Haven fm., Buffkin fm., Grayville fm., McClearys Bluff fm., Friendsville fm., *St. Wendells fm.*, and Parker fm.; and also showed Wabash as resting on Merom ss.

†Sakonnet sandstone.

Pennsylvanian: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 357–365, and map, pl. 31). *Sakonnet ss.*—Shales with a predominating amount of dark-gray or blackish sss. and fine cgl. which form upper part of Aquidneck series on E. side of Sakonnet River and also across Portsmouth and Middletown Twps on W. side of Sakonnet River. They correspond to upper green shales of Aquidneck series of other parts of Narragansett Basin. Thickness 110 to 300 ft. East of river some of the sss. contain scattered pebbles, or even thin streaks of cgl. Overlie the dark-blue shales of Aquidneck series and underlie Purgatory cgl. [Mapped as a distinct fm.]

A part of Rhode Island fm.

Salada formation.

Pliocene: Mexico (Lower California).

A. Heim, 1922 (Geol. Mag., vol. 59, p. 544).

Salado halite.

Permian (upper): Delaware Basin and Pecos Valley of southeastern New Mexico and western Texas.

W. B. Lang, 1935 (A. A. P. G. Bull., vol. 19, No. 2, pp. 262–270). In 1923 writer recognized that the salt section of Delaware Basin is divisible into 2 major units, and orally introduced the terms "upper salt series" and "lower salt series," the basis for the separation at that time being that the upper series was shaly, pinkish, and by analysis showed more than 1 percent of K_2O, while the lower series has a dull-grayish appearance and on analysis yields less than 1 percent of K_2O. The upper salt series is dominantly rock salt with massive anhydrite beds, redbeds, shaly sands, and prominent beds and lenses of polyhalite that are characteristic of this fm. only. Although this upper salt series underlies an area of over 60,000 sq. mi. it has no known outcrop, the nearest approach to an outcrop being in eastern Culberson Co., where weathering has so deeply altered the anhydrite to gyp. that if the disrupted anhydrites of the upper series were present they would be difficult to recognize. The name *Salado halite* is given to this upper salt series, from Salado Wash, in northern Loving Co., Tex., *salado* being the Spanish word for "salted." The fm. has suffered pre-Rustler erosional truncation in Eddy Co., N. Mex., and in Reeves, Culberson, and western Loving Counties, Tex., and has also been affected in those areas where the more prominent reef masses accumulated. In Means well it extends from 920 ft. depth to 2,350 ft. The lower salt series outcrops in Eddy Co., N. Mex., and Culberson Co., Tex. It is the fm. to which Richardson gave name *Castile gyp.* as including all rocks btw. Delaware Mtn and Rustler fms. Richardson was not then aware of what took place in subsurface. As the outcropping gyp. is the lower salt series and but a surficial alteration by weathering of the main mass of anhydrite in subsurface, it seems fitting to apply to the lower salt series the name *Castile anhydrite*. The Castile anhydrite extends downward from 2,350 ft. depth to 4,990 ft., where it is uncon. on Delaware Mtn fm. The Castile in Delaware Basin consists of massive beds of gray anhydrite, clean white rock salt, dolomitic and crystalline lss. that are chemical precipitates, and some sss.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7), discriminated *Salado halite* farther N. in Pecos Valley of N. Mex., where it is overlain by Rustler fm. and rests on Castile anhydrite.

Salamanca conglomerate member (of Cattaraugus fm., where Cattaraugus can be separated from Oswayo fm.; of Conewango fm. where Cattaraugus and Oswayo cannot be separated).

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_3). *Salamanca cgl. or Ellicottville rock*.—Physically similar to Panama cgl., but cannot be easily decided whether they occur at same horizon. [On p. 124 he stated Salamanca horizon is 200 to 300 ft. higher than Panama rock. The Panama cgl. is now believed to be older than Salamanca cgl. and to correspond to Wolf Creek cgl.] Assigned to Chemung. [Now considered to be younger than Chemung.]

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, pp. 967–989). *Salamanca cgl. lentil of Cattaraugus beds* occurs at about middle of that fm. and varies in thickness from 0 to 40 ft. In Olean quad. it is a hard gray ss. 10 to 15 ft. thick. In Salamanca quad. it is a massive cgl. Bulk of rock is coarse gritty sand. The ss. phase is well exposed in a number of small quarries on Mount Herman, just S. of Olean, where it is locally called *Mount Herman ss.* Is older than Kilbuck cgl. lentil and younger than Wolf Creek cgl. lentil. Separated from Kilbuck cgl. by 50 to 70 ft. of beds and from Wolf Creek cgl. by a considerable thickness of beds. Assigned to Dev. [In same bulletin (pp. 696–699) J. M. Clarke assigned Cattaraugus beds to Carbf.]

L. C. Glenn, 1904 (Geol. Soc. Am. Bull., vol. 14, pp. 522–531), stated that Salamanca, Pope Hollow, and Tuna are same cgl., and tentatively assigned it to Dev.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 425). In N. Y. Salamanca cgl. varies from hard gray ss. to quartz-pebble cgl., with pebbles distinctly flattened. It is not found outside of Cattaraugus Co., but it has extensive distribution in Pa. It has been called "Panama," "Pope Hollow," "Wrightsville," and "Tuna," but Panama cgl. is now believed to be older and=Wolf Creek cgl.

Whether Cattaraugus fm. is late Dev. or early Carbf. is still an open question.

Named for Salamanca "rock city," N. Y.

Salamanca formational suite.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 85–86). *Salamanca formational suite* is composed of 3 members, 2 cgls. and a separating sh. In Salamanca area the cgl. is a single memb., but traced to S. the lower beds of cgl. disappear and sh. replaces them; while still farther S., in Warren Co. and elsewhere in NW. Pa., a lower cgl. memb. which carries typical Salamanca fauna appears. It seems that this lower cgl., which is here named *Bimber Run cgl. memb.*, initiates a suite of cgl. deposition and therefore is justifiably linked with the better-known upper cgl. In this rept the upper cgl., which has heretofore been known as the only representative of the Salamanca, is being considered under the new category of *suite* as the top memb. of a trio of members which is being termed *Salamanca suite*. This grouping better shows genetic relationship and does not violate usage, as the casual worker can still speak of "Salamanca cgl." meaning the medial Venango cgls., which happen to be a unit which is a little more extensive vertically than was previously known. The upper memb. of the suite has figured largely in repts on Pa. geol., especially those discussing relationships of Venango oil sands. The Salamanca suite, or at least the predominant memb., has been widely traced through the region and variously correlated with locally named cgls. N. Y. State Mus. Bull. 69, 1903, pp. 974–977, gives description of typical development of the cgl. in Olean-Salamanca region. Assigned to Dev., and included in Venango stage. [In table opp. p. 60 of this book, the author shows *Salamanca formational suite* as including (descending) Pope Hollow cgl., North Warren sh. memb. (new name), and Bimber Run cgl. memb. (new name), and as underlying Saegerstown sh. memb. and overlying Amity sh.]

Salamanca moraine.

Name applied to a Pleist. moraine in N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, p. 635, 1932.)

Salamonie moraine.

Pleistocene (Wisconsin stage): Northern Ohio and northeastern Indiana. Shown in part on moraine map (fig. 8) in U. S. G. S. Columbus folio (No. 197), p. 12, and in part on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Salamonie River, Ind. Replaces Winchell's name St. Johns moraine, but not St. Johns moraine of Mich.

†Salem syenite.

E. Cornelius, 1821 (Am. Jour. Sci., vol. 3, p. 232), described specimens from *Salem sienite* at Salem, Mass. This syenite is now known as *Beverly syenite*. A. Hyatt, 1877 (Boston Soc. Nat. Hist. Proc., vol. 18, pp. 220–224), applied name *Salem syenites* to rocks now called *Salem gabbro-diorite*.

Named for occurrence in town of Salem, Mass.

†Salem breccia.

Lower Ordovician (early Chazy): Northern central Alabama (Bessemer quadrangle).

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. Cahaba coal field, p. 152). [For definition see †*Birmingham breccia*.]

Name preoccupied. Replaced by Attalla chert cgl. memb. of Chickamauga ls.

Named for exposures in Salem Hills, SW. of Bessemer, Jefferson Co.

†Salem limestone. (Of Meramec group.)

Mississippian: Southern Indiana.

E. R. Cumings, 1901 (Jour. Geol., vol. 9, p. 233; Am. Geol., vol. 27, p. 147). *Salem ls.*—Gray oolitic ls. formerly called *Bedford ls.* (preoccupied). Overlain by bastard ls., which forms basal part of Mitchell ls., and underlain by bryozoal ls. forming upper zone of Harrodsburg ls.

Same as *Spergen ls.*, the name employed by U. S. Geol. Survey. The Ind. and Ill. Geol. Surveys, however, use *Salem ls.* For further explanation see under *Spergen ls.*

Named for Salem, Washington Co.

Salem gabbro-diorite.

Early Paleozoic: Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass., pp. 5, 7, 8, 11). *Salem gabbro diorite*, with olivine-bearing gabbro facies. [Gabbro at Nahant treated as distinct fm.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 178–181 and map). *Salem gabbro diorite.*—Includes several types of rock. Most characteristic and widely distributed rock contains quartz, labradorite, hornblende, augite, and biotite, and might be called a quartz-augite diorite, a quartz-hornblende gabbro, or an augite-hornblende tonalite, or, better still, a quartz gabbro-diorite. Grades into quartz diorite and granodiorite and into hornblende diorite and amphibolite. Named for occurrence at Salem. [Gabbro at Nahant treated as distinct fm.]

C. H. Clapp, 1921 (U. S. G. S. Bull. 704), treated gabbro at Nahant as distinct from *Salem gabbro-diorite*, which he stated is intruded by Quincy and Andover granites.

L. LaForge, 1932 (U. S. G. S. Bull. 839), treated the isolated area of *gabbro at Nahant* as part of Salem gabbro-diorite.

Salem limestone. (In Allegheny formation.)

Pennsylvanian: Northeastern Ohio.

W. Stout and R. E. Lamborn, 1924 (Ohio Geol. Surv., 4th ser., Bull. 28, pp. 146–150). *Salem ls.*—Bluish-gray, rather hard and dense ls., blocky in form, of fresh-water origin. Generally siliceous and ferruginous and in places changes into a calc. ss. and in other places into iron ore. Occurs in Allegheny fm., lying 4 in. to 10 ft. below Middle Kittanning coal, and lying on or only a few ft. above Oak Hill clay. Thickness varies from 5 in. to 1 foot 2 in. No fossils except small gastropods.

Named for exposures at Salem, Columbiana Co.

Salem Church granite.

Cambrian: Northwestern Georgia (Tate quadrangle).

W. S. Bayley, 1928 (Ga. Geol. Surv. Bull. 43, pp. 103-108, map). *Salem Church granite.*—White or light-gray gneissoid granite. Intrudes Hiwassee schist and Great Smoky fm., which is believed to be Camb. Occupies about 8 sq. mi., extending a little E. of Sharp Mtn Creek to W. margin of Tate quad. Best seen at Salem Church and to W. and SW.

Salem Point shale member.

Pennsylvanian: Southeastern Nebraska, Kansas, and Oklahoma.

G. E. Condra and C. E. Busby, 1933 (Nebr. Geol. Surv. Paper No. 1). *Salem Point sh. memb. of Grenola fm.*—The newly established Grenola fm. is divided into following members (descending): Neva ls., Salem Point sh., Burr ls., Legion sh., and Sallyards ls. The Salem Point memb. consists of gray sh. with a thin sandy-limy layer at Roca, Nebr.; of gray argill. sh. with a thin nonfossiliferous sandy zone in southern Nebr. and northern and central Kans.; of gray calc. and sandy sh. thinning to past Hooser, Kans., and Burbank, Okla., becoming red sh. at Fairfax, Ralston, and Pawnee, Okla. It is less organic in origin and therefore less fossiliferous than Legion sh. and Sallyards ls. Thickness 3½ to 10 ft. Type loc., the road cuts at Salem Point, 1½ mi. NW. of Salem, Richardson Co., Nebr.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred this unit to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Salem School limestone member (of Graham formation).

Pennsylvanian: Central northern Texas (Young and Jack Counties).

Wallace Lee (rept completed and soon to be published by Tex. Geol. Surv.). *Salem School ls. memb.*—Yellowish earthy ls. crowded with marine fossils, lying near base of Graham fm. in Jack Co. Thickness 8 in. to 2 ft. Rests on both the channel deposits of Kisinger channel (which comprise basal part of Graham fm.) and on Home Creek ls. memb. of Caddo Creek fm. It is well exposed ½ mi. SE. of Salem School, in SE. part of Young Co., where it lies 5 ft. above Home Creek ls. A short distance S. of Ming Bend School it is 17 ft. above the Home Creek. During the interval represented by the 5 ft. of sh. a channel over 150 ft. deep was eroded and filled. Regional extension of this ls. is unknown, but it was recognized above the Home Creek ls. N. of Finis, at least 1 mi. from margin of the channel. Where Home Creek ls. is absent this ls. has previously been mapped as Home Creek.

Salesville shale member (of Mineral Wells formation).

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, p. 77 and charts). *Salesville sh. memb. of Mineral Wells fm.*—Sandy clays with few lentils of ss. and near base a thin layer of ls. Thickness 150± ft. Underlies Turkey Creek ss. and overlies Lake Pinto ss. Named for small town (in Palo Pinto Co.) N. of Mineral Wells. Well exposed in a number of smaller streams N. and W. of Mineral Wells.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534), followed above definition.

Salida schists.

Pre-Cambrian: Central Colorado (Chaffee County).

W. Cross, 1893 (Colo. Sci. Soc. Proc., vol. 4, in a paper entitled "On a series of peculiar schists near Salida, Colo.," pp. 286-293), casually referred to the schists in several places as *Salida schists*, but evidently did not intend to name them.

†Saliferous epoch.

Time term used by J. D. Dana (early editions of his Textbook of geology) and other writers to cover time during which the rocks of Cayuga group were deposited.

†Saliferous group.

A descriptive term applied in early N. Y. repts to the rocks now known as *Cayuga group*, which includes the salt deposits of the State.

Salina formation. (In Cayuga group.)

Silurian; New York, Michigan, and northern Ohio.

J. D. Dana, 1863 (Man. of geol., 1st ed., pp. 246–251). *Salina period.*—Includes epoch of Galt [Guelph] lss. and Saliferous epoch or that of Onondaga Salt group. Succeeds Niagara period and precedes Lower Helderberg period, which includes at base Tentaculite and Waterlime group. The rocks of the period consist of shales or marls and marly sss., with some impure lss., impregnated with salt and almost destitute of fossils. Thickness 700 to 1,000 ft. in Onondaga and Cayuga Counties [N. Y.], and only a few ft. on the Hudson. In Onondaga Co. the lower half consists of tender clayey deposits called marls and fragile clayey sss. of red, gray, greenish, yellowish, or mottled colors, and upper half consists of calc. marls and an impure drab-colored ls. containing beds of gyp. overlain by an hydraulic ls. [C. S. Prosser, 1890 (Am. Geol.) gave thickness of 1,418 ft. for the Salina.]

Many years ago the Guelph was transferred to Niagara group, in which it is now included.

In 1894 (N. Y. State Geol. 13th Ann. Rept., pp. 15–18) James Hall stated that upper memb. of *Salina "group"* is the waterlime extensively quarried at Rosendale, which is "of gray or drab color and varies greatly in development and thickness along its outcrop." In 1893 Hall called this ls. *Rosendale ls.* In some succeeding repts it was designated as "Salina waterlime." The Salina fm. as mapped by Hall in 1894 and by Merrill in 1901 included †Waterlime group and †Onondaga salt group.

In 1903 (Am. Geol., vol. 31, pp. 160–175) C. Schuchert defined *Bertie fm.* of N. Y. as underlying Cobleskill ls. and overlying *Salina proper*, but he stated: In southern half of Appalachian region Bertie fm. is not lithologically distinguishable from the Salina, and here the latter term is extended to embrace entire interval btw. the Niagara and Manlius, in latter of which Schuchert then included Cobleskill ls.

C. A. Hartnagel in 1903 (N. Y. State Mus. Bull. 69, pp. 1109–1175) divided *Salina beds* into (descending): (1) Salina waterlime 8+ ft. (Bertie fm. of Schuchert; Eurypterid fauna); (2) Wilbur ls., 8 in.; (3) gypseous shales with beds of rock salt in middle; (4) Pittsford sh. (Eurypterid fauna). Overlain by Cobleskill ls. and underlain by Guelph dol. (Niagaran). [The beds in eastern N. Y. that overlie the Wilbur are now called *Rosendale ls.*, and are believed to be = (in part at least) Bertie ls. memb. of Salina fm., which, according to C. A. Hartnagel, 1912 (Hdb. 19), is known to extend as far E. as Otsego Co., N. Y. From top of the Bertie (or Rosendale) to base of the Pittsford (or top of the Guelph) constitute present boundaries of Salina fm.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 337). All workable gyp. deposits of N. Y. are in Salina fm., and also the salt deposits. The Salina deposits of SE. N. Y. were laid down in a separate basin from those of central and western N. Y., and apparently under conditions not conducive to deposition of salt and gyp., but these SE. beds need further exploration.

Basal fm. of Cayuga group. Essentially same as †Onondaga salt group of early repts.

Type loc. Syracuse, N. Y. Named for the salt it contains. Supplies salt wells at Salina, N. Y.

†Salina period.

Time term used by J. D. Dana in early editions of his Textbook of geol. to include the time covered by deposition of beds btw. base of Helderberg and base of Guelph dol.

†Salina waterlime.

A term applied in some early N. Y. repts (N. H. Darton, N. Y. State Mus. 47th Ann. Rept., 1894; and H. Ries, N. Y. State Geol. 17th Ann. Rept., 1899) to "the attenuated eastern extension of the great Salina fm.," consisting of a few ft. of impure mag. ls. or cement rock, with some shaly intercalations, underlying †Tentaculite ls. and overlying Niagara group. Has also been applied to Rosendale and Bertie lss.

†Salina red shales.

A term applied in some early N. Y. repts to lower part of Salina fm., which consists predominantly of soft red sh. but also includes bluish-gray and green sh. and some thin lss.

Salinan.

A time term covering the epoch during which Salina fm. (Sil.) was deposited.

†Salinas shale.

Miocene (middle): Southern California (Salinas Valley region).

W. A. English, 1918 (U. S. G. S. Bull. 691, pp. 219–250). *Salinas sh.*—Probably best known of Calif. Tert. fms. is the marine diatomaceous sh. which extends from Monterey southward. This sh. was known as "bituminous sh." by early Calif. geologists, but is now commonly called "Monterey sh." The name *Monterey* has been adopted as a group name by U. S. Geol. Survey to include the so-called "Monterey sh." and the underlying Vaqueros ss. The name "Monterey sh." is therefore no longer applicable as a fm. name. The name *Maricopa sh.* was used in writer's rept. on Cuyama Valley (U. S. G. S. Bull. 621, 1916) on mistaken assumption that the sh. previously called "Monterey sh." was essentially contemp. with the sh. exposed in vicinity of Maricopa, but latter has since been found to include representatives not only of the sh. previously called "Monterey" in area under consideration, but also of overlying Santa Margarita fm. The name *Maricopa sh.* is therefore not appropriate as a substitute for "Monterey sh." The name *Salinas sh.* is here proposed for the diatomaceous sh. which is well developed on W. side of Salinas Valley within area mapped, and which is believed to extend as a single fm. northward along W. side of the valley to town of Monterey.

This name was abandoned by U. S. Geol. Survey in 1935, being replaced by *Monterey sh.* See W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, pp. 125–148).

Saline Bayou member. (In Claiborne group.)

Eocene: Eastern Texas (Angelina and Sabine Counties) and northwestern Louisiana.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Saline Bayou memb. of Claiborne fm.*—The series of beds that occur at type loc. of St. Maurice fm. on Saline Bayou, St. Maurice, La. As described by L. C. Johnson in 1888 this section is as follows (descending): (1) Detrital material resembling orange sand and consisting of rather stiff clay with pebbles, 1 to 3 ft.; (2) calc. gray clay, 10 ft.; (3) clay, more tenacious and calc., 15 ft.; (4) indurated glauconitic sand with a ferruginous seam at base, 10 ft.; (5) indurated, glauconitic fossiliferous sand, less sandy, and lighter in color than No. 4, 1½ ft.; (6) lignitic sand, 4 ft.; (7) glauconitic sand, 1 ft.; (8) dark lignitic sand, 4 ft.; (9) glauconitic sand, 1 ft.; (10) lignitic sand, 4 ft. Underlies Cockfield memb. and overlies Milams memb. Is top memb. of Harris' St. Maurice and Spooner's St. Maurice fm.

These beds are now treated as top memb. of Cook Mtn fm.

Saline Creek cave conglomerate.

Pennsylvanian: Central Missouri.

S. H. Ball and A. F. Smith, 1903 (Mo. Bur. Geol. and Mines vol. 1, 2d ser., pp. 92–95). *Saline Creek cave cgl.*—Coarse cgl. in matrix of aren. ls., calc. sh., or calc. ss. Thickness 0 to 60 ft. Irregular cave deposits of undet. age, but younger than Burlington ls. and older than or contemp. with Coal Measures. Rests uncon. on Upper Burlington ls. or on Cambro-Ord. fms.

E. N. Babcock and J. Minor, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 1, pp. 22–27). [See 1904 entry under *Graydon ss.*]

Is a channel filling.

Named for exposures on Saline Creek, Miller Co.

Salineno sandstone member (of Fayette formation).

Eocene (upper): Southern Texas (Starr County).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, pp. 1375, 1383, 1387). [See under *Los Guerras ss. memb.*, basal memb. of Fayette fm., which is said to be same ss. Crops out at Salineno, Starr Co., Tex.]

Saline River formation.

Cambrian: Canada (Mackenzie).

M. Y. Williams, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. B, p. 77).

†Salisbury schist.

Ordovician (?): Northwestern Connecticut (Salisbury-Canaan region).

A local name applied by J. D. Dana (Am. Ass. Adv. Sci. Proc., vol. 22, pp. 25–27, 1874) to the schist overlying Stockbridge ls. in Salisbury, NW. Conn., which was mapped as Berkshire schist by H. E. Gregory and H. H. Robinson (Conn. Geol. and Nat. Hist. Surv. Bull. 7, 1907).

W. M. Agar, 1932 (Am. Jour. Sci., 5th, vol. 23, pp. 31–48). *Salisbury schist.*—A schist with a variety of structural and petrographic types, that overlies Stockbridge ls. (probably of Ord. and Camb. age) in Salisbury-Canaan region. Has previously been called *Berkshire schist*, but since that is a comprehensive name which includes a number of rocks that may not be related, the name *Salisbury schist* will be applied to it in this loc. It includes the schist composing the ridges E. of Salisbury village and that in Taconic Range and its southern continuation, Indian Mtn. It includes 2 strikingly different types of rock, which, however, clearly grade one into the other. The schist of Canaan Mtn seems to be a different fm. [Long petrographic description of each type of schist. Mapped. Thickness not given.]

†Salkehatchie marl.

†Salkehatchie phase.

Miocene: Southern South Carolina (Colleton County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 18, 19). *Salkehatchie phase.*—During a phase of gradual land elevation, which probably immediately succeeded Edisto phase (but as yet with admitted possibilities of much later origin), the Salkehatchie phase, which comprised a deposit of phosphatic sediments, oozes and glauconites with numerous vertebrate remains, extended over the shoal areas of Edisto (Ecphora Miocene) marls, and contributed to their conversion into the great economic beds of phosphate rock. These deposits also extended over the Oligocene shales along Salkehatchie and Combahee Rivers, and over the Ashley-Cooper marls along upper drainage area of Ashley and Cooper Rivers. [Sloan also called the deposit *Salkehatchie marl.*]

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). The †Salkehatchie marl or "phase" of Sloan is included in Hawthorn fm., and name is abandoned.

Named for exposures along Salkehatchie River.

Sallisaw marble.

Silurian: Central eastern Oklahoma (Sequoyah County).

C. Schuchert, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 670). [In a section of the rocks near Marble City, Sequoyah Co., Okla., he describes a white ls. of upper Oriskanian age, 5 to 8 ft. thick, containing a large fauna, and resting uncon. on middle Sil. *St. Clair marble or Sallisaw marble of Taff*. The compiler has been unable to find that Taff ever published the name Sallisaw.]

Sallisaw sandstone.

Middle Devonian: Eastern Oklahoma (Cherokee County).

I. H. Cram, 1930 (Okla. Geol. Surv. Bull. 40QQ, pp. 24+ and map). *Sallisaw ss.*—A calc. ss. of earliest Middle Dev. age which occurs in vicinity of Marble [Sequoyah Co.?], where it has been mapped with Sylamore ss. Inasmuch as true Sylamore is herein considered to be of Miss. age, the beds containing the Middle Dev. fossils are separated from the Sylamore, and given the name *Sallisaw ss.*, from exposures along Sallisaw Creek. Distribution unknown. The fossils were found in one place only. The ss. is probably present only as remnants beneath true Sylamore ss. Further collecting may prove the entire calc. basal Sylamore to be Sallisaw ss. Overlies Frisco ls. uncon. and uncon. underlies Sylamore ss.

Sallyards limestone member.

Pennsylvanian: Southeastern Nebraska, Kansas, and northern Oklahoma.

G. E. Condra and C. E. Busby, 1933 (Nebr. Geol. Surv. Paper No. 1). *Sallyards ls. memb. of Grenola fm.*—The newly established Grenola fm. is divided into following members (descending): Neva ls., Salem Point sh., Burr ls., Legion sh., and Sallyards ls. The Sallyards memb. is fossiliferous massive earthy ls. at Roca, Nebr.; in southern Nebr. and northern Kans. it is shaly, fossiliferous, and limy; in Okla. it is impure ls. grading into ss. Its numerous pelecypods at most points indicate that it is a near-shore marine deposit. Where there is a comprehensive fauna (as at Sallyards, Grenola, and Hooser, Kans.) it is more typically marine. Thickness 6 in. to 3 ft. 6 in. It rests on Roca sh. Type loc., S. bank of ravine 1 mi. NE. of Sallyards, Greenwood Co., Kans.

G. E. Condra, 1935 [see under *Roca sh.*]. R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), assigned Grenola fm. to Perm. This change in Perm.-Penn. bdy has not been considered by U. S. Geol. Survey for its publications.

Sallyards sand.

Subsurface unit. The main producing sand of Sallyards oil field, Greenwood and Butler Counties, Kans., which lies in Cherokee sh., about 300 ft. below Fort Scott ls. Also called *Blankenship sand.*

Salmon hornblende schist.

Pre-Cambrian (?): Northern California (Trinity and Shasta Counties).

O. H. Hershey, 1901 (Am. Geol., vol. 27, pp. 225–245). *Salmon hornblende schist.*—Of remarkable uniformity throughout its thickness of probably not less than 2,500 ft. Largest area of this schist is traversed by south fork of Salmon River btw. its head and vicinity of village of Cecilville.

According to J. S. Diller (unpublished report on Weaverville quad.), also H. G. Ferguson, is probably intrusive into Abrams mica schist.

N. E. A. Hinds, 1932 (Univ. Calif. Pub., Bull. Dept. Geol. Sci., vol. 20, No. 11, pp. 375–410), introduced *Siskiyou terrane* to include Abrams and Salmon fms.

N. E. A. Hinds, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1, 2, p. 82). *Salmon schist* is of eruptive igneous origin except for a few sed. interbeds. Thickness probably 5,000+ ft. In Weaverville quad. it includes notable volumes of chlorite schist.

Salmon series.

A term employed by C. [R.] Keyes to cover pre-Camb. rocks in Cordilleran region interpreted as having been formed during earlier part of Keewatin epoch, called "Coutchiching" by some geologists. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Salmon Arm schist.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 124).

R. A. Daly, 1913 (Canada Geol. Surv. Summ. Rept. 1912, p. 157). *Salmon Arm schist* is pre-Beltian.

†Salmon River sandstone.

Upper Ordovician: Northern New York (Lewis County).

T. A. Conrad, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 58, 62–63). *Salmon River ss.*—Olive-colored ss. characterized by *Pterinea carinata*. Underlies Niagara ss. Separated from older Trenton ls. and sl. by green sl. containing *Agnostis pisiformis*. [Includes Oswego ss. and Pulaski sh., according to A. F. Foerste (Canada Dept. Mines, Geol. Surv. Mem. 83, pp. 4–13, 1916).]

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Ann. Rept., p. 374). *Salmon River ss.*—Gray and greenish (latter prevailing in lower part and former in upper part) sss.; frequently a thin coating of green sh. on lower layers, with and without markings or configurations like fucoids. Forms falls of Salmon River in town of Orwell and above Redfield village. Underlies Medina ss. and overlies Pulaski shales. [Same as Oswego ss.]

†Salmon River sandstones and shales.

Upper Ordovician: New York.

T. A. Conrad, 1840 (N. Y. Geol. Surv. 4th Rept., p. 201). By the name *Salmon River sandstones and shales* I have indicated a fm. which overlies and immediately succeeds the Trenton ls. series and was the first to show that it possessed a distinct group of fossils very different from those above or below it.

Includes Oswego ss. and Pulaski sh.

Salmon River monzonite.

Tertiary (Miocene ?): Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 7, 117° to 117°30'). *Salmon River monzonite* (*stock*), Tert. (?). [Lies short distance to E. of Salmon River, B. C., not far N. of Int. Bdy.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 304). *Salmon River monzonite*, Mio. (?).

Salmon River conglomerate.

Jurassic: Northwestern British Columbia (Salmon River district).

S. J. Schofield and G. Hanson, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. A, p. 8). *Salmon River fm.*—Cgl., 300+ ft. thick, conformably underlying Nass fm. and conformably overlying Bear River fm.

Salmontrout limestone.

Middle Devonian: Northeastern Alaska (Porcupine River region).

E. M. Kindle, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 262, 325–327). Lowest div. of Dev. in Porcupine Valley is fossiliferous ls., 325± ft. thick, massive, light gray to blue, weathering buff, and much broken by joints. Rests apparently uncon. on black Sil. graptolite shales and is overlain by brown sh., probably several hundred ft. thick and believed to be Upper Dev. The ls. outcrops on both banks of Porcupine River immediately above Salmontrout River, and hence is named *Salmontrout ls.* It contains Middle Dev. fauna [listed].

Salona formation.

Middle Ordovician: Central and central southern Pennsylvania.

R. M. Field, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 404, 420). *Salona fm.*—Basal fm. of Trenton group. Consists of 240 ft. of black argill. lss., very different from underlying lss. of Stones River group and lithologically and faunally different from overlying Coburn fm. of Trenton group. Appears to attain max. thickness at Salona [Clinton Co.].

R. R. Rosenkrans, 1933 (Wash. Acad. Sci. Jour., vol. 23, No. 9, pp. 414–415), gives detailed section of *Salona fm.* in central Pa., where he shows it resting on Rodman ls.

Salt sand.

Drillers' term. Has been applied in SW. Pa. to Homewood ss. memb., to Connoquenessing ss. memb., to Homewood and Connoquenessing sss. combined, of Pottsville fm.; to Clarion and other ss. members of Allegheny fm.; to Mahoning ss. memb. of Conemaugh fm.; to Burgoon and other ss. members of Pocono fm.; to Maxton sand of Ky.; and to Murrysville sand of Pocono fm. Also to a sand of Penn. age in Okla.

†Salt Creek gravel beds.

Pleistocene: North-central Kansas.

W. N. Logan, 1897 (Kans. Univ. Geol. Surv. vol. 2, p. 218). *Salt Creek gravel beds.*—Gravel bed or cgl. gravel stones derived from disintegration of shales and lss. of upper group of Benton. Lie about 15 ft. above saliferous shales of Upper Dakota, which form bottom of creek bed. Probably later than Tert.

Is lower gravel bed on Saline River. The name has not had further usage.

Named for Salt Creek, Russell Co.

Salt Creek member (of Moenkopi formation).

Lower Triassic: Northeastern Arizona (Holbrook region).

D. Hager, 1921 (Oil possibilities of Holbrook area, NE. Ariz., private publication). *Salt Creek memb. of Moenkopie fm.*—Basal memb. of Moenkopie fm. Consists of 3 to 4 ft. of red sh. (below) and 12 ft. of massive cream to light-brown ss. (above), the latter locally stained pink to red and even dark red in places, but never for any great distance. A good place to study this memb. is at mouth of Salt Creek, mouth of Clear Creek, and at SE. corner of Winslow (where it trends in NE.-SW. direction), and also just S. of Holbrook. Overlies Kaibab ls., where that fm. is present.

Salt Creek marble. (In Blaine formation.)

Permian: Northwestern Oklahoma (Blaine County).

G. G. Suffel, 1930 (Okla. Geol. Surv. Bull. 49, p. 69). A phase of Medicine Lodge gyp. in vicinity of Salt and Bitter Creeks [Blaine Co.] is known as *Salt Creek marble.* It appears to be largely anhydrite.

Salt Creek fanglomerate.

Pleistocene (?): Eastern Utah (southern Wasatch Mountains).

A. J. Eardley, 1933 (Mich. Acad. Sci., Arts, and Lett., vol. 18, pp. 310, 336). *Salt Creek fangl.*—A thin fm. uncon. overlying the volcanic water-laid deposits and the Jurassic shales in Salt Creek Canyon, southern Wasatch Mtns. From main highway it can be seen as a red capping on W. side of mouth of Toots Canyon and over the castellated volcanic ash at junction of North Fork and main canyon. Is composed of a mixture of large and small angular rock fragments, rudely sorted, with matrix of red earthy material. Cementation usually poor. Stratification rough and channeled. In most places the fm. is a fangl. No fossils. Separation from Eocene Wasatch cgl. by 2 unconformities suggests late Tert. or Pleist. age for the fangl.

Salt Creek Bend shale. (In Cisco group.)

Pennsylvanian: Central Texas (McCulloch County, Colorado River region).

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 245, 249). *Salt Creek Bend sh.* is here proposed for the strata of Pueblo fm. btw. Stockwether ls. below and Camp Colorado ls. above. Drake called this interval "Bed No. 13." At type loc. (a sharp bend on Colorado River 0.1 mi. E. of mouth of Salt Creek) it is 128 ft. thick and consists of chiefly maroon-colored shales with 2 thin lss. near middle. The lower ls. lies 17 ft. below the upper ls., 90± ft. above Stockwether ls. memb., and consists of 2 ft. of nodular aren. gray ls. weathering greenish. The upper ls. lies 22 ft. below top of Salt Creek Bend memb. and consists of 6 in. of yellow massive ls. that breaks into large rectangular slabs.

Salt Fork division. (In Cimarron group.)

Permian: Central southern Kansas and western Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 18). *Salt Fork div.*—Lower 900 to 1,000 ft. of Cimarron series. Divided into (descending) Cave Creek gypsums or fm., Flower-pot shales, Cedar Hills sss., Salt Plain measures, and Harper sss. Overlies, probably uncon., Big Blue series, and underlies Dog Creek shales of Kiger div. [In 1897 (Am. Geol., vol. 19, pp. 351–363) Cragin included Dog Creek shales in his Salt Fork div. In 1897 C. S. Prosser excluded Dog Creek shales and Cave Creek gyp.]

C. S. Prosser, 1897 (Univ. Geol. Surv. Kans., vol. 2, pp. 92–94). *Salt Fork fm.* includes beds below Medicine Lodge gyp. down to base of Harper ss.

E. Haworth and J. Bennett, 1908 (Univ. Geol. Surv. Kans., vol. 9, p. 77). *Salt Fork stage* includes (descending) Dog Creek fm., Cave Creek gyp., Glass Mtn fm., and Kingfisher fm. or Harper ss. Underlies Kiger stage and overlies Sumner stage.

This name has not been used in subsequent repts.

Named for Salt Fork, Comanche and Barber Counties, Kans.

Salt Grass shale member (of Pierre shale).

Upper Cretaceous: Northwestern Kansas (Wallace County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7). *Salt Grass sh. memb. of Pierre sh.*—Gray clayey sh., with few thin bentonite beds, medium-sized ls. concretions, many with cone-in-cone structure, and limonite concretionary streaks in abundance.

Thickness 60 ft. Lowest zone in many places contains several layers of light-gray to nearly white ls. concretions and in places irregular bodies of ls. in which *Lucina occidentalis* is very abundant. Overlies Lake Creek sh. memb. of Pierre and lies 600 to 700 ft. below top of Pierre sh. in Wallace Co. Named for Salt Grass Canyon, the southern tributary of Goose Creek in secs. 1 and 12, T. 12 S., R. 42 W.

†Saltillo limestone.

Middle Ordovician: Western Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 33–35, 44). *Saltillo ls.*—Fine-grained gray or bluish-gray ls. layers, 2 to 5 in. thick, interbedded with equal thicknesses of shaly clay. Thickness more than 70 ft. Utica fossils. Underlies Lorraine ls. in Tenn. River Valley. Oldest fm. of Cincinnati group. Typical section at Clifton, Wayne Co.

Same as Hermitage fm., better-established name.

Named for Saltillo, Hardin Co.

Salt Lake formation.

Tertiary (probably Pliocene): Northern Utah and southeastern Idaho.

F. V. Hayden, 1869 (U. S. Geol. and Geog. Surv. Terr. Rept. on Colo. and N. Mex., 3d Ann. Rept., p. 92). In valley of Weber River from Morgan City to Devil's Gate there is 1,200 ft. of sands, sss., and marls, of light color for most part, which I regard as of upper tertiary age. These beds must have not only occupied this expansion of Weber Valley, but also all of Salt Lake Valley, for remnants of it are seen all along margins of mtns enclosing Salt Lake Valley. I found this series of beds so widely extended and so largely developed in Weber Valley and Salt Lake Valley that I have named it *Salt Lake group.*

G. R. Mansfield, 1920 (Am. Jour. Sci., vol. 49, pp. 402–406). *Salt Lake fm.*—[Quoted Hayden's definition, and stated:] This term was introduced into SE. Idaho by A. C. Peale (U. S. G. S. Terr. 11th Ann. Rept., pp. 588, 640, 1879). In above citation the name appears to be used in a strictly geographical sense, with neither a definite implication of lacustrine origin of the beds nor implication of connection with Great Salt Lake. It is true, however, that members of Hayden Surveys did regard these beds as lacustrine. The long usage of the name in this region and fact that it was directly applied by Peale to the beds under consideration make its retention desirable. It has been shown by Gilbert, however (U. S. G. S. Mon. 1, p. 214, 1890), that these deposits long antedate origin of present Great Salt Lake, and it is now believed that the beds, though probably partly lacustrine, are largely of fluviatile origin. They most commonly consist of light-gray or buff-colored cgls. in which matrix is white, relatively soft, loose-textured, and calc. The pebbles (of variable size) are generally of local materials and rather angular, though many are subangular or even rounded. There are also beds of white marls, calc. clays, sss., and grits. Thickness, few in. to 1,000+ ft. Fossils [listed] are few and poor but are regarded as probably Plio. Strat. position indicates later age than Wasatch fm. The fm. is therefore classified as Tert. (Plio.?).

Salt Lake conglomerate.

Quaternary (?): Western Wyoming (Lincoln County).

A. C. Peale, 1879 (U. S. Geog. and Geol. Surv. Terr. 11th Ann. Rept., pp. 552, 612, 641). *Salt Lake cgl.*—At various points in lower valley of Salt River, especially on E. side, there are fragments of a ls. cgl. which is horizontal in position. I have included it with the Quat., although no facts were observed bearing on its age. It abuts against Carbf. lss. The Salt River receives greater portion of drainage of Salt River Range [Wyo.]. [In table on p. 612 he called it *Salt River cgl.*]

Salt Lake tuff.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, p. 64). In Salt Lake region the oldest fm. is Koolau basalt, which is followed by the older parts of the reef ls. Next younger is Fort Shafter gravel. The oldest tuff is next in age and appears to be contemp. with parts of the gravel. The youngest distinct fm. of region is the younger tuff. The 2 tuff fms. are so nearly coextensive in area that they will be called *Lower Salt Lake tuff* and *Upper Salt Lake tuff*. The older tuff is believed to be the product of combined action of Salt Lake, Aliamanu, and Makalapa.

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Salt Lake tuff*.—Subaerial tuff, 300± ft. thick, deposited on dissected Kaena (+95-ft.) terraces on Salt Lake Crater. Is younger than Aliamanu tuff and contemp. with Makalapa tuff. Included in middle part of Honolulu volcanic series [q. v.]. Assigned to late Pleist. [This is Upper Salt Lake tuff of Wentworth.]

Saltlick beds.

Pennsylvanian: Eastern Kentucky (Magoffin, Floyd, and Knott Counties).

W. C. Morse, 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 296, 303). *Saltlick beds*.—Just S. of gap btw. Grassy Creek and Raccoon Branch (Prestonburg quad.) and just NE. of the one btw. Saltlick Creek and Quicksand Creek (Hindman quad.) are impure lss. that might easily be mistaken for Magoffin beds, because of their strat. position so near the Magoffin beds, and also because of their structure at Saltlick-Quicksand gap, where the beds consist of 2 thin layers of ls. separated by a thin interval of sh. Careful study at this gap showed beds lie 35 ft. above Magoffin beds and that they are lithologically different. They lie 127 ft. below Lost Creek ls. Best exposed at head of Saltlick Creek, where they consist of (descending): (1) ls., blue, impure, shaly at top, fossiliferous, 1.3 ft.; (2) shales, blue, carbonaceous, sandy, fossiliferous, 5½ ft.; (3) ls., impure, sandy, blue, ½ ft. Fossils listed. Doubtfully identified also at gap btw. Mare Creek and Buffalo Creek. Extent of Saltlick beds unknown. They have not been recognized outside of 3 gaps mentioned above.

Salt Mountain limestone. (In Wilcox group.)

Eocene (lower): Southwestern Alabama.

D. W. Langdon, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 589–605. See also Ala. Geol. Surv. Rept. Coastal Plain, pp. 107–122, 1894). The uppermost or *Salt Mtn div.* of this group [White Orbitoidal ls.] is seen nowhere E. of typical locality and so does not enter into geol. features of this section of Ala. [E. of Alabama River]. As a matter of fact the character of *Salt Mtn ls.*, composed as it is of corals and species of echini, and the occurrence of this isolated elevation point rather to Salt Mtn being an atoll or coral island built up in Tert. seas, rather than any extensive deposit justifying the constitution of a group. Is top div. of White Orbitoidal ls. and of Eocene. [Later repts. by Langdon and others, gave thickness of *Salt Mtn fm.* as 100 to 150 ft., and defined it as overlying the white orbitoidal Vicksburg ls. (Marianna ls. of modern nomenclature), and assigned it to the †Coral ls.]

C. W. Cooke, 1923 (U. S. G. S. P. P. 133, pp. 1–9), replaced the descriptive name "Coral ls." with *Glendon ls.* and replaced the paleontologic name "Orbitoidal ls." with *Marianna ls.* Both of these lss. are exposed near Salt Mtn, "which is now considered to be a tilted block brought up by the Jackson fault."

B. W. Blanpied, 1932 (9th Ann. Field Trip of Shreveport Geol. Soc., correlation chart at end of book), assigned *Salt Mtn ls.* to a position in lower Eocene Wilcox group btw. Tuscahoma sand and Nanafalia fm. This is now generally accepted as true position of that ls. Its identification at this strat. horizon was ascertained through the study of well logs, and does not involve a redefinition of either *Tuscahoma sand* or *Nanafalia fm.*, because it is not present at type localities of either of those fms., its only known outcrops being at Salt Mtn and at 2 places within a mile of that mtn. (See C. W. Cooke, A. A. P. G. Bull., vol. 19, No. 8, 1935, pp. 1162+, where Salt Mtn ls. is assigned to Wilcox group, lower Eo.)

Named for exposures at Salt Mtn, Clarke Co.

Salt Plain shale. (In Cimarron group.)

Permian: Central southern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 20–24). *Salt Plain measures*.—Red clay shales, probably with some sss., 155 ft. thick, impregnated with salt and constituting what may be regarded as upper or secondary salt measures of Kans. Perm. Overlain by Cedar Hills sss. and underlain by Harper sss. Included in Salt Fork div.

In later Kans. repts (R. C. Moore, 1917 and 1920) this sh. was treated as a memb. of Enid fm.

Named for Great Salt Plain of Cimarron River, Kans.

Salt River cgl.

See under *Salt Lake cgl.*

Saltsburg sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3, p. 22). *Saltsburg ss.*—Named for fine exposures along Conemaugh and Loyalhanna Rivers near Saltsburg [Indiana Co., Pa.]. Thickness 25 to 40 ft. Underlies Berlin(?) [Maynardier?] coal in Fayette and Westmoreland Counties, and overlies Platt (?) [Upper Bakerstown?] coal. Lies 165 ft. above Mahoning ss. and 100 ft. below Morgantown ss.

According to U. S. G. S. folios, also G. H. Ashley, 1908 (Topog. and Geol. Surveys Pa.), the Saltsburg ss. underlies Pittsburgh Reds and lies higher than Cambridge ls. memb.

Saltsburg (Lower) sandstone. (In Conemaugh formation.)

See Reger, 1924, under *Thomas ss.*

Saltsburg formation. (In Conemaugh formation.)

Pennsylvanian: Southwestern Pennsylvania (Punxsutawney quadrangle).

G. H. Ashley, 1926 (Pa. Topog. and Geol. Atlas, No. 65, Punxsutawney quad., pl. 4, pp. 23–24). *Saltsburg fm.* includes beds from base of Ames ls. to base of Bakerstown coal (which is made top of Buffalo fm.).

Saltsburg member. (In Conemaugh formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include (descending) Pittsburgh Reds, Saltsburg ss., Upper Bakerstown coal, Woods Run ls., and Bakerstown coal.

Saltsville chert.

See *Saltville chert*, the correct spelling.

Saltville chert. (In Helderberg group.)

Lower Devonian: Southwestern Virginia.

F. M. Swartz, 1929 (Pa. Acad. Sci. Proc., vol. 3, p. 80), applied name *Saltsville* [Saltville] *chert* to 5 to 60± ft. of beds in SW. Va., which he showed (in section) as overlying Rocky Gap ss. (correlated with Shriver chert and underlying New Scotland ls.), and as doubtfully correlated with basal part of Ridgeley ss. of northern W. Va. and western Md. He applied the name from Tumbling Creek, Va., near Saltsvil'e [Saltville], to Gala, Va., and showed the beds as consisting of chert and ss., with some thin lss., their greatest thickness being in Tumbling Creek section.

Salt Wash sandstone member (of Morrison formation).

Upper Jurassic: Central eastern Utah (San Rafael Swell to northern San Juan County) and central western Colorado.

C. T. Lupton, 1914 (U. S. G. S. Bull. 541, p. 127). *Salt Wash ss. memb. of McElmo fm.*—Gray conglomeratic ss. that crops out in cliffs. In places is lenticular, soft, and friable. Thickness 150 to 175 ft. Top lies 325 to 350 ft. below Dakota ss. [Dakota? now], and base lies 700± ft. above the very cross-bedded coarse gray La Plata ss., the 700 ft. of intervening beds consisting of red ss., thin-bedded above and massive below. [Named for Salt Wash, Grand Co., Utah.]

As a result of detailed work in eastern Utah and western Colo. by several geologists (especially J. B. Reeside, Jr., W. T. Thom, Jr., W. T. Lee, H. D. Miser, A. A. Baker, and J. Gilluly) the so-called "McElmo fm." of some Utah repts is now divided into Morrison fm. above and Summerville fm. below, and the so-called "McElmo fm." of other Utah repts is now divided into Morrison, Summerville, Entrada, and Carmel fms. The so-called "La Plata ss." is also now divided into several fms., and

"McElmo fm." and "La Plata ss." have both been discarded. The base of Morrison fm. is drawn at base of Salt Wash ss. memb. (See U. S. G. S. Press Bull. 6064, Mar. 30, 1926; A. A. P. G. Bull., vol. 11, No. 8, pp. 785–808, 1927; and U. S. G. S. P. P. 150D, Feb. 15, 1928.)

Salt Water Pond series.

Cambrian or pre-Cambrian: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, p. 32).

†Salt Wells group.

Upper Cretaceous (early Montana and late Colorado): Southwestern Wyoming, northwestern Colorado, and northeastern Utah (Uinta Mountains).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 49, 154). *Salt Wells group.*—Sss. or aren. shales, often very friable, producing badlands, with carbonaceous shales and lignitic coal. Thickness 1,800 ft. Underlies Golden Wall ss. (basal memb. of Point of Rocks group) and overlies Sulphur Creek group. [Mapped at and around Salt Wells Station, Sweetwater Co., Wyo.]

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed Salt Wells group of Powell as in places=Baxter sh. and in places=Blair fm. and Baxter sh., and of early Montana and late Colorado age. This reconnaissance term has been discontinued.

Saluda limestone. (In Richmond group.)

Upper Ordovician: Southeastern Indiana, north-central Kentucky, and southwestern Ohio (?).

A. F. Foerste, 1902 (Am. Geol., vol. 30, p. 369). *Saluda bed.*—Replaces Madison bed (preoccupied). Includes all material in Richmond group overlying the coral beds, which form its base. These beds usually consist of large numbers of *Columnaria alveolata, Columnaria halli,* and *Calapoecia cribiformis.* Named for Saluda Creek, 6 mi. S. of Hanover, Ind. Although the coral bed is practically absent along Saluda Creek, the section nevertheless is sufficiently distinct to enable anyone to draw line btw. the nearly unfossiliferous base of Saluda bed and the richly fossiliferous beds of the Richmond immediately beneath. The typical exposures must ever remain those at Madison.

A. F. Foerste, 1909 (Denison Univ. Sci. Lab. Bull. 14, pp. 289–324). *Saluda* wedges in btw. Liberty and Whitewater. Includes Madison coral reef at base.

A. F. Foerste, 1910 (Denison Univ. Sci. Lab. Bull. 16, pp. 77–100). *Saluda* includes Hitz layer at top.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull. 17). Hitz layer occurs immediately above the Saluda.

W. H. Shideler, 1914 (Ohio Nat., vol. 14, pp. 229–235). There are two *Columnaria alveolata* reefs at base of Saluda beds, the upper one being 2 ft. thick and lying 6 ft. above the lower one, which is 1 ft. thick. Cumings includes both reefs in his Saluda and identifies the lower one with the reef at base of the Saluda farther N. But, as will be presently shown, it is the upper reef, not the lower, that extends toward the N. and NE. Hence it seems best here to consider the top reef as the base of the Saluda. Even should we base the Saluda with the lower *Columnaria* reef at Madison the result would be but little change, and nowhere could the Saluda be said to be beneath the Whitewater. The Saluda is in part=Whitewater.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21). Hitz ls. belongs to Whitewater, and not to *Saluda.* It contains a typical Whitewater fauna. The Saluda wedge forms a conspicuous bdy in Ind. btw. the Whitewater and the Liberty. In some places the Whitewater is=Whitewater and nearly all of Saluda. The Saluda fails entirely in Ohio. Aside from the Hitz bed the fauna of the Saluda is meager [listed].

A. F. Foerste, 1924 (Canada Geol. Surv. Mem. 138, pp. 7–8). *Saluda* is an aren. phase which during Whitewater time entered SE. Ind. from the SW. It carries a fauna sufficiently distinct from that of typical Whitewater as seen farther N. in Ind. to make it possible to speak of a Saluda fauna and of a Whitewater fauna, though in point of time the Saluda must be included in the Whitewater. The typical Saluda forms an horizon entering as a wedge into the typical Whitewater from the S.

Saluda zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 8, 12). *Saluda zone (partly Archean)* comprises an irregularly shaped area bordered on NW. by Oconee Creek zone, from Tugaloo River to N. C. line; this State line constitutes northerly limit of this zone to head of Gap Creek (near Saluda Gap). It is separated from Tyger zone on SE. by a line extending from Gap Creek southwesterly near Pendleton, and thence to Tugaloo River near long. 83° (above Hattons Ford), whence Tugaloo River completes westerly bdy to initial point. Consists of granite, granite gneisses (some porphyritic), granulite, gneissoid slates and schists, hornblende slates and schists (very prominent), peridotite, dikes of granite, diorite (occasional), pegmatite.

Named for exposures in Saluda Mtn range [S. C. ?].

Salvation sand.

A subsurface sand in Mauch Chunk fm. (Miss.) of SW. Pa.

Salvisa limestone member (of Perryville formation).

Middle Ordovician: North-central Kentucky.

A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, p. 329). *Salvisa memb.*—Fine-grained fossiliferous ls., usually exhibiting conchoidal fracture; dove-colored to white where typically developed in Mercer and Boyle Counties, but northward does not always possess these characteristics. Thickness 0 to 20 ft. Middle memb. of Perryville div. of Lexington ls. Overlies Faulconer memb. of Perryville and underlies Cornishville memb. of Perryville.

A. F. Foerste, 1914 (Cincinnati Soc. Nat. Hist. Jour., vol. 21, btw. pp. 109 and 145). *Salvisa ls. memb. of Lexington ls.* consists of very fine-grained hard ls. of whitish or light dove color, containing abundant ostracodes. Underlies Cornishville ls. and overlies Faulconer ls.

A. M. Miller, 1914 (Ky. Geol. Surv., 4th ser., vol. 2, pt. 3, btw. pp. 18 and 36). *Salvisa bed* of Perryville memb. is 0 to 20 ft. thick, and generally consists of light-colored fine-grained compact "birdseye" ls. Is the "Upper Birdseye" of Linney. [Miller, 1919 (Dept. Geol. and Forestry of Ky., ser. 5, Bull. 6) and 1925 (Ky. Geol. Surv., ser. 6, vol. 21, pp. 126–142) continued to recognize *Salvisa memb.* as distinct from Cornishville above and Faulconer below, but Foerste, 1924 (Canada Dept. Mines Geol. Surv. Mem. 138, No. 121 geol. ser., chart opp. p. 58), divided Perryville into Cornishville above and Faulconer below. See also under *Perryville fm.*]

Subsequent repts, by other geologists, continue to apply *Salvisa* to the beds below Cornishville memb. and above Faulconer memb.

Named for Salvisa, Mercer Co.

Sam Creek limestone member (of Savanna sandstone).

Pennsylvanian: Eastern Oklahoma (Muskogee County).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Sam Creek ls. memb. of Savanna ss.*—Consists of (descending): (1) Gray ls. containing so many *Marginifera muricata* that it is almost a coquina, 6 in.; (2) gray sh., 3½ ft.; (3) alternating gray ls. and fossiliferous gray sh., the ls. containing *Campophyllum torquium*, 11 ft.; (4) gray ls. with layers of gray sh., 3 ft. 8 in. Total thickness 0 to 18± ft. Named by S. W. Lowman, in ms. in preparation, from exposure in center of W½E½ sec. 15, T. 14 N., R. 18 E., along S. bank of Sam Creek. Occurs as far S. as T. 13 N., R. 18 E. Lies very close below Spiro ss. memb. of Savanna ss. and 40 to 50 ft. above Spaniard ls. memb.

Sample sandstone member (of Gasper oolite).

Mississippian: Western Kentucky.

C. Butts, 1917 (Ky. Geol. Surv., Mississippian fms. of western Ky., pp. 67, 70). *Sample ss. memb.*—Typically exposed 1 mi. E. of Sample, Breckinridge Co., where it consists of 40 ft. of massively bedded ss. It varies greatly in character and thickness in short distances. In highway N. of Sample it consists of 5 ft. of ss. overlain by 15 ft. of coarse sandy, mealy sh. with a few fossils. On a low knob ¼ mi. S. of Sample it is coarse thick-bedded ss. occupying upper 25 ft. of the knob, and its full thickness is unknown. Near East View, Hardin Co., it has

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

degenerated to about 20 ft. of sh. and flaggy ss. It lies near middle of Gasper oolite, and is known to be present in Breckinridge, Meade, Hardin, Grayson, and perhaps Hart Counties.

A. H. Sutton and J. M. Weller, 1932 (Jour. Geol., vol. 40, No. 5, pp. 430–442). *Sample ss.* is same as Bethel ss.

Sampson Rock sandstone. (In Pottsville formation.)

Pennsylvanian: Western Maryland (Allegany and Garrett Counties).

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 571). *Sampson Rock ss.* (*Homewood ss.*).—Thick and massive ss., locally conglomeratic. Well exposed at Sampson Rock, W. of Frostburg. Overlies Upper Mercer sh. and fauna. Top memb. of Pottsville fm.

San Andreas limestone.

See *San Andres ls.*, the approved spelling of the geographic feature for which it was named.

San Andres limestone member (of Chupadera formation).

Permian: Central and southeastern New Mexico.

W. T. Lee, 1909 (U. S. G. S. Bull. 389). *San Andreas ls.*—Essentially massive ls., often cherty and poorly fossiliferous, although at several localities fossils were abundant. Thickness 500 ft. This ls. was not included by Herrick in Manzano group, but he refers to it, in his description of region E. of Socorro, as an unfossiliferous ls. overlying Manzano red beds, and includes it in the illustration of his section. The writer, however, found in it fossils which are said to be unquestionably of Penn. [Perm. now] age, and which prove that San Andreas ls. should be included in Manzano group. So far as known at present the San Andreas ls. is uppermost memb. of Manzano group. Typically developed at N. end of San Andreas Mtns. Until further information is available the San Andreas ls. cannot be definitely separated from Yeso fm., except in its type loc. in San Andreas Mtns, where it is 500 ft. or more thick and clearly separable from underlying beds. In Caballos and Fra Cristobal Mtns, to W., and at Carthage, to N., the uppermost ls. of the sections is correlated with some confidence on lithologic evidence with San Andreas ls.; but since the San Andreas fauna is apparently not sufficiently characteristic for purposes of correlation, it is not known whether the capping ls. shown in the sections from other localities is the San Andreas or one of the lss. within Yeso fm. The large coiled shells of the genus *Euomphalus*, the long pencil-shaped scaphopods *Plagioglypta canna* and *Dentalium mexicanum*, and the genus *Aviculipinna* are conspicuous in uppermost lss. provisionally correlated with the San Andreas, but are not entirely absent from the lower ones. The San Andreas ls. differs from the older fms. of Manzano group in having a more restricted geographic range. The beds provisionally correlated with it are well developed in southern part, but become less prominent northward and are not represented in northern part of region described.

N. H. Darton, 1922. [See under *Chupadera fm.*]

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). *San Andres ls. memb. of Chupadera fm.* is here applied to the rocks in Pecos Valley of N. Mex. that were named *Picacho ls.* in 1933; and *Hondo ss. memb. of Chupadera fm.* (above) and *Yeso memb. of Chupadera fm.* (below) are here applied to the rocks designated as *Nogal fm.* in 1933. *Picacho ls.* and *Nogal fm.* are both abandoned. [The recognition of Hondo ss. involves a slight redefinition of both Yeso and San Andres.]

San Angelo sandstone.

Permian: Central northern Texas (Stonewall and adjoining counties).

W. F. Cummins and O. Lerch, 1891 (Am. Geol., vol. 7, pp. 73–77, 321–325). *San Angelo beds.*—Consist of (descending): (1) Lighter-buff and whitish thin beds of loose friable ss. and clays, 50± ft.; (2) series of red and yellow clays and sss., 100± ft.; (3) quartz cgl., 12 ft. Rests uncon. on Red Beds and is uncon. overlain by Trinity sands. Well exposed a few mi. W. of San Angelo, near center of that section of Tex. Lithologically very different from fms. above and below.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, pp. 7–8). *San Angelo beds* are=Blowout Mtn ss. of Wrather, and will replace latter name.

J. W. Beede, 1919 (A. A. P. G. Bull., vol. 3, pp. 117–123). *San Angelo fm.* as exposed in SE. corner of Coke Co. is 125 to 150 ft. thick, and is 400 to 500 ft. thick 4 mi. W. of Robert Lee. Is largely coarse cgl., intercalated with beds of ss. and sh. To NW. the coarse cgl. gives way to finer cgls. and sss. of buffish hue. Farther up Colorado River these beds are of finer texture, and wedges of sh. come in and thicken up btw. the sss. and cgls. Is basal fm. of Double Mtn stage.

J. W. Beede, 1920 (Univ. Tex. Bull. 1847, pp. 3–7). *San Angelo fm.*, basal part of Double Mtn stage in Coke Co., consists of 400 ft. of cgl., sh., and sss., with locally some sheets of gyp. and dol. Rests uncon. on Choza fm. of Clear Fork stage.

J. W. Beede and W. P. Bentley, 1921 (Univ. Tex. Bull. 1850). *San Angelo fm.* uncon. overlies Choza fm. The uncon. may be of very great extent. Is sharply but probably conformably separated from overlying Eskota or Greer beds. Assigned to Perm.

J. W. Beede and D. D. Christner, 1926 (Univ. Tex. Bull. 2607). *San Angelo fm.*, named for its occurrence in central Tex., has been traced from San Angelo, Tom Green Co., to Foard Co., where it is 100 to 160 ft. thick, uncon. overlies Clear Fork stage, and conformably underlies Blaine gyp. Is basal fm. of Double Mtn series. Has also been traced from San Angelo, Tom Green Co., N. to its crossing on Red River, in Wilbarger Co., and thence to Duncan, Okla., where it is continuous with Duncan ss. Is same as Blowout Mtn ss. In central Tex., Okla., and Kans. it is separated from the Blaine by Chickasha fm.

G. G. Henderson, 1928 (Univ. Tex. Bull. 2807). *San Angelo fm.* is 126 ft. thick in Tom Green Co. [type loc.], uncon. underlies Blaine fm., and uncon. overlies Choza fm., top fm. of Clear Fork stage.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13). As described in this paper the Blaine fm. contains considerably more than in Okla. section. The terms "Chickasha fm." and "Dog Creek shales" are not used because the equivalents of these members in Tex., although recognizable in most places, are not especially outstanding. Those beds btw. San Angelo fm. and Whitehorse ss. have been included in the Blaine, as all are similar and obviously belong together. The SW. Okla. section of the Blaine commences approx. 200 ft. above Duncan ss.

The San Angelo being largely ss., the U. S. Geol. Survey has adopted the name *San Angelo ss.*, and recognizes the overlying fm. as the Chickasha. See also *Duncan ss.*, to which it is equivalent.

San Antonio formation.

Pleistocene: Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *San Antonio fm.*—A great series of alluvial fans at foot of steep face of Berkeley Hills btw. East Oakland and Berkeley, built up by streams that emerge from the hills. Is divisible into an older gravel, which consists of rock fragments derived from the front of the hills and does not contain any chert, and a later or upper part, here called *chert-gravel memb.*, because it contains abundant fragments of chert. The fm. has been thoroughly dissected and terraced. [Fossils listed.] Uncon. underlies Merritt sand and uncon. overlies Alameda fm. Named for development in San Antonio Twp, Alameda Co.

Sanatoga member. (In Brunswick formation.)

Upper Triassic (Newark group): Southeastern Pennsylvania (Montgomery County).

D. G. McLaughlin, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 179). *Sanatoga sh.*, 200 ft. of dark sh. in Brunswick fm. Exposed at Sanatoga, Schwenksville, and Lederachsville [all in Montgomery Co.], Pa.

D. B. McLaughlin, 1933 (Mich. Acad. Sci., Arts, and Lett., vol. 18, pp. 430, 433). *Sanatoga memb.*—The highest black-sh. memb. of Brunswick fm. studied by writer. (Term *black sh.* as here used covers all gray, green, or black shales in Brunswick and Lockatong fms.) Consists of 200± ft. of dark-gray and green sh. Along Perkiomen Creek lies 2,000± ft. above Graters members of Brunswick, but in Schuylkill section it is probably only 1,100 ft. above the Graters. Forms part of Perkasie shales of Lyman. Wherry has pointed out (Proc. Acad. Nat. Sci. Phila., vol. 64, p. 376, 1912) that the Perkasie should not be regarded as a definite fm., since a large part of it is merely red sh. which has been altered by the diabase intrusion. The Sanatoga memb., however, although slightly altered in places, does not owe its dark color nor most of its hardness to baking. Named for excellent exposures in a large quarry and in the railroad cut at Sanatoga Station on Schuylkill River.

San Augustine group. (In Claiborne group.)

Eocene: Eastern Texas.

E. T. Dumble, 1924 (A. A. P. G. Bull., vol. 8, No. 4, p. 428). *San Augustine group.*—Brown ferruginous marine sands interbedded with clays and sandy clays, underlying Nacogdoches beds and overlying Carrizo sands. Abundant Lower Claiborne fauna. Is the "Marine" of Kennedy. Includes Cook Mtn and Mount Selman fms., which are not constant subdivisions but depend entirely on local conditions. At any rate they are practically a unit paleontologically, and a group name is desirable. As "Marine" is not a suitable name, after consultation with Kennedy the name San Augustine is suggested as a substitute, since the town of that name [in San Augustine Co.] is located near center of an excellent section including both subdivisions.

B. C. Renick, 1928 (A. A. P. G. Bull., vol. 12, pp. 531, 534). *San Augustine memb.*—Basal memb. of Cook Mtn fm. Consists of 15 to 75 ft. of fossiliferous glauconitic and glauconitic calc. marl, brown sand, and some brown clay, green and greenish blue where fresh and brownish red at outcrops. Underlies Nacogdoches memb. and overlies Queen City memb. of Mount Selman fm. [As thus applied—to the beds beneath Nacogdoches and above Queen City sand (=Carrizo ss.)—San Augustine memb. appears to correspond to San Augustine group of Dumble.]

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, p. 1342). *San Augustine* abandoned for Weches memb. of Claiborne fm. (See under *Weches memb.*)

San Benito gravels.

Pleistocene: Western California (San Benito County).

A. C. Lawson, 1893 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 1, pp. 151–153). [Correlated Merced "series" (Plio.) with "the delta gravels on the San Benito." On p. 153 he casually used the term *San Benito gravels*, but apparently not as a geologic name.]

P. F. Kerr and H. G. Schenck, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 468–469, 470, 477, and map). Yellow, loosely consolidated sss., blue sh., blue, red, and gray bedded gravel, indurated ss. in places, strata often brilliantly colored. Thickness 1,000± ft. The gravel was called Plio. by Whitney and accepted by Lawson, but carries characteristic Pleist. vertebrate fossils. These Pleist. gravels were named "San Benito gravels" by Lawson (1893), who thought they were Plio. Uncon. overlie Plio. Paicines fm. [The fm. is mapped along San Benito River.]

Sanborn formation.

Pleistocene: Western Kansas.

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7, pp. 163+). The name *Sanborn fm.* is proposed for the Pleist. loess, with some gravel and sand at base, which is widely distributed on divides in western Kans. Major part of fm. is loess. It seems to writer that only the loess that covers the divides can be considered to be Pleist., the loess of the valley slopes and bottoms being largely if not wholly redeposited from the divides, the redeposition having taken place probably for the most part in late Pleist. and Recent times. The name *Sanborn fm.* is intended as a substitute for the old terms "Tertiary marl" or "Plains marl," introduced for this fm. by Robt. Hay. The new name is derived from Sanborn, Nebr., which is nearest town to a locality of the fm. in NW. corner of Cheyenne Co., Kans., where the loess is 180 ft. thick, is exposed in steep bluffs of numerous canyons on S. side of Arikaree River, and is underlain by a few ft. of Ogallala and by Pierre sh. In other parts of the county the loess on the divides is 20 to 60 ft. thick. Basal part of fm. is always sandy, and in many places coarse gravel was seen at its base.

A. L. Lugn, 1934 (Nebr. State Mus., vol. 1, Bull. 41, p. 355). *"Sanborn fm."* (Elias, 1931) of western Kans. is a composite of sand, gravel, and loess, ranging in age from early Pleist. (Kansan or perhaps older) to Peorian or younger (the "yellow dirt"). The separate parts of "Sanborn fm.," especially the loess, are differentiated in Nebr. and should not have been grouped together as a fm.; at least a new fm. name should not have been assigned.

San Bruno sandstone. (In Franciscan group.)

Jurassic (?): Western California (San Francisco region).

R. Crandall, 1907 (Am. Phil. Soc. Proc., vol. 46, pp. 3–58). *San Bruno ss.*—Chiefly hard blue-gray ss. interbedded with shales and some coarse cgls.; several hundred ft. of ss. at top. Thickness great. Is a subdivision of Franciscan series. Overlain by lower jasper bed of the Franciscan and rests on crystalline lss. of the Franciscan. Named for fact it forms San Bruno Mtns.

A. C. Lawson (U. S. G. S. San Francisco folio, No. 193, 1914) mapped above-described rocks as *Cahil ss.*, toward the middle of which occurs Calera ls. memb. Since Crandall's San Bruno ss. rests on the ls. it is=upper part of Cahil ss. of Lawson.

San Carlos formation.

Upper Cretaceous (Gulf series): Western Texas.

T. W. Vaughan, 1900 (U. S. G. S. Bull. 164, pp. 81–82). *San Carlos fm.*—Fossiliferous sss. and clays containing coal, underlying Vieja series and extending to base of San Carlos section. [Thickness not stated but appears to be at least 1,400 ft.] Upper Cret. fossils.

J. A. Udden, C. L. Baker, E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 78–79, table opp. p. 59), correlated *San Carlos fm.* with Taylor marl and lower part of Navarro fm.

According to T. W. Stanton (personal communication, 1919) these beds are=to, in part at least, Taylor marl, which is of Pierre age.

Named for San Carlos, Presidio Co.

San Carlos formation.

Pleistocene: Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 259).

San Cayetano formation.

Jurassic: Cuba.

R. E. Dickerson and W. H. Butt, 1935 (A. A. P. G. Bull., vol. 19, No. 1, pp. 116–118).

Same as *Cayetano fm.*, De Golyer, 1918.

Sanchez sandstone member (of Fayette formation).

Eocene (upper): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, p. 1387). *Sanchez ss. memb. of Fayette fm.*—Soft gray ridge-making ss. with hard dark-brown calc. concretionary masses. Two fossil horizons containing gastropods and bivalves and, at base, several beds of ss. with plentiful *Ostrea georgiana*. Thickness 139 ft. Lies 280 ft. below top of Fayette fm. in section measured on both sides of Rio Grande btw. Roma and Rio Grande City [Starr Co.], Tex. [Derivation of name not stated.]

San Cristobal limestone.

Cretaceous: Guatemala and Chiapas, Mexico.

See under *Cristobal fm.*

†Sand Brook trap.

Name applied by H. B. Kümmel, 1898 (N. J. Geol. Surv. Ann. Rept. State Geol. 1897), to 425 ft. of extrusive basalt interbedded in upper half or third of Brunswick sh., of Newark group (Upper Triassic), near Sand Brook village, Hunterdon Co., N. J. "In a way contemporaneous with Watchung basalt." In U. S. G. S. Trenton folio, No. 167, 1909, this name was not considered necessary, and the rock near Sand Brook village was mapped as basalt, without a name.

†Sand Coulee beds.

Eocene (lower): Western Wyoming (Bighorn Basin).

W. Granger, 1914 (Am. Mus. Nat. Hist. Bull., vol. 33, pp. 202–205). *Sand Coulee beds.*—Red-banded shales, 0 to 200 ft. thick, underlying, apparently conformably, Gray Bull beds (*Systemodon*-bearing shales) and overlying, perhaps with angular uncon., the gray Clark Fork beds near head of Big Sand Coulee in Clark Fork Basin, Bighorn Basin, Wyo. Fossiliferous, but do not contain *Systemodon*, and fauna is radically different from Clark Fork fauna.

According to H. F. Osborn (U. S. G. S. Mon. 55, 1929) these beds belong to his *Eohippus-Coryphodon* zone in lower part of Wasatch fm., and are older than Gray Bull beds of Granger.

G. L. Jepsen, 1930 (Am. Phil. Soc. Proc., vol. 69, No. 7, pp. 474, 494), included these beds in Gray Bull, as explained under *Gray Bull memb.*

Sand Creek formation.

Pennsylvanian: Central northern Oklahoma (Osage County).

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 79). *Sand Creek fm.*—Named by K. C. Heald, in unpublished ms. Consists of (1) Foraker ls. memb., 60 to 110 ft. thick, at top; (2) shales and thin sss.; (3) Grayhorse ls. memb., 4 ft. thick, at base. Thickness 200 ft. Overlies Buck Creek fm. and underlies Elmdale fm. Is of late Penn. (Monongahela) age. Named for Sand Creek, N. part of Osage Co. Outcrops also in western Osage, eastern Pawnee, and Payne Counties, where it merges with undiff. red beds.

Sanders Bridge limestone. (In Palo Pinto formation.)

Pennsylvanian: North-central Texas.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 24). *Sanders Bridge ls.*, in Palo Pinto fm., lies 7 to 10 ft. below Balsora ls. and 12± ft. above Boone Creek ls. Thickness 16± ft. Consists of a single hard ls. ledge. Has characteristic Palo Pinto cleavage and thin-bedded stratification. Thins to E. and NE. Well exposed at Sanders Bridge over Boone Creek, on Booneville-Willowpoint road.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 105). Type loc. of Sanders Bridge ls. is on Boone Creek, 3¼ mi. NW. of Booneville, Wise Co.

Sandgrass andesite.

Tertiary: Central Nevada (Tonopah district).

J. E. Spurr, 1915 (Econ. Geol., vol. 10, p. 729). *Sandgrass andesite.*—Intrusive; 500 ft. thick. Is the "calcite andesite" of earlier repts.

T. B. Nolan, 1930 (Univ. Nev. Bull., vol. 24, No. 4, pp. 13–15). *Sandgrass andesite.*—In Spurr's earliest examination of dist., rocks belonging to Sandgrass andesite were considered to be an altered phase of Mizpah trachyte and were called by him "calcitic phase of earlier andesite." When the fm. was recognized as distinct from Mizpah trachyte, the name was shortened by those working in the dist. to "calcite andesite." In his final publication (Econ. Geol., vol. 10, 1915) Spurr proposed name *Sandgrass andesite* for this fm., and this name is here retained, although microscopic study has shown the fm. contains relatively little andesite, most of the rock being keratophyric. Exposed in all the mines examined including 1,000-ft. and 1,140-ft. levels of Sand Grass mine. Spurr considered the fm. to be intrusive; J. A. Burgess implied that it is a flow, a view accepted by Locke. So far as present examination went the bulk of the fm. as exposed underground is definitely extrusive. The fm. is dominantly gray green to dark green, although locally bands of nearly black basalt are interlaid with it. Bulk of rock is porphyritic. Some probable flow breccias are also included. Total thickness of fm. not definitely known. On 1,540-ft. level of Tonopah Extension mine 500± ft. are exposed and lower limit concealed by faulting. Is interbedded with Tonopah fm. and therefore of same age.

Sand Hills.

Cretaceous: New Jersey.

W. B. Clark and G. B. Shattuck, 1897 (Johns Hopkins Univ. Circ. 128, pp. 13–16, in a description of the Sand Hills of N. J.), casually alluded in one place to *Sand Hills series* and in two places to the *Sand Hills deposits*, but evidently did not intend to name the deposits, although the name is listed in U. S. G. S. Bull. 191.

†Sand Hills formation.

Pleistocene (Peorian): Western and central northern Nebraska (Sand Hills region).

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, pp. 321, 322, 326, 331, 350). *Sand Hills fm.*—Eolian dune sand, believed to have been derived by wind action from the older Tert. fms. and pre-Peorian Pleist. materials. It is the material left behind after the loess had been sifted out by wind action and carried eastward to become the yellow loess. In some parts of Sand Hills area it can be seen to grade into Peorian loess and is believed to be exact equiv. of this loess. The Sand Hills occupy 20,000± sq. mi. of central and northern Nebr., or half the area of the State.

Sandia clay.

Quaternary: Central northern New Mexico (Sandia Mountains).

E. D. Cope, 1875 (Ann. Rept. Chief Eng. U. S. A., Rept. Secy War to 44th Cong., vol. 2, pt. 2, p. 997). *Zandia clay.*—Indurated clay; lacustrine deposit; 40 ft. thick; post-Plio. Overlies Tert. gravel and cobblestones in Zandia [Sandia is approved spelling] Mtns, N. Mex.

Sandia formation. (Of Magdalena group.)

Pennsylvanian: Central northern New Mexico.

C. L. Herrick, 1900 (Jour. Geol., vol. 8, pp. 112–126; Am. Geol., vol. 25, pp. 234–237; N. Mex. Univ. Bull., vol. 2, pt. 3, pp. 1–14). *Sandia series.*—Series of shales, sss., and cgls., with occasional bands of sandy ls. Thickness 150 ft. Separated from overlying Coyote ss. by thick series of dark conchoidal lss. and shales. Rests on qtzite of unknown age. Present in Sandia, Manzano, and San Andreas Mtns.

C. R. Keyes, 1904 (Am. Jour. Sci., 4th, vol. 18, pp. 360–362). *Sandia fm.* consists of 800 ft. of lss. underlying Madera ls. and overlying Lake Valley ls.

C. H. Gordon, 1907 (Jour. Geol., vol. 15, pp. 810–816). *Sandia fm.*—Alternating beds of blue and black clay sh., compact earthy ls. and cgl., vitreous ss. or qtzite; sh. and ls. predominate. Includes Incarnacion fire clay of Herrick at base. Thickness 500 to 700 ft. Underlies Madera ls. Is lower fm. of Magdalena group. In Magdalena Mtns rests on Kelly ls. (Miss.).

†Sandia series.

A term used by C. R. Keyes (Rept. Gov. N. Mex. to U. S. Secy Interior, 1903) to cover what appears to be Manzano and Magdalena groups of present nomenclature.

Sandia quartzites.

A name applied by C. R. Keyes (Ores and Metals, vol. 12, p. 48, July 1903) to the "basal cgl. and associated sss." of his Middle Carbf., in Sandia Mtns, N. Mex., "which probably corresponds to the coal measures of Miss. Valley."

Probably refers to Sandia fm. of other geologists.

San Diego formation.

Pliocene (middle): Southern California (San Diego region).

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 337). *San Diego beds.*—Plio. sandy marls exhibited in well explored by Hemphill in city park; below Pleist. at Pacific Beach, San Diego, on shores of False Bay near by; and on Coronado Peninsula, opposite San Diego. Same horizon crops out in various places northward, especially at Dead Mans Island and Harbor Hill, San Pedro, and on coast of Todos Santos Bay, Lower California.

A. J. Ellis, 1919 (U. S. G. S. W. S. P. 446). *San Diego fm.*—An extension of Dall's use of the name. Consists of lenticular deposits of cgl., sandy marls, sand, and clay, with rare lenses of ls. The sandy marls which are exposed around Mission Bay and in Mission Valley and underlying the cgls. E. of San Diego have been referred to in the literature as *San Diego beds.* Fossil collections obtained from them have been classified as Plio. Orcutt has assembled data in regard to fossil collections obtained from these deposits in a well boring in city of San Diego. The beds described by Orcutt are near base of later Tert. section. They are best developed in immediate environs of city of San Diego, but have been recognized by their lithologic character as far S. as Otay, and in N. part of the area in vicinity of Oceanside. They seem to be integral parts of a simple fm. and chronologically inseparable from the other lenticular strata with which they are interbedded. On this ground it is proposed to include all of the later Tert. marine deposits in this area under the name *San Diego fm.* It is essentially a shallow-water deposit. Rests on Eocene beds and is overlain by San Pedro fm. Thickness 500 ft.

To N. the *San Diego* becomes a memb. of Pico fm. (See W. P. Woodring 1932 (16th Int. Geol. Cong. Guidebook 15, pl. 2, etc.)

San Diego formation.

Cretaceous: Puerto Rico.

H. A. Meyerhoff, 1931 (Sci. surv. Porto Rico and Virgin Islands, vol. 2, pt. 3, p. 289, N. Y. Acad. Sci.), and 1933 (Geol. of Puerto Rico, p. 44).

San Dimas formation.

Pleistocene (upper): Southern California (southwestern part of San Bernardino County).

R. Eckis, 1928 (Jour. Geol., vol. 36, pp. 228, 235–236). [*San Dimas fm.* on map, *San Dimas alluvium* in heading.] Dissected alluvium with decomposed gravels and red, brown, or yellow color commonly occurring as high fan-head remnants and as isolated or nearly isolated midfan mesas. Called "earlier alluvium" by W. C. Mendenhall in U. S. G. S. W. S. P. 219, pp. 10–12, 1908. Type loc. is at San Dimas, 5 mi. W. of Claremont. Overlain by Recent alluvium, from which it is sometimes difficult to distinguish it. Is generally undeformed.

R. Eckis, 1934 (Calif. Dept. Pub. Works, Div. Water Res. Bull. 45, p. 38), assigned this fm. to upper Pleist.

†Sand Mountain conglomerate.

Pennsylvanian: Northern central Alabama (Jefferson and Blount Counties).

J. L. Campbell and W. H. Ruffner, 1883 (Phys. surv. from Atlanta, Ga., across Ala. and Miss., pp. 54–57). *Sand Mtn cgl. or Cliff Rock.*—Whitish ss., unusually coarse though not always so; usually about 100 ft. thick. Divides Carbf. rocks of Ala. into two groups. Is bottom memb. of Great Conglomerate or Millstone Grit. Rests on Lower or so-called Sub-Carbf. group.

The ss. of Sand Mtn is Boyles ss. memb. of Pottsville fm. (a later but better-defined name), and is so mapped in U. S. G. S. Birmingham folio, No. 175, 1910, by C. Butts.

Sandoval granite.

Pre-Cambrian: Central northern New Mexico (Magdalena and Sandia Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 11). *Sandoval granites.*—Red granites penetrating all pre-Cambric rocks of Sandia, Magdalena, and other ranges. [Derivation of name not given. On p. 4 they are assigned to pre-Camb.]

Sandpoint conglomerate.

Late Carboniferous (?): Northern Idaho (Pend Oreille region).

A. L. Anderson, 1930 (Idaho Bur. Mines and Geol. Bull. 12). *Sandpoint cgl.*—Cemented pebbles and boulders from sill rocks and Belt terrane. Very variable texture. Dominantly boulders from gravel size to 3 or 4 ft. diam., embedded in fine siliceous or sandy matrix. Thickness 4,000 to 5,000 ft. at least. Lies in Purcell trench, N. of Sandpoint, Bonner Co. Rests uncon. on Algonkian rocks. Deposited under torrential conditions in great valley carved in Belt terrane. Top removed by erosion. Much disturbed by faulting. Probably late Carbf.

†Sand Pond gneiss.

Pre-Cambrian: Northern New Jersey.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 439). *Sand Pond gneiss.*—Coarse foliated syenitic gneiss.

In U. S. G. S. Franklin Furnace folio, No. 161, 1908, this name was discarded, the rock being an inseparable part of Byram gneiss.

Sandro shale.

Upper Cretaceous: Alberta.

R. L. Rutherford, 1935 (Alberta Research Council 11th Ann. Rept., No. 28, 1932, pp. 33–38). Included in Belly River series of Smith and Cold Lake dist.

Sand Springs basalt.

Pleistocene: Southern Idaho (Gooding and Jerome Counties).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Sand Springs* *basalt.*—A massive pahoehoe flow, 500± ft. thick. Exposed for 14 mi. up Snake River, or to point where Sand Springs cascade into Snake River, in Gooding Co. Older than Burley lake beds and younger than McKinney basalt. The Bliss basalt may possibly be a subaqueous facies.

Sandstorm rhyolite.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 43, etc.). *Sandstorm rhyolite.*—Thin, originally glassy rhyolite flows overlying the latite and most of the Kendall tuff. Usually nearly white, shows conspicuous flow lamination, and weathers in thin, shelly flakes. It is the rock of Sandstorm mine and of hills lying W. of road from the mine to Columbia. Thickness 100 to 400± ft. Upper part of Kendall tuff is intermingled with the rhyolite. Is much older than Siebert [Esmeralda] fm. [which is upper Mio.].

Sandsuck shale.

Lower Cambrian: Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 3). *Sandsuck sh.*—Bluish-gray shales with lighter-gray bands. Shales weather dull yellow. Thickness at least 1,000 ft. Lowest fm. in Chilhowee Mtn. Underlies Cochran cgl.

Named for exposures on Sandsuck Branch of Walden Creek, Sevier Co., Tenn.

Sandusky limestone.

Middle Devonian: Northern and central Ohio.

J. S. Newberry, 1873 (Ohio Geol. Surv. vol. 1, table opp. p. 89, pp. 143–144). *Sandusky ls.*—Blue thin-bedded ls., 15 to 20 ft. thick, present in northern and middle Ohio; quarried at Sandusky and Delaware. Composes upper fm. of Corniferous ls. Lies above Columbus ls., lower fm. of Corniferous ls., and is overlain by Hamilton group (ls. and marl).

E. Orton, 1878 (Ohio Geol. Surv. vol. 3), and 1888 (Ohio Geol. Surv. vol. 6), 1890, 1893; also J. A. Bownocker, 1898 (Denison Univ. Sci. Lab. Bull., vol. 11). *Sandusky ls.* is=Delaware ls.

C. S. Prosser, 1903 (Jour. Geol., vol. 11, btw. pp. 519 and 546). *Sandusky ls.*, 30 ft. thick, is="Delaware ls." and has 5 yrs. priority.

C. S. Prosser, 1905 (Jour. Geol., vol. 13, pp. 413–443). Since it is proved that nearly all of the rock to which Dr. Newberry gave name "Sandusky ls." belongs in *lower* instead of *upper* division of what he called "Corniferous ls.," it appears to writer that name "*Sandusky ls.*" ought to be dropped. If it were now applied to lower fm. it would cause serious confusion, since that was named, at same time, Columbus ls., under which designation it is well known.

C. K. Swartz, 1907 (Johns Hopkins Univ. Circ. 7, pp. 56–65). Sandusky and Delaware are not equivalent. Sandusky is in part of Delaware age and in part of Columbus age, and name should be dropped.

Sandy Creek beds.

Upper Ordovician: Northern New York (Black River Valley).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 85, 137, 141, 149, 154, etc.). *Sandy Creek beds* overlie Worthville beds and underlie Bennett Bridge beds. Next to top div. of Pulaski fm. Divided into two paleontologic zones. Exposed along upper Sandy Creek, Jefferson Co.

Sandy Huff shale. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 193). *Sandy Huff sh.*—Dark gray laminated, argill., 5 to 70 ft. thick. Underlies Harvey cgl. and overlies Castle coal. Exposed just below mouth of Sandy Huff Branch, McDowell Co.

San Emedio series.

Pre-Cambrian (?): Southern California (Kern County).

O. H. Hershey, April 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pl. 1, map). [*San Emidio schists* on legend of map lie btw. Camb. above and Archean gneiss below.]

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 273-290). *San Emedio series*.—A series of thoroughly crystalline schists and ls. Tentatively assigned to pre-Camb. (?). Relations to Pelona schist series unknown and can not be conjectured.

Probably named for Range or Mtn in Kern Co., which U. S. Geog. Bd. states should be spelled *Emigdio*.

See *San Emigdio fm.*

†San Emigdio formation.

Oligocene: Southern California (Kern County).

G. C. Gester, 1917 (Calif. Acad. Sci. Proc., 4th ser., vol. 7, pl. opp. p. 220). [Gives section of Midway and Tejon districts, in which the name *San Emigdio* is applied to shales and sands underlying the lower Mio. and apparently referred to Olig.]

C. M. Wagner and K. H. Schilling, 1923 (Calif. Univ. Pub. Dept. Geol. Bull., vol. 14, pp. 235-252). *San Emigdio fm.*—Basal fm. of San Lorenzo group [expanded definition]. Discon. underlies Pleito fm., upper fm. of San Lorenzo group, and uncon. overlies Tejon fm. East of San Emigdio Canyon it consists of 700 ft. of alternating yellowish and grayish sss. and sandy shales containing very fossiliferous dark-red bands and lenses; underlain by 150 ft. of bluish-black sh. carrying fossils in calc. concretions; with, at base, 150 ft. of light-gray and tan unfossiliferous ss., in places conglomeratic and gritty. Mapped along E. side of San Emigdio Creek, SW. part of Kern Co. Carries *Molopophorus lincolnensis* zone. Correlated with Butano ss., which is older than typical San Lorenzo fm.

Is a faunal zone in San Lorenzo fm.

San Felipe formation.

Upper Cretaceous: Mexico.

I. C. White, 1913 (Geol. Soc. Am. Bull., vol. 24, p. 255).

San Fernando formation.

Eocene: Trinidad.

R. J. L. Guppy, 1866 (London Geol. Soc. Quart. Jour., vol. 22, p. 572). Assigned to Mio.

T. W. Vaughan, 1924 (Geol. Soc. Am. Bull., vol. 35, p. 726), and G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol. No. 7, p. 41), assigned this fm. to Eo.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 700), assigned these deposits to Olig.

San Fernando formation.

Oligocene: Mexico.

E. T. Dumble, 1908 (Sci., n. s., vol. 27, p. 273), and 1911 (Sci., n. s., vol. 33, p. 233).

Sanford formation. (In Newark group.)

Triassic (Upper): Central North Carolina.

M. R. Campbell and K. K. Kimball, 1923 (N. C. Geol. and Econ. Surv. Bull. 33, pp. 20, 43-45). *Sanford fm.*—Almost universally red rocks, largely cgl., ss., and sh., in a monotonous succession. So far as known contains no coal beds. Includes all rocks of Triassic age above Cumnock fm. Is top fm. of Newark group. Thickness probably 4,000 or 5,000 ft. Overlies Cumnock fm.

Named for development under and around town of Sanford, Lee Co.

†San Francisco sandstone.

Jurassic (?) and late Tertiary: Western California (San Francisco Bay region).

W. P. Blake, 1856 (Expl. and Surv. for R. R. route Mississippi River to Pacific Ocean, vol. 5, 33d Cong., 2d sess., S. Ex. Doc. 78, pp. 145-156). Fine-grained compact sss. associated with thin shales. Thickness 1,000 to 3,000 ft. Tertiary in part at least, but Upper Cret. may also be represented. Forms greater part of hills and mtns around the [San Francisco] bay and, so far as explored, a considerable part of mass of Coast Mtns. Believed to be most extensive and highly developed sed. fm. of Calif. coast, and may appropriately be known as *San Francisco or California ss.* [Includes sss. of Franciscan group and rocks belonging to Merced fm.]

A. C. Lawson, 1895 (Am. Geol., vol. 15, p. 347, and U. S. G. S. 15th Ann. Rept., p. 417). *San Francisco ss.*, the dominant sed. fm. of Franciscan series, consists of moderately fine-grained ss. with subordinate beds of sh. and cgl. Is interbedded with foraminiferal lss., radiolarian cherts, and volcanic rocks, including basaltic lavas, diabases, pyroclastic accumulations, etc.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193), divided Franciscan rocks into five named fms., three of which are ss.

The term "San Francisco ss." is no longer used by geologists.

†San Francisco group.

Late Tertiary and Franciscan (Jurassic?): Western California (San Francisco region).

J. S. Newberry, 1857 (Pacific R. R. Repts., vol. 6, pt. 2, pp. 10–12). Upon the serpentine lies a deposit of sss. and shales, several hundred ft. thick. They are somewhat interstratified, their strata conformable, and apparently belong to same geological epoch, being members of a group widely spread over Pacific coast, and to which, under the name *San Francisco group*, I shall frequently have occasion to refer. The ss. where long exposed is light gray, soft, and easily worked. It forms the slopes of the axis lying btw. Bay of San Francisco and the ocean and the rocky basis upon which the city of San Francisco rests. The shales are greenish or yellowish brown. No fossils found in either the ss. or sh. in vicinity of San Francisco, but on San Pablo Bay this group is highly fossiliferous. Assigned to Mio.

Apparently includes Franciscan and late Tert. rocks.

San Gabriel formation.

Pre-Cretaceous (pre-Cambrian?): Southern California (San Gabriel Mountains).

W. J. Miller, 1934 (Univ. Calif. at Los Angeles Pub. in Math. and Phys. Sci., vol. 1, No. 1, pp. 12, 25–65, map). *San Gabriel fm.*—A metamorphic complex, consisting chiefly of Rubio metadiorite and Placerita meta-sediments intimately injected by Echo granite. Usually exhibits banded structure. Some of schist may be of sed. origin; a porphyritic gneiss is also present. The fm. is cut by Wilson diorite, Lowe granodiorite, and Echo granite. Named because extensively developed in San Gabriel Mtns. Assigned to pre-Cret. (pre-Camb.?). Presumably younger than Placerita fm. (probably pre-Camb.), but the two are intimately associated and relations are not clear.

Sangamon stage of deglaciation (Pleistocene).

Sangamon stage is name applied to the interglacial stage during which the *Sangamon soil and gumbotil, vegetal and other deposits* were formed. The name was proposed by F. Leverett (Jour. Geol., vol. 6, pp. 171–181, 1898), from exposures of the soil in Sangamon Co., Ill. The soil overlies the Illinoian glacial till and underlies the main loess deposit, and has generally been considered to be older than Iowan drift. See under *Iowan*.

San German limestone.

Cretaceous; Puerto Rico.

G. J. Mitchell, 1922 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 3, p. 253).

Sangre de Cristo formation.

Pennsylvanian and Permian: Central southern Colorado (Sangre de Cristo Range).

R. C. Hills, 1899 (U. S. G. S. Elmoro folio, No. 58, p. 1). The exposures in neighboring mtns to W. indicate that it was not until near end of Carbf., when *Sangre de Cristo cgl.* was formed, that any considerable accumulation of sediments took place.

R. C. Hills, 1900 (U. S. G. S. Walsenburg folio, No. 68). In Sangre de Cristo Range the strat. section corresponds very nearly with that at S. extremity of Greenhorn Mtns [in this quad.] except in respect to thickness of the cgl. Below

Morrison fm. there is in each case about same thickness of capping red ss., but the coarse cgl. and ss. on which it rests attain in the Sangre de Cristo a thickness of several thousand ft. In that locality the beds have yielded an upper Carbf. fauna and flora. Evidence of similar character from Fountain fm. on E. slope of Rocky Mtns is meager and contradictory, and it is still a question whether it should be classed as Perm. or Triassic. As Fountain and *Sangre de Cristo* fms. have not sufficient geologic importance to warrant separation on areal geol. sheet, they are grouped together under name *Badito fm.* and referred to upper Carbf. The upper part of the Badito consists of 100 ft. of massive or thick-bedded brick-red ss., sometimes shaly on weathered surface, and apparently corresponds to some part of Fountain fm. The lower part consists of coarse brownish red cgl. [In chart in back of folio Fountain fm. is shown as overlying *Sangre de Cristo fm.* and both as=Badito fm.]

R. C. Hills, 1901 (U. S. G. S. Spanish Peaks folio, No. 71, p. 2). A few mi. W. of the dist. [Spanish Peaks quad.] there are extensive exposures of reddish-brown coarse cgl. (*Sangre de Cristo fm.*) which attains an enormous thickness and is regarded as of upper Carbf. age. It was the erosion of this cgl. that furnished bulk of material composing Huerfano beds of Spanish Peaks area.

F. A. Melton, 1925 (Jour. Geol., vol. 33, pp. 807–815). *Sangre de Cristo cgl.*—Cgls., arkoses, and shales, noteworthy for red color throughout nearly entire fm. Most characteristic development and greatest thickness is in central part of Sangre de Cristo Range near village of Crestone [Saguache Co.], where it is probably at least 13,000 ft. thick and where it forms backbone of the range. From this place it thins irregularly in both directions until it is 6,000 ft. at Culebra Range, near S. border of State. To N. of Crestone it thins to 4,300 ft. in valley of Arkansas River SE. of Salida. Near Crestone it is divisible into 2 groups of strata: *Upper Sangre de Cristo cgl.* (Perm.), consisting of 5,500± ft. of very coarse red cgls.; and *Lower Sangre de Cristo cgl.* (Penn.), consisting of 7,500± ft. of finer cgls. and arkoses, of darker color than Upper Sangre de Cristo cgl., and containing at base the Veta Pass ls. memb. Rests on Leadville ls. (Miss.). Though an angular uncon. was not seen btw. the Upper and Lower Sangre de Cristo cgls., it is believed that further search in this area may reveal such a break. The coarse conglomeratic beds in Upper Sangre de Cristo cgl. are "here named *Crestone cgl. phase of the Upper Sangre de Cristo cgl.*" [See under *Crestone*.]

J. H. Johnson, 1929 (Colo. Sci. Soc. Proc., vol. 12, pp. 3–18). There is distinct uncon. btw. *Upper Sangre de Cristo fm.* and *Lower Sangre de Cristo* at some localities.

Sangre de Cristo granite.

R. D. George, 1913 (Colo. Geol. Surv. geol. map of Colo.), mapped the pre-Camb. granite of Sangre de Cristo Range as *Sangre de Cristo granite*.

San Jacinto series.

Pleistocene and Pliocene: Southern California (Riverside County).

P. H. Dudley, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 223). *San Jacinto series*, Pliocene-Pleistocene, sedimentary. [Appears to be named for town, as the paper is on an area btw. towns of Riverside and San Jacinto.]

San Joaquin formation.

Pliocene: Southern California (San Joaquin Valley).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 178–192). *San Joaquin clays* applied to upper third of Etchegoin fm. [See description under *Etchegoin fm.*]

W. P. Woodring, 1934 (U. S. G. S. geol. map and structure sections of Kettleman Hills), restricted *Etchegoin ss.* to lower two-thirds of Etchegoin fm. of previous publications, and applied *San Joaquin fm.* to upper part (previously called *San Joaquin clays*), which he assigned to Plio.

San Juan tuff.

Tertiary (Miocene?): Southwestern Colorado.

W. Cross, 1896 (Colo. Sci. Soc. Proc., vol. 5, pp. 225–228). *San Juan fm.*—Stratified and water-laid andesitic tuffs and breccias, forming lower memb. of volcanic complex of Telluride dist., SW. Colo. Plays important part in composition of large part of San Juan Mtns. Texture varies from thin-bedded fine-grained tuff containing no large fragments to a tuff breccia consisting of large subangular blocks embedded in a finer-grained matrix. Upper limit not always clearly definable, but in mtns about Marshall Basin it is very sharply defined by appearance of first massive lava flow of augite andesite. Thickness 1,000 to 2,500+ ft. Rests conformably [uncon. reported in some areas] on San Miguel cgl. [preoccupied, and later replaced by Telluride cgl.].

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120) and 1907 (Ouray folio, No. 153). *San Juan tuff* uncon. underlies Silverton volcanic series and uncon. overlies Telluride cgl. Thickness 100 to 3,000 ft.

San Juan series.

In some early repts the *San Juan tuff* of SW. Colo. was called *San Juan series*. The name has also been applied to Paleozoic rocks in Wash. (See beyond.)

†San Juan glacial epoch.

A name applied by W. W. Atwood and K. F. Mather (Sci., n. s., vol. 35, p. 315, 1912; Jour. Geol., vol. 20, p. 388, 1912; and G. S. A. Bull., vol. 23, p. 732, 1912) to the time during which the oldest till sheet of San Juan Mtns, SW. Colo., was laid down. They later replaced the name with *Cerro glacial stage*.

†San Juan moraine.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1912 (Jour. Geol., vol. 20, pp. 392–409), mapped and described "San Juan moraine" in San Juan Mtns of SW. Colo. Later (U. S. G. S. P. P. 95, pl. 1, 1915, and P. P. 166, 1932) they replaced term "San Juan" by unpreoccupied name *Cerro till*, the present accepted name.

San Juan formation.

Upper Cretaceous: Northeastern Mexico.

E. T. Dumble, 1915 (Am. Inst. Min. Engrs. Bull. 104, p. 1626, Aug. 1915, and Calif. Acad. Sci. Proc., 4th ser., vol. 5, p. 170, Dec. 1915).

E. A. Trager, 1926 (A. A. P. G. Bull., vol. 10, No. 7, pp. 672, 675–681), stated that this name is replaced by *San Felipe fm.*

San Juan formation.

Pleistocene: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 10, 11).

San Juan series.

Carboniferous and Devonian: Northwestern Washington (San Juan Islands).

R. D. McLellan, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 217). The majority of fms. exposed in San Juan Islands of State of Wash. belong to one more or less conformable series, here called *San Juan series*, which is composed of highly metamorphosed sed. and volcanic rocks of Paleozoic age. Divided into Orcas group (Miss. and Dev.) below and Leech River group (Penn., "which no doubt includes Clapp's Leech River 'formation' ") above.

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2). On Vancouver Island is a series of rocks known as *Sicker series*, which is apparently unfossiliferous. It is suspected by writer that Sicker series and San Juan series are identical, even though former has been provisionally assigned to Jurassic.

San Juan Bautista formation.

Oligocene: Southern California (San Benito County).

P. F. Kerr and H. G. Schenck, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 470, 471, 472, 493 and map). *San Juan Bautista fm.*—Blue indurated calc ss., also fine-grained argill. buff-colored ss., carbonaceous grit, and clay sh. Thickness about 1,500 ft. Base not exposed. Contains numerous fossils, which establish its Olig. age and marine origin. Lower fm. of San Lorenzo series. Named for exposures in vicinity of San Juan Bautista.

San Juan Raya formation.

Cretaceous: Mexico.

W. A. Ver Wiebe, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 282).

Sankaty sand.

Pleistocene: Southeastern Massachusetts (Nantucket Island and Cape Cod).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 975–988). *Sankaty beds (first interglacial epoch)*.—Compound gravels and sands with local clay deposits. Of marine origin. Named for Sankaty Head, on Nantucket, but also occur on Gardners Island, Marthas Vineyard, and Block Island. Overlie basal boulder bed (of first glacial stage) and precede Gay Head interval of erosion and folding, which intervened btw. Sankaty beds and Tisbury beds.

J. B. Woodworth, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 197–212). *Sankaty group*.—Gravels and sands of granitic character, 25 ft. thick, uncon. underlying Tisbury beds on Marthas Vineyard. The uppermost beds involved in the principal folding over island of Marthas Vineyard. For reason that beds occupying a similar position with reference to the folding on island of Marthas Vineyard carry the well-known marine fauna at Sankaty Head, the name *Sankaty group* has been proposed for this horizon. Overlies boulder bed.

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 766–776). *Sankaty beds (interglacial)* of Long Island consist of 50–150 ft. of blue clay, considerable lignite, and occasional fragments of shells, and occupy strat. position of these beds on Marthas Vineyard and Nantucket. Preceded Gayhead interval and overlie Jameco gravel. Correlated with Yarmouth interglacial stage of Mississippi Valley.

M. L. Fuller, 1905 (Geol. Soc. Am. Bull., vol. 16, pp. 367–390). Sankaty beds of Woodworth = Herod gravel and Jacob sand. If term is to be retained, as it possibly will be, because of well-known fauna of Sankaty Head, it should, in writer's opinion, be limited to a single class of deposits, namely, the interglacial deposits here separately described under headings *Gardiner clay* and *Jacob sands*. The glacially derived Herod gravels should be excluded.

A. C. Veatch, 1906 (U. S. G. S. P. P. 44). *Sankaty fm.* on Long Island varies in thickness from 0 to 150 ft. and varies in character from truly swampy deposits to relatively fine sands and clays which show no trace of swamp origin and which contain shallow-water mollusks. On N. shore occurs merely as erosion remnants. Overlies Jameco gravel and precedes Gay Head period of folding.

M. L. Fuller, 1906 (Sci., n. s., vol. 24, pp. 467–469). Jacob sand is equiv. in part to Sankaty beds of Nantucket.

F. G. Clapp, 1908 (Geol. Soc. Am. Bull., vol. 18, table opp. p. 512). Sankaty of Woodworth and Veatch = Jacob sand and Gardiner clay.

M. L. Fuller, 1914 (U. S. G. S. P. P. 82, p. 92). Sankaty beds of Woodworth are = Herod gravel memb. of Manhasset fm. and Jacob sand. Sankaty beds of Veatch are = Gardiners clay.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll., Mus. Comp. Zool. Mem., vol. 52). Pleistocene of Nantucket Island divided (descending): (1) Nantucket moraine, of Wisconsin age; (2) Vineyard interglacial stage of erosion; (3) Manhasset fm. (glacial), consisting of Hempstead (?) gravel memb. and Montauk till memb., the basal Herod gravel memb. being absent; (4) Jacob sand; (5) Gardiners clay; (6) Jameco gravel and associated till deposits of Marthas Vineyard not recognized above sea level; (7) stony blue clay passing laterally into stratified gravel, and locally contorted drift of probable Mannetto age; rests uncon. on (8). *Sankaty sand*, fossiliferous marine sands on horizon of glacial Weyquosque fm. of Marthas Vineyard and Block Island; (9) the ferruginous gravel of Desor and the uncon. underlying light-brown sandy clay of Desor not now exposed. Tertiary absent, but Upper Cret. believed to be present below sea level. The *Sankaty sand* as here defined occurs only on Nantucket Island and Cape Cod. Is older than glacial Mannetto fm. and is correlated with part of Nebraskan stage of Mississippi Valley.

The 1934 definition of Sankaty by Woodworth, which separated the fossiliferous marine sands from the contemp. glacial gravels and sands (Weyquosque fm.), and restricted *Sankaty* to the old marine sands at Sankaty Head and Cape Cod, is the U. S. Geol. Survey's present accepted definition.

Sankaty beds.

Sankaty group.

See under *Sankaty sand*.

†Sankaty Head beds.

Pleistocene: Massachusetts (Nantucket Island and Cape Cod).

J. H. Wilson, 1905 (Jour. Geol., vol. 13, pp. 713–734) and 1906 (Glacial history of Nantucket and Cape Cod, pp. 13–30). *Sankaty Head beds.*—Fossiliferous interglacial beds underlying Wisconsin drift and resting, apparently uncon., on an unfossiliferous old clay at Sankaty Head. Consist of sands and gravels, including 2 beds of ferruginous gravel in lower part.

J. H. Wilson, 1907 (Geol. Soc. Am. Bull., vol. 17, pp. 710–711). *Sankaty Head deposits* underlie late Wisconsin ice sheet and overlie interglacial fms. Included in Pleist.

Same as *Sankaty sand.*

San Lorenzo formation.

Oligocene: Southern California (Santa Cruz Mountains region).

R. Arnold, 1906 (U. S. G. S. P. P. 47, p. 16). *San Lorenzo fm.*—Essentially a series of grayish "muddy" shales and fine sss., typically exposed along bed of San Lorenzo River about 2 mi. above Boulder Creek, Santa Cruz Co. Extends W. from type loc. into Big Basin, on N. side of which it rests conformably against the older yellowish sss. of Butano Ridge [later named Butano ss.]; possibly Olig. in age. Conformably [uncon.] underlies Vaqueros ss. [Fossils listed.] Thickness about 2,300 ft. in vicinity of type loc.

E. R. Atwill, 1935 (A. A. P. G. Bull., vol. 19, No. 8, p. 1204). Recent work points to conclusion type San Lorenzo may range from Olig. (or even Eo.) to Mio.

†San Lorenzo series.

Oligocene: Southern California.

B. L. Clark, 1918 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, pp. 54–111), used *San Lorenzo series* to include "all known marine beds in Calif., Oreg., Wash., and British Columbia that have generally been referred to the Olig." In Sobrante anticline, in Concord quad., he divided his San Lorenzo series into (descending) Concord fm. (=lower part of Lawson's Sobrante ss.), Kirker tuff, and San Ramon fm., and stated that it represents *Agasoma gravidum* zone. In this expanded San Lorenzo Clark later included lower part of Sobrante ss. of Lawson; the San Lorenzo fm. and underlying Butano ss. of Santa Cruz Mtns and their equivalent; and the Kreyenhagen sh.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770). After reviewing the paleontological data pertaining to type section of San Lorenzo fm. it seems best, in view of poor preservation and small number of species in the fauna, to discard that name as a general one for Olig. series, and to use only the local formational names, correlating them with the general established faunal horizons.

San Lorenzo quartz diorite.

Age (?): Puerto Rico.

C. R. Fettke, 1924 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 2, p. 153).

†San Luis formation.

Jurassic (?): Southern California (San Luis Obispo region).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *San Luis fm.*—Usually earthy ss., but in places there is a great thickness of dark sh. very similar to Toro fm. Contains many lentils of radiolarian jasper and some contact-metamorphic schist. Local representative of Franciscan. Represents all of Franciscan present in the area. Uncon. underlies Toro fm. (Knoxville) and uncon. overlies serpentine and other basic igneous rocks. Named for development in San Luis Valley, San Luis Obispo Co.

Replaced by Franciscan fm.

San Luis formation.

Eocene (late): Cuba.

C. Schuchert, 1935 (Hist. Geol. Antillean-Caribbean region, p. 492).

San Mateo formation.

Pliocene (?): Southern California (San Diego and Orange Counties).

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7, pp. 169, 217–219). *Post-Capistrano fm.*—The younger [than Capistrano fm.] rocks are of slight significance in present study. They are very patchy in distribution and lie uncon. on the older rocks. There is the tilted *San Mateo fm.*, doubtful correlative of San Diego Plio., consisting of arkosic sands and gravels with a little admixture of blue schists and containing an occasional marine fossil; and topping all the very slightly deformed or untilted Terrace gravels and Alluvium. Thickness several hundred ft. Classified as Plio. (?). [Mapped.]

Named for occurrence along San Mateo Creek, in NW. corner of San Diego Co.

San Miguel formation.

Upper Cretaceous (Gulf series): Southern Texas.

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 224–230). *San Miguel beds.*—Thin- to heavy-bedded sss. separated by bands of clay and containing seams of glauconitic material with many fossils and occasional heavy beds of clay, especially toward top. Thickness 800 ft. Included in Eagle Pass div. Underlies Coal series (Olmos fm.) of Eagle Pass div. and overlies Upson clays. Named for locality at which it was first observed by Dr. Comstock and myself. In Rio Grande section it first occurs in hills N. of Carter's ranch, where the hills show exposures of it 75 to 100 ft. in height. The exposures are excellent for several mi. S. of this point.

E. Böse and O. A. Cavins, 1927 (Univ. Tex. Bull. 2748, p. 44). A good locality for observing *San Miguel beds* is near Arroyo de las Navajas, on road from Piedras Negras to El Moral.

L. W. Stephenson, 1931 (personal communication): The name *San Miguel* was proposed by Dumble and was derived from the abandoned village of San Miguel. In a letter to L. W. Stephenson dated Mar. 1, 1937, F. M. Getzendaner, of Uvalde, Tex., says: "Mr. Ed Smidt, who was born and reared at Eagle Pass, once told me that San Miguel was a ranch headquarters at the old rock house on Elm Creek, now within the boundaries of the J. K. Burr ranch, and about 13 miles N-NE. of Eagle Pass. I know definitely that the old rock house was built and occupied for many years by one San Miguel, a pioneer ranchman in Maverick County. * * * As you know, the old rock house is within the outcrop of the San Miguel formation."

†San Miguel conglomerate.

Eocene: Southwestern Colorado.

W. Cross, 1896 (Colo. Sci. Soc. Proc., vol. 5, pp. 235–241). *San Miguel cgl.*—Characteristically a coarse cgl., in which pebbles of many kinds are recognizable at a glance—granite, schists of various kinds, hard bluish qtzites, lss., red sss., and some dense porphyritic eruptive rocks. Thickness 200 to 1,000 ft. in Telluride dist. Great uncon. at base. Rests on rocks of Colorado Cret. age. Conformably overlain by San Juan fm. Typically exposed on N. side of San Miguel River, from Marshall Creek westward for several miles.

Later replaced by Telluride cgl., because of prior use of San Miguel for a Cret. fm. in Tex.

†San Miguel cherts.

Jurassic (?): Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, p. 416). *San Miguel cherts*, radiolarian, 530 ft. thick. Underlie Bonita ss. and overlie Marin ss. A fm. in the Franciscan.

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, pp. 544–545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). [The rocks of San Miguel Hills, San Francisco Co., which appears to be type loc., are mapped as Ingleside chert, Marin ss., and Sausalito chert. The name *San Miguel* is preoccupied.]

San Miguel limestone.

Late Cretaceous or early Tertiary: Costa Rica.

J. Romanes, 1912 (Geol. Soc. London Quart. Jour., vol. 69, p. 106).

San Onofre breccia.

Miocene (middle): Southern California (San Diego County).

A. J. Ellis, 1919 (U. S. G. S. W. S. P. 446). *San Onofre breccia.*—Very coarse breccias or aggls., made up almost entirely of angular boulders and slabs of garnetiferous glaucophane schists and other schistose rock fragments. Forms San Onofre Hills, in San Diego Co. Older than Poway cgl. and San Diego fm. Assigned to lower Mio. [M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7), stated Poway fauna is Eo.]

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7). [Described above fm. as *San Onofre facies of Temblor fm.* or *Turritella ocoyana* zone; gave thickness as 2,610 ft., and stated that the Temblor beds underlying the San Onofre facies consists of 300 or more ft. of gray or white ss. and sh. Doubtful correlatives of San Onofre are described under headings *San Pedro schist breccia and ss., Catalina schist breccia,* and *Bouquet Canyon breccia.*]

San Pablo group.

San Pablo formation (where undivided).

Miocene (upper): Western California coast region.

J. C. Merriam, 1898 (Calif. Univ. Pub., Dept. Geol. Bull. vol. 2, pp. 109–118). *San Pablo fm.*—Marine sss., tuffs, and ashes, 1,500 ft. thick, characterized by *Astrodapsis* and *Scutella (Clypeaster) gabbi.* A considerable thickness of tuffs and ashes, most prominent in upper part of fm., and peculiar weathering of the sss. are constant and striking characters of greatest value in identifying the fm. where fossil remains are rare or absent. Overlies Contra Costa County Mio., without distinct uncon., although a break is indicated at several localities.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). [Described *San Pablo fm.* as resting uncon. on Briones ss. and as uncon. overlain by Plio. rocks (Pinole tuff in some areas and the younger Orinda fm. in other areas). According to B. L. Clark (Jour. Geol., vol. 29, pp. 586–614, 1921) the San Pablo fm. (renamed by him *Cierbo group*) occurs only in general region of San Francisco Bay, lies discon. below Santa Margarita fm., and rests discon. on Briones ss.]

B. L. Clark and R. Arnold, 1918 (Geol. Soc. Am. Bull., vol. 29, p. 298), applied *San Pablo group* to all upper Mio. deposits of western Calif., including Briones ss. at base and Santa Margarita fm. at top.

B. L. Clark, 1921 (Jour. Geol., vol. 29, pp. 586–614), used *San Pablo series* to cover all upper Mio. fms. of western Calif., including Santa Margarita fm., Mint Canyon fm., and Maricopa sh. In Mount Diablo region he divided it into (descending): (1) Santa Margarita fm. (300 to 3,000 ft. thick), resting discon. on (2) Cierbo group (600 to 1,300 ft. thick and the fm. heretofore called *San Pablo fm.*), which in turn is discon. on (3) Briones ss. (2,300 ft. thick and formerly included in Monterey group). As thus applied *San Pablo series* is described as resting on Rodeo sh. in Mount Diablo region, on Salinas sh. in Salinas Valley, and on rocks designated *Temblor* by B. L. Clark; and it is described as uncon. overlain, in different areas, by Pinole tuff, Jacalitos fm., and Fernando group. (See also under *Cierbo fm.*)

P. D. Trask, 1922 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 13, No. 5, pp. 133–147). Briones ss. was transferred from Monterey group to San Pablo group by Bruce Clark in 1921. It should probably be classified with San Pablo group (upper Mio.) instead of with Monterey group (lower and middle Mio.).

B. L. Clark and A. O. Woodford, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, No. 2, pp. 65–81), divided *San Pablo group* into *Nerola fm.* above and *Cierbo fm.* below, but did not define the fms.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770). *San Pablo group* (upper Mio.) is several thousand ft. thick in San Francisco Bay region. Includes (descending) Neroly fm. (*Astrodapsis tumidus* zone), Cierbo fm. (*Scutella gabbi* zone), and *Briones fm.* (locally known as *Astrodapsis brewerianus* zone). The Briones was formerly included in Monterey group, but Parker Trask (1922) showed that stratigraphically and faunally it is more closely related to overlying San Pablo group. [This is present approved definition of U. S. Geol. Survey.]

Named for occurrence on San Pablo Bay, Contra Costa Co., near town of Rodeo.

San Pablo series.

See under *San Pablo group.*

San Pedran epoch.

Pleistocene: Southern California.

O. H. Hershey, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pp. 1–29). *San Pedran epoch (deposition)*.—Arnold's Upper San Pedro series seems to include the deposits of the three lower [of the 10] terraces of San Pedro Hill, and perhaps it might be convenient to extend the name, in the form of *San Pedran*, to the epoch as well. May be approx. = Iowan. [He applied *Los Angelan epoch* to the erosion epoch preceding the upper San Pedro and correlated Arnold's lower San Pedro with what he called the *Red Bluff epoch (deposition)*. See under *Sierran*.]

San Pedro sand.

Pleistocene (lower): Southern California (San Diego, Los Angeles, and Ventura Counties).

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, 1898—first published in 1897 as House Doc. 5, 55th Cong., 2d sess.—p. 335). *San Pedro beds*.—Extensive beds of unconsolidated Pleist. sand replete with molluscan shells in very perfect condition, best exhibited at Harbor Hill, at head of San Pedro Harbor, Los Angeles Co. Assigned to Pleist. Same horizon is recognizable above the Plio. of Pacific Beach, San Diego; at various points on Coronado Beach peninsula opposite San Diego, especially at a cove called Spanish Bight; and also at Santa Barbara and elsewhere. Uncon. overlies Merced group.

W. S. W. Kew, 1923 (A. A. P. G. Bull., vol. 7, p. 420). *San Pedro fm. (Pleist.)*.—This series of beds, which is typically developed in vicinity of San Pedro, has been described in detail by Ralph Arnold (Calif. Acad. Sci. Mem., vol. 3, 1903), who has divided it into two members, separated by an uncon. The San Pedro occurs at many places in Los Angeles Basin, resting uncon. on Saugus fm. or upon beds of San Diego age.

A. J. Tieje, 1926 (A. A. P. G. Bull., vol. 10, pp. 502–512), applied *Palos Verdes sands* to upper memb. of typical San Pedro, and restricted *San Pedro* to lower memb. of Arnold's San Pedro. He stated these changes were made upon suggestion of W. S. W. Kew. *This is present approved definition of U. S. Geol. Survey.*

J. E. Eaton, 1928 (A. A. P. G. Bull., vol. 12, No. 2, pp. 123–125), restricted *San Pedro fm.* to lower part of San Pedro and named the uncon. upper part in Ventura Basin, *Hall Canyon fm.*, which he stated is older than Palos Verdes fm. (See 1928 entry under *Hall Canyon fm.*).

U. S. Grant, IV, and H. R. Gale, 1931 (San Diego Soc. Nat. Hist. Mem., vol. 1, p. 37). In the Pleist. *San Pedro fm.* (or *group*) there can be recognized the lower or Las Posas zone, the middle Deadman Island "Plio.," or Timms Point zone, as it might be called, and the upper or typical San Pedro zone.

W. P. Woodring, 1932 (16th Int. Geol. Cong. Guidebook 15, pl. 2), showed typical *San Pedro sand* (restricted) of San Pedro Hills as younger than Saugus fm. and uncon. overlain by older terrace deposits, which in turn underlie Palos Verdes sand.

T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 490–492). *San Pedro fm.* consists of 3,000 to 3,500 ft. of poorly consolidated light-gray to buff fine to coarse sands and gravels, buff-weathering sandy silts, and greenish-gray, drab-gray, and, locally, grayish-maroon clays and silty clays; over 75 percent of it is sands and pebble to cobble gravels. It has been called *Saugus* by Kew, Cartright, Waterfall, and Driver, and most of it has been called *Las Posas* by Pressler, Grant, and Gale. Eaton (1928) [rept cited above] has arbitrarily divided it into 3 so-called fms.—Hall Canyon, San Pedro, and Saugus—which cannot be consistently separated or recognized for any distance, either paleontologically or lithologically. Because of large number of confusing local names for the southern Calif. Pleist., writer prefers to use Arnold's original name *San Pedro*, even though type San Pedro probably comprises only a meager remnant of the Ventura San Pedro. Overlies Santa Barbara fm.

U. S. Grant, IV, 1935 (Pan.-Am. Geol., vol. 64, No. 1, pp. 73–74), gave following as succession of marine Pleist. fms. at San Pedro: Palos Verdes fm., San Pedro fm., Timm Point fm., and Lomita fm., and listed fossils from each fm.

†San Pedro shales.

Eocene(?): Western California (San Francisco region).

R. Crandall, 1907 (Am. Phil. Soc. Proc., vol. 46, pp. 3–58). *San Pedro shales*.—Thin-bedded black coarse-grained hard shales, 4,000 ft. thick, exposed in cliffs N. and S. of San Pedro Point. Included in Franciscan series. Rest on coarse basal cgl. of the Franciscan and are overlain by crystalline ls. of Calera Valley [Calera ls. memb.], which is also included in the Franciscan.

The name is preoccupied in southern Calif. The rocks of the San Pedro Point SW. of San Francisco and in San Mateo Co., and of adjacent areas are mapped by A. C. Lawson (U. S. G. S. San Francisco folio, No. 193, 1914) as *Martinez (?) fm.*

San Pedro andesite.

Age (?): Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 323).

San Pedro schist breccia and sandstone.

Miocene or Pliocene: Southern California (San Pedro and San Pedro Hill).

A. O. Woodford, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 7, pp. 210–211). *San Pedro schist breccia and ss.*—Point Fermin at San Pedro is composed of blue schist ss., with a little breccia of various sorts, interfingering with more or less purely diatomaceous sh. One may trace in the sea cliffs the gradual change from a section that is chiefly blue ss. to one exclusively made up of thin beds of white sh. At very tip of Point Fermin there are 100 ft. of tar-saturated blue schist ss. intercalated in the sh. series. In this ss. are included several 1- to 3-foot beds of breccia and, near top and bottom, thin beds of sh. The San Pedro-Point Fermin Oil & Gas Co. well at Point Fermin passed through the following materials (oral communication from officers of the company, supplemented by inspection of samples):

0–600 ft. below sea level. Chiefly fine ss. and sh.
600 ft.–1,200 ft. Blue ss., schist breccia, some sh.
1,200 ft.–1,800 ft.? Soft sh., with blue schist flakes.
1,800 ft.?–2,500 ft. Bedrock, chiefly blue-green quartzose schist.

In San Pedro Hill, 5 mi. NW. of Point Fermin, the schists in place are separated from overlying sh. by a few ft. of fine schist breccia, which along eastern edge of the schists becomes much thicker and probably grades out into sh. as at the Point. The overlying sh. contains blue ss. beds and pockets, as well as numerous pumice fragments. The fossil evidence is inadequate for certain correlation of the San Pedro occurrences. Fossils [listed] suggest Lower Mio. age for at least part of the section. However, W. S. W. Kew, of U. S. Geol. Survey, who has studied San Pedro region in detail, considers the beds below the Point Fermin breccia to be Upper Mio. and those above Plio., on basis of resemblance of the shales to those of the Upper Mio. and Plio., respectively, of Santa Monica Mtns. Below the breccia chert predominates, and Kew has never been able to find diatoms; above, soft diatomaceous sh. predominates. [Described under center heading "Doubtful correlatives of the San Onofre facies."]

San Rafael formation.

Oligocene: Mexico.

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, pp. 144, 147). Assigned to Tert.

W. A. Ver Wiebe (Am. Jour. Sci., 5th, vol. 8, p. 492, 1924), T. W. Vaughan (Geol. Soc. Am. Bull., vol. 35, 1924, p. 732), and R. H. Palmer (A. A. P. G. Bull., vol. 11, p. 1196, 1927) assigned this fm. to Olig.

San Rafael group.

Upper Jurassic: Southern and eastern Utah and western Colorado.

Name adopted at joint conference of J. Gilluly, J. B. Reeside, Jr., H. E. Gregory, and R. C. Moore, from area specially studied by Gilluly and Reeside. Name first appeared in print in A. A. P. G. Bull., vol. 11, p. 787, 1927, in paper by Reeside, C. E. Dobbin, A. A. Baker, and E. T. McKnight. Name was proposed for the marine Upper Jurassic succession of rocks in SE. Utah. Includes (descending) Summerville, Curtis, Entrada, and Carmel fms., which are fully described by Gilluly and Reeside in U. S. G. S. P. P. 150, pp. 73–80, 1928. Uncon. underlies Morrison fm. and overlies, probably uncon., Navajo ss. Named for splendid exposures of the fms. in San Rafael Swell of SE. Utah. (See also U. S. G. S. P. P. 183, 1936, p. 6.)

San Ramon sandstone.

Oligocene: Western California (San Francisco Bay region).

B. L. Clark, 1918 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, pp. 54–111). On Sobrante anticline, in Concord quad., the *San Ramon fm.* consists for most part of medium-fine gray sss., which at base are massive, rather coarse, and somewhat calc., but toward top are not so massive; thin beds of micaceous gray, medium-fine ss. alternating with thinner layers of sandy sh. and clay sh., well exposed on side of road just S. of divide btw. Bear and Pinole Creeks, on N. side of the anticline. The fm. is basal div. of San Lorenzo series in this region, where it is overlain by Kirker tuff and rests uncon. on Tejon fm. The San Lorenzo series of San Ramon syncline, Mount Diablo region, is considerably different from that of Sobrante anticline. Only one distinct fm. was recognized in Ramon syncline, and this is called *San Ramon fm.*, the name already applied to basal memb. of the San Lorenzo of Sobrante anticline. It seems very probable San Ramon fm. of this section represents a longer period of deposition than the San Ramon of Sobrante anticline, but whether the time of the deposition of Kirker tuffs and Concord fm. [the two upper fms. of his San Lorenzo series in Sobrante anticline] is represented in this record may be open to doubt. It rests uncon. on Tejon fm.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770). San Ramon horizon (Olig.) is locally known as *Agasoma gravidum* zone. [On a later page Clark assigned it to upper Olig.]

W. P. Woodring, 1931 (Carnegie Inst. Wash. Pub. 418, p. 17). *San Ramon fm.* of B. L. Clark, with its modernized fauna, looks suspiciously like Mio. The modernization of the marine Mio. fauna is clearly brought out by A. M. Davies (Proc. Geol. Assoc., vol. 40 (1929), pp. 307–327, 1930). The Mio. affinities of San Ramon fauna have been discussed by R. B. Stewart in rept (Acad. Nat. Sci. Phila. Spec. Pub. No. 3, pp. 19–20, 1930) issued after this paper was written.

San Saba series.

Lower Ordovician and Upper Cambrian(?): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxii, 301–306). *San Saba series.*—Dolomites and chert, without evidence of dynamic uncon., divided into Deep Creek div. (above) and Hinton div. (below). Overlies Leon series. Upper beds of Sil. [Ord.] of central mineral dist. of Tex.

Is a part of Ellenburger ls.

Named for San Saba Co. and San Saba River Valley.

San Sebastian shale.

Tertiary: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 10, 17). [Assigned to Tert. in this and other repts. by other geologists, up to 1933, when H. A. Meyerhoff (Geol. of Puerto Rico, p. 65) assigned it to Olig.]

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region). San Sebastian sh. is upper Olig.

San Simon limestone.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 52). *San Simon lss.*, 300 ft. thick, underlie Truxton ls. and compose basal fm. of Mississippian in Nev.

Derivation of name not stated. May be same as Simon terrane of Keyes.

Santa Ana limestone.

Triassic: Southern California (Orange County).

J. P. Smith, 1898 (Jour. Geol., vol. 6, pp. 779–780). *Santa Ana ls.*—Hard black siliceous ls. on W. slope of Santa Ana Range, Orange Co.

Santa Ana.

Triassic: Southern California.

F. J. H. Merrill, 1914 (Geology and mineral resources of San Diego and Imperial Counties, Calif. State Min. Bur., p. 9). [Name is used in table as "local" name for Triassic. Statement on page 10 indicates it is intended to be applied to same metamorphic rocks in Orange Co. (in which are Santa Ana Mtns) as those to which *Julian group* is applied in adjoining San Diego Co.]

Santa Ana sandstone.

Probably upper Pliocene or lower Quaternary (mapped as Pliocene): Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull. vol. 13, No. 9, pp. 344, 378–379, and map). *Santa Ana ss.*—Ss. and sh., for most part of medium-gray color, although brown and reddish streaks are present. Also includes strata of coarse granitic detritus up to 5 and 6 ft. thick, btw. which are finely laminated shales and occasional calc. seams. Cannot be correlated with much certainty with any other fm. in dist. May possibly have been formed at same time as Hathaway fm. of S. side of range. Is uncon. overlain by Cabezon fangl. Present position of the evenly bedded ss. and sh. in bottom of a deep canyon can only be explained by faulting.

Named for Santa Ana River, San Bernardino Co., along which it is exposed.

Santa Anna shale member (of Moran formation).

Permian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 419). *Santa Anna bed.*—Bluish and reddish sandy clay, 25 to 75 ft. thick. Memb. of Cisco div., near top. Overlies Horse Creek bed and underlies bed No. 18 (15 to 25 ft. of ls. interstratified with clay).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 177–183 and charts). *Santa Anna sh. memb. of Moran fm.*—Underlies Sedwick ls. memb. of Moran and overlies Horse Creek ls. memb. of Moran in Colorado River Valley. Thickness 25 to 75 ft.

Named for exposures in buttes at Santa Anna, Coleman Co., and at various points to N. of that town.

Moran fm. was transferred to Wichita group (Perm.) in 1933.

Santa Anna Branch shale member (of Putnam formation).

Permian: Central and central northern Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 420). *Santa Anna Branch bed.*—Bluish clay, gray shaly sandy clay, a little coal in places, and some thin ls. and ss. strata. Thickness 100 to 150 ft. Top memb. of Cisco div.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 184–188). Putnam fm. (top fm. of Cisco group), as here defined, consists of Coleman Junction ls. memb. above and Santa Anna Branch sh. memb. below. The Santa Anna clay bed as described by Drake at his type loc. along Santa Anna Branch [Coleman Co.] corresponds almost exactly to the section of Putnam fm. below Coleman Junction ls. as measured by Applin S. of Santa Anna. Therefore, although it is possible that in some of Drake's other sections he has included in bottom of his Santa Anna Branch beds yellow lss. that are = lentils in top of Moran fm., the Santa Anna Branch beds are regarded as essentially = the strata btw. Coleman Junction ls. and the yellow ls. strata at top of Moran fm., and the name has been retained. [Sections given show thickness of Santa Anna Branch memb. as 119 to 174 ft.]

Putnam fm. was transferred to Wichita group (Perm.) in 1933.

Santa Barbara beds (also marls).

Pliocene (upper): Southern California (Santa Barbara County).

J. P. Smith, 1912 (Calif. Acad. Sci. Proc., 4th ser., vol. 3, pp. 161–182). The upper Plio. is recorded under name *Santa Barbara*, because it is by no means certain that the name *Merced*, which has been used for the upper Plio., is applicable in southern Calif.

J. P. Smith, 1915 (Nature and science on Pacific coast, p. 51, San Francisco, Elder & Co.). [*Santa Barbara beds* is used in chart for uppermost Plio. beds in Coast Ranges, which are shown as younger than San Diego and Merced.]

C. M. Carson, 1925 (Pan-Am. Geol., vol. 43, pp. 265–270). *Santa Barbara marls.*—Composed of evenly bedded soft brownish-yellow sandy bryozoan marls giving place above to fine soft sands. Thickness 1,000 ft. Probably rests uncon. on Mio. shales. Younger than Ventura sands and San Diego clays. The Santa Barbara fm. represents coldest part of Plio. epoch, immediately preceding the very cold early Pleist. It occurs at Santa Barbara and San Pedro.

U. S. Grant, IV, and H. R. Gale, 1931 (San Diego Soc. Nat. Hist. Mem., vol. 1, p. 35). Type loc. of *Santa Barbara fm.* is at Packard's Hill, Santa Barbara.

T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 3, pp. 492–494). Pressler's Kalorama memb. of Las Posas fm. contains typical Santa Barbara fauna and is here included in *Santa Barbara fm.* Upper half of the Santa Barbara is here tentatively placed in Lower Pleist., instead of Upper Plio., on basis of a mastodon tooth found at Santa Barbara and stated by Stock to be too large for Plio. mastodon. From evidence available the Plio.-Pleist. div. line appears to be near middle of Santa Barbara fm. At type loc. on Santa Barbara "mesa," at Rincon Point near Santa Barbara-Ventura Co. line, and at other places near edge of the basin, where it has a shallow-water facies, the Santa Barbara can be divided into 2 faunal zones on basis of its mega-fauna—(1) an upper *Pecten caurinus* zone, and (2) a lower *Pecten bellus* zone.

Santa Catalina gneiss.

Pre-Cambrian: Southern and central Arizona.

W. P. Blake, 1908 (Sci., n. s., vol. 28, pp. 379–380). *Santa Catalina gneiss.*—The extensively developed pre-Camb. gneiss on S. side of Santa Catalina Mtns near Tucson. Remarkable for its tabular form, regular stratification, altitude at low angles, broad, flat surfaces, and, in places, extreme foliation, passing from coarse-grained tabular granitic gneiss into micaceous sericitic and hornblende schists. These gneissic and schistose rocks are members of the series of pre-Camb. schists for which I proposed the name *Arizonian*. They are widely distributed in middle and southern Ariz.

Santa Catalina formation.

Middle Cambrian: Southeastern Arizona (Santa Catalina Mountains).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 476, 477, 480, 482). *Santa Catalina fm.*—Alternating thin-bedded red to black and ocherous qtzites, red to yellow sss., and light-colored, often pinkish and greenish micaceous shales, having, in type loc. (in Peppersauce Canyon, on N. side of Santa Catalina Mtns), thickness of 415 ft. Is a unit characterized by a trilobite that persists through entire thickness of fm. and that does not occur in underlying Troy qtzite nor in the younger Abrigo fm. [here restricted to middle part of Abrigo ls. of previous repts]. Is overlain by Southern Bell qtzite [new]. Is Middle Camb.

Santa Clara formation.

Pliocene and Pleistocene: Western California (Santa Clara County).

J. G. Cooper, 1894 (Calif. Acad. Sci. Proc., 2d ser., vol. 4, p. 171). *The Santa Clara lake beds.*—Fossil fresh-water shells have been found at several points on both sides of this valley, and at different heights above it, but sufficient specimens have not yet been collected to determine the ages, elevations, disturbances, etc., of the various beds. The oldest known is that at San José Mission, where a ridge apparently of Plio. date remains as a remnant of a thick bed of gravel and alluvium once filling greater part of valley to depth of probably 300 ft. above tides. The same deposit is seen at intervals from East Oakland along the foothills southward on E. side of valley, and less abundantly on W. side to near Redwood City, but does not everywhere contain fossils. It is considerably disturbed in some places, usually by elevation of the mtns since its deposit. Fossils from San José Mission listed.

J. C. Branner, J. F. Newsom, and R. Arnold, 1909 (U. S. G. S. Santa Cruz folio, No. 163). *Santa Clara fm.*—Coarse gravel, sand, and sandy clay, locally lignitic, containing a fresh-water fauna. Thickness at least 500 ft. Greater part is contemp. with Paso Robles fm. Rests, probably conformably, on Purisima fm. Overlain by Quat. deposits. Recent alluvium rests uncon. on it in at least one place. Considered contemp. with Merced fm.

Appears to have been named for its considerable development in Santa Clara Co.

Santa Claran epoch.

Pleistocene: California.

O. H. Hershey, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pp. 1–29). *Santa Claran epoch (erosion).*—The epoch of erosion that initiated Sierran period of Le Conte precedes Red Bluff epoch of deposition. There is no portion of State in which this epoch is so clearly defined as on Upper Plio. area of Santa Clara River Valley of the South. Therefore I suggest for it the name *Santa Claran* as being eminently appropriate. (See under *Sierran.*)

Santa Cruz Island formation.

Pleistocene: Southern California (Santa Cruz Island).

R. W. Chaney and H. L. Mason, 1934 (Carnegie Inst. Wash. Pub. 415, pp. 4–6, 48; preprint 1930). Resting on truncated edges of Tert. deposits (of Mio. or Eo. age) exposed in valley of Willow Creek, on Santa Cruz Island, is a nearly horizontal alluvial deposit with max. thickness of 30 to 35 ft., which is here designated *Santa Cruz Island fm.* The fm. consists of clay, yellow to gray sands, and gravel, with numerous seams and pockets of carbonaceous material, and appears to have been largely derived from underlying Tert. Flora is closely related to that of Pleist. deposits of Carpinteria [Santa Barbara Co.], which have been named *Carpinteria fm.*

Santa Fe formation.

Miocene (upper) and Pliocene: Northern New Mexico and central southern Colorado.

F. V. Hayden, 1869 (U. S. Geol. and Geog. Surv. Terr. 3d Ann. Rept., pp. 66, 90). From Santa Fe to banks of Gallisteo Creek, 18 mi., we pass over the recent marls and sands which seem to occupy greater part of valley of Rio Grande above and below Santa Fe, which I have named *Santa Fe marls.* They are mostly of light cream color, sometimes rusty yellow, sometimes yellowish white, with layers of ss. varying in texture from a very fine aggregate of quartz to a moderately coarse puddingstone. These marls and sands weather into unique forms N. of Santa Fe like the "badlands" of Dakota. Are much younger than Gallisteo sand group. In Taos Valley they rest on metamorphic rocks. They are doubtless of Upper Tert. age. Thickness 1,200 to 1,500 ft. N. of Santa Fe, in Rio Grande Valley. [According to C. B. Hunt the thickness of this fm. in wells reaches 5,000 ft.]

Santa Fe schist.

Age (?): Cuba.

C. W. Hayes, T. W. Vaughan, and A. C. Spencer, 1901 (Rept. geol. reconn. Cuba, p. 114).

Santa Fe granite.

Pre-Cambrian (?): Central northern Colorado (Clear Creek, Summit, and Park Counties).

H. B. Patton, 1909 (Colo. Geol. Surv. 1st Rept., pp. 126–128, map). *Santa Fe granite.*—Gray medium-grained biotite-muscovite granite. Forms highest point of Santa Fe Peak. On this peak it occurs in well-defined dikes. This method of occurrence is a striking peculiarity as compared with Montezuma granite. Always in contact with Idaho Springs fm. [pre-Camb.]. Is younger than that fm., and believed to be older than Montezuma granite.

Santa Francisca rhyolite.

Age (?): Mexico.

G. E. Anderson, 1926 (Am. Inst. Min. and Met. Engrs. Trans. [preprint], No. 1551, p. 5).

Santa Isabel series.

Recent: Puerto Rico.

E. T. Hodge, 1920 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, pt. 2, p. 166).

Santa Lucia granite.

Santa Lucia quartz diorite.

Pre-Cretaceous: Southern California.

A. C. Lawson, 1893 (Calif. Univ. Pub. Dept. Geol. Bull., vol. 1, pp. 1–89). *Santa Lucia granite*, pre-Cret., forms main ridge of Santa Lucia Range.

P. D. Trask, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 6). *Santa Lucia quartz diorite.*—The term *Santa Lucia* was first applied by Lawson (1893) to the porphyritic granite in vicinity of Carmel Bay, but the porphyritic variety that he describes is only of local extent in Point Sur quad. As it apparently grades into the main quartz diorite mass of the region, and hence is probably a differentiate of the quartz diorite, the name *Santa Lucia* is retained for the entire plutonic mass. Intrudes Sur series.

F. A. Nickell, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 313–314). Evidence is that *Santa Lucia quartz diorite* has intruded and is later than *Santa Lucia granite* of Gavilan Range, and presumably both intrusives cut Sur series.

Santa Lucia series.

Pre-Franciscan (possibly pre-Cambrian): Southern California (Monterey, San Benito, and San Luis Obispo Counties).

B. Willis, 1900 (Sci., n. s., vol. 11, p. 221). *Santa Lucia series* is pre-Franciscan. Separated from Franciscan by erosion interval. [All there is about it.]

J. P. Smith, 1916 (Calif. State Min. Bur. Bull. 72, pp. 9, 25–26). *Santa Lucia fm.*—Schists, gneisses, and crystalline ls. of Santa Lucia Range in Monterey and San Luis Obispo Counties, and Fremont's Peak of Gavilan Range in San Benito Co., have been named by Bailey Willis [above citation] the *Santa Lucia series*. The rocks have never been fully described, but a partial description is given by H. W. Fairbanks (Calif. State Min. Bur. Rept. 12, pp. 493–526) without naming the series. No definite fossils known, but round crinoid stems are said to have been found in the Gavilan lss. of Fremont's Peak. They are certainly pre-granitic, and the granite of Santa Lucia Range is older than Franciscan. The rocks are thoroughly metamorphosed and look as old as the pre-Camb. rocks of southern Calif. Thickness and structural relations unknown, but Franciscan rocks lie uncon. upon them in the few places where contacts have been observed.

Same as Coast complex of Willis and Sur series of Trask.

Santa Margarita sandstone.

Miocene (upper): Southern California (Santa Cruz Mountains and southward).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *Santa Margarita fm.*—Alternating beds of cgl. and soft ss., with several strata of diatomaceous earth and pumice. Thickness about 1,500 ft. Occurs in N. part of area, and considered to be contemp. with Pismo fm. of S. part of area, though the two fms. are not known to have been connected. Uncon. underlies Paso Robles fm. and uncon. overlies Monterey sh.

Named for exposures at Santa Margarita, San Luis Obispo Co.

†Santa Maria formation.

Pliocene and Pleistocene: Southern California (Santa Barbara County).

C. M. Carson, 1925 (Pan-Am. Geol., vol. 43, pp. 265–270). In Santa Maria dist. the Fernando fm. is sometimes called *Santa Maria fm.* It consists of a succession of shaly cgls., fine white and yellow sss., coarse gray sands, and thick beds of incoherent cgls. having aggregate thickness of not less than 3,000 ft., according to Arnold and Anderson.

San Tamaulipas formation.

Lower Cretaceous (Comanche series): Northeastern Mexico.

E. T. Dumble and E. R. Applin, 1924 (Pan-Am. Geol., vol. 41, p. 336). *San Tamaulipas fm.*—A very highly bituminous and calc. sh., which very closely resembles basal portion of Eagle Ford fm. of central Tex. and which occupies strat. interval btw. 4,554 and 4,666 ft. in well log of Idolo or Idol Island, Mexico, btw. Tampico and Tuxpam. Underlies San Juan fm. and overlies Tamasopa fm. [On p. 343 is called *Tamaulipas fm.*, as explained under *Tamasopo series*.]

Santa Monica slate.

Triassic (?): Southern California (Santa Monica Mountains).

H. W. Hoots, 1931 (U. S. G. S. P. P. 165C). *Santa Monica sl.*—Dark-gray and bluish gray to black sl. and phyllite, much of which has undergone contact and regional metamorphism and is locally altered to mica schist. Thickness 5,000 to 7,000± ft. Is of pre-Chico age. Assigned to Triassic (?); may be Jurassic or Paleozoic. Is intruded by Jurassic (?) granite and granodiorite. Named for occurrence in Santa Monica Mtns.

Santa Paula formation.

Lower Pliocene and Miocene (?): Southern California (Ventura Basin).

J. E. Eaton, 1926 (Oil and Gas Jour., Nov. 11, 1926, p. 72, also Oil Age, Nov. 1926, p. 16). *Santa Paula fm.*—Previously unrecognized. Well-bedded sss., blue sandy and brown sticky shales and cgls., locally present in Los Angeles Basin. 10,000 ft. exposed NW. of Santa Paula; absent S. of Ventura Basin (on upthrown side of Santa Clara River fault) from South Mtn to and including type loc. of Pico fm. Best exposed on great monocline NW. of Santa Paula. The exposed Santa Paula sediments in Ventura Basin are Lower Plio., but base is not there exposed and is elsewhere indicated to be of Santa Margarita (Upper Mio.) age. Basal fm. of Fernando group. Underlies Pico fm. and uncon. overlies Modelo fm.

J. E. Eaton, 1929 (A. A. P. G. Bull., vol. 13, No. 7, p. 755). *Santa Paula fm.*—Consists of (1) heavy-bedded gray to blue arkosic ss., with lesser members of thin- and medium-bedded ss. and brown and blue clay; locally conglomeratic; 7,500 ft.; (2) calc. ss. and brown and blue sandy clay, locally conglomeratic; 1,750 ft. Of Middle and Lower Plio. age. Underlies Pico fm. and overlies Santa Margarita fm.

W. P. Woodring, 1932 (16th Int. Geol. Cong. Guidebook 15, correlation chart). Santa Paula fm. of Eaton as originally defined included deposits of late Repetto (lower Plio.) and early Pico age. [The Pico is middle and upper Plio.]

Santa Rita limestone.

Silurian: Southwestern New Mexico (Sierra County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. No. 19, pp. 7–21). *Santa Rita ls.*—Dark-drab compact lss., 0 to 10 ft. thick, containing Sil. fossils. Type loc. Santa Rita, Grant Co. Underlies, uncon., Silver sh. (Dev.) and overlies El Pasan series (Ord.).

Santa Rita limestone.

Middle (?) Devonian: Southeastern Arizona (Santa Rita Mountains region).

C. R. Stauffer, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 133). Lower third of Dev. in Santa Rita Mtns, Ariz., contains fauna very different from that of Martin ls. and at once marked as much older. This fauna somewhat resembles that found by Kindle in Jefferson ls. of Mont., although it has a greater variety of Mollusca and fewer Brachiopoda. The fm. carrying this older fauna in Ariz. may be called *Santa Rita ls.* Its age is probably Middle Dev.

C. R. Stauffer, 1928 (Geol. Soc. Am. Bull., vol. 39, No. 2, pp. 430–433). *Santa Rita ls.*—Fairly massive dark-bluish to black ls. and calc. sh. Has not been recognized outside of Santa Rita Mtns. Is cut by many veins of white calcite and metamorphosed, with consequent destruction of fossils, but fossils obtained indicate Dev., at least as early as Middle Dev., and hence much older than Upper Dev. Martin ls. [The Martin ls. has long been classified as Upper and Middle Dev.]

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, p. 495). Writer considers it unwise to include Santa Rita ls. in Paleozoic strat. column of Ariz., until description of Middle Dev. fossils cited from Santa Rita Mtns has been given by Stauffer.

Santa Ritan series.

A term employed by C. R. Keyes to cover Santa Rita ls.

Santa Rosa beds.

A term applied by E. T. Dumble (Am. Inst. Min. Engrs. Trans., vol. 29, pp. 122–152, 1900) to sandy cgls. and red slates in Sonora, Mexico, assigned by him to Carbf. or Dev.

Santa Rosa sandstone. (In Dockum group.)

Triassic (Upper ?): Northeastern New Mexico (Guadalupe County).

D. Hager and A. E. Robitaille, 1919 (Geol. rept. on oil possibilities in eastern N. Mex., correlation table). *Santa Rosa ss.* in Las Vegas area and to E. is 500 to 600 ft. thick. Lies below 800 ft. of Triassic red and white beds, and lies above San Andres ls.

J. L. Rich, 1921 (Am. Jour. Sci., 5th, vol. 2, pp. 295–298). *Santa Rosa ss.*—Coarse gray ss., conglomeratic at base. Thickness 50 to 100 ft. Is a very definite unit exposed at Santa Rosa and Puerto de Luna and along canyon of Pecos for many mi. both above and below those places. From Santa Rosa it can be traced up valley of Pecos as a continuous unbroken escarpment to Estaritos Dome, E. of Anton Chico, where it forms the rim rock surrounding the dome. In center of dome, 200± ft. below base of Santa Rosa ss., the San Andreas ls., 10 to 25 ft. thick, is exposed. Beneath the San Andreas on the dome is the Permian Glorieta ss. The Santa Rosa ss. is Upper Triassic.

N. H. Darton, 1922 (U. S. G. S. Bull. 726E, p. 183, Mar. 31, 1922). [The name *Santa Rosa ss.* was adopted by U. S. Geol. Survey, for Mr. Darton's rept, in July 1919, but the rept was not published until Mar. 1922.] East of Glorieta Mesa and Hills of Pedernal the strata overlying Chupadera fm. consist of 800 ft. or more of red shales and sss. representing Dockum group, including near bottom a resistant massive ss. which is prominent in mesas of Guadalupe Co. and along Pecos River at Santa Rosa. This ss. appears to occur at about horizon of Shinarump cgl., but no definite correlation is possible, and I here propose for it, tentatively at least, the name *Santa Rita ss.* Case has found in it and above it Triassic bones. It rests on sh. that may be either Triassic or Perm.

Santa Rosa littoral marine formation.

Permian (middle and lower): Mexico and Guatemala.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 330).

Santa Rosa conglomerate.

Permian (lower): Guatemala.

C. Schuchert, 1935 (p. 341 of book cited above). Basal bed of Santa Rosa fm.

Santa Rosa beds.

Miocene (middle): Isthmus of Tehuantepec.

C. Schuchert, 1935 (p. 376 of book cited above).

Santa Susana formation.

Eocene (middle): Southern California (Ventura County).

B. L. Clark, 1924 (Pan-Pacific Sci. Cong. Proc., Australia, 1923, pp. 874-879). *Santa Susana fm.*—A fm. only recently recognized and as yet differentiated only in region of Simi Valley, Ventura Co. Richard Nelson, who has completed a mon. on Martinez of Simi Valley, proposes to call it *Santa Susana fm.* The beds referable to it had previously been mapped as part of the Martinez. Consists very largely of sh. and shaly sss. with heavy cgls. at base. Thickness 1,000 to 1,500 ft. Fauna entirely different from that of underlying Martinez and has very little in common with that of uncon. overlying Meganos group, although it is more closely related to Meganos fauna than to Martinez fauna.

R. N. Nelson, 1925 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 11, p. 401 and map). *Santa Susana sh.*—Predominately light-gray sh. with some fine-grained ss. and a lens of cgl. at base toward its E. end. Sporadic boulders of qtzite up to 6 in. diam. have been found in both ss. and sh. [Thickness not stated.] Grades into upper sh. of underlying Martinez group and into overlying Domengine fm. Is middle Eo. Occurs E. of main fault S. of Simi Valley. Fauna includes several distinctive genera, such as *Corbis* and *Velates*, which are new to Eo. of Calif. Other forms are closely related to those in the Meganos but distinct from any known in the Martinez. Named for its occurrence in proximity to town of Santa Susana.

†Santee beds.

Eocene (Jackson and Claiborne): Eastern and central South Carolina.

M. Tuomey, 1848 (Geol. of S. C., pp. 156, 190, 211). *Santee beds*, which I consider the lowest of the calc. portion of the Eocene [the lower part of the Eocene being called *Buhrstone fm.*]. Fossils [listed on pp. 160-162]. Consist of thick beds of white ls., marl, and greensand, best seen on the Santee, where, interstratified with the greensand, they dip gently to S. The coralline marl of Eutaw is found near upper edge of these beds. Overlie Buhrstone fm. and underlie Coralline marl, which is in turn overlain by Ashley and Cooper beds [Cooper marl of present nomenclature]. Are basal part of Ruffin's Carolinian bed. [As interpreted by C. W. Cooke (U. S. G. S. Bull. 867, 1936) the Santee beds of Tuomey included Cooper marl, Santee ls., and part of McBean fm.]

W. H. Dall, 1897 (U. S. G. S. 18th Ann. Rept., pt. 2, published in 1897 as House Doc. 5, 55th Cong., 2d sess., p. 342). *Santee beds.*—Upper Eocene of Santee River, S. C. See Tuomey, Geol. S. C., 1848, p. 156. Tuomey included Claibornian as well as Jacksonian marls in his series. The term as adopted here refers to upper green marls from which *Zeuglodon* has been obtained. The series when undisturbed would probably be divisible into several horizons corresponding to the different members of the Upper Eocene. Included in Jacksonian stage. [As interpreted by C. W. Cooke (U. S. G. S. Bull. 867, 1936) Santee beds of Dall is a larger unit than Santee ls. of present nomenclature, and includes Santee ls. and overlying Cooper marl.]

Santee limestone.

Eocene (Jackson): Eastern and central South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 17). *Santee marl*, also *Santee phase*.—The upper limit extends along a line from Shell Bluff by Kennedy's scarp (Tinkers Creek), by Hollomans Bridge (South Edisto Fork), by Jenkins Hill, by Warley Hill (Stout Creek), by Weeks Landing (Santee River), by Creston, by Cave Hill, by Whaley's Mill (Poplar Creek), by Pinckney Landing (Santee River), by Potato Creek, by Vances Ferry, by Wittee Lake (Williamsburg County), and thence toward ocean along ridge E. of Lenuds Ferry. The lower limit of exposures extends from mouth of Lower Three Runs to Utseys Bluff (eastern scarp of Edisto River SW. of St. Georges), whence it passes along Four Hole Ridge and thence to Wambaw Creek, in SE. part of Berkeley Co.; it probably approx. follows the edge of Cooper marls, under which it passes, with the Barnwell sands intervening in a thick series W. of St. Georges anticline, but in a very thin layer, if at all, along southerly contact of St. Georges anticline. The Mount Hope marl should also be found intervening. The materials of Santee phase consist of high-grade marls of a yellow-white color and compact texture.

In 1911 the U. S. Geol. Survey adopted *Santee marl memb. of McBean fm.* for essentially the same fm. as Santee marl of Sloan. In 1929 (Fla. Geol. Surv. 20th Ann. Rept.) C. W. Cooke and S. Mossom removed the Santee from McBean fm., because the Santee fauna was of Jackson age, while the rest of the deposits heretofore included in the McBean are of Claiborne age and probably uncon. with the Santee. They defined *Santee ls.*, as they called it, as consisting of the light-colored ls. exposed along Santee River, and as in some places overlain by Barnwell sand and in other places by Cooper marl.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). Barnwell sand of western S. C. includes at base a ls. that appears to be=Santee ls. of Santee drainage.

Santee River beds.

A term applied by F. S. Holmes (Phosphate rock of S. C., 1870, pl. 1) to the Eocene marl along Santee River, S. C., which he in text called *Santee marl*.

Santiago formation.

Age (?): Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 241).

†Santiago chert.

Devonian(?): Southwestern Texas (Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, p. 41). *Santiago chert*.—A chert fm. of Marathon region is thought by Ulrich to be possibly lower Miss. (Kinderhook) in age. This is named by Baker the Santiago chert. It overlies Caballos novaculite uncon. Is thin-bedded, banded or ribboned, of dull shades of practically every color, but mostly green. Observed thickness 20 to 450 ft. [The 1919 edition of Bulletin 44 discarded Santiago chert and used Caballos novaculite to include it.]

C. L. Baker and W. F. Bowman, 1917 (Univ. Tex. Bull. 1753, p. 93). [See under *Caballos novaculite*.] Named for a locality at E. base of Santiago Range, E. of range's summit, where it was first seen.

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, p. 1078). [See 1931 entry under *Caballos novaculite*.]

San Timoteo beds.

Pliocene (upper): Southern California (San Jacinto quadrangle, Riverside County).

C. Frick, 1921 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 12, pp. 283–288). *San Timoteo beds.*—Great thickness of beds of late Plio. age, coarser than Eden beds, the upper div. of lower Plio. in this region, and containing vertebrate fossils which correlate in general way with the Blanco of Tex. Occur in San Timoteo Canyon area.

R. Eckis, 1934 (Calif. Dept. Pub. Works, Div. Water Res. Bull. 45, p. 51). It seems possible that upper beds of San Timoteo of Frick may well be lower Pleist.

Santo limestone. (In Millsap Lake formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.). *Santo ls.* lies 60± ft. below Goen ls., and higher than Barton Creek ls., all members of Mineral Wells fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 106). *Santo ls.* is memb. of Garner fm., the name *Mineral Wells fm.* being restricted to upper part of original Mineral Wells fm.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 15–24). *Santo ls.*—Blue ls., weathering lemon yellow. Contains a few crinoid fragments. Thickness 1¾ ft. Lies 75+ ft. above base of Grindstone Creek memb. of Millsap Lake fm., and 50 ft. below Goen ls. bed in Grindstone Creek memb. Is typically exposed along the creek 0.4 mi. by road S. of railroad crossing in Santo, Palo Pinto Co. [This bull. describes Santo ls. as a single bed. The columnar section on the map (of Palo Pinto Co.) accompanying this bull. shows 2 lss. near together in this part of Millsap Lake fm., but the name *Santo ls.* is placed opp. the upper of these lss.]

Santo Domingo rhyolite.

Age (?): Mexico.

R. T. Hill, 1904 (Greene Consolidated Gold Co. [Prospectus], p. 16).

Santo Domingo flood plain deposits.

Quaternary: Mexico (Santo Domingo River, Sonora).

R. T. Hill, 1904 (Greene Consolidated Gold Co. [Prospectus], pp. 11, 12).

Santos shale.

Miocene (lower): Central California (San Joaquin Valley).

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169), divided Temblor fm. in McKittrick-Midway-San Emigdio region into (descending) Gould sh., Button bed ss., Media sh., Carneros ss., *Santos sh.*, and *Phacoides* reef.

L. M. Clark and A. Clark, 1935 (A. A. P. G. Bull., vol. 19, No. 1, p. 137). Vaqueros fossils have recently been found at several localities in Agua ss. (a memb. in upper part of Santos sh.), which prove Vaqueros age of at least lower two-thirds of Santos sh. and necessitate its removal from the Temblor [middle Mio.].

San Vicente formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 334).

Sapello quartzite.

Pre-Cambrian: Central northern New Mexico (Las Vegas region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 11). *Sapello qtzites.*—Main body of Archeozoic qtzites below the thick ls. section in Solitario Peak region, NW. of Las Vegas. Thickness 300 ft. [Derivation of name not given.]

†Sapulpa group.

Pennsylvanian: Central northern and central Oklahoma.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, pp. 6, 11). *Sapulpa group.*—Includes all beds btw. base of Lenapah ls. below and base of Pawhuska fm. of J. P. Smith above.

Named for Sapulpa, Creek Co.

Sapulpa sand.

A subsurface sand, 10 to 40 ft. thick, of early Penn. (Cherokee) age in central Okla., said to be same as Mounds sand, to correlate with Dutcher sand, and to lie lower than Taneha sand in Sapulpa dist. In that dist. the sand below Taneha sand is called *Dutcher* in Okla. Geol. Surv. Bull. 40Q, 1928, p. 141.

Saracachi formation.

Age (?): Mexico.

R. T. Hill, 1904 (Greene Consolidated Gold Co. [Prospectus], p. 16).

Saragossa quartzite.

Probably Carboniferous: Southern California (San Bernardino Mountains).

F. E. Vaughan, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 9, pp. 344, 352–363, and map). *Saragossa qtzite.*—At least 3,500 ft. of rocks (upper limit unknown) consisting of (descending):

1. Very heavy-bedded saccharoidal qtzites containing occasional strata of schist.
2. Series of soft biotite and muscovite schists.
3. Saccharoidal qtzite, cross-bedded.
4. Schists, 200 ft. thick, rather thin-bedded and varying from fine biotite schist to coarse gritty quartz-biotite schist; toward top free from dark constituents.
5. Quartzite-pebble cgl. Several ft.
6. White and pink qtzite, so recrystallized as to have lost all semblance of original clastic structure, 120 ft.
7. Soft decomposed biotite schist, 50 ft.

Is intruded by granites. Grades downward into Furnace ls. Is probably Sil. or Dev. Named for Saragossa Spring, San Bernardino Co., around which it is well developed.

A. O. Woodford and T. F. Harriss (1928) collected Miss. fossils from upper part of underlying Furnace ls., so that Saragossa qtzite is probably Carbf.

Saranac formation.

Pre-Cambrian: Northeastern New York (Clinton and Franklin Counties).

See under †*Dannemora fm.*

Saratoga sand.

Pleistocene: Eastern New York.

A. Fitch, 1850 (Historical, topographical, and agricultural survey of county of Washington, [N. Y.], pt. 3, p. 878). The *Saratoga sand fm.*, for which no name more definite and appropriate can probably be given, and which will be readily understood without explanation, reaches into Washington Co. in SW. part of Kingsbury, and occupies all that part of this town and of Fort Edward which is S. and W. of Fort Edward Creek, being a tract of nearly 5,000 acres. It also extends a half mile S. of mouth of Fort Edward Creek, forming the flats along the river here, and occurs in Saratoga and the counties S. of it. Overlies Albany clay. Is composed chiefly of grains of white and of hyaline quartz, more or less rounded and worn, scattered with minute fragments of hornblende and other minerals. Along the Hudson and Wood Creek occur tracts of sand similar to and which seem to be cotemporary with the Saratoga sands, though some of them may be more recent deposits.

Saratoga chalk.

Upper Cretaceous: Southwestern Arkansas.

J. C. Branner, 1898 (Am. Inst. Min. Engrs. Trans., vol. 27, pp. 52–59). *Saratoga chalk.*—Light-gray chalk, outcropping E. of Saratoga, W. of Columbus, N. of Washington, and thence E. to near Arkadelphia. Overlies upper White Cliffs [Annona] chalk, and underlies calc. ss. or marl [Nacatoch sand]. Thickness 20 to 40 [60] ft.

According to 1925 and 1926 work of L. W. Stephenson and C. H. Dane, the Saratoga chalk is a distinct fm., uncon. underlying Nacatoch sand

and uncon. overlying Marlbrook marl (restricted). In some previous repts it has been treated as a memb. of Marlbrook marl. It is younger than Annona chalk. (See C. H. Dane, U. S. G. S. Press Bull. 8823, Sept. 10, 1926; L. W. Stephenson, A. A. P. G. Bull., vol. 11, No. 1, Jan. 1927; and C. H. Dane, Ark. Geol. Surv. Bull. 1, 1929.)

Named for typical outcrops just N., also E., of Saratoga, Hempstead Co.

†Saratoga formation.

†Saratoga series.

†Saratogan group.

Terms that have been applied by some geologists to rocks in Saratoga region, N. Y., that are divided into Little Falls dol., Hoyt ls., Theresa fm., and Potsdam ss. See also †*Sarceen series.*

†Saratogan epoch (or series).

Discarded name for Upper Cambrian or St. Croixan series. See U. S. G. S. Bull. 769, pp. 96–97. Originally spelled "Saratogian."

Sarbach formation.

Lower Ordovician: Alberta.

C. D. Walcott, 1920 (Smithsonian Misc. Coll., vol. 72, No. 1, p. 15). *Sarbach fm.*, Ord., Alberta. [Walcott fully defined this fm. in Smithsonian Misc. Coll., vol. 67, No. 8, p. 459, Mar. 5, 1923. Uncon. overlies Mons fm. Thickness 1,120 ft.]

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 302–307), assigned this fm. to upper Beekmantown and Mons fm. to lower Beekmantown.

†Sarceen series.

C. D. Walcott, 1923 (Smithsonian Misc. Coll., vol. 67, No. 8, pp. 466–476). *Sarceen series* (*Lower Ozarkian*).—To replace Saratogan as used by E. O. Ulrich in Geol. Soc. Am. Bull., vol. 22, 1911 [which included Little Falls, Hoyt, Theresa, and Potsdam fms.]. Named for Sarcee Indian tribe, which ranged in western Alberta N. of Blackfeet (Siksika) tribe and hunted up the river valleys to Continental Divide. Type fm. is Mons fm. Fauna of lower Mons is "predominantly Upper Camb.," but "trilobites midway of the Mons fm. strongly foreshadow the change to Ord. fauna."

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 301), assigned *Mons fm.* to Lower Ord. (Beekmantown).

J. A. Allan and R. L. Rutherford, 1934 (Alberta Research Council Rept. No. 30, p. 31). *Sarceen series* is Ord.

Sarten sandstone.

Lower Cretaceous (Comanche): Southwestern New Mexico (Deming region).

N. H. Darton, 1916 (U. S. G. S. Bull. 618, pp. 19, 43). *Sarten ss.*—Almost entirely light-gray massive ss., most of it qtzitic or very hard. Some beds are slabby, and a few contain a little calcium carbonate. At base more or less cgl., part of it containing angular and subangular fragments. Thickness in Sarten Ridge (type loc.), Goat Ridge, and ridges E. of Cooks post office, Deming quad., 300 ft., but in many areas top has been removed by erosion or covered by later deposits. Comanche (Washita) fossils from limy beds not far below middle. Overlain by Colorado sh. Rests uncon. on Lobo fm. (Triassic ?).

Sasakwa limestone member (of Holdenville shale).

Pennsylvanian: Central southern Oklahoma (Pontotoc and Seminole Counties).

G. D. Morgan, 1923 (Okla. Geol. Surv. Circ. 12, pp. 9, 10) and 1924 (Bureau Geol. [Okla.] Bull. 2, pp. 103–105). *Sasakwa ls. memb.*—Fossiliferous ls. occurring about 35 ft. below top of Holdenville fm. in Stonewall quad., Okla. Its outcrop passes through town of Sasakwa. Thickness 1 to 15 ft. Lies 17 to 70 ft. above top of Homer ls. memb. of Holdenville fm.

Named for exposures in Sasakwa, Seminole Co. Also especially well exposed in railroad cut and quarry about ¼ mi. S. of Sasakwa.

†Saskatchewan gravels.

Pleistocene: Saskatchewan and Alberta.

R. G. McConnell, 1886 (Canada Geol. Surv., n. s., vol. 1, pp. 70C–71C).

†Sassafras River greensand.

Upper Cretaceous: Northeastern Maryland.

W J McGee, 1888 (U. S. G. S. 7th Ann. Rept., p. 612). *Sassafras River greensand.*—A nearly homogeneous massive bed of richly glauconitic sand, with glauconite diminishing somewhat near base. More or less ferruginous, but destitute of distinctive bedding. Thickness probably more than 100 ft. No fossils found, but it is doubtless Cret. Rests with erosion uncon. on Potomac fm. and is uncon. overlain by Columbia fm. Was noted only along Sassafras River for short distance above its mouth to Back Creek Neck and on Mauldens Mtn and a few neighboring eminences.

According to L. W. Stephenson (personal communication) the beds at locality described on Sassafras River include Magothy, Matawan, and Monmouth fms., all of Upper Cret. age. See U. S. G. S. Tolchester folio, No. 204, and Dover folio, No. 137. Is same as Severn fm. of Darton.

Satan tongue (of Mancos shale).

Upper Cretaceous: Northwestern New Mexico (Gallup region).

J. D. Sears, 1934 (U. S. G. S. Bull. 860A). The upper tongue of Mancos sh. (marine) that grades laterally into Hosta ss. memb. of Mesaverde fm. in part of area from Gallup eastward toward Mount Taylor is here named *Satan tongue of Mancos sh.*, because its beginning and growth are well shown in Satan Pass. Is of Colorado age.

Satanka shale.

Permian: Southeastern Wyoming and northeastern Colorado.

N. H. Darton, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 430, etc.). *Satanka sh.*—Red sh. with 10-ft. bed of gyp. a short distance below top and a 15-ft. bed of gyp. 25 ft. lower in fm. Thickness 200 to 232 ft. Underlies Forelle ls. and overlies Casper fm. Named for R. R. station a few mi. S. of Laramie, Wyo. [Albany Co.].

See under *Chugwater fm.*

†Satilla formation. (Of Columbia group.)

Pleistocene: Georgia Coastal Plain.

J. O. Veatch and L. W. Stephenson, 1911 (Ga. Geol. Surv. Bull. 26, pp. 60, 424, 434–445). *Satilla fm.*—Latest Pleist. deposits in Ga., consisting of coastal-terrace deposits and fluviatile or river-terrace deposits. The *coastal deposits* lie upon a wave-cut terrace which extends 20 to 30 mi. back from present ocean at elevations of 15 to 40 ft. above sea level. The western limit of this terrace or plain is marked by the high sand ridge E. of Folkston, Charlton Co., and by the escarpment at Waynesville and Mount Pleasant, Wayne Co., and at Walthoursville, Liberty Co. Is first marine terrace. The deposits on Satilla plain rest uncon. on Plio. or Mio. strata. They consist of greenish and bluish marine clays; gray, white, and yellow sands; and thin layers of gravel; all unconsolidated. Thickness 15 to 50 ft. The relative age of fm. with respect to the older Okefenokee fm. is determined by its topographic position and not by strat. sequence or paleontologic evidence. The Satilla fm. is fossiliferous; the topographically higher Okefenokee fm. is not fossiliferous. The *fluviatile deposits* form low terraces along larger rivers of Coastal Plain, and consist of unconsolidated sands, clays, and gravels which merge coastward into marine or fluviomarine deposits. The river terraces are comparatively flat plains from 10 or 15 to 40 or 50 ft. above the rivers, and vary in width from 300 or 400 yards to an original width of 8 or 10 mi. Thickness 10 to 40 ft. Included in Columbia group.

Named for development along both sides of Satilla River, in Camden and Charlton Counties.

The Pleist. terrace deposits of Atlantic Coastal Plain from Del. to Fla. are now divided into the 7 fms. enumerated under *Columbia group*, and Satilla and Okefenokee fms. have been abandoned.

Satsop formation.

Pleistocene: Western Washington.

J. H. Bretz, 1914 (Geol. Soc. Am. Cordilleran sect., abstract of meeting in May 1914) and 1915 (Geol. Soc. Am. Bull., vol. 26, p. 131). *Satsop fm.*—Grand deposit widely distributed along Wash. coast and in Chehalis Valley, but not found in Puget Sound region.

J. H. Bretz, 1917 (Geol. Soc. Am. Bull., vol. 28, No. 1, p. 170). *Satsop fm.* is a widespread fluviatile deposit in river valleys of SW. Wash., in Columbia River Valley for at least 200 mi. above mouth, and in lower Willamette Valley of NW. Oreg., and is a coastal deposit exposed at intervals along almost entire Pacific coast of Wash. and Oreg. Extends inland as far as Yakima Valley, on E. flank of Cascade Mtns of Wash. From strat. relations and fossils the coastal phase is known to be Quat.

J. H. Bretz, 1917 (Jour. Geol., vol. 25, pp. 446–458). *Satsop fm.* is here extended to cover that Quat. fm. of Pacific coast whose minimum limits reach from Strait Juan de Fuca N. of Wash. to Coquille Valley, within 80 mi. of Oreg.-Calif. line. Type section is Satsop Valley, a tributary of Chehalis Valley. Thickness 300 ft. in Chehalis Valley, 200 ft. S. of Grays Harbor, 75 ft. in Willapa Bay region, 150 ft. at least in Cowlitz Valley, 500 at least along Sandy River, 500 at Angels Rest, 700 in Benson Plateau, Cascade Range. At The Dalles what is regarded as a local phase of Satsop fm. is 1,000 ft. thick. The Satsop rests uncon. on Tert. and older rocks. It was mapped by Ralph Arnold as Pleist. gravel, sand, and clay. In Columbia Valley it rests on eroded Columbia River lava.

Satsop fm. continued to be assigned to Pleist. until 1921, when Bretz (Geol. Soc. Am. Bull., vol. 32, pp. 36–37) assigned it to Plio. or Pleist. In 1927 (Sci., n. s., vol. 66, p. 236) and 1929 (Geol. Soc. Am. Bull., vol. 40, p. 177) J. P. Buwalda and B. N. Moore assigned the beds that had been called *Satsop fm.* by Bretz in Columbia River gorge to late Tert. (Neocene). In 1930 (Carnegie Inst. Wash. Pub. 404, pp. 11–26) Buwalda and Moore assigned to middle Neocene the beds in Columbia River gorge that had been called "Satsop fm.," and applied to them the name *Hood River cgl.*, stating that they are now known to be older than type Satsop of Chehalis Valley, Wash., 100 mi. distant, and that they rest on Columbia River lava and underlie the Dalles beds. They stated: "It is the *Portland delta gravel* and related deposits to the north and south which constitute the Quaternary valley fill." This appears to make Satsop fm. (restricted to Pleist. deposits) same as their Portland delta gravel.

Saturday Mountain formation.

Upper Ordovician: Southern central Idaho (Custer County).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Saturday Mtn fm.*—Dark massive dol. interbedded with argillite and shaly dol., in part carbonaceous. Thickness 3,000 (?) ft. Contains same fauna as Fish Haven dol. of SE. Idaho, but lithology is different. Underlies Laketown dol. and overlies Kinnikinic qtzite. Named for Saturday Mtn, on W. side of lower course of Squaw Creek, on W. border of Bayhorse quad.

C. P. Ross, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 952, etc.). *Saturday Mtn fm.*—Named for ridge that lies W. of lower Squaw Creek, near middle of W. bdy of Bayhorse quad., where it consists dominantly of more or less shaly dol. and mag. ls., mostly black on fresh fracture. Usually surficially bleached to dirty buff and locally stained brown. Thickness 300 (T. 12 N., R. 19 E.) to 3,000± ft. in W. part of quad. Younger than Kinnikinic qtzite and older than Trail Creek fm. (Sil.). Fossils.

Saucesian stage.

Tertiary: California.

See under *Zemorrian stage*, R. M. Kleinpell, 1934.

H. G. Schenck and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 224, etc.). *Saucesian stage* includes middle and upper members of Rincon sh., middle Temblor, etc.

Saucito sandstone member (of Cook Mountain formation).

Eocene (middle): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, p. 1384). *Saucito ss.*, top memb. of Cook Mtn fm. in section along Rio Grande from San Pedro de Roma on Mexican side from Roma [Starr Co.], Tex. Consists of 94 ft. of medium coarse-grained poorly bedded gray ss. [Derivation of name not stated.]

Sauer Dough sand.

A local sand bed, about 10 ft. thick, in Vaqueros ss. of Coalinga dist., Calif. It is uppermost sand in some wells along W. edge of sec. 22, T. 19 S., R. 15 E., and lies about 40 ft. above Pulaski sand.

Saugeen clay.

Pleistocene: Ontario.

W. E. Logan, 1863 (Canada Geol. Surv. Repts. 1843-63, pp. 887, 896-907, 909). *Saugeen clay*, the upper of the two divisions of stratified clays which overlie the boulder fm. or glacial drift of western Canada [Ontario], is a fresh-water deposit, well exposed along Saugeen River. With exception of a yellow band sometimes found at top, it consists of a thinly bedded brown calc. clay, in layers seldom more than an in. thick, separated by thin partings of drab or olive color; in places this clay div. is underlain by beds of sand, and in certain parts of its distribution it is also interstratified with sands and gravels. In two or three instances fresh-water shells have been found in beds apparently belonging to this div. Rests uncon. on the blue Erie clay. On shore of Lake Erie the Erie and Saugeen clays are well exposed. They apparently belong to a distinct basin, so that their relations to lower and upper divisions of the stratified drift of eastern Canada and Vt. cannot yet be determined. The Saugeen clay is considered to be older than Artemisia gravel.

J. W. Spencer, 1888 (Am. Geol., vol. 2, pp. 294-297). Upon the Erie clay rests the more sandy yellow and brown *Saugen* [*Saugeen*] *clays*, a name including a group of clays. These stratified deposits of interior of continent are probably the equivalents in part of the more eastern marine Champlain beds, but their exact relationship has not been made out. Some of the included beds are doubtless the deeper lacustrine equivalents of some beaches of the next series.

J. W. Spencer, 1892 (Phil. Soc. Wash. Bull., vol. 11, p. 506). Amongst the deposits of the later Pleist. period there is a well-stratified, hardened brown clay charged with pebbles which are more or less glaciated, resting upon the typical blue boulder clay N. of Toronto. In Canadian classification of the Pleist. deposits there is no place for this deposit. Indeed, all stratified deposits of this region need revision, in light of progress that has been made in surface geology during last 20 years. Thus, the *Saugeen clay* is resolvable into three series. The relation of all the clays to the older beaches requires special study, as some of them may represent deep-water deposits of the Beach epoch, while some of the later beaches rest upon such clays.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 222). In Ontario the boulder clays are superimposed by the Erie clay, which in turn is overlain by the *Saugeen clay and sands*.

Saugus formation. (In Fernando group.)

Pleistocene (lower): Southern California (Los Angeles County).

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 349-372). *Saugus div.*—Great series, 2,000 ft. thick, of unlithified sand, gravel, and clay, stratified, water-worn, and water-deposited. Is an alluvial deposit, a river delta progressively sinking. Splendidly exposed in railway cuts in Soledad Canyon near Saugus, Los Angeles Co. Conformably overlies Soledad div.

W. S. W. Kew, 1923 (A. A. P. G. Bull., vol. 7, pp. 411-420) and 1924 (U. S. G. S. Bull. 753, p. 81). *Saugus fm.* was first recognized by Hershey as "Saugus division of the upper Pliocene series." In previous repts the Saugus deposits have been included in Fernando fm., of which they constitute the upper uncon. part. In this rept the Saugus deposits are treated as a distinct fm. and the Fernando is made a group. In most places the Saugus fm. rests uncon. on the Pico, the lower fm. of Fernando group, and is uncon. overlain by Pleist. terrace deposits. Is of upper Plio. and lower Pleist. age. Fauna is younger than Pico fauna.

J. E. Eaton, 1928 (A. A. P. G. Bull., vol. 12, No. 2, p. 123), stated that *Saugus fm.* grades up into San Pedro fm. (restricted) in deeper parts of Ventura and Los Angeles Basins.

J. E. Eaton, 1931 (A. A. P. G. Bull., vol. 15, No. 4, p. 381). *Saugus* of U. S. G. S. Bull. 753 is an undiff. succession of pre-San Pedro, San Pedro, and Hall Canyon age. A characteristic fauna was listed, however, from basal (pre-San Pedro) part on W. The name *Saugus* has priority, regional significance, and utility only when restricted to basal unit of pre-San Pedro age, which carries type fauna. Writer uses the name in this restricted sense. As restricted the fm. is dominantly a poorly bedded, somewhat coarse-grained clastic succession, which commonly contains more clay than does overlying San Pedro. Rests on Pico with very sharp contact.

U. S. Grant and H. R. Gale, 1931. (See under *Ventura sands.*)

W. P. Woodring, 1932 (16th Int. Geol. Cong. Guidebook 15, pl. 2, p. 35), showed Saugus fm. (restricted to marine and nonmarine deposits of lower Pleist. age) of Los Angeles Basin as older than San Pedro sand [restricted], and the Saugus of Santa Ynez Range, Santa Clara Valley, and Simi Valley as including, in upper part, the equiv. of the San Pedro restricted. The deposits of upper Plio. age that had previously been included in the Saugus were here transferred to underlying Pico fm. On p. 49 W. S. W. Kew stated: *Saugus fm.* was deposited in a shallow basin and embraces both marine and nonmarine deposits; at type section it is mainly nonmarine, but in Ventura Co. the lower part contains several marine faunal zones of Pleist. age. [This is present approved definition of U. S. Geol. Survey.]

†Saugus granodiorite.

†Saugus quartz diorite.

Early Paleozoic: Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass.), applied *Saugus* to a quartz diorite and to a granodiorite. B. K. Emerson (U. S. G. S. Bull. 597, 1917) renamed the quartz diorite *Newburyport quartz diorite* and showed the granodiorite to be same as Dedham granodiorite.

Sault St. Mary sandstones.

A name applied by A. R. C. Selwyn (Sci., vol. 1, 1883, p. 11) to the Upper Camb. ss. (Lake Superior ss.) of Sault Ste. Marie region, Mich.-Ont.

Saunders formation.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Iron River district).

R. C. Allen, 1910 (Mich. Geol. and Biol. Surv. Pub. 3, pp. 33, 36). *Saunders fm.*—Cherty dol.; massive white and pink dol.; quartzose dol.; impure carbonate slates; qtzites and talcose slates. Thickness 3,750± ft. Underlies, with possible uncon., Michigamme sl. and uncon. overlies Archean. Named for [exposures E. of] village of Saunders, in Iron Co., Mich.

Sauquoit beds.

Silurian: East-central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 333, 341). *Sauquoit beds.*—"This name is temporarily extended over all the sh. and ss. beds between Oneida cgl. and the oolitic ore bed in Oriskany and Sauquoit Valleys, where it is about 100 ft. thick, with type section on Swift Creek, north of Sauquoit village and in its vicinity. It may be desirable later to restrict the term to some definite unit within this series, in which are probably present true Sodus, Martville, and perhaps Maplewood and other horizons." Fossils listed.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 338). "The matter of a geographic name for the Middle Clinton of N. Y. is in doubt." "Chadwick's name Sauquoit may then be the one that will finally be adopted." [See further explanation under *Clinton fm.*]

Sausalito chert. (In Franciscan group.)

Jurassic (?): Western California (San Francisco region).

R. Arnold, March 1902 (Sci., n. s., vol. 15, table on p. 416). *Sausalito cherts*, radiolarian, 900 ft. thick. [Shown in table as underlying Marin ss., overlying Bolinas ss., and as a subdivision of the Franciscan.]

A. C. Lawson, February 1903 (Geol. Soc. Am. Bull., vol. 13, table on pp. 544-545). [Same as above.]

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Sausalito chert.*—Radiolarian chert, prevailingly dull brownish red, especially in thicker and more evenly bedded parts, but includes some rock of yellow, green, and other colors, interbedded with thousands of thin layers of sh. Underlies Marin ss. and overlies Cahil ss. Included in Franciscan group.

Named for exposures W. of town of Sausalito, on Marin Peninsula, Marin Co.

Savage formation.

Pennsylvanian: Northeastern West Virginia and western Maryland.

N. H. Darton and J. A. Taff, 1896 (U. S. G. S. Piedmont folio, No. 28). *Savage fm.*—Nearly equally divided btw. ss. and sh.; contains 4 coals of economic importance, and 2 thin beds of ls., the upper of which is 5 ft. thick and lies 53 ft. below top of fm. Thickness 130 to 160 ft. The roof of the coal bed commonly known as 6-foot bed or Davis seam is top of fm., and base rests on upper ss. and cgl. of Blackwater fm. Is overlain by Bayard fm. Savage River has cut through Savage fm.

Savage fire clay.

See *Mount Savage fire clay.*

Savanna sandstone.

Pennsylvanian (Allegheny): Eastern and central southern Oklahoma and western Arkansas.

J. A. Taff, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 437). *Savanna ss.*—Shales, with 5 heavy ridge-making sss., 50 to 200 ft. thick, the ss. at top and base being usually thicker than the other sss., the distinctive feature of the fm. being the sss. Thickness 1,150 ft. Overlies McAlester sh. and underlies Boggy sh.

This name was later misapplied in Ark., as explained under *McAlester fm.*

Named for Savanna, Pittsburg Co., Okla., which is located on the fm.

Savant group.

Pre-Cambrian: Ontario.

E. S. Moore, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 551) and 1930 (Ont. Dept. Mines 37th Ann. Rept., vol. 37, pt. 4, p. 56). Occurs in Lake Savant area, 140 mi. NW. of Lake Superior.

Saverton shale. (In Kinderhook group.)

Mississippian: Northeastern Missouri, southeastern Iowa, and western Illinois.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 149, 151, 153-156). *Saverton sh.*—Blue shales, 2 to 75 ft. thick, underlying Louisiana ls. and overlying Grassy (black) sh. Usually included in Grassy sh. [Grassy Creek sh.].

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 282, etc.), stated that Saverton sh. (Miss.) is well developed in Pike and Calhoun Counties, western Ill. A. H. Bell, 1932 (Ill. Geol. Surv. Press Bull. 24), gave 47 to 83 ft. of Saverton sh. in wells in Warsaw area, Hancock Co., Ill., and included it in Kinderhook group, as did R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245).

J. M. Weller (1935) proposed to redefine this fm., as explained under *Grassy Creek sh.*

Some writers have included this sh. in Dev.; others have included it in Miss. The U. S. Geol. Survey has recently (June 1937) assigned it to Kinderhook group.

Named for exposures in vicinity of Saverton, Ralls Co., Mo.

Savoy schist.

Ordovician: Western Massachusetts and southeastern Vermont.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form.

although cited in U. S. G. S. Bull. 191, 1902). *Savoy schist,* sericite schist, with beds of amphibolite. Underlies Hawley schist and overlies Chester amphibolite.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 156–163, 220–221 and pl. 34). *Savoy schist.*—Sericite schist with garnet and chlorite locally developed. Underlies Hawley schist and overlies Chester amphibolite. Thickness 5,000 ft. (?). [See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 42).]

Named for development in E. part of Savoy Twp, Mass.

Sawatch quartzite.

Upper Cambrian: Western and central Colorado.

G. H. Eldridge, 1894 (U. S. G. S. Anthracite-Crested Butte folio, No. 9). *Sawatch qtzite.*—Lowest sedimentary series in region. *Lower div.* consists of 50 to 200 ft. of white qtzite with a persistent cgl. of pure white quartz at base. *Upper div.* consists of 130 to 160 ft. of red ferruginous and somewhat calc. ss. composed chiefly of quartz and feldspar with small amount of mica. A green glauconitic mineral occurs in both divisions but more abundantly in upper div., which also contains a few fossils of Potsdam type. The upper div. is absent at head of Taylor Creek. The Sawatch rests on Archean granite and gneiss and is overlain by Yule ls. Named for persistent occurrence around flanks of Sawatch Range.

The upper red sandy and shaly beds of Sawatch qtzite are in some areas known as "transition shales" and "red cast beds." In Leadville region they have been named *Peerless sh. memb.*

Sawatch schist.

Pre-Cambrian: Central Colorado (Sawatch Range).

J. T. Stark and F. F. Barnes, 1935 (Colo. Sci. Soc. Proc., vol. 13, No. 8, pp. 466–479, map). [See description under *Holy Cross schist.*]

†Sawatchan series.

Upper Cambrian: Colorado.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 281, 286). The upper series of Cambric period in Colo. Divided (descending) into three unnamed fms.: Sss., 150 ft.; qtzites, 400 ft.; and cgls., 50 ft. "An adaptation of Eldridge's title" [Sawatch qtzite]. These rocks encircle Sawatch uplift in central part of Colo.

Sawback formation.

Lower Ordovician (?) and Cambrian: British Columbia and Alberta.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 120); also J. A. Allan, p. 182 of same book; also J. A. Allan, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 172). [In all these repts *Sawback fm.* was assigned to *Dev.*]

L. D. Burling and J. A. Allan, 1916 (Canada Geol. Surv. Summ. Rept. 1915, pp. 99, 101), assigned this fm. to Camb., which is where it is now placed by all workers.

E. M. Kindle, 1924 (Pan-Am. Geol., vol. 42, p. 117). The *Sawback fm.* of Banff, Alberta, embraces Mons, Lyell, and Sullivan fms. [Walcott in 1920 assigned these 3 fms. to Camb., but later he assigned Mons fm. to lower Ozarkian of Ulrich. In 1930 (Am. Jour. Sci., 5th, vol. 20, p. 301) P. E. Raymond assigned Mons fm. to Lower Ord. (Beekmantown), but, so far as records show, the Lyell and Sullivan fms. are still assigned to Upper Camb.]

Sawbackian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, pp. 285, 288, 289). Dol., 1,700 ft. thick, of Late Cambric age, lying uncon. below Sherbrookian series and uncon. above Paget fm., of Late Cambric age. "For present the Sawback fm. is best treated as having serial rank."

Sawridge formation.

Upper Cretaceous: Alberta.

J. A. Allan, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. C, p. 11), and 1934 (Alberta Research Council Rept. No. 30, p. 20).

Sawyer limestone member (of Waxahatchee slate).

Paleozoic or pre-Cambrian: Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 51). *Sawyer ls. memb. of Talladega sl.*—Thick-bedded fine-grained bluish-gray ls. in places a highly variegated marble, 100 to 500 ft. thick, occurring in lower part of Talladega sl. No fossils. Lies about 4,500 ft. above base of Talladega sl. [In Montevallo-Columbiana quads. this ls. is a memb. of Waxahatchee sl.]

Named from fact it underlies Sawyer Cove, Shelby Co., in Columbiana quad.

Sawyer quartz syenite.

Devonian or Carboniferous: New Hampshire (Belknap Mountains). See 1936 entry (D. Modell) under *White Mtn magma series*. Named for farm at W. base of Gunstock Mtn.

Sawyer Hill moraine.

Pleistocene (Wisconsin stage): Northeastern New York (Essex County). Named for Sawyer Hill. See N. Y. State Mus. Bull. 187, 1916.

Saxet sand.

A subsurface sand in Frio clay of Driscoll pool, Duval Co., Tex.

Saxian series.

Upper Cretaceous: Northwestern Iowa.

C. [R.] Keyes, 1925 (Pan-Am. Geol., vol. 43, p. 300). The chalk beds represented by Crill and Niobrara fms., which doubtless come together at no very great distance E. of Missouri River, and where they should unquestionably be distinctly recognized by special title, under some such name as *Saxian series*, from locality of easternmost known outcrops of the terranes in Iowa.

†Saxicava sand.

A paleontologic term applied in early repts on New England region to beds of Pleist. marine sand containing the fossil *Saxicava rugosa* and said to underlie †Leda clay (also paleontologic) and to form part of †Champlain epoch.

Saxton conglomerate member (of Chemung formation).

Upper Devonian: Central Pennsylvania (Blair and Huntingdon Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 523, 535). *Saxton cgl. memb. (of Chemung fm.)*.—Introduced to replace [I. C.] White's name Lackawaxen cgl. in Blair and Huntingdon Counties, as it seems very uncertain whether this cgl. is same as typical Lackawaxen. Exposed in and about Saxton, Huntingdon Co.

Saxton shale. (In Catskill formation.)

Upper Devonian: Central southern Pennsylvania (Bedford County) and eastern West Virginia.

D. B. Reger, 1927 (Geol. Soc. Am. Bull., vol. 38, pp. 157, 397–410). *Saxton sh.*—Green sh., carrying fossil plants, located in upper part of Catskill series at Riddlesburg, Bedford Co., Pa., where its visible thickness is 5 ft. and where it lies 330 ft. below base of Berea ss. or top of Catskill. Well exposed on N. side of deep cut. Has been recognized by writer at localities [mentioned] in Dauphin, Monroe, Westmoreland, Indiana, and Cambria (near Johnstown) Counties, Pa., also in Morgan and Randolph Counties, W. Va. Distance below base of Pocono varies from 100 to 800 ft. May correlate with Montrose red sh. or with Paupack ss.

Sayabec formation.

Silurian: Quebec (Matapedia Valley).

G. W. Crickmay, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 368–385). *Sayabec fm.*—Gray, dove-colored ls., typically exposed at a quarry on shore of Lake Matapedia 3 mi. E. of Sayabec, where it consists of a lower part made up of nearly unfossiliferous aren. ls. and dol., and an upper part of fossiliferous dense argill. ls. Thickness exposed 290 ft., but may be 500 ft. thick. Conformably overlies Val Brilliant fm. and conformably underlies St. Leon fm. Fossils (listed).

Saypo limestone member.

Mississippian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 46+). *Saypo ls. memb.*—In lower part of Madison ls. Thickness 72 to 141 ft. Lower 91 ft. is shaly fine-grained argill. lss. interbedded with white smooth and thicker-bedded argill. lss.; weathers bright buff. Overlying 20 ft. is massive thick-bedded gray crinoidal lss. that weather gray. Upper 30 ft. is massive chocolate-colored crinoidal lss., thick-bedded in upper part and thinner-bedded in lower part. In Pentagon Mtn area the very top of the Saypo is a thin zone of shaly thin-bedded tan ls. crowded with poorly preserved fenestellid Bryozoa. Underlies Dean Lake chert memb. and overlies Silvertip cgl., basal memb. of Madison. Named for Saypo quad., over much of which it is well exposed. Type loc. on S. side of upper part of Pentagon Mtn, SW ¼ sec. 14, T. 25 N., R. 12 W., where it forms a buff-colored, relatively gentle slope beneath the harder Dean Lake chert.

Scajaquada limy shale.

Silurian: Western New York.

G. H. Chadwick, 1917. (See 1917 entry under *Bertie ls. memb.*)

Derivation of name not stated.

†Scalent series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 106, 134–136+, and vol. 2, p. 754). Divided into (descending): (1) *Scalent ls. (Water Lime group of N. Y.)*, 250 ft. thick on the Juniata; (2) *Scalent grey marls*, 800 ft. thick on the Juniata; and (3) *Scalent variegated marls*, about 400 ft. thick on the Juniata. Nos. 2 and 3 stated to "probably represent Onondaga salt group of N. Y."

†Scalent limestone.

†Scalent marls.

See under *†Scalent series.*

Scanlan conglomerate. (Of Apache group.)

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Scanlan cgl.*—Imperfectly rounded pebbles of glassy vein quartz with an occasional small flake of schist, held together by an abundant pink matrix consisting of cleavage particles of orthoclase or microcline and quartz. The material appears to have been of local derivation and to represent the surficial detritus of the ancient granitic plain, slightly reworked by waves of an encroaching sea. Named for Scanlan Pass, Globe quad., through which the trail passes just E. of Barnes Peak. Basal fm. of Apache group. Overlies, uncon., Pinal schist.

Scarboro beds.

Pleistocene: Ontario.

A. P. Coleman, 1907 (10th Int. Geol. Cong., Mexico, 1906, p. 1249), and 1909 (Ont. Bur. Mines Ann. Rept., vol. 18, pt. 1, p. 297). Included in Toronto fm.

Scarboro phyllite. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). *Scarboro phyllite.*—A carbonaceous sericite phyllite. Included in Casco Bay group.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 171). *Scarboro phyllite.*—Uniformly fine-grained sericite phyllite, chiefly dark bluish gray to black from presence of biotite and carbonaceous matter, but locally light gray and white in upper half of fm. Typically not siliceous. In places somewhat garnetiferous, and dark-colored parts are in general heavily impregnated with pyrite. Vein quartz in chunky lenticles and irregularly contorted seams is characteristic, as are knobby and undulatory cleavage surfaces. Estimated thickness 200 to 600 ft. Belongs to Casco Bay group. Overlies Diamond Island sl. and, in places, Cape Elizabeth fm. Conformably underlies Spurwink ls. Assigned to Penn. (?). Named for exposures in Scarboro, Cumberland Co.

Scarboro moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), 1913, p. 17.

Schaghticoke shale.

Lower Ordovician (Beekmantown): Eastern New York (Rensselaer County).

R. Ruedemann, 1903 (N. Y. State Mus. Bull. 69, pp. 934–966), described the slates outcropping at Schaghticoke, and in places called them *Schaghticoke slates, Schaghticoke beds,* and *Dictyonema beds.* Consist of very fine-bedded black and prevailing dull-greenish to olive siliceous and argill. slates with intercalations of thin beds of hard gray, very fine-grained ls. Assigned to "highest Upper Cambric."

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, chart), showed *Schaghticoke sh.* as topmost Camb. fm. in eastern N. Y.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 32 and chart). *Schaghticoke sh.* (*1903 Ruedemann*).—Typically exposed along Hoosic River at and in vicinity of Schaghticoke, Rensselaer Co. Fauna characterized by *Dictyonema flabelliforme,* which is considered by some European geologists as marking closing stage of Cambric time, but by others as belonging to early Ordovicic. Is here included in Ordovicic. Lowest Ordovicic fm. in eastern N. Y.

R. Ruedemann and H. P. Cushing, 1914 (N. Y. State Mus. Bull. 169, p. 73). *Schaghticoke sh.* assigned to Beekmantown. Consists of light greenish-gray glazed argill. sh., that weathers light drab or whitish, with intercalations of light bluish-gray sandy sh. and streaks of black sh. containing graptolites. Older than Deepkill sh. [In 1921 (N. Y. State Mus. Bull. 227, 228, p. 130) Ruedemann classified this sh. as lowest Beekmantown.]

R. Ruedemann, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 311). *Schaghticoke sh.* is basal fm. of Ord.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 414), showed this sh. as basal Beekmantown, as beneath Deepkill sh., and as uncon. above Nassau (Lower Camb.).

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 269–270). *Schaghticoke sh.* contains 2 graptolite zones, one of which occurs in Canada and Europe, where it is considered by some as early Ord. and by others as latest Camb. Total thickness unknown; only about 50 ft. exposed, but thickness is probably considerably more. [In tables on pp. 194 and 268 she placed *Schaghticoke sh.* below Tribes Hill ls. and included it in "Canadian system," but excluded it from Beekmantown.]

Schell shale.

Lower Ordovician: Eastern Nevada (Ely region).

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53) and 1924 (Pan-Am. Geol., vol. 41, p. 78). *Schell shales,* 100 ft. thick, underlie Egan lss. and overlie Pogonipan series in Nev. [On p. 78 of 1924 definition the shales are stated to be basal memb. of Mid-Ordovicic section.] Named for outcrops in full thickness in a fault block near middle of Schell Creek Range E. of Ely.

A part of Pogonip ls.

Schenectady formation.

Middle Ordovician (Trenton): East-central New York.

R. Ruedemann, 1912 (N. Y. State Mus. Bull. 162). *Schenectady fm.*—Olive-gray shales more argill. than underlying Canajoharie sh. and contain more ss. beds than the other sh. fms. of N. Y. Thickness 1,700 to 2,000 ft. Fossils of Trenton age, probably middle and upper Trenton. Formerly called Frankfort sh., but older than true Frankfort and older than true Utica sh. Type exposures at Dettbarn quarries, at Schenectady, and at Aqueduct and Rexford Flats, near Schenectady. Does not extend far W. and ends abruptly eastward against the folded region. At Indian Ladder, near Meadowdale, Albany Co., it is uncon. overlain by Indian Ladder beds, of post-Utica age. Between Central Bridge and Howes Cave [Schoharie Co.] overlain by Brayman sh., largely if not wholly of Upper Ordovicic age.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 40). *Schenectady beds (1912 Ruedemann).*—These beds of shales and sss., typically exposed in vicinity of Schenectady, were formerly included with the Hudson River and usually correlated with the Lorraine or the Frankfort. They overlie Canajoharie sh. and are of upper Trenton age. In Albany Co. these beds have at top the Indian Ladder beds, while in Schoharie Co. the Brayman sh. is above them. West of Schenectady Co. the upper limits and exact relation to higher beds of Utica and Frankfort shales have not been established.

H. P. Cushing and R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, p. 51). *Schenectady fm.*—Grits and sss. with interbedded black and gray argill. shales, 2,000 ft. thick in Saratoga Springs region. Carries a middle and upper Trenton fauna. Uncon. underlies Indian Ladder beds and overlies Canajoharie sh.

P. E. Raymond, 1916 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, pp. 247–251), suggested that *Schenectady fm.* is probably to be correlated with the Utica and the Frankfort.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258), correlated *Schenectady beds* with upper Trenton and lower Utica; but in 1929 (Geol. Soc. Am. Bull., vol. 40, p. 414) he assigned *Schenectady sh.* wholly to Trenton and showed Utica as absent.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 268, 287). *Schenectady beds* overlie Canajoharie sh. and are older than Indian Ladder beds, of Frankfort age. They are now known to be of upper Trenton age.

Schenley red beds. (In Conemaugh formation.)

Pennsylvanian: Southwest Pennsylvania.

M. E. Johnson, 1925 (Pa. Geol. Surv., 4th ser., Topog. and Geol. Atlas of Pa., No. 37, Greensburg quad., pp. 54, 121). Name applied to the red shales and clays, of variable extent and thickness, occupying interval in Conemaugh group btw. Wellersburg clay and Birmingham sh. So called because of their excellent exposure in Schenley dist., Pittsburgh. Just N. of Blackburn, on Turtle Creek branch of Pa. R. R., the Schenley red beds are quarried, and consist of 17 ft. of structureless clay underlain by 6 ft. of clay sh.

†Schloenbachi beds.

A paleontologic name applied by R. T. Hill (Geol. Soc. Am. Bull., vol. 2, 1891, p. 515) to Kiamichi fm.

Schodack formation.

Lower Cambrian: Eastern New York (Washington and Rensselaer Counties) and southwestern Vermont (Rutland County).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 67–70 and map). *Schodack shales and lss.*—Black shales and lss. overlying Eddy Hill grit—all Lower Camb. Named for exposures 2 mi. S. of Schodack Landing, N. Y.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, No. 2, p. 414), placed *Schodack beds* beneath Nassau beds.

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285, pp. 25, 73, 79, and map), gave following downward succession: *Schodack shales and lss.*, Troy shales and lss., Diamond Rock qtzite, Bomoseen grit, and Nassau beds. On p. 27 he gave following downward succession: Troy shales and lss., Diamond Rock qtzite, Nassau beds, *Schodack sh. and ls.*, and Bomoseen grit.

L. M. Prindle and E. B. Knopf, 1932 (Am. Jour. Sci., 5th, vol. 24, p. 277). *Schodack fm.*—Thinly bedded black sh. containing thin beds of impure blue ls. that carries fragments of Lower Camb. trilobites in N. part of Hoosick quad., which establish age of fm. as Lower Camb. The black sh. itself has so far yielded only sponge spicules found by Dale. The fm. is=Schodack sh. and ls. of Ruedemann in Capital dist., N. Y. Rests, with apparent conformity, on Mettawee sl. and is conformably overlain by Eagle Bridge qtzite.

Schoharie grit.

Middle Devonian: Eastern New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 378). *Schoharie layers.*—These are the layers so abundant in fossils and have furnished such numbers to the collectors of Schoharie. Underlie Onondaga ls. and overlie the "argillaceous mass" called *Fucoides Cauda-Galli* [Esopus grit].

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, p. 131). *Schoharie grit.*—Calc. fine-grained ss., from which, when long exposed, the carbonate of lime disappears without altering the form of the rock. Readily recognized by peculiar mineral characters and fossils. Underlies Onondaga ls. and overlies Cauda-galli grit [Esopus grit]. [This is present commonly accepted definition of Schoharie grit.]

E. Emmons, 1846 (N. Y. Nat. Hist. Agric., vol. 1), gave thickness of Schoharie grit as 2 to 4 ft.

N. H. Darton, 1894 (N. Y. State Mus. 47th Ann. Rept., pp. 393–422). *Schoharie grit.*—A very aren. ls., which weathers to dark-buff or brown porous massive, rather tough sandrock. Is a thin memb. Merges into Onondaga ls. above but is more sharply separated from underlying fm. [Esopus sl.]. Is a local deposit, developed in vicinity of Schoharie and extending through Schoharie and Albany Counties and along eastern outcrop to Ulster Co. Appears to be a local phase of earlier Onondaga deposits. Is about 6 ft. thick ¾ mi. S. of Callahan's Corners.

F. J. H. Merrill, 1898 (N. Y. State Mus. Bull. 4, No. 19). *Schoharie grit* is a hard calc. ss.; when freshly quarried looks like a gray ls.; weathers to gritty yellow ss. Found only from Cherry Valley eastward. Thickness 4 or 5 ft.

C. S. Prosser, 1899 (N. Y. State Mus. 17th Ann. Rept.), assigned thickness of 12 ft. to Schoharie grit in Schoharie Co. and 3 ft. in Albany Co. A. W. Grabau, 1903 (N. Y. State Mus. Bull. 69), reported 200 ft. of Schoharie grit in Becraft Mtn, Columbia Co., N. Y.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 63). *Schoharie grit* is found in Schoharie, Albany, and Otsego Counties and in Hudson River Valley, but does not appear to be everywhere continuous. Has extensive fauna.

The present N. Y. State Survey treats Schoharie grit as a fm. younger than its Oriskanian and as underlying Onondaga ls. and overlying Esopus grit. (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931, p. 370.) This is present definition of U. S. Geol. Survey.

†Schoharie stage.

Term used by A. W. Grabau (Buffalo Soc. Nat. Hist., vol. 6, p. xviii, 1898) to include Schoharie grit and Esopus sh.

Schoolcraft member.

Silurian (Niagaran): Northern Michigan.

See under *Cordell memb.*

Schooler Creek formation.

Triassic (Upper): British Columbia.

F. H. McLearn, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. B, p. 2). Assigned to Triassic. [All subsequent repts. by other geologists, assign this fm. to Upper Tr.]

School Land sandstone. (Buried.)

Ordovician: Northeastern Oklahoma (Oklahoma City field).

D. A. McGee and W. W. Clawson, Jr., 1930 (A. A. P. G. Bull., vol. 16, No. 10, pp. 967, 973+). *School Land ss.*—An Ord. oil and gas horizon, 85 ft. thick, lying about 220 ft. below "Wilcox" sand in Oklahoma City oil field, and 0 to 20 ft. above Hammer-Haindl ss. Basal 30 ft. of School Land ss. is often called *Mollman sand.* [Derivation of names not stated.]

Schooner Head series.

Cambrian or pre-Cambrian(?): Southeastern Maine (Mount Desert Island).

N. S. Shaler, 1889 (U. S. G. S. 8th Ann. Rept., pt. 2, pp. 1037, 1041, 1060, and map). *Schooner Head series.*—Micaceous, contorted argill. schists and aren. shales or slates, with associated injected rocks, on E. face of Mount Desert Island, extending from near Schooner Head to Rodick's Cove. Probably of same age as Bartlett's Island series of W. side of island, but of less distinctly schistose character and thicker-bedded; appears to have originally been more like flags than shales. Assigned to Camb. or pre-Camb. Named for exposures at Schooner Head, E. coast of Mount Desert Island.

On 1933 geol. map of Maine, by A. Keith, these rocks appear to be included in igneous block labeled "mainly Sil., but some Dev."

Schooner Hill facies.

Name applied by **P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 137, etc., 1931)** to a lithologic development of his Locust Point fm. in a part of southern Ind.

Schott sand.

A subsurface lenticular sand in Eocene Yegua fm. (of Claiborne group) of southern Tex. Lies 300 ft. below Mirando sand.

Schramm sand.

A subsurface sand in Pottsville fm. (Penn.) of SE. Ohio.

Schreyfogel's limestone.

Mississippian: Northeastern Pennsylvania (Sullivan County).

F. Platt, 1880 (2d Pa. Geol. Surv. Rept. G_2, pp. 187, 199). *Schreyfogel's ls.*—Thin greenish siliceous ls., poor and sandy, exposed on hillside S. of Schreyfogel's Hotel and 170 ft. above level of Loyalsock Creek. Is clearly in Pocono ss. and must lie 300± ft. beneath Pottsville cgl.

Schroeppel shale.

See *Phoenix or Schroeppel shale.*

Schroyer limestone. (In Wreford limestone.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 33). *Schroyer ls.*—Top memb. of Wreford ls. Chert-bearing ls., 8 or 9 ft. thick in vicinity of Cambridge, Cowley Co., Kans., and about 20 ft. thick in Big Blue Valley, in vicinity of Randolph. In Nebr. its max. exposed thickness is about 10 ft., in a small creek valley 3 mi. SE. of Wymore. Type loc. on E. side of Big Blue Valley, about 1¼ mi. below Schroyer, Marshall Co., Kans. Overlies Havensville sh. and underlies Wymore sh. memb. of Matfield fm.

Schubert Creek limestone.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). As described elsewhere in this Guidebook by Jewett, the lowermost fm. of Bronson group includes 3 ls. lentils which are named (ascending order) *Schubert Creek, Critzer,* and *Sniabar.* The Schubert Creek ls. was apparently studied by Hinds and Greene in vicinity of Uniontown as a supposedly authentic representative of "Hertha" ls. in Kans., and this rock was correlated by them with the prominent ls. that appears next below Bethany Falls ls. in Kansas City and NW. Mo. dist. Latter bed is now called Sniabar. [See also under *Swope fm.*]

J. M. Jewett, 1932 (pp. 100, 103 of book cited above). *Schubert Creek ls.*—Ls., rather light in color, crystalline, and generally brecciated. Lowest memb. of Swope fm. Type loc. on Schubert Creek, btw. Bronson and Uniontown, Kans., on U. S. Highway 54. Thickness, few in. to 15 ft. Present along line of outcrop of Bronson group from T. 22 S. to T. 28 S.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 80), discarded *Schubert Creek ls.* (See under *Critzer ls.*) He appears to include it in his Bourbon fm.

Schultze granite.

Probably Tertiary: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Schultze granite.*—Granitite or biotite granite. Intrudes Pinal schist in Globe quad. Forms the light-colored hills about Schultze's ranch.

F. L. Ransome, 1919 (U. S. G. S. P. P. 115), assigned this fm. to early Tertiary (?).

Schumann formation.

Pleistocene and Pliocene (?): Southern California (Santa Maria district).

R. D. Reed, 1933 (Geol. of Calif., p. 232). *Schumann fm.*—Fresh-water beds with thin marine intercalation; contains vertebrate fossils suggesting Pleist. Lower part may be Upper Plio. Thickness 2,000± ft. Overlies *Dendraster* cgl. (Upper Plio.).

R. D. Reed, 1936 (letter dated May 18). "Schumann fm." is a name in local use for some of the strata exposed near N. end of Schumann cut, where the railroad enters the Casmalia Hills S. of Guadalupe (Guadalupe quad.). It has been discussed at several meetings here, but so far as I know has not been described in print.

H. W. Hoots and S. C. Herold, 1935 (Geol. of nat. gas, A. A. P. G., p. 156). *Schumann fm.*—Fresh-water gravels, sands, clays, and ls., with sand-dollar bed at base. Of Plio. age. Thickness 2,000 ft. Uncon. underlies Orcutt fm. and overlies, with local uncon., Upper Foxen sand, top fm. of Etchegoin group.

Schunemunk conglomerate.

Schunnemunk conglomerate.

Variant spellings of *Skunnemunk cgl.* used by E. C. Eckel in N. Y. State Geol. 20th Ann. Rept., 1902.

Schuyler soapstone.

Pre-Cambrian: Central Virginia.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. edition of geol. map of Va.). *Schuyler soapstone.*—Intrusive into Lynchburg gneiss. Mapped at and around Schuyler, Nelson Co.

Schwatka andesites.

Tertiary (?): Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 42).

Scio sand.

A subsurface sand, of probable Dev. age, in western N. Y., lying higher than Bradford and Richburg sands.

Scioto freestone. (In Allegheny formation.)

Pennsylvanian: Central southern Ohio.

D. D. Owen, 1859 (Rept. Geol. Reconn. State of Ind. in 1838, pt. 2, p. 50). *Scioto freestone* rests on cgl. or millstone grit [Pottsville] in Ohio and underlies coal measures. Equiv. to Knob freestone of Ind.

Probably named for Scioto Valley, Ohio.

†Scioto slates and shales.

Upper Devonian: Southern Ohio.

D. D. Owen, 1859 (Rept. geol. reconn. State of Ind. in 1838, pt. 2, p. 59). The black sl. in base of these knobs [in Indiana] is equiv. of *Scioto slates and shales.*

Replaced by Ohio sh., better defined and established.

Probably named for Scioto Valley, Ohio.

Scioto Valley shale facies.

Mississippian: Southern Ohio (Scioto Valley).

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 657, 757–758). *Scioto Valley sh. facies of Cuyahoga fm.*—Argill. shales with thin ss. beds tongued into them from either side. Includes (descending): Portsmouth memb., 253 ft.; Buena Vista ss. memb.; Henley sh. memb., 200+ ft. Underlies Logan fm. and overlies Sunbury sh.

Includes Cuyahoga fm. and lower part of Black Hand fm.

Sciotoville fire clay. (In Pottsville formation.)

Pennsylvanian: Southern Ohio.

E. B. Andrews, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, p. 166, pl. opp. p. 242). *Sciotoville fire clay.*—Fire clay extensively worked at Sciotoville. Immediately overlies Logan or Upper Waverly ss.

Well-known economic memb. of Pottsville fm. According to C. S. Prosser and W. C. Morse (Outlines of field trips in geology for central Ohio, 1915) the Sciotoville fire clay lies above Sharon coal No. 1 and below Connoquenessing ss. memb. of Pottsville fm.

Scossa slates.

Jurassic: Northwestern Nevada (Pershing County).

J. C. Jones, A. M. Smith, C. Stoddard, 1931 (Univ. Nev. Bull., vol. 25, No. 4, pp. 6, 7, 8). Jurassic slates, schists, sss., etc., that cover greater part of Scossa dist. are, for brevity, here called *Scossa slates*. Ribs or bands of harder rock fms. intersect the veins and cut obliquely across all members of Scossa fm.

Scotia ore bed.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geology of Newfoundland, No. 4). *Scotia ore bed.*—Oolitic hematite, fossiliferous; discon. (?) overlain by chamosite sl. and underlain by gray sh. Included in Wabana series.

Scotland beds.

Eocene: West Indies (Barbados).

J. W. W. Spencer, 1902 (London Geol. Soc. Quart. Jour., vol. 58, p. 356). [No age assigned. R. J. L. Guppy, 1911 (London Geol. Soc. Quart. Jour., vol. 67, p. 693) assigned *Scotland beds* of Barbados to Cret.; E. H. C. Craig, 1913 (Rept. on oil fields of Barbados, p. 2), assigned them to Tert. (?); C. T. Trechmann, 1925 (Geol. Mag., vol. 62, p. 481), and C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 715), assigned them to Eo.]

Scotland schist.

Late Carboniferous or post-Carboniferous (?): Eastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 132, 141, and map). *Scotland schist.*—Coarse muscovite schist squeezed into minute folds as result of metamorphism. Is practically a mass of muscovite with some biotite and occasionally garnet and quartz. Covers town of Scotland. Of sedimentary origin. Believed to be older than Willimantic gneiss. Evidence indicates that Putnam gneiss underlies Scotland schist. The two fms. are conformable and pass into each other without noticeable change. Hebron gneiss grades into Scotland schist.

W. G. Foye and A. C. Lane, 1934 (Am. Jour. Sci., 5th, vol. 28, p. 128). *Scotland schist* is same as Brimfield schist, which is pre-Carbf.

Scots Bay formation.

Triassic: New Brunswick and Nova Scotia.

S. Powers, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 93).

Scott shale. (In Pottsville group.)

Pennsylvanian: Eastern Tennessee.

A. Keith, 1896 (U. S. G. S. Briceville folio, No. 33). *Scott sh.*—Mainly argill. and sandy shales, but includes many beds of shaly ss., a few massive sss., and five or six coal seams, all very similar in composition to those of Wartburg ss. Contains more sh. than ss., and the sss. are thinner than in the Wartburg. Thickness 450 to 600 ft. Overlies Wartburg ss. and underlies Anderson ss. Named for its frequent occurrence in Scott Co.

Scott limestone.

An abbreviation of *Fort Scott ls.* that is employed by C. [R.] Keyes.

Scott sand.

A subsurface sand, of early Penn. (Cherokee) age, in central and central northern Okla., lying lower than Taneha sand and correlated with Dutcher sand. In type region (Scott field, Creek Co.) it lies at 2,510 ft. depth. The name has also been applied to an oil sand in Strawn fm. (Penn.) of Young Co., Tex., lying about 830 ft. below Palo Pinto ls. (basal memb. of Canyon group) on the Scott lease.

†Scotts Bluff formation.

A term loosely applied by H. Engelmann (Eng. Dept. U. S. Army, J. H. Simpson's expl. of Great Basin of Terr. of Utah, 1876, pp. 247, 282–284) to Tert. deposits on North Fork of Platte River in SW. Nebr., which he assigned to Mio. and stated that they are apparently coeval with the Mio. strata of badlands of White River and overlie another series of Tert. strata, which in turn overlies his Platte River or Lignite fm., of Eo. or Upper Cret. age. In U. S. G. S. Scotts Bluff folio, No. 88, 1903, the Tert. deposits of Scotts Bluff quad., Nebr., are divided into (descending) Ogallala fm., Arikaree fm., Gering fm., Brule clay, and Chadron fm. The present age designations of these fms. are as follows: Ogallala fm., Plio. and upper Mio.; Arikaree and Gering fms., Mio.; and Brule clay and Chadron fm. (which compose White River group), Olig.

Scotts Creek flint.

Mississippian: Eastern Ohio.

E. Orton, 1880 (Review of strat. of Ohio, p. 22). *Scotts Creek flint*, found on all tributaries of Scott's Creek, is base of Maxville ls. and is=Logan flint of my Hanging Rock rept in vol. 3, p. 900.

Scottsmore quartzite.

Lower Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 10).

Scottsville sand.

A subsurface sand, of Sil. age, in western Ky.

Scotty Wash quartzite.

Mississippian (upper): Eastern Nevada (Pioche district).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171, pp. 7, 21, map, etc.). *Scotty Wash qtzite.*—A red-brown thin- and thick-bedded qtzitic ss. with some shaly ss., which apparently conformably overlies Peers Spring fm. (Miss.) and is provisionally correlated with Diamond Spring qtzite of Eureka dist. Base not shown, as it is separated from lower Miss. fms. by fault contacts. Overlain, apparently conformably, by Bailey Spring ls. (Miss. and Penn.). Thickness 700 to 1,000± ft. No fossils. Named for fact Scotty Wash passes through the fm. E. of Silverhorn.

Scrag granite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Ammonoosuc River region, Franconia, Moosilauke, and Littleton quadrangles).

C. R. Williams, 1934 (Appalachia, vol. 20, No. 4, pp. 69–78). *Scrag granite.*—Pink, largely quartz and feldspar, with few dark minerals. Carbf. (?). Found only on Scrag Hill [Franconia quad.].

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., p. 11, and map). *Scrag granite* is younger than Bethlehem gneiss and is late Dev. or late Carbf. Assigned to New Hampshire magma series.

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H.), mapped and described this granite in Moosilauke and Littleton quads.

Scranton sandstone. (In Pottsville formation.)

Pennsylvanian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 45, 46, 48+). *Scranton ss.*—Current-bedded pebbly ss.; dark gray, in portions almost black; contains numerous small white quartz pebbles. Thickness 60 to 75 feet. Is upper div. of Pottsville cgl. and first great pebbly ss. mass above lowest workable coal of Scranton region and easily recognized by its extraordinary oblique lamination. Well exposed along railroad, about ½ mi. S. of depot, and at many other places around Scranton. It looks very much as if the Scranton current-bedded ss., the *McIntire Upper cgl.*, the *Blossburg Monkey ledge*, the *Johnson Run rock* of McKean, and Homewood ss. of Beaver River country were all the same.

Scranton shale. (In Shawnee group, Kansas.)

Scranton shale member (of Shawnee formation, Missouri).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

E. Haworth and J. Bennett, 1908 (Kans. Acad. Sci., vol. 21, pt. 1, pp. 71–85). *Scranton shales of Bennett.*—Previously called Burlingame shales, but that name is retained for the ls., both being named at same time. Is top fm. of Shawnee stage. Underlies Burlingame ls. and overlies Howard ls.

Scranton sh. is still applied by Nebr. Geol. Survey and U. S. Geol. Survey to the beds underlying Burlingame ls. and overlying Howard ls., but R. C. Moore in 1936 (Kans. Geol. Surv. Bull. 22) discarded the name from the Kans. classification, treating the named subdivisions into which Condra had in 1930 divided it as fms. in Wabaunsee group. Moore stated (p. 210) that Rock Lake sh., South Bend ls., Plattford sh., and Cass ls. of Condra do not belong to Scranton sh. Condra in 1930 transferred his Rock Lake sh. and South Bend ls. to Stanton ls., and in 1935 stated (Nebr. Geol. Surv. Paper No. 8) his Plattford sh. is same as Weston sh., but did not explain what replaces his Cass ls., although he abandoned that name in 1930.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Scrubgrass fire clay. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Scrubgrass fire clay,* 10 ft. thick in Lawrence Co., Pa., underlies Scrubgrass coal and is probably nearly a rider to or top bench of Clarion coal.

E. Orton, 1884 (Ohio Geol. Surv. vol. 5, p. 660). *Scrub Grass clay,* 4 ft. thick, underlies Upper Clarion or Scrub-Grass coal and lies higher in section than Lower Clarion coal.

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31). *Scrubgrass coal* lies 4 ft. 9 in. above Clarion coal in Vinton Co., and 2 ft. 2 in. below Vanport ls.

†Scutella limestone.

Lower Devonian: Eastern New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 377). *Scutella ls.*—Underlies Oriskany ss. and overlies Delthyris shaly ls. [New Scotland ls.]. Named for peculiar fossil which it contains.

Replaced by Becraft ls. in 1893. Has also been called "Upper Pentamerus ls."

Seaforth limestone.

Tertiary (Oligocene?): West Indies (Antigua).

J. W. W. Spencer, 1901 (London Geol. Soc. Quart. Jour., vol. 57, p. 494).

Seahorne limestone.

Name applied by H. R. Wanless (Geol. Soc. Am. Bull., vol. 42, 1931, pp. 801–812, and Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a ls., 0 to 10± ft. thick, in upper part of Pottsville fm. (Penn.) of central western Ill. Shown as lying 30± ft. higher than his Bernadotte ss. and 100± ft. higher than coal No. 1, and to contain a distinctive fauna. Derivation of name not stated.

Seahorne cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a portion of upper part of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated.

†Sea Island sands.

†Sea Island loams.

Pleistocene: Southern South Carolina (Charleston and Beaufort Counties).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908 publication cited below); 1907 (Summary of mineral resources of S. C., table on p. 12); 1908 (S. C. Geol. Surv. ser. 4, Bull. 2, p. 485, definition). [*Sea Island sands* in first two publications cited. *Sea Island loams* in last publication cited.] The Sea Island loams extend from point near McClellanville to mouth of Broad River along a curved zone which approx. conforms to inland waterway. They feather out on Ten Mile Ridge in a progressively impoverished state. On seaboard side they are delimited by a barrier of sands, which are probably senior to the Sea Island loams; the extreme seaward border consists of recent sea sands largely accumulated through eolian forces. It appears that the fine-grained Sea Island loams were derived from Bohicket marl sands by accentuated action of waters, which partly reworked the latter and deposited them over the Wando sands in form of a fine glauconitic silt mixed with fine sands. Is a marine Pleist. fm.

C. W. Cooke (personal communication, 1935). The beds described are a facies of Pamlico fm.

Named for development on islands off coast of Charleston and Beaufort Counties.

Seaman Ranch shale member (of Brad formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 111+). *Seaman Ranch beds*.—Chiefly sh., with thin lss. and some sss. Average thickness 150 to 200 ft. Upper part usually consists of 50 to 110 ft. of dark-gray soft sandy sh. containing 1 or 2 lentils of reddish-brown ss. and a thin layer or two of dark-brown ls.; lower part consists of 60 to 100 ft. of sh. Usually nonfossiliferous. Is lower memb. of Brad fm. in Brazos River Valley. Underlies Ranger ls. memb. of Brad and overlies Adams Branch ls. memb. of Graford fm. Occupies position of Placid sh., Clear Creek ls., and Cedarton sh. of Colorado River Valley section of the Brad. Named for Seaman ranch, in W. part of Palo Pinto Co., where typically exposed along Caddo Creek.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 111), extended Graford fm. up to top of Merriman ls., and restricted Brad fm. of Colorado River Valley to Placid sh. memb. and overlying Ranger ls. memb. He stated that in Brazos River Valley the fm. consists of Ranger ls. memb. and underlying Seaman Ranch beds.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 55). Brad fm. of Palo Pinto Co. divided into Ranger ls. (above), 45 ft. thick, and Seaman Ranch beds (below), 135 ft. thick. Rests on Merriman ls. (top memb. of Graford fm.), which in previous repts was miscorrelated with Adams Branch ls. of Colorado River region. Fossils listed.

Seattle formation.

Oligocene: Northwestern Washington and Puget Sound region.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 579, 582, 604). *Seattle fm*.—Ashy shales with ls. nodules, sandy and massive sh., shaly ss., and ss. Thickness 3,000 to 4,000 ft. Is older than Twin River fm., younger than San Lorenzo fm., and=middle part of Astoria series. Includes Aturia bed at Astoria. [Probably named for Seattle, Wash.]

B. L. Clark and R. Arnold, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 303–308). C. E. Weaver has apparently shown (Calif. Acad. Sci. Proc., 4th, vol. 6, No. 3, 1916, pp. 41–52) that the beds forming Twin Creek fm. are part of Arnold and Hannibal's Seattle fm. (*Acila gettysburgensis* zone), and they are here included in *Seattle group*.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 245, 261–264). [See 1925 entry under *Blakeley fm.*]

†Sebastian stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Sebastian stage*.—Includes (descending): Greenwood ss. (100 ft. thick); Tomlinson sh. (500 to 600 ft. thick); Hartwell ss. (0 to 100 ft. thick); Belva sh. (0 to 500 ft. thick); and

Ozark ss. (0 to 500 ft. thick). Underlies Poteau stage, and in Ark. overlies Spadra stage, which is absent [?] in Okla., as are Hartwell ss., Belva sh., and Ozark ss.

Includes McAlester sh. and Savanna ss.

Probably named for Sabastian Co., Ark.

Seboomook slate.

Silurian: Western Maine (Moosehead Lake region).

E. H. Perkins, 1925 (Am. Jour. Sci., 5th, vol. 10, pp. 374–375). *Seboomook sl.*—Apparently underlies Moose River ss. (of Oriskany age) on NW. side of that fm., and contains *Monograptus*, which fixes its age as Sil. Outcrops limited to lake shore, rapids of streams, and a few cuts along roads of Great Northern Paper Co. In most outcrops the rock is a dark-bluish sl., often with well-developed cleavage. Fresh pyrite cubes are common on unweathered surfaces, while weathered surfaces are iron-stained from decomposed pyrite. Some localities show interbedded ss. layers which often contain clay balls closely resembling the sl. in composition. Best exposure of fm. is at Seboomook Dam, on West Branch of Penobscot River [in extreme E. part of Somerset Co.].

Seboruco formation.

Pleistocene: Jamaica and Cuba.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, pp. 419, 499).

Sebree sandstone. (In Carbondale formation.)

Pennsylvanian: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 27). *Sebree scarp-making ss.*—Coarse massive ss., 10 to 50 ft. thick, forming basal memb. of De Koven fm. in Webster Co. Rests uncon. on Tradewater fm.

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 97). *Sebree ss.*—Caps Sebree Hills. Forms ridge that extends from Sebree E. to Green River. Named for prominent development btw. Sebree and Steamport Ferry, where it caps the hills and in places forms prominent cliffs. Is basal memb. of Carbondale fm.

Seco formation.

Eocene: Central Texas (Medina County).

R. A. Liddle, 1921 (Univ. Tex. Bull. 1860, p. 85, map, columnar section). *Seco fm.*—Variegated aren. shales, predominantly deep red; a few lenses of brown-red to deep-red aren. lss. Thickness 100± ft. Top fm. of Wilcox group in Medina Co. Overlies Buttsgin fm. and underlies Carrizo ss. of Claiborne group. Exposed in Seco Creek, 3 mi. S. of W. of Yancey, Medina Co.

†Secondary.

See explanation under †*Primitive*.

†Second Bottoms.

A descriptive term applied in early repts on geol. of Miss. to most widely developed and best-preserved Pleist. terrace in State. Thickness of deposit 0 to 100± ft. "Underlies loess and overlies loess." Probably same as Port Hudson fm.

†Second Pentamerus limestone.

Lower Devonian: New York.

T. A. Conrad, 1840 (Am. Jour. Sci., 1st, vol. 38, pp. 89–90). Second Pentamerus ls. underlies the shaly ls. of Catskill Creek [New Scotland ls.] and overlies the Water ls. (characterized by *Tentaculites annulatus*, *Delthyris*, *Orthis*, unnamed univalves, and *Cytherina*).

†Second Pentamerus limestone.

Silurian (Cayugan): New York.

T. A. Conrad, 1839 (N. Y. Geol. Surv. 2d Rept., pp. 62–63). *Second Pentamerus ls.* underlies Helderberg lss. and overlies gypseous shales that contain *Eurypterus remipes* and succeed the Rochester shales. Carries *Pentamerus Knightii* and *Euomphalus profundus*. [Applies to a ls. or lss. of Cayuga group.]

†Secretan series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53) and 1924 (Pan-Am. Geol., vol. 41, p. 78), to Secret Canyon sh. of Nev.

Secret Canyon shale.

Middle Cambrian: Eastern Nevada (Eureka region).

Arnold Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 255–259). *Secret Canyon sh.*—Yellow and gray or brown argill. shales, passing [upward] into transition beds of shaly ls., 25 to 200 ft. thick; near top interstratified layers of sh. and thinly bedded lss. Grades into underlying Prospect Mtn qtzite and is overlain by Hamburg ls. Thickness 1,600 ft. Named for exposures in Secret Canyon, Eureka dist.

Sedalia limestone.

Name casually used by A. W. Vogdes (St. Louis Acad. Sci. Trans., vol. 5, p. 615, 1892), as follows: "From Sedalia [Mo.] we have the new species [of trilobites] described in this paper. The fossil Crustacea of the Sedalia limestones have a strong Devonian facies." This name is listed in Bull. 191 of U. S. G. S. but was not defined by Vogdes.

Sedalia limestone. (Of Osage group.)

Mississippian: Central and northeastern Missouri and western Illinois (Jersey, Calhoun, and Pike Counties).

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 61, 78, 84, 86, 90, 91, 144, 146, 149–154, 166, 254). *Sedalia ls.* here proposed for the gray to light-buff "silico-mag." ls. which was termed Upper Chouteau by Swallow and other geologists. Occurs in thick beds, which contain disseminated masses of white or limpid calc. spar. It is really a siliceous dol. throughout region of its typical development; is massively bedded, individual layers being in many places 10 to 20 ft. thick. At different horizons it contains layers of grayish of bluish-black, very dense, hard chert nodules, and locally thin chert bands. Thickness of fm. 0–40 ft. in central Mo.; 10 to 15 ft. in NE. Mo. Rests (uncon. in places) on Chouteau ls. restricted (=Lower Chouteau of previous repts), or uncon. on older rocks, and is overlain by Lower Burlington ls. Is 30 ft. thick at Chouteau Springs, Cooper Co., Mo., type loc. of Chouteau ls., where it rests on 20 ft. of "Lower Chouteau" (=Chouteau ls. as here restricted). Appears to correspond to Fern Glen ls.; carries related fauna but is lithologically different. Where Sedalia is present no Fern Glen beds are found, and where Fern Glen appears no Sedalia is recognized. The Sedalia appears to grade laterally into the Fern Glen, but it is not certain whether it is=all of Fern Glen, or, as seems probable, only lower part. It probably corresponds to Pierson ls. of SW. Mo., but is lithologically different. Is believed to correspond to bed 7 of the Kinderhook at Burlington, Iowa. [The Fern Glen ls. is now included in Osage group. In table opp. p. 282 Moore lists Sedalia ls. in Jersey, Calhoun, and Pike Counties, Ill.]

Named for exposures in vicinity of Sedalia, Pettis Co., Mo.

Sedwick limestone member (of Moran formation).

Permian: Central and central northern Texas (Shackelford County region).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 40). *Sedwick ls. memb. of Moran fm.*—Persistent yellowish lss., commonly 3 in number, closely associated and characterized by widely distributed and abundant small silicified fossil casts, mainly gastropods. Forms top memb. of Moran fm.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 176, 179–183). The persistent and prominent ls. at top of Moran fm. was designated Sedwick in course of field work, but it appears desirable to apply a geographic term to entire ls. division in the [Moran] fm. above Santa Anna bed. The *Sedwick memb.* may then be defined to include the series of thin yellow lss. with interbedded shales which lie at summit of Moran fm. The upper bed of Sedwick is 1 to 2 ft. thick, of rather dirty yellow color, contains numerous small stringers of calcite and, locally, numerous fossils, and is more or less cherty. The next lower bed in Sedwick memb., designated in field work *Hart School bed*, occurs 3 to 12 ft. below top of the ls. It is of yellow color, 2 to 6 ft. thick, and characterized by abundance of small silicified gastropods and other fossils. [Several detailed sections of Moran fm. show Sedwick memb. as consisting of 2 to 6 ls. beds, chiefly yellow, but in some places blue in lower part, varying in thickness from 1 to 6 ft., separated by sh. beds varying in thickness from 1 to 19 ft., the total thickness of Sedwick memb. varying from 15 to 42 ft.] Named for outcrops W. of Sedwick, Shackelford Co.

Moran fm. was transferred to Permian Wichita group in 1933.

Seekonk beds.

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 173–176). *Seekonk beds.*—A series of ss. and cgl. beds, somewhat less than 2,000 ft. thick. While sss. form dominant exposures and leading topographical feature, shales enter about equally into thickness of the series, which lies about 1,000 ft. higher stratigraphically than Tenmile River beds and is included in upper part of Rhode Island Coal Measures. The Seekonk cgl., although here tentatively included in Dighton group, may belong to Seekonk beds.

Named for occurrence in Seekonk Twp, Bristol Co., Mass.

Seekonk conglomerate.

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 174, 176). [In table on p. 134 *Seekonk cgl.* is included in Dighton group. On p. 174 it is described, with a subheading, under major heading *Seekonk beds* (which are included in Rhode Island Coal Measures) and is said to be very massive, 50 to 60 ft. thick, and because of its striking resemblance to the cgls. of Dighton group it is tentatively considered=the coarse cgl. at base of that group and is so represented on map. On p. 176 author "raises the question whether the Seekônk cgl. is the coarse cgl. elsewhere found at the base of the Dighton group or a lower cgl. comprised within the Seekonk beds proper."]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks of Seekonk Twp and along Seekonk River as Rhode Island fm., and showed no areas of Dighton cgl. in that vicinity.

Named for occurrence in Seekonk, Bristol Co., Mass.

Seekonk sandstone.

See under *Westville shale.*

Seeley slate.

Pre-Cambrian (middle? Huronian): Central southern Wisconsin (Sauk County).

S. Weidman, 1904 (Wis. Geol. Nat. Hist. Surv. Bull. 13, p. 46). *Seeley sl.*—Gray clay sl., 500 to 1,000± ft. thick. Appears to grade into overlying Freedom fm. and to rest on Baraboo qtzite without evidence of uncon. Does not outcrop, but is found only by exploration. Named for occurrence near Seeley Creek.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 720), indicated *Seeley sl.* may be middle Huronian.

Sego sandstone member (of Price River formation).

Upper Cretaceous: Central eastern Utah (Book Cliffs) and central western Colorado.

D. J. Fisher, 1935 (U. S. G. S. Bull. 852). *Sego ss. memb. of Price River fm.*—An eastward-pointing tongue of Price River fm., dominantly ss., buff-weathering in the main, massive and cliff-forming to thin-bedded and shaly. Thickness 140 to 210 ft. Carries marine fauna of Lewis age. Not recognized NW. of Beckwith Plateau. Underlies Neslen coal-bearing memb. of Price River fm. and overlies Castlegate ss. memb. of the Price River. In part of area the Buck tongue of Mancos sh. wedges in btw. the Sego and Castlegate sss. Named for settlement in T. 20 S., R. 20 E., Utah.

This name first appeared in print in U. S. G. S. Bull. 851, 1934, by C. E. Erdmann, in a rept. on E. part of Book Cliffs coal field, where he treated it as a fm. (40 to 300 ft. thick) in Mesaverde group, underlying Mount Garfield fm. and overlying Buck tongue of Mancos sh. Erdmann credited the name to Fisher. (See also 1932 correlation chart of Utah, compiled by M. G. Wilmarth.)

Seguin formation. (In Wilcox group.)

Eocene: Eastern Texas (Trinity River to Rio Grande).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 558, 574, 634). *Seguin fm.* here proposed to designate all marine strata btw. the compact silty clays of Midway group and base of nonmarine Rockdale fm. of Wilcox group. In most places base is marked by contact of thinly laminated carbonaceous and fossiliferous sands with silty clays. Top is limited by a thin concretionary layer made up largely of shells of *Ostrea multilirata* Conrad. Type loc. is the section exposed along the banks of Moss Branch 10 mi. NW. of Bastrop, in NW. part of Bastrop Co., about 1 mi. N. of old Caldwell village. Another equally good locality is the exposure along Solomon's Creek, 6 mi. S. and 1 mi. W. of Elgin, Bastrop Co. The fm. at Seguin is obscured largely by alluvium along Guadalupe River. It can be seen in Geronimo Creek 1½ mi. E. of town, and along the highway 2 mi. S-SW. of town, S. of Guadalupe River. Can be mapped most of distance from Trinity River to Rio Grande. Thickness throughout central Tex. 50 to 75 ft.; in Rio Grande Valley may be 190 ft.; in wells S. of its outcrop its thickness ranges from 100 to 160 ft. Rests conformably on upper (Kerens) memb. of Wills Point fm. in NE. Tex., discon. on middle Wills Point in places in south-central Tex., and discon. on Kincaid fm. in SW. Tex. It underlies Rockdale fm., probably conformably.

Seignelay till.

A term applied by C. [R.] Keyes to an old till sheet (pre-Nebraskan, he stated) in Ill. or Iowa. (See Pan-Am. Geol., vol. 58, pp. 203, 217, 1932.)

Seine series.

Pre-Cambrian: Ontario.

A. C. Lawson, 1912 (Canada Geol. Surv. Mem. 28, p. 10).

Seine conglomerate.

Pre-Cambrian (lower Huronian): Western Ontario.

A. C. Lawson, 1913 (Canada Geol. Surv. Mem. 40, p. 59).

F. F. Grout, 1926 (Minn. Geol. Surv. Bull. 21). Ogishke cgl. is same as "Seine" cgl. of Lawson.

Seine River series.

Pre-Cambrian: Western Ontario.

F. D. Adams, 1915 (Problems of American geology, p. 56).

Selenurus limestone.

A paleontologic name applied in early N. Y. repts to Onondaga ls.

Seligman limestone.

Permian: Northwestern Arizona (Aubrey Cliffs).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 338). *Seligman lss.* is suggested for the calc. strata in lower part of Supaian series as exposed best perhaps in Aubrey Cliffs, near Seligman. Thickness 500 ft.

†Selinsgrove upper sandstone.

Middle Devonian: Central Pennsylvania.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 78–81). *Selinsgrove upper ss.*, a bed, 202 ft. thick, in Hamilton group. Lies 125 ft. [325 ft., J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2)] above Selinsgrove lower ss.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 78–81). *Selinsgrove upper ss.* is 202 ft. thick below Selinsgrove, Snyder Co., and to S. thickens to 300 ft. Finely exposed where N. C. R. R. cuts through just opposite town of Selinsgrove and 1 mi. below Selinsgrove Junction, Northumberland Co. Lies 950 ft. below top of Hamilton group and 125 ft. [325 ft., J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2)] above Selinsgrove lower ss.

†Selinsgrove lower sandstone.

Middle Devonian: Central Pennsylvania.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 78–81). *Selinsgrove lower ss.*: Hard gray ss. in 3 layers separated by thin shales. Below Selinsgrove, Snyder

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Co., it is 5 ft. thick, but to S. it thickens to 100 ft. Lies 125 ft. [325 ft., J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2)] below Selinsgrove upper ss. and 800 ft. above Selinsgrove upper ls., all of which are included in Hamilton group.

†Selinsgrove upper limestone.

Middle Devonian: Central Pennsylvania.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 78–81). *Selinsgrove upper ls.*—Below Selinsgrove, Snyder Co., is divided (descending): Light-gray impure ls. with dull fracture, 10 ft.; drab limy shales, 20 ft.; shaly impure ls., 10 ft. Overlies Marcellus sl. and lies 800 ft. below Selinsgrove lower ss.

†Selinsgrove lower limestone.

Middle Devonian: Central Pennsylvania.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 78–81). *Selinsgrove lower ls.*—Hard light-gray rock, somewhat impure, in layers 1 to 3 in. thick, interstratified with thin gray shales. Thickness 65 ft. below Selinsgrove, Snyder Co.; 100 ft. near S. line of Northumberland Co. Rests on Selinsgrove sh., and is overlain by Marcellus sl.

Same as Onondaga ls., the older name.

†Selinsgrove shale.

Lower Devonian: Central Pennsylvania.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 78–81, 363). *Selinsgrove sh.*—Light-gray sh. weathering into splintery-shaped pieces and containing at top a few thin layers of impure ls. Underlies Selinsgrove lower ls. Thickness 140 ft. Exposed about ¼ mi. below Selinsgrove Junction, Northumberland Co.

Same as Esopus sh., older name.

Selkirk series.

Pre-Cambrian: British Columbia.

G. M. Dawson, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 165, 171). *Selkirk series*, Cambro-Sil., British Columbia.

More recent Canada Geol. Surv. Repts (by Daly, Schofield, and others) assign these rocks to pre-Camb. They are included in Belt series by U. S. Geol. Survey.

Selkirk limestone.

Ordovician: Manitoba.

A. F. Foerste, 1929 (Denison Univ. Bull., vol. 29, No. 2, Sci. Lab. Jour., vol. 24, pp. 35, 37; and vol. 29, No. 7, p. 130). *Selkirk ls.*, Ord., Manitoba.

A. K. Miller, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 211). *Selkirk ls.* of Manitoba correlates with middle part of Bighorn fm., of Richmond age.

Selkirk volcanics.

Pleistocene and Recent: Yukon Territory.

H. S. Bostock, 1934 (Canada Geol. Surv. Summ. Rept. 1933, pt. A, p. 7).

Selkirkian period.

Selkirkic period.

Terms introduced by C. [R.] Keyes to cover the time of Selkirk series of Canadian geologists, and later expanded to include more than that series. (See Iowa Acad. Sci. Proc., vol. 21, p. 23, 1914; Pan-Am. Geol., vol. 44, p. 218, 1925.)

Sellersburg limestone.

Middle Devonian: Southern Indiana and north-central Kentucky.

E. M. Kindle, 1899 (Bull. Am. Pal., vol. 3, No. 12, pp. 8, 20, 110). *Sellersburg beds.*—Fine-grained calc. ss., with thin bed of ls. at top; 6 to 20 ft. thick. Overlain by black New Albany sh. and underlain by Jeffersonville ls.

Adopted by U. S. Geol. Survey as originally defined. Some writers have restricted name to upper part of fm. Includes Beechwood ls. memb.

[library stamp]

above (Sellersburg ls. restricted of Siebenthal) and Silver Creek ls. memb. below. Contains Hamilton fossils.

Named for Sellersburg, Clark Co., Ind.

Selma chalk.

Upper Cretaceous: Alabama, northeastern Mississippi, and western Tennessee.

E. A. Smith, L. C. Johnson, and D. W. Langdon, 1894 (Ala. Geol. Surv. Rept. Geol. Coastal Plain of Ala., pp. 15, 22, 27, 255, 276–286). *Selma chalk or Rotten ls.*—Of comparatively uniform composition. Gray to bluish argill. fossiliferous ls., traversed at intervals by beds of purer ls., harder in texture. In some places consists of dark-bluish clay marl. Thickness 0 to 1,200 ft. Underlies Ripley group and overlies Coffee (or Eutaw) group.

In western Tenn. and parts of northern Miss. overlies Coffee sand and underlies Ripley fm. In east-central Miss. and western Ala. overlies Tombigbee sand memb. of Eutaw fm. and for many years included all deposits up to the Eocene. In central Ala. overlies Tombigbee sand memb. of Eutaw fm. and underlies Ripley fm. To E. is replaced by Ripley fm. In NE. Miss. a tongue of the chalk (named Oktibbeha tongue) was described by Stephenson as overlying Ripley fm. (See L. W. Stephenson, U. S. G. S. P. P. 81, 1914, Ga. Geol. Surv. Bull. 26, 1911, and Wash. Acad. Sci. Jour., vol. 7, pp. 243–250, 1917, for explanation of relations to adjacent fms.) In April 1937 Stephenson proposed (and the U. S. Geol. Survey adopted) that the beds for many years called *Prairie Bluff tongue of Selma chalk* be raised to rank of a fm., called *Prairie Bluff chalk*, and redefined so as to include the beds previously called *Oktibbeha tongue of Selma chalk*, the latter name being discarded. This is a restriction of *Selma chalk* as defined by U. S. Geol. Survey since 1917. The Prairie Bluff chalk is uncon. on the Selma restricted. (See L. W. Stephenson and W. H. Monroe, A. A. P. G. Bull., 1937.)

Named for Selma, Dallas Co., Ala.

†Selma division (of Selma chalk).

Upper Cretaceous: Alabama.

E. A. Smith, 1903 (58th Cong., 1st sess., S. Ex. Doc. 19, pp. 12–20 and map). *Lower or Selma div. (of Selma chalk)*.—Clayey ls., in many parts a calc. clay instead of ls.; of dark-gray to bluish color, usually striped with lighter-colored purer ls. Underlies middle or Demopolis div. of Selma chalk and overlies Eutaw fm. Along Alabama River is seen in bluffs from Kings Landing to Selma and beyond.

Conflicts with use of Selma in broad sense. Later workers did not find it feasible to make the 3 subdivisions of the Selma indicated in above-cited rept. and the 3 names (*Selma div.*, *Demopolis div.*, and *Portland div.*) have been discarded. (See Ala. Geol. Surv. Spec. Rept. No. 14, 1926, p. 239.)

Named for exposures at Selma, Dallas Co.

Seminoe formation (iron bearing).

Pre-Cambrian: Southern Wyoming (Carbon County).

T. S. Lovering, 1930 (U. S. G. S. Bull. 811D). *Seminoe fm. (iron bearing)*.—A banded jaspery iron-bearing qtzite, a few ft. to 350± ft. thick, which lies uncon. on the early greenstone schists and is overlain by the late greenstone schists of Seminoe Mtns. Contains some interbedded schist. Probably of Archean age and sed. origin.

Seminole conglomerate.

Pennsylvanian: Central southern and central Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Seminole cgl.*—Lower 50 ft. cgl. of white chert in brown-sand matrix; upper 100 ft. brown ss. Overlies Holdenville sh. Is youngest Carbf. fm. in area.

R. W. Clark and C. M. Bauer, 1921 (A. A. P. G. Bull., vol. 5, pp. 282–292). Overlying Holdenville sh. in Ocmulgee dist. is a cgl. which in writers' opinion is to be correlated with Seminole cgl. as mapped by Taff in Coalgate folio. Its thickness is 15 to 355 ft. In some places the cgl. is at base, in other places at top, and in still other places it forms lenses in ss. It is overlain by 100 to 120 ft. of sh. that belongs to Tulsa group. [Tulsa group is older than Seminole cgl.]

G. D. Morgan, 1923 (Okla. Geol. Surv. Circ. 12). In Stonewall quad. [Pontotoc Co.] the *Seminole fm.* is 150± ft. thick and consists of (descending): (1) Almost unbroken greenish-blue sh., 15 to 30 ft.; (2) cgls. and sss. become thinner and percentage of sh. increases over No. 3, 70 to 85 ft.; (3) chert cgls. or coarse brown sss., "the 50-foot conglomeratic phase of type area," 30 to 50 feet. Overlies Holdenville fm. with local uncon. Is overlain by the newly discriminated Francis fm., to be described in forthcoming paper, the basal memb. of which is here named De Nay ls. memb. This ls. is included in Francis fm., instead of Seminole fm., because Taff did not mention any ls. memb. in the Seminole. It lies 150± ft. above base of Seminole fm., which is thickness of Seminole as given by Taff.

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 48). *Seminole cgl.* consists of 20 to 150 ft. of cgl. of white chert in brown matrix succeeded by brown ss. It extends NE. from central Pontotoc Co., crossing Seminole, Okfuskee, and Creek Counties.

Named for Seminole Nation, Okla., the typical area being in NW. corner of Coalgate quad., near edge of Seminole Nation.

Seminole sand member (of Simpson formation).

Ordovician: Central Oklahoma (Seminole County).

A. I. Levorsen, 1928 (Okla. Geol. Surv. Bull. 40BB). *Seminole sand memb.* (subsurface), 0 to 80 ft. thick, lies 20 to 175 ft. below top of Simpson fm. in Seminole Co. and 10 to 100± ft. above Wilcox sand memb. ("Second Wilcox" sand of oil fields). It is the "Wilcox" or "First Wilcox" sand of oil fields and is separated from underlying Wilcox sand memb. by dol. Is probably a lens, grading into dol. toward S. part of Co. and thinning out to N. and NE. parts of State. Distinguished from the older Wilcox sand by its dol. content and the uniformity and slightly smaller size of its sand grains.

T. E. Weirich, 1930 (A. A. P. G. Bull., vol. 14, No. 12, p. 1510). In Lovell pool, Logan Co., the "Seminole sand" is composed of green shales and sands; in Seminole dist. of sand; and in Maud and Ada dists. of dol.

Seneca limestone.

Middle Devonian: New York.

L. Vanuxem, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 275–278). *Seneca ls.*—So dark from carbonaceous matter as to be almost black. First met with in Seneca Co., where it is separate from all other masses of ls.; hence its name. Rests on 15 to 20 ft. of black brittle ls. terminated by one or two layers containing nodules of flint; "the layers below the flint I understand are the true 'cornitiferous rock' of Prof. Eaton." Is overlain by pyritiferous sl., slaty sh., and ss.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 292–295, 310). *Seneca ls.*—Fine-grained, compact, often brittle; contains thin layers and nodules of hornstone and a shaly stratum. Succeeds the gray crinoidal Onondaga ls. and in some instances alternates with it. Is recognized by its darker-blue color, fine texture, and homogeneous structure, generally very brittle. Uncon. underlies Marcellus shales.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept). *Seneca ls.* underlies Marcellus shales and overlies "Corniferous limerock" of Prof. Eaton, which rests on Onondaga ls.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 139–144). *Seneca ls.* underlies Marcellus shales and rests on Corniferous ls. Is terminal part of Corniferous ls., which rests on Onondaga ls. Reason for considering it a distinct rock was finding it in Seneca Co., the first year of the Survey, unconnected with any other rock, and subsequently in the third dist., containing in both districts *Strophomena lineata* in great abundance, none of which had then been discovered in any part of dist. below that rock.

In 1843 James Hall included this ls. in his "Corniferous ls.," which he treated as distinct from Onondaga ls. In 1846 E. Emmons included it, along with "Corniferous ls.," in Onondaga ls., as now universally recognized. Since then the name has practically fallen into disuse, although P. F. Schneider in 1894 called these lss. the *Seneca group.*

Seneca group.

See under *Seneca ls.*

Seneca quartz porphyry.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Green Lake County).

R. D. Irving, 1877 (Geol. Wis., vol. 2, p. 520). *Seneca (Pine Bluff) quartz porphyry.*—Occurs in sec. 2, T. 17, R. 11 E.

†Seneca chert. (In Boone limestone?)

Mississippian: Southwestern Missouri.

W. P. Jenney, 1894 (Am. Inst. Min. Engrs. Trans., vol. 22, p. 178). "Ore occurs in upper beds [of "Subcarboniferous" of SW. Mo.], designated as Cherokee ls. and *Seneca chert.*"

C. E. Siebenthal, 1907 (U. S. G. S. Joplin folio, No. 148, p. 4). Jenney in applying name "Seneca chert" presumably meant the chert herein called Grand Falls chert memb. of Boone ls., but his reference is too indefinite to satisfy demands of geologic terminology. The chert at Seneca [Newton Co.] is *not* to be correlated with the Grand Falls, and Seneca is preoccupied.

Seneca sandstone.

Seneca Red sandstone.

Seneca Creek sandstone.

Commercial terms applied to a ss. in Newark group of Md. (See E. B. Mathews, Md. Geol. Surv. vol. 2, pp. 199-208, 1898.)

Seneca Falls moraine.

Name applied to Pleist. moraine in central N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 627+, 1932.)

Senecan group.

Upper Devonian: New York.

J. M. Clarke and C. Schuchert, 1899 (Sci., n. s., vol. 10, pp. 874-878). *Senecan period or group* includes Portage beds, Genesee sh., and Tully ls., which are excellently exposed along shores of Seneca Lake, in Seneca Co.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), followed above definition.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), also 1924 (N. Y. State Mus. Bull. 251), excluded from top of Senecan (and from the Portage group) certain beds (Dunkirk sh., Gowanda sh., Laona ss., etc.) that had previously been included in Senecan (and in the Portage), and apparently also restricted Senecan at base, drawing its base at base of the Middlesex sh.

The present N. Y. State Survey draws top of *Senecan* at base of Dunkirk sh. to W., at base of Longbeards Riffs ss. in west-central part of State, and at base of Cayuta sh. memb. of Chemung fm. in central N. Y. (See W. Goldring, N. Y. State Mus. Hdb. 10, 1931, p. 369.)

Senora formation.

Pennsylvanian: Eastern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Senora ss.*—Brown ss., generally thick-bedded in N. part of Coalgate quad. and thin and shaly in SW. part of quad. Thickness 140 to 500 ft. Overlies Stuart sh. and underlies Calvin ss.

Named for old post village of Senora, which was located in S. part of Okmulgee Co.

Senorito sandstone lentil (in Chinle? formation).

Triassic (Upper): Central northern New Mexico (Sandoval County).

B. C. Renick, 1931 (U. S. G. S. W. S. P. 620). *Senorito ss. lentil.*—Consists of (descending): (1) Massive cross-bedded ss., with streaks of cgl. at several intervals, of tan color, with greenish tint, 33 ft.; (2) cgl. and ss., 4 ft.; (3) massive cross-bedded ss., tan, yellow, white, and greenish, 55 ft.; (4) at most places 10 ft. of ls. cgl. at base. Total thickness 13 to 92 ft. Well exposed in Senorito Canyon, western Sandoval Co. Lies 10 to 50 ft. above base of Chinle (?) fm.

Sensori agglomerate and limestone.

Oligocene: Panama and Costa Rica.

D. F. MacDonald et al., 1919 (A. A. P. G. Bull., vol. 3, p. 364).

Sentinel granodiorite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 125, map). Is less uniform in composition than most other intrusive bodies. In W. part of the zone crossed by Yosemite Valley the rock is relatively light-colored and homogeneous, but in E. part of valley it is darker and more streaky and contains many dark inclusions. Constitutes greater part of both walls of Yosemite Valley from Three Brothers nearly to Royal Arches and from the Fissures eastward to Glacier Point. Oldest known fm. of Tuolumne intrusive series. Next older than Half Dome quartz monzonite, and generally contains more biotite and hornblende than the Half Dome.

Named for fact that it composes Sentinel Rock.

Sentinel dolomite.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group*. Derivation of name not stated.]

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct., 1932, pp. 329–356). *Sentinel dol.*—White, slightly aren. dol., characterized by irregular patches or segregations of coarsely crystalline carbonates or, more rarely, chert. Thickness 100 ft. Conformably underlies Radcliff fm. and conformably overlies Wildrose fm.—all included in Telescope group (lower Paleozoic?). [Derivation of name not stated, but map shows the dol. on Sentinel Peak, southern part of Panamint Range.]

Sentinel Butte shale member (of Fort Union? formation).

Eocene: Southwestern North Dakota and northeastern Montana.

A. G. Leonard, 1908 (N. Dak. Geol. Surv. 5th Bien. Rept.). *Sentinel Butte coal group* of SW. N. Dak. is in upper part of Fort Union fm. and includes coals Q, R, S, T, and V. The underlying Beaver Creek coal group includes coals N, O, P.

W. T. Thom, Jr., and C. E. Dobbin, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 484, 495–497). *Sentinel Butte sh. memb. of Fort Union (?) fm.*—Is classed as Fort Union (?) by U. S. Geol. Surv., though regarded as Wasatch by [C. J.] Hares and the writers. Typically developed at Sentinel Butte [Billings Co.], N. Dak. Consists of dark clay shales resembling those of Hell Creek memb. of Lance fm. and Lebo sh. memb. of Fort Union fm. Overlies Tongue River memb. of Fort Union fm. and underlies Ulm coal group of Wasatch fm. Is essentially=Intermediate coal group of northern Wyo. plus Roland coal bed and to lower part of Kingsbury cgl., which overlaps on granite core of Big Horn Mtns. This uncon. overlap C. H. Wegemann (personal communication) regards as marking base of Wasatch. In northern Wyo. and southern Mont., and perhaps in Dakota areas as well, the base of Sentinel Butte sh. is marked by Roland coal beds.

C. J. Hares, 1928 (U. S. G. S. Bull. 775). *Sentinel Butte sh. memb. of Fort Union (?) fm.* is 325± ft. thick in Marmarth field, SW. N. Dak., and consists of dark, somber sandy sh., gray ss., and lignite interbedded. Overlies Tongue River memb. of Fort Union fm. and uncon. underlies White River (?) fm. The Bullion Creek lignite bed lies near top and HT lignite bed at base.

Sequatchie formation.

Upper Ordovician (Richmond): Eastern Tennessee, southwestern Virginia, and northeastern Alabama.

E. O. Ulrich, 1912 (12th Int. Geol. Cong., Canada, pp. 614, 646, 647, 648, 649, 651, 665, and plate). *Sequatchie fm.*—Local designation for all deposits of Richmond age in southern Appalachian Valley. Consists of red shales and argill. lss., heavier-bedded in upper part. Uncon. overlies Fairview fm. and uncon. underlies Clinch ss. Eastern border of the Sequatchie is usually confined to Clinton trough. Is equiv. to Arnheim, Waynesville, Liberty, Whitewater, and Elkhorn stages of Ind. and Ohio. The Juniata attains its greatest development in central Pa. and thins southwardly. Nearing the border of Tenn. it seems to pass into the more calc. Sequatchie fm., in which facies the deposits of this age extend into NE. Ala.

The present accepted definition of Sequatchie fm. limits it to marine limy beds W. of Powell's Valley, in eastern Tenn., SW. Va., and northern Ala., which are the time equiv. of Juniata ss. of Clinch Mtn and northward. In SW. Va. and NE. Tenn. it is overlain by Clinch ss. and underlain by Reedsville sh.

Sequoyah formation. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44). *Sequoyah fm.*—Sss. and shales overlying Dotson ss. and extending up to top of a heavy ss. 450 ft. above base of fm. Includes some coal seams. Underlies Tellowa fm. [Type loc. not stated and unknown.]

†Seral series.

Pennsylvanian: Appalachian region.

H. D. Rogers, 1844 (Am. Jour. Sci., 1st, vol. 47, p. 156). *Seral series* embraces one vast and multiform body of coal strata, 3,000 ft. thick in western Pa. and Va. and probably still thicker in the anthracite basins. Consists of (1) the *true coal fm.* (divided into following 4 distinct members, i. e., new shales, new coal measures, older shales, and older coal measures); and (2) the *Seral cgl.* [Pottsville fm.], the great cgl. under the coal measures. Overlies Vespertine series. [Nongeographic name for all of Penn. rocks of Pa. and Va.]

H. D. Rogers, 1858 (Geol. Pa., vol. 1, pp. 109, 146–148+; vol. 2, p. 758), introduced "Umbral series or Middle Carboniferous," for 3,000± ft. of fossiliferous soft red shales and red sss. previously included in his Vespertine series, and described the siliceous cgl. or millstone grit forming basal memb. of his Seral series as resting on Umbral series [Mauch Chunk sh.].

Named to indicate "twilight period of the great Appalachian Palaeozoic day," according to Rogers, 1844 citation above.

†Seral conglomerate.

See under *†Seral series.* As used in some early repts "Seral cgl." applied to all of Pottsville fm., and in other repts to only the upper (Homewood) ss. memb. of the Pottsville.

Sergeant shale.

Upper Cretaceous: Northwestern Iowa.

C. [R.] Keyes, 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 148, 150). *Sergeant shales.*, 75 ft. thick, underlie Ponca ss. and overlie Nishnabotna ss. All included in Dakotan series.

Named for Sergeant Bluff, Woodbury Co.

Serge Island marble.

Upper Cretaceous: Jamaica.

C. T. Trechman, 1936 (Geol. Mag., No. 864, vol. 73, No. 6, p. 258).

Serna schist.

Pre-Cambrian: Central northern New Mexico (Santa Fe region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 11). *Serna schists.*—Basal part of Archeozoic section near Picuris, N. of Santa Fe, on W. flank of Rocky Mtns. Thickness 1,500 ft. [Derivation of name not given.]

Serpent quartzite.

Pre-Cambrian (Huronian): Western Ontario.

W. H. Collins, 1916 (Canada Geol. Surv. Mus. Bull. 22, p. 4). Included in Bruce series.

Sespe formation.

Oligocene and upper Eocene: Southern California (Ventura County).

W. L. Watts, 1897 (Calif. State Min. Bur. Bull. 11, pp. 22–38). *Sespe brownstone fm.*—Ss., shales, and cgl., all more or less brown. Widely exposed in Sespe dist. Underlain, with apparent conformity, by white ss., and overlain, also with apparent conformity, by drab ss. Is of Tert. age, and younger than rocks containing Eo. fossils and older than beds containing Mio. fossils.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753). *Sespe fm.*—Nonmarine red, brown, and yellow cgl. and ss. with interbedded sh. Corresponds to Sespe brownstone fm. of Watts. Thickness 3,500 ft. at type loc. on Sespe Creek, in NW. part of Camulos quad. Ranges up to 4,000 or more ft. Conformably underlies marine Vaqueros fm. (with true Vaqueros—*Turritella inezana*—fauna), and uncon. overlies marine Tejon fm. Top 500 ft. of Tejon consists of light-gray ss. with some sh. and corresponds to "white ss." of Watts. The Vaqueros corresponds to "drab ss." of Watts. Typical Sespe corresponds to middle memb. only of Sespe fm. of G. H. Eldridge and R. Arnold, as mapped and described in U. S. G. S. Bull. 309, 1907.

The Sespe fm. and overlying and underlying fms. are exposed in gorge of Sespe Creek near entrance of Tar Creek and in region that extends E. btw. waters of Tar and Little Sespe Creeks.

Seth limestone. (In Kanawha formation.)

Pennsylvanian: Southwestern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 168). *Seth ls. of Krebs* (C. E. Krebs, Boone Co. Rept. W. Va. Geol. Surv., 1914 [1915]), belonging, at its type loc. near Seth, in Boone Co., 15 to 20 [25 in later repts] ft. below Williamson coal, 35 to 50 ft. below Dingess ls., and 180 ft. above base of lower bench of Campbell Creek (No. 2 Gas) coal, was not observed in territory covered by this rept. where it is evidently replaced by Upper Cedar Grove ss. [Later repts state that in some areas the Seth ls. occurs in sh. underlying the Upper Cedar Grove ss.]

Setters formation.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania, Maryland, Virginia.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Rept., vol. 1, pp. 130–132). *Setters Ridge quartz schist or qtzite*, extensively quarried N. of Baltimore, and affording at many other places a definite geological horizon. Always perfectly foliated by parallel muscovite-mica layers, at variable distances from each other, with plenty of stretched and broken tourmaline crystals in the foliation planes.

G. H. Williams and N. H. Darton, 1892 (U. S. G. S. map of Baltimore and vicinity, to accompany "Guide to Baltimore" prepared for Baltimore meeting Am. Inst. Min. Engrs., Feb. 1892). *Setters quartz schist.*—A peculiar schist composed mostly of quartz and divided into beds of varying thickness by parallel layers of muscovite. Underlies Cockeysville marble and overlies Baltimore hornblende gneiss. Most characteristic occurrence is in Setter's Ridge.

W. B. Clark, 1904 (Md. Geol. Surv. map of Harford Co., Md.) gave thickness of *Setters qtzite* as 750 ft.

The Glenarm series was formerly classified by U. S. Geol. Survey as belonging to "Algonkian system," but that term having been discarded it is now classified as pre-Camb.

Setters Ridge quartzite.

Same as *Setters fm.*

Seven Devils volcanics.

Permian: Central Idaho (Seven Devils region).

W. Lindgren, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, pp. 193–198, pl. 8). *Seven Devils series.*—Strongly compressed slates and crystalline ls. accompanied by large masses of Mesozoic or Paleozoic effusive rocks and schists derived from these. Poor in fossils. Probably Carbf. [Mapped over large area at and around Seven Devils. According to C. P. Ross (personal communication, April 1933) the "effusive rocks and schists" correspond to Seven Devils volcanics of Anderson.]

A. L. Anderson, 1930 (Idaho Bur. Mines and Geol. Pam. 34). *Seven Devils volcanics* [in text], *Seven Devils series* [on map].—The Perm. rocks of Orofino region are a continuation of those in Seven Devils region and Snake River Canyon, where they are dominantly of volcanic origin, mainly andesitic flows and pyroclastics with some fossiliferous calc. tuffs bearing a Phosphoria fauna. This lava group is herein designated *Seven Devils volcanics*, from type loc. in Seven Devils Mtns. Thickness probably more than a mile. They outcrop in 3 places in SW.

part of Orofino dist. As a whole the rocks are greatly altered and in most places resemble greenstones; apparently the series includes both surface lava flows, mainly of andesitic composition, and intrusive dikes and stocks of dioritic and gabbroic composition; the dikes and stocks cut the flows in a bewildering fashion; some of intrusives are probably much later than the flows and probably related to Triassic or Jurassic activity. Overlain, discon., by Triassic (?) rocks in Snake River Canyon.

†seven-foot tier.

A term applied in early N. Y. repts to post-Lowville part of Black River group. See under *Watertown ls.*

Seven Rivers gypsiferous member (of Chalk Bluff formation).

Permian: Southeastern New Mexico (Pecos Valley).

O. E. Meinzer, B. C. Renick, and Kirk Bryan, 1926 (U. S. G. S. W. S. P. 580–A, pp. 6–7, 13–15, and map). *Seven Rivers gypsiferous memb. of Chupadera fm.*—The upper 60 ft. or more consists of interbedded greenish limy sh. and ls., which in places changes laterally into ls. breccia; W. of Atchison, Topeka & Santa Fe Railway tracks the breccia becomes a persistent bed. Lower part of Seven Rivers memb. consists of an undet. thickness, but at least 100 ft., of thick beds of gyp. and associated red sand and sh. The Seven Rivers is basal memb. of Chupadera fm. as exposed in Carlsbad region, where it underlies Carlsbad ls. memb. of the Chupadera.

A. G. Fiedler and S. S. Nye, 1933 (U. S. G. S. W. S. P. 639). *Seven Rivers tongue of Pecos fm.*—Underlies Carlsbad ls. tongue of Capitan ls. and is underlain by basal deposits of Pecos fm.; in places it rests on Picacho ls.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7), made following changes: (1) Divided the rocks formerly called *Pecos fm.* into several fms. (see under *Pecos fm.*); (2) abandoned *Pecos;* (3) introduced *Chalk Bluff fm.* for the beds overlying San Andres ls. memb. of Chupadera fm. and underlying Castile anhydrite in Pecos Valley, where the Castile is only the upper attenuated part of the Castile of Delaware Basin; (4) redefined *Seven Rivers gypsiferous memb.* by removing its upper part, which he named *Three Twins memb.* of Chalk Bluff fm.; (5) showed Seven Rivers and Three Twins members as composing upper part of Chalk Bluff fm., the Seven Rivers resting on Queen ss. memb. of Chalk Bluff fm.; (6) introduced *Azotea tongue of Carlsbad ls.* for the tongue of ls. that separates the Seven Rivers and Three Twins members. This is present approved classification of U. S. Geol. Survey.

†Seven Sisters sandstone.

Pennsylvanian: Eastern Kentucky (Middlesboro coal field).

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, p. 119), inadvertently failed, in one place, to change "Seven Sisters ss.," which in ms. they had originally used but later discarded for *Naese ss. memb.*, the present approved name for the ss., which is also exposed at a well-known geographic feature on Cumberland River that is known as Seven Sisters.

Severn formation.

Upper Cretaceous and Eocene: Eastern Maryland.

N. H. Darton, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 431, 438). *Severn fm.*—The continuous southern extension of the N. J. Cret. green sand series, but whether it represents all or part of these members is not yet determined. In Md. it is a strat. unit, distinctly separable from the N. J. series as a whole by its homogeneity of constitution, and it is with this restriction that the term Severn is applied. Consists almost entirely of fine black sand, more or less flecked with scales of mica, very sparingly but irregularly glauconitic, and usually containing considerable carbonaceous materials. Thickness 10 to 100 ft. Exposed in high cliffs at Round Bay on Severn River. Uncon. underlies Pamunkey fm. and uncon. overlies Potomac fm. [group].

N. H. Darton, 1893 (Am. Jour. Sci., 3d, vol. 45, pp. 407–419). *Severn fm.* (mapped) is separated from underlying Magothy fm. by an erosion uncon.

N. H. Darton, 1896 (U. S. G. S. Bull. 138, pp. 124–126). *Severn fm.*—Black argill. and carbonaceous sands, 3 to 150 ft. thick. Underlies Pamunkey fm. and overlies Magothy fm.

Discarded by U. S. Geol. Survey. Includes Rancocas fm. (Eo.) and Monmouth and Matawan fms. (Upper Cret.), which have been separated.

Severn limestone.

Silurian: Ontario (Hudson Bay region).

A. F. Foerste and T. E. Savage, 1927 (Denison Univ. Bull., Sci. Lab. Jour., vol. 22, pp. 6, 14).

Severn River limestone.

Silurian: Canada.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 341, 359, 367).

Severy shale. (In Shawnee group, Kansas.)

Severy shale member (of Shawnee formation, Missouri).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

E. Haworth, 1898 (Kans. Univ. Geol. Surv., vol. 3, p. 66). *Severy shales* proposed by G. I. Adams in field notes, for shales, 50 to 75 ft. thick, overlying Elk Falls ls. and underlying Howard ls. in Chautauqua, Elk, and Greenwood Counties, Kans. With Howard ls. it forms light escarpment traceable from Eureka to Cedar Valley.

Was for many years treated as a memb. of Shawnee fm. In Kans. the Shawnee is treated as a group and the Severy as a fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 203, 206). Shunganunga sh. of Beede is unnecessary name. The few ft. of beds to which it was applied are included, without differentiation, in Severy sh. where Bachelor Creek ls. memb. of Howard ls. is absent. Where Coal Creek memb. of Topeka ls. is recognized, the Severy rests on it. Where Hartford is only memb. of Topeka represented, the lower bdy of Severy is top of Hartford ls. Severy is here treated as basal fm. of Wabaunsee group.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for Severy, Greenwood Co., Kans., which is built on this sh.

Sevier shale. (In Blount group.)

Lower Ordovician (late Chazy): Eastern Tennessee, western North Carolina, and southwestern Virginia.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 4). *Sevier sh.*—Shales overlying Tellico ss. and underlying Bays ss. in Knoxville quad., Tenn. As a whole is a thick series of calc. yellow shales, weathered from light-blue shaly ls. Is similar to Athens sh. With it occur occasional beds of gray ls. or variegated marble and beds of sandy sh. and calc. ss. SE. of Knoxville it consists of 200 to 300 ft. of gray argill. ls., gray and variegated marble, and shaly ls. overlain by 1,000 to 1,200 ft. of calc. yellow shales with occasional thin ls. beds and sandy shales. North of Montvale Springs there are two heavy beds of sandy sh. and calc. ss. interbedded with light-blue shaly ls. The shales are precisely like Athens sh. and the sss. very similar to Tellico ss. Passing NE. the sss. diminish in thickness and are more interbedded with shales. Fossils similar to those of Chickamauga ls. are common in the lss. and marbles of this fm.

Foregoing is original definition in type area. The name, however, first appeared in print in 1894, in a paper on SW. Va. by M. R. Campbell (Geol. Soc. Am. Bull., vol. 5, p. 176, pl. 4), who accepted Keith's name and correlated the rocks of SW. Va. with those of Knoxville quad., Tenn. As described by Campbell, the fm. in SW. Va. underlies Bays ss. and overlies Shenandoah ls. The name was also used by Campbell in U. S. G. S. Estillville folio (No. 12), published in 1894, where the fm. is described as 440 to 4,000 ft. thick; consisting of yellow or blue calc. sh., becoming quite sandy in upper part to SE.; basal part N. of Clinch River consisting of few ft. to 800 ft. of black sh.; underlies Bays ss. and overlies Chickamauga ls. N. of Clinch River and Moccasin ls. S. of Clinch River.

The Ottosee sh. of Ulrich is basal calc. memb. of typical Sevier sh. In early repts and folios of SW. Va. the younger Martinsburg sh. was erroneously mapped as Sevier sh.

Named for exposures in Sevier Co., Tenn.

Seville limestone. (In Pottsville formation.)

Pennsylvanian: Central western Illinois (Fulton County).

H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 3, p. 805), showed *Seville ls.* above coal No. 1, in basal part of Penn. [Pottsville] of western Ill.

J. E. Lamar and H. B. Willman, 1934 (Ill. Geol. Surv. Bull. 61, p. 135). *Seville ls.* of Fulton Co., which lies above Rock Island (No. 1) coal, locally reaches thickness of 5 to 20 ft., but is absent in places.

Probably named for Seville, Fulton Co.

Seville cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a portion of middle part of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 1. Derivation of name not stated.

Sevy dolomite.

Middle Devonian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Sevy dol.*—Remarkably homogeneous throughout. Typical rock a well-bedded light mouse-gray dol. in layers 6 to 12 in. thick, which weathers very light gray; extremely dense; breaks with conchoidal fracture; most beds show faint lamination parallel to bedding. The fm. contains a few beds of darker dol. near top and locally beds containing tiny nodules of light-colored chert. Basal bed is conglomeratic. Thickness 450± ft. No diagnostic fossils. Grades into overlying Simonson dol., which contains Middle Dev. fossils. Overlies, uncon., Laketown dol., of Sil. age. Named for exposures in Sevy Canyon, on W. side of Deep Creek Range, Gold Hill region.

See also U. S. G. S. P. P. 177, 1934.

Sewanee conglomerate. (In Lee group.)

Pennsylvanian (lower Pottsville): Southern Tennessee.

J. M. Safford, 1893 (Tenn. State Bd. Health Bull., vol. 8, No. 6, pp. 89–98). *Sewanee cgl.*—As studied at Sewanee the cgl. is a heavy-bedded ss., abounding in white quartz pebbles of various shapes, from size of buckshot to that of pigeon's eggs and larger, which are scattered through it like plums in a pudding, the pebbles being in places so numerous that the rock is quarried for pebble gravel. Very generally a thickness of 3 to 24 in. of very base of the cgl. is a hard iron rock, a ferruginous cgl. The Sewanee cgl. caps Sewanee Plateau and rests on shales, with occasionally a bed of clay and a few in. of coal at some points on the mtn. Thickness 25 to 100 ft.; average about 60 ft.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., p. 150). *Sewanee cgl.*—The great cgl. on which Sewanee, the site of the University of the South, is located. Forms topmost stratum of Bon Air Measures. [Later work by C. Butts showed that the cgl. forming topmost stratum of Bon Air Measures of Safford in type loc. is not Sewanee cgl. but the much younger Bonair ss., and that all of †Bon Air Measures are above true Sewanee cgl.]

Overlies Gizzard fm. and underlies Whitwell sh. Thickness 200 ft. Is= upper part of Lookout ss.

Sewell formation. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell and W. C. Mendenhall, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, pp. 487, 494). *Sewell fm.*—Shales and sss. overlying Raleigh ss. and underlying

Fayette [Nuttall] ss. along New and Kanawha Rivers, W. Va. Includes Sewell coal, about 70 ft above base. Thickness of fm. 280 to 650 ft.

Comprises all of middle Pottsville in region described. Later definitions include at top the Nuttall ss. memb., which is same as Fayette ss. (preoccupied) of Messrs. Campbell and Mendenhall.

Named for Sewell, Fayette Co., W. Va.

†Sewell formation. (In Rancocas group.)

Eocene: New Jersey.

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 316–338). *Sewell marls*.—Dark greensand marls, with glauconite thickly disseminated. Thickness 20 to 30 ft. Basal div. of Rancocas fm. Overlies Monmouth fm. and underlies Vincentown limesands, the top div. of Rancocas fm. Named for Sewell, Gloucester Co.

This name being preoccupied, it was replaced by *Hornerstown marl*, which is now classified as a fm. of Rancocas *group*.

†Sewickley limestone. (In Monongahela formation.)

Pennsylvanian: Western Pennsylvania and Maryland and northern West Virginia.

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_5, pp. 55–104, 286). *Sewickley ls.*, 8 to 10 ft. thick, is middle memb. of Pittsburg ls. group, and lies 90 ft. above Pittsburg coal. It is lower than Sewickley coal and higher than Redstone coal.

J. J. Stevenson, 1877 (2d Pa. Geol. Surv. Rept. K_2). *Fish-pot or Sewickley ls.*, 25 ft. thick, lies 30 ft. below Sewickley coal and 20 ft. above Redstone coal.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 61–62). I have deemed it preferable to apply the name *Sewickley ls.* to the whole ls. group which lies btw. the Sewickley and Redstone coal beds.

The Sewickley ls. of Platt and Stevenson is same as Fishpot ls. memb. of Monongahela fm., the older name.

Sewickley sandstone member (of Monongahela formation).

Pennsylvanian: Southwestern Pennsylvania, western Maryland, and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 60). *Sewickley ss.*—Flaggy, also massive and even pebbly ss., 0 to 60 ft. thick. Overlies Sewickley coal and underlies "Great" [Benwood] ls., 160± ft. thick. Its massive character is well shown along Monongahela River btw. Morgantown and Fairmont [W. Va.], in vicinity of Big Falls.

Sewickley member. (In Monongahela formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa., No. 27, Pittsburgh quad., p. 31, 1929) to include Benwood ls. and Sewickley coal [btw. which occurs Sewickley ss.].

Sextant formation.

Devonian: Ontario.

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 341, 374, 375).

†Sexton terrane (also †Sexton limestone).

An abbreviated form of *Sexton Creek ls.* employed by C. [R.] Keyes.

Sexton Creek limestone.

Silurian (early): Southwestern Illinois and eastern Missouri.

T. E. Savage, 1909 (Am. Jour. Sci., 4th, vol. 28, p. 518). *Sexton Creek ls.*—Lss. of Niagaran (Clinton) age, 16 to 70 ft. thick, in Alexander Co., Ill. Lower part thin layers of hard gray ls. and chert interbedded; upper part thicker layers of pink or reddish, mottled subcrystalline ls. Separated from underlying Edgewood ls. of Alexandrian series by 2-in. band of red residual clay. Uncon. underlies Dev. Helderbergian series. Named for exposures on Sexton Creek, Alexander Co., Ill.

T. E. Savage, 1910 (Ill. Geol. Surv. Bull. 16, pp. 304–341). *Sexton Creek ls.* was proposed to include all strata in this part of Miss. Valley [SW. Ill.] that belong to Clinton group. Fossils correlate it with Clinton of Ohio and Ind., which is probably as low as any Clinton previously described.

T. E. Savage, 1913 (Ill. Geol. Surv. Bull. 23). *Sexton Creek ls.* of Ill. and Mo. is=Brassfield ls. of Ohio, formerly included in Clinton but now known, by fossils, to be pre-Clinton. Sexton Creek and Brassfield are both now considered top fm. of Alexandrian series. The Sexton Creek overlies Essex ls. with a possible break in deposition.

T. E. Savage, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 111–112), divided his Alexandrian series into (descending) *Sexton Creek (Brassfield) ls.*, Essex ls., Edgewood ls., and Girardeau ls., and stated "the several fms. are uncon. among themselves." [On later pp. (353+) he used *Sexton Creek ls.* in NE. Ill.]

T. E. Savage, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 305–324). *Sexton Creek ls.* is restricted to rocks in southern basin, and *Kankakee ls.* (new name) introduced for contemp. deposits in NE. Ill., western Ill., and eastern Mo. N. of St. Louis.

T. E. Savage and M. L. Nebel, 1923 (Ill. Geol. Surv. Bull. 43). *Sexton Creek ls.*, 50 to 70 ft. thick, was deposited in sea that advanced from S. as far N. as Jackson Co. The sea that deposited *Kankakee ls.* at about same time invaded from E. or NE. and extended as far as Calhoun and Jersey Counties, Ill.

T. E. Savage, 1926 (Ill. Acad. Sci. Trans., vol. 19, pp. 286–287). *Sexton Creek (Brassfield) ls.* extends as far N. as Belvidere, near N. border of State [in McHenry Co.].

T. E. Savage, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 526+). Writer now believes that all Alexandrian strata in Ill. and Iowa were deposited in a sea that advanced from S., and thus belong to same province as Alexandrian strata in SW. Ill. [But he used *Kankakee (Brassfield) ls.* in NW. Ill. and *Sexton Creek (Brassfield) ls.* in SW. Ill., and discarded his Waucoma ls. for Kankakee and discarded his Winston ls. for Edgewood. A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 270–274), also used *Kankakee ls.* in NE. and NW. Ill.]

Seymour formation.

Pleistocene: Central northern Texas.

W. F. Cummins, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 181–190). *Seymour beds.*—Unstratified beds of sandy clay, few ft. to 50 ft. thick, in Baylor and Knox Counties. Overlies Permian red beds. Often at base beds of sandy pebbles cemented into solid masses by lime.

Named for Seymour, Baylor Co.

Shabu series.

Pre-Cambrian: Ontario.

G. D. Furse, 1934 (Ont. Dept. Mines 42d Ann. Rept., pt. 6, p. 24).

Shades sandstone member (of Pottsville formation).

Pennsylvanian: Central Alabama.

C. Butts, 1910 (U. S. G. S. Birmingham folio, No. 175, pp. 10, 11). *Shades ss. memb.*—Thick-bedded, rather coarse ss., generally somewhat conglomeratic in lower part. Thickness 200 ft. Basal ss. memb. of Pottsville fm. in Cahaba and Coosa coal fields. Either rests on Brock coal or is separated from that coal by 50 ft. of shale.

Named for presence on Shades Mtn, Jeffersonville Co.

Shadrick Mill sandstone. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 376). *Shadrick Mill ss.*—Ss., usually massive but with some flaggy beds and a thin cgl. Thickness 150 feet. Memb. of Strawn div. Overlies Elliott Creek bed and underlies bed No. 8 (250 to 300 ft. of clay interstratified with ss. at base).

Named for Shadrick Mill, Lampasas Co.

Shady dolomite.

Lower Cambrian: Eastern Tennessee, northern Alabama, northwestern Georgia, western North Carolina, and southwestern Virginia (as far north as Roanoke).

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 5). *Shady ls.*—Thick and massive beds of gray, bluish-gray, and mottled-gray ls., with nodules and masses of black chert, and a few beds of almost white ls. or marble. Thin seams of blue and gray sh. occur in many parts of fm., and in upper layers a few beds of red sh. make transition to overlying Watauga sh. Thickness 750 to 800 ft. Overlies Erwin qtzite.

In most areas the Shady is almost wholly dol. In Ala. it rests on Weisner qtzite.

Named for Shady, Johnson Co., Tenn.

†Shafer limestone.

A name applied locally, in Moab region, central eastern Utah, to a marine ls. 0 to 25 ft. thick, in places lying at top of Rico fm. (Permian) and in other places 10 ft. below top of Rico. Named for Shafer dome, but impossible to identify the ls. in other nearby domes of the region, according to J. B. Reeside, Jr. (personal communication). (See also A. A. Baker, U. S. G. S. Bull. 841, 1933.)

Shaffer shale.

Middle Devonian: West-central New York (Ontario County).

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, table and p. 22). In Ontario Co. the succession of Hamilton beds is (ascending) *Shaffer sh.* (=Skaneateles sh.), Centerfield ls., Canandaigua sh. (=Ludlowville sh.), Encrinal (Tichenor) ls., and Moscow sh.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63). The Skaneateles sh. is evidently continuous into Canandaigua area, and hence that name is employed for it rather than *Shaffer sh.*

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 217–219), replaced *Shaffer sh.* with *Levanna sh.*, because latter type loc. afforded better exposures. See under *Levanna sh.*

These are the only records of *Shaffer sh.* or *Levanna sh.*

Shafter limestone. (Of Trinity group.)

Lower Cretaceous (Comanche series): Western Texas (Presidio County).

J. A. Udden, 1904 (Univ. Tex. Min. Surv. Bull. 8, pp. 10, 11, 25, 30–39). *Shafter beds.*—Alternating lss., stony marls, clays, and fine-grained straight-bedded lenticular masses of yellow and brown sss. Thickness 700 ft. Lower Cret. fossils. Underlie Edwards ls. and overlie Presidio beds. Lower 400 or 500 ft. are=Glen Rose; upper part believed to belong to horizon of Walnut clays.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745). All but uppermost part of *Shafter beds* are=Finlay ls.

C. P. Ross and W. E. Cartwright, 1935 (Univ. Tex. Bull. 3401, pp. 577, 586). *Shafter ls. (restricted)*.—Chiefly ls., 1,075± ft. thick. A restriction of Udden's *Shafter beds*, by excluding Walnut fm., here for first time mapped separately. Rests uncon. on Presidio fm. Is all of Trinity age and appears to be identical with Glen Rose ls. If detailed study of fossils confirms Glen Rose age, the local name Shafter ls. may be dropped.

Named for Shafter, Presidio Co. Exposed in and around the town.

Shaggy Peak rhyolite.

Tertiary (Eocene?): Central northern Utah.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, pp. 59–60). Shaggy Peak, Fairfield quad., is entirely composed of the intrusive rock here named *Shaggy Peak rhyolite*.

Shakopee dolomite. (In Prairie du Chien group.)

Lower Ordovician: Southern Minnesota and Wisconsin, Iowa, and northern Illinois.

N. H. Winchell, 1874 (Minn. Geol. and Nat. Hist. Surv. 2d Ann. Rept., pp. 138–147). *Shakopee ls.*—Mag. ls. alternating with calc. ss. Thickness in Minn. Valley 70 ft. Is uppermost memb. of Lower Magnesian [later named *Prairie du Chien group*]. Outcrops at Shakopee [Scott Co., Minn.]. Rests on ss. seen at Jordan—the Jordan ss.

The ss. upon which this uppermost memb. of †Lower Mag. rests was in foregoing rept mistaken for the older Jordan ss. In 1882 Wooster, in describing the †Lower Mag. rocks of St. Croix Valley, Wis., applied *Willow River beds* to uppermost memb. and *New Richmond ss.* to underlying ss. In 1886 (Minn. Geol. and Nat. Hist. Surv. 14th Ann. Rept., pp. 334–337) Winchell corrected his miscorrelation of the white ss. underlying his Shakopee ls. with Jordan ss., and adopted for it Wooster's name *New Richmond ss.* Winchell's name *Shakopee* continued to be used (usually for the beds above New Richmond ss., but in some early repts for all of the †Lower Mag.) in Minn., Wis., and Iowa repts, and *Willow River* was not again used until revived by Powers in 1935. (See under †*Willow River ls.*)

In 1889 (Minn. Acad. Nat. Sci. Bull., vol. 3, pp. 125–136) C. W. Hall applied †*Shakopee A* to the dol. beds in Minn. now known as Shakopee dol., †*Elevator B* to a ss. at their base, and †*Shakopee B* to the dol. now known as Oneota dol. In 1891 (U. S. G. S. 11th Ann. Rept., pt. 1) W J McGee applied *Oneota ls.* to the beds underlying New Richmond ss. of Wis. and Minn. repts and overlying the Jordan ss. (or the beds which had been called "Shakopee B" by C. W. Hall), and applied *Shakopee ls.* to the beds underlying the St. Peter ss. and overlying the New Richmond ss.

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 65–73). If the beds exposed at Shakopee are not in reality Oneota, evidence to contrary is paleontological. If Shakopee is to be retained for uppermost part of the Prairie du Chien, it should be recognized that the outcrops at Shakopee may not be included in it. If it should prove true that the beds at Shakopee belong in lower part of the dol. rather than in upper part, Shakopee could not properly be applied to upper part of the Prairie du Chien. In that case it might be advisable to discard *Shakopee* and return to Wooster's name *Willow River beds*. However, Wooster's name for these beds has not come into general use, and the Oneota is much thicker and more conspicuous in the section along Willow River than are these younger [Shakopee] beds. On the whole it seems best to continue to use *Shakopee* for these younger dolomites and sss., at least until the age of the beds at Shakopee is conclusively determined.

E. H. Powers, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 171), gave detailed section of the rocks exposed at Shakopee, Minn., in which he identified: Willow River dol. [Shakopee], 61 ft.; New Richmond ss., 2 ft.; Oneota dol., 126 ft.

In Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, *Willow River* is used in Iowa and Wis., by Powers and Trowbridge, but does not appear to have been adopted by the Ill., Minn., and Wis. Geological Surveys. (See fig. 2, pp. 83, 172–174.) G. M. Kay, however, adopts it (p. 283), although he stated (p. 282) that Stauffer (Jour. Geol., vol. 42, 1934, pp. 347–352) has rechecked the section at Shakopee "and concludes that Winchell was correct in classifying the outcropping beds as younger than the New Richmond and calling them Shakopee." Kay also says (p. 283) the type section of Shakopee "may be of Oneota age."

†Shakopee A limestone.

A term applied by C. W. Hall (Minn. Acad. Nat. Sci. Bull., vol. 3, pp. 125–136, 1889) to the beds now known as *Shakopee dol.*

†Shakopee B limestone.

A term applied by C. W. Hall (Minn. Acad. Nat. Sci. Bull., vol. 3, pp. 125–136, 1889) to the beds now known as *Oneota dol.*

†Shakopee group.

A term employed by F. W. Sardeson (Pan-Am. Geol., vol. 41, btw. pp. 107 and 122, 1924) to include Shakopee dol. and Oneota dol., instead of *Prairie du Chien group*, which he considered objectionable.

Shaktolik group.

Upper Cretaceous: Southwestern Alaska (Lower Yukon and Norton Bay-Nulato region).

P. S. Smith and H. M. Eakin, 1911 (U. S. G. S. Bull. 449, p. 57). *Shaktolik group* (so called after river of that name, which affords good section of the beds) includes thick series of sss., shales, and grits, lying btw. Ungalik cgl. below and top of sed. series in Norton Bay-Nulato region. Divided into a lower sandy div. and an upper shaly div. Includes Nulato sss. of Dall, but further work is needed to determine whether Nulato can be used for one of fms. of the group.

G. C. Martin, 1926 (U. S. G. S. Bull. 776, p. 398, chart opp. p. 474), divided the Upper Cret. rocks of Lower Yukon and Norton Bay dists. into (descending) Kaltag, Nulato, and Melozi fms. and Ungalik cgl., and stated that the first 3 are contemp. with Shaktolik group.

P. S. Smith (U. S. G. S. P. P. 192). The beds above Ungalik cgl. have been described as *Shaktolik group*, but later, without much additional field evidence and mainly on theoretical grounds, this group was subdivided by G. C. Martin [U. S. G. S. Bull. 776, 1926] into 3 fms., named (ascending) *Melozi*, *Nulato*, and *Kaltag*. These subdivisions have not yet been given a tryout in field practice.

†Shaly limestone.

A descriptive term applied in a titular sense in early N. Y. repts to New Scotland ls., which was also called "Lower Shaly ls.," in contradistinction to "Upper Shaly ls." (Port Ewen ls.).

Shamattawa limestone.

Ordovician: Manitoba.

See *Shammattawa ls.*

Shammattawa limestone.

Ordovician: Manitoba (Hudson Bay region).

T. E. Savage and F. M. Van Tuyl, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 342, 345).

Shamokin black shale member.

Middle Devonian (Marcellus): Central Pennsylvania (Northumberland County).

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, Proc. Pal. Soc. Feb. 28, pp. 202–203). *Shamokin black sh. memb.*—Basal memb. of Marcellus fm. in central Pa. Mostly fissile black sh., but in part finely aren. Fossils. Thickness 250± ft. at Selinsgrove Junction. Named for Shamokin Creek, in W. part of Northumberland Co., where exposed in N. limb of northern Selinsgrove Junction anticline. Underlies Turkey Ridge ss. memb.

†Shandon quartzite.

Upper Cambrian: Southwestern New Mexico.

C. H. Gordon, 1907 (Jour. Geol., vol. 15, pp. 91–92). *Shandon qtzite.*—Qtzites, sss., and shales with occasional ls. bed. Thickness 50 to 1,100 ft. Of Upper Camb. age. Underlies Mimbres ls.

Same as Bliss ss., and this local name is no longer used.

Named for Shandon, eastern part of Sierra Co.

Shandro shale.

Upper Cretaceous: Alberta.

J. A. Allan, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 12). Included in Belly River series.

Shannon sandstone member (of Steele shale).

Upper Cretaceous: Central Wyoming.

C. H. Wegemann, 1911 (U. S. G. S. Bull. 452, pp. 43, 47). About 1,025 ft. above base of Pierre fm. in this [Salt Creek] oil field lies the ss. here named *Shannon ss. lentil of Pierre fm.* It forms the rim rock of Salt Creek dome, and S. of Shannon is 170 ft. thick. It is somewhat variable in character, but usually contains 2 resistant beds separated by 100± ft. of softer ss. Lies 1,100 ft. below Parkman ss. memb.

Later work resulted in differentiating (in 1915) the deposits of Pierre age in this part of Wyo. into Mesaverde fm. (above) and Steele sh. (below), and the Shannon ss. has for many years been treated by U. S. Geol. Survey as a *memb.* of Steele sh., since it is of considerable geographic extent.

Shannon Run limestone. (In Washington formation.)

Permian: Northern West Virginia (Monongalia County).

E. L. Core, 1929 (W. Va. Acad. Sci. Proc., vol. 3, p. 205). Immediately beneath Waynesburg "B" coal in this region (near Core, Monongalia Co.) there occurs a local ls. which present author for convenience has designated *Shannon Run ls.*, from its exposure on Shannon Run, 2 mi. W. of Mount Morris. It is here a foot thick and has eroded to greater extent than overlying coal. It lies 30 to 35 ft. above Colvin Run ls.

Shannopin sand.

Drillers' term for a sand in SW. Pa., of Upper Dev. or early Carbf. age, which is considered=Hundred-foot sand, in part at least.

Shark River marl.

Eocene (middle): Northeastern New Jersey.

T. A. Conrad, 1865 (Acad. Nat. Sci. Phila. Proc., vol. 17, pp. 70–73). *Shark River marl*, the bed of the oldest Eo. ocean. Consists of fossiliferous indurated clay with disseminated grains of greensand. Thickness unknown.

W. B. Clark, 1893 (N. J. Geol. Surv. Ann. Rept. 1892, pp. 208–210). *Shark River marl.*—A marked greensand with slight admixture of argill. materials, with usually a hardened stony layer at top. Thickness 12 ft. Eo. fossils. Typically developed in valley of Shark River. Overlain uncon. by Miocene [Kirkwood fm.]. Rests conformably on Manasquan marl. [Later repts give thicknesses up to 19 ft.]

Sharon shale member (of Pottsville formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477, 489+). The Seral ss. and cgl., 50 to 100 ft. thick, embraces locally the *Sharon coal group* as a member.

F. Platt, 1875 (2d Pa. Geol. Surv. Rept. H, pp. 8–9). Hodge [J. T.] in 1839 named and described *Sharon series* as underneath Cgl. No. XII, from his explorations W. of Allegheny River. Lesley in 1841 [where?] named and described the *Tionesta series* as overlying Cgl. No. XII as he approached Allegheny River from Potter Co. The Tionesta ss. is Cgl. XII, and therefore *Tionesta series* of coal beds is same as *Sharon series*. It is therefore necessary to expunge the whole Tionesta group, sandrock and coal beds, from Mr. Rogers' column.

J. P. Lesley, 1877 (2d Pa. Geol. Surv. Rept. H_5, p. xxiii). *Sharon and Quinnimont coal group* included in Pottsville cgl.

J. J. Stevenson, 1877 (2d Pa. Geol. Surv. Rept. K_2). *Sharon coal group* included in Upper Umbral [Mauch Chunk sh.].

W. G. Platt, 1878 (2d Pa. Geol. Surv. Rept. H_4). [*Sharon and Quinnimont coal group* placed btw. Pottsville cgl. and Mauch Chunk sh.]

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Sharon shales.*—Dark shales containing 1 ft. of iron ore at top and filled below with fossil plants characteristic of Sharon coal, and containing thin layers of coal in lowest exposed part. Thickness 7 ft. to bed of Connoquenessing Creek, Beaver Co., Pa. Underlie Connoquenessing ss.

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 65–66). The so-called *Sharon coal series* is a name adopted by J. T. Hodge in first geological survey of Beaver River waters 40 years ago and retained by Prof. H. D. Rogers in his Final Rept. of 1858. It is synonymous with Beaver River group. [Further along in this rept, btw. pp. 308 and 316, he states that Sharon coal series underlies Connoquenessing ss.]

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Interconglomerate or Sharon group* extends from base of Piedmont (Tionesta) ss. (=Homewood ss.) to base of Sharon coal. [In footnote on p. xxxi J. P. Lesley says *Sharon* here should read *Mercer*. In same rept I. C. White applied *Sharon iron shales* to 0 to 25 ft. of dark-bluish sandy shales (with much iron ore scattered in nodular masses and a more or less regular stratum of iron ore near top) underlying Lower Connoquenessing ss. and overlying Sharon coal.]

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2, pp. xxi-xxxvi and 319–333). *Sharon series* (also *Sharon group*).—Includes (descending) *Sharon Upper or Iron shales*, Sharon coal, *Sharon Lower shales*, and *Sharon cgl.*

D. White and M. R. Campbell, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, p. 132). *Sharon sh. group*.—Underlies Connoquenessing ss. and uncon. overlies Mauch Chunk fm. Includes (descending): (1) Sh. with some coal in places; (2) Sharon coal; and (3) *Sharon cgl.*

The U. S. Geol. Survey treats Sharon sh. and Sharon cgl. as two distinct members, the cgl. being the basal one. In N. Y. the Sharon sh. has been called "Olean sh."

Named for Sharon, Mercer Co., Pa.

Sharon conglomerate member (of Pottsville formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2, pp. xxi-xxxvi and 319–333). *Sharon cgl.*—Basal part of *Sharon series or group*. Underlies Sharon Lower shales. Whether it be the base or whether it has anything whatever to do with the Pottsville cgl. will be seen hereafter. The reader of this volume must be on his guard against Mr. White's prepossession in favor of assumption that the Homewood, Connoquenessing, and Sharon, taken together, represent the great Pottsville cgl., No. XII. [Page xxxiv.] [The index to this volume states that the Sharon cgl. is the "lower member of Pottsville cgl. (No. XII)."]

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3). *Sharon cgl.*—At Sharon, Mercer Co., Pa., it is a pebbly ss. about 20 ft. thick, in 2 layers of equal thickness and without interval. Upper layer is moderately coarse ss., almost snow white; lower layer is a mere mass of pebbles, loosely cemented in matrix of coarse bluish-gray sand. In Mercer Co. it rests on Shenango shales [Burgoon ss.] and is separated from overlying Sharon coal by 5 ft. of fire clay and shales.

I. C. White, 1891 (U. S. G. S. Bull. 65, p. 204). *Sharon cgl.*, massive cgl., 0 to 40 ft. thick in Pa. and Ohio. On New River, W. Va., is represented by 300 to 400 ft. of shales, sss., and cgls. Basal memb. of Pottsville series. Underlies New River series in W. Va. Overlies Mauch Chunk series.

D. White and M. R. Campbell, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, p. 132). *Sharon cgl.*, basal memb. of Sharon sh. group.

The U. S. Geol. Survey treats Sharon cgl. of NW. Pa. as a *memb.*, underlying Sharon sh. memb. In NE. Ohio the Sharon cgl. is sole representative of the Pottsville and is treated as a *fm.*

Sharon coal group. (In Pottsville formation.)

The coal-bearing strata in Pottsville fm. of western Md. that overlie Sharon cgl. memb., and are essentially the same as Sharon sh. memb.

†Sharon group.

†Sharon series.

See under *Sharon sh. memb.*

Sharon sandstone.

Same as *Sharon cgl.*

Sharon clay.

A name applied in some Ohio repts to the clay, 0 to 3 ft. thick, underlying the Sharon coal.

Sharon syenite.

Devonian (?): Southeastern Massachusetts (Norfolk County).

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 182–184 and map). *Sharon syenite.*—Chiefly dark mafic rocks that range in composition from augite-hornblende syenite through diorite to gabbro. Principal development in town of Sharon. They form Moose Hill.

Sharon Mountain quartz diorite.

Pre-Cambrian (?): Northwestern Connecticut.

W. M. Agar, 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 202–238). *Sharon Mtn quartz diorite.*—Biotite-andesine quartz diorite; a medium-grained gray gneiss with a cataclastic texture composed of strained and broken quartz, slightly strained andesine with occasional spindles of low-refracting potash feldspar; considerable titanite. Occurs in one large mass in Barrack Mtn granite gneiss. Contacts hidden and probably gradational, but is believed to be younger than Barrack Mtn gneiss and is younger than Grenville. Is intruded by Becket quartz monzonite gneiss. Confined, so far as known, to range of hills btw. Sharon, Conn., and Housatonic River. Assigned to pre-Camb. [As mapped it appears to occur on Sharon Mtn, Litchfield Co.]

Sharon Springs member (of Pierre shale).

Upper Cretaceous: Northwestern Kansas (Logan and Wallace Counties) and eastern Colorado.

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7). *Sharon Springs sh. memb.*—Basal memb. of Pierre sh. in Wallace Co., Kans., and its lithology differs widely from that of rest of fm. *Upper 65 ft.* consists of flaky, somewhat bituminous black sh. and, rarely, porous light-gray sh., both with abundant fish scales, gigantic septarian and smaller ordinary tough ls. concretions, also abundant soft concentric concretions, and very few thin bentonite streaks. *Lower 90 ft.* consists of flaky, somewhat bituminous black sh. with abundant small fish bones and scales, also gray, somewhat rusty sh.; thin rusty limonite streaks rare; concretions nearly absent. Underlies Weskan sh. memb. of Pierre and overlies Niobrara chalk. Is believed to extend into Nebr. and S. Dak. Does not seem to be developed W. and S. of western Kans. [Mapped at and around Sharon Springs, Wallace Co., Kans.]

Sharpsville sandstone member (of Cuyahoga formation).

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3, pp. 61–62). *Sharpsville ss.*—A well-defined and persistent group of alternating layers of ss. and sh., in beds 1 to 5 ft. thick. The sh. layers are usually much thinner than the ss. layers. The sss. are of peculiar dark grayish-brown color and fine grain and are quarried at many places along Shenango River [Mercer Co., Pa.], especially at Sharpsville. Thickness of fm. 50 to 60 ft. Underlies Crawford shales [Meadville sh. memb.] and overlies Orangeville shales. [This is commonly accepted definition of Sharpsville ss.]

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 83–90), separated Sharpsville ss. into 3 divisions, as explained under †*Meadville group.* The U. S. Geol. Survey, however, does not apply the same name to a unit and to a part of that unit. It therefore uses *upper ss.* and *lower ss.*, and, Meadville being adopted for a younger sh. memb., the thin ls. in the Sharpsville ss. is simply called *ls. bed* (not *Meadville Lower ls.*).

In NE. Ohio the Cuyahoga is treated by U. S. Geol. Survey as a *group* and the Sharpsville ss. as a *fm.*

Sharpsville formational suite.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal. vol. 21, No. 71, table opp. p. 61, p. 131). *Sharpsville formational suite* underlies Byham ls. memb., overlies Orangeville sh. memb., and is divided into (descending) *Sharpsville ss. memb.* [*restricted* to upper part of Sharpsville ss. memb.], West Mead ls. (formerly called *Lower Meadville ls.*), and Shaws ss. memb. [lower part of Sharpsville ss. memb. of other geologists]. [*West Mead* and *Shaws* are here used for first time.]

Shasta series (or **epoch**).

Lower Cretaceous: California and Oregon.

W. M. Gabb, 1869 (Calif. Geol. Surv. Pal., vol. 2, pp. vii, xiv, 129, 133).

A provincial series term applied to lower part of marine Cret. rocks as developed on Pacific coast. These rocks are now divided into Horsetown fm. above and Knoxville fm. below, and are uncon. overlain by Chico fm. and uncon. underlain by Franciscan fm.

Named for development of the rocks in Shasta Co., Calif. (For definition see U. S. G. S. Bull. 769, p. 61.)

†Shasta-Chico series.

Lower and Upper Cretaceous: California and Oregon.

J. S. Diller, 1893 (Geol. Soc. Am. Bull., vol. 4, pp. 205–224). An essentially conformable and continuous series of sediments formed without distinct interruption. For this series Mr. [T. W.] Stanton and I have agreed to use the name *Shasta-Chico series*. Includes Chico, Horsetown, and Knoxville fms., or all of known Cret. of Calif.

†Shastan system.

†Shastian system.

Terms proposed by T. C. Chamberlin and R. D. Salisbury (Geology, vol. 3, pp. 107–137, 1906) for major part of Lower Cret. series. (See U. S. G. S. Bull. 769, pp. 60–61 and plate.)

Shawangunk conglomerate.

Silurian: Southeastern New York and northern New Jersey and Pennsylvania.

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 246–250). *Shawangunk grit.*—Varies from cgl. to fine-grained grit rock and is almost entirely siliceous. Generally white or light gray, *but there is one bed at the upper part of its mass that is red.* In some places the upper strata are more or less loaded with pyrites. Thickness 0 to 500 ft. Is millstone grit of Eaton. [On pp. 254–255 is heading *Red rock of the Shawangunk group*, which is subordinate to *Shawangunk grit* heading, and beneath which is following statement:] A stratum of red rock has been mentioned as *lying on top* of Shawangunk grit. It is observed covering it in several places, but it is usually thin, and varies in texture from compact hard red grit to red crumbling shale. [The red qtzitic ss. and sh. overlying the coarse qtzite and cgl. are now known as *High Falls fm.*, and are treated as distinct from Shawangunk cgl.] Conformably underlies Helderberg ls. group [here applied to Helderberg and Cayuga rocks] and uncon. overlies Hudson River sl. group.

In subsequent repts. the Shawangunk was considered to be same as Oneida cgl. Later it was regarded by many geologists as younger than the Oneida and of Salina age, Salina fossils having been reported from it by J. M. Clarke in 1907 (N. Y. State Mus. Bull. 107). In 1910, however, Gilbert Van Ingen (Sci., June 11, 1911, p. 905) stated his conviction, after discussing the fossil evidence, that the Shawangunk is of "Medina, Clinton, and Niagara age," and therefore older than Salina; and in 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 531–534) Schuchert assigned it to Medina and Clinton epochs. But Grabau and other stratigraphers stated Shawangunk deposition was continuous with overlying beds of Salina age, "with which no physical break is discernible." Schuchert, however, considered, from evidence to W. and S., that there is a break at top of Shawangunk cgl. In northern N. J. the Shawangunk rests uncon. on Ord. Martinsburg sh., is overlain by High Falls fm., and has estimated thickness of 1,500 to 1,600 ft. (Grabau gives 1,900 ft. in Delaware Water Gap.)

In 1924 (Geol. Soc. Am. Bull., vol. 35, p. 105) C. K. Swartz stated: In going E. cgls. replace first the lower, then the upper beds of the Tuscarora, of Medinan age, passing into the Shawangunk of eastern N. Y. Also: The Clinton appears to merge with the Shawangunk of N. J. The same year (Pa. Geol. Surv. 4th ser., Bull. M$_5$) E. S. Moore and T. G. Taylor stated that typical Tuscarora qtzite merges into Shawangunk grit in E. part of Pa.

In 1926 (N. Y. State Mus. Bull. 270) F. Holzwasser stated: It is thought likely Shawangunk cgl. is Lower Sil. in age.

B. Willard, 1928 (Jour. Pal., vol. 1, pp. 255-258), argued for Ord. age of Shawangunk cgl.

C. K. and F. M. Swartz, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 467-474) and 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 622-661). Both faunal and strat. evidence combine to show that the Shawangunk is united Clinton and Tuscarora at Delaware River. The Shawangunk cgl. at Delaware Water Gap can be followed without break NE. into Shawangunk Mtn at Otisville, Orange Co., N. Y. The relationship of upper or Otisville sh. memb. (484 ft. thick) of the Shawangunk of Otisville, N. Y., to the deposits observed elsewhere is unknown. A similar sh. occurs above the cgls. of the Shawangunk at Delaware Water Gap. [They described the Shawangunk of other areas as consisting almost wholly of conglomeratic sss. Their Otisville sh. memb. is a local unit.] At that place the same 5 species of eurypterids that are found in Rose Hill fm. (of the Clinton) and in the Tuscarora of Swatara Gap, Pa., are found in black sh. bands in massive gray conglomeratic ss. resembling in all respects, lithologically, the corresponding beds of Delaware River. [They correlated their Otisville sh. memb. with Rochester sh., which they showed as later than their Rose Hill fm.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 318, 333), included *Shawangunk cgl.* in Clinton epoch on p. 318 and stated on p. 333: Latest view is that this basal Sil. deposit began earlier in Pa., and that, as it overlaps northward upon the old land surface, its base is made by younger and younger beds, so that in N. Y. the Shawangunk is mainly or entirely of Clinton age or younger (Ulrich).

Named for occurrence on Shawangunk Mtn., Ulster Co., N. Y., which is N. continuation of Kittatinny Mtn of N. J.

†Shawangunk group.

A term applied by Mather to High Falls fm. See under *Shawangunk cgl.*

Shawmut group.

Devonian or Carboniferous: Eastern Massachusetts (Boston Basin region).

W. O. Crosby, 1877 (Geol. map of eastern Mass.). *Shawmut group* consists of amygdaloid above and breccia below.

W. O. Crosby, 1880 (Boston Soc. Nat. Hist. Occ. Papers No. 3, with map). A series of semicrystalline rocks, of very dissimilar composition, but appearing to be identical in age and geognostic relations, which, having their greatest development in vicinity of Boston, I have named collectively the *Shawmut group*, Shawmut being the ancient Indian name of Boston. The rocks included in Shawmut group are those commonly known in vicinity of Boston as the breccia and the amygdaloid. They are found chiefly within radius of 10 to 15 mi. of Boston, and occur also on Marblehead Neck and neighboring islands and in basin of Parker River. Have been unable to satisfy myself whether the breccia underlies the amygdaloid, or vice versa.

Is a part of Mattapan volcanic complex, as mapped by B. K. Emerson in U. S. G. S. Bull. 597, 1917.

Shawmut amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Is younger than Shawmut cgl. The mineralized part is the Shawmut lode. Named for occurrence in Shawmut mine, Houghton Co.

Shawmut flow.

Includes Shawmut amygdaloid and the underlying trap.

Shawmut conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 527, 536, 546, 554, pls. 11, 12, fig. 50). Thickness of *Shawmut cgl.* 74 ft. Occurs at Shawmut mine, on Elm River property.

According to B. S. Butler (personal communication) this cgl. is probably No. 11 or No. 12 of Central Mine group and is older than Shawmut amygdaloid.

Named for occurrence at Shawmut mine, Houghton Co.

†Shawnee limestone. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 888, 895, plates opp. pp. 889, 900, 921). *Shawnee or Buff ls.*—Buff ls., 1 to 3 ft. thick, 100 to 110 ft. above Hanging Rock or Gray ls. [Vanport ls.] in Hocking Valley and 130 to 140 ft. above that ls. in Hanging Rock dist. About 100 ft. below Cambridge ls.

Later repts state that this ls. is same as Upper Freeport ls. memb

Named for Shawnee, Perry Co.

Shawnee group. (In Kansas and Nebraska.)
Shawnee formation. (Missouri and Iowa.)

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1898 (Kans. Univ. Geol. Surv., vol. 3, pp. 93–94). *Shawnee fm.*—Alternating lss. and shales in general characterization decidedly similar. Extend from top of Oread ls. up to base of Burlingame ls.

Until 1931 the commonly accepted definition of Shawnee included all beds btw. base of Burlingame ls. (at top) and top of Oread ls.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart), redefined *Shawnee group*, by including in it the deposits beneath base of Severy sh. (=top of Topeka ls.) and above Lawrence sh. This definition subtracted several fms. at the top and included Oread ls. at base.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 93, 96). It is proposed to redefine *Shawnee group* to include the prominent lss. and intervening shales that occur btw. base of Oread fm. and top of Topeka fm. [This definition was adhered to by Moore and G. E. Condra in their Oct. 1932 revised classification chart of the Penn. of Kans. and Nebr., by Condra in his 1935 classification, and by Moore in his 1936 classification.]

In eastern Kans. and Nebr. the Shawnee is treated as a group; in the other States it has usually been treated as a fm. and its subdivisions as members. The modified definitions have not been considered by U. S. Geol. Survey.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Shawnee sandstone.

See under *Thurman ss.*

Shaws sandstone member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 132), proposed *Shaws ss. memb.* for basal part of Sharpsville ss. memb. of other geologists, and restricted Sharpsville ss. memb. to upper part, applying *West Mead ls. memb.* to the thin ls. in Sharpsville ss. of other geologists. Good exposures of this ss. in ravine behind Shaws brick school house on Meadville-Franklin highway, Meadville quad.

Sheep Bay granite.

Paleozoic (?): Southeastern Alaska (Prince William Sound region).

U. S. Grant and D. F. Higgins, 1910 (U. S. G. S. Bull. 443, pp. 43, 46). *Sheep Bay granite.*—Light-gray coarsest-grained granite of the Sound region. Occupies NE. third of point of land separating Port Gravina from Sheep Bay. Cuts rocks referred to Orca group.

Sheep Creek beds.

Miocene: Western Nebraska and eastern Wyoming.

W. D. Matthew and H. J. Cook, 1909 (Am. Mus. Nat. Hist. Bull., vol. 26, art. 27, pp. 362–363). *Sheep Creek beds*.—Soft fine-grained sandy "clays," light buff, free from pebbles and containing harder calc. layers. Near top is 2-ft. layer of dark-gray volcanic ash. Middle Mio. fossils. Thickness 100 ft. Uncon. underlies Snake Creek beds and uncon. overlies lower Mio. beds equiv. to *Daemonelix* beds of Niobrara Valley. [According to H. F. Osborn, 1909 (U. S. G. S. Bull. 361, pp. 72, 73), the *Daemonelix* zone is lower part of Harrison fm. of repts and is lower Mio.] Named for Sheep Creek, Sioux Co., Nebr.

H. J. Cook, 1915 (Nebr. Geol. Surv. vol. 7, pt. 11, pp. 72–75). *Sheep Creek beds* (middle Mio.) underlie Snake Creek beds at Spoon Butte, Wyo. In Whistle Creek Valley, Sioux Co., Nebr., they are 100 ft. thick, and overlie Upper Harrison beds.

C. C. O'Harra, 1920 (S. Dak. School Mines Bull. 13, p. 36). *Sheep Creek beds* are Middle Mio.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 16, 17), assigned these beds to early middle Mio., but H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5, p. 44), assigned them to upper and middle Mio.

Sheep Creek conglomerate.

Mesozoic or late Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 91, map). *Sheep Creek cgl.*—Cgls. of pebbles $\frac{1}{16}$ in. to 4+ in. diam., but prevailingly less than 1 in., usually water-worn and rounded, and of chert, quartz, qtzite, argillite, and andesite, cemented by an argill. ss. The cgl. grades into hardened sh. and sandy sh., always dark gray. Lava flows are interbedded. Thickness probably at least 500 ft. Exposed on E. side of Sheep Creek at Int. Bdy. Contemp. with Rossland volcanic series. No fossils collected by writer, but leaf impressions collected by Canadian Geol. Surv. from the same cgls. just N. of bdy are determined by Prof. Penhallow to indicate Tert. age. [See *Rossland volcanic group.*]

Sheep Mountain andesite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13). [The field name *Sheep Mtn fm.* crept into print in this bulletin, along with the formally adopted name *Summitville andesite*. (See under *Summitville*.) Mr. Larsen later discovered that the rocks around Summitville are older, instead of younger, than Treasure Mtn latite, and that they belong to Conejos andesite. He therefore abandoned "Summitville andesite," and adopted *Sheep Mtn andesite* for the fm. overlying Treasure Mtn latite and underlying Alboroto quartz latite, as shown in following definition.]

E. S. Larsen, 1933 (U. S. G. S. Bull. 843). *Sheep Mtn andesite*.—Overlies Treasure Mtn quartz latite rather regularly, but where it overlies Conejos andesite it was deposited on a surface made up of mtns and deep canyons. The fm. is present in 3 parts of the mtns and differs considerably in the 3 areas. One is a volcanic cone in drainage of Lost Trail Creek near center of San Cristobal quad.; one is about Sheep Mtn in NW. part of Summitville quad.; and the third and by far the largest is in Del Norte and Saguache quads. Most of Lost Trail Creek area is largely chaotic breccia of light-colored andesite-latite with much glass in ground-mass. Small bodies of massive rock that varies from rhyolites to andesites are scattered through the breccia. These commonly show irregular relations and are in part intrusive and in part effusive. The predominant rock of both the massive rock and the breccia is a dark-colored hornblende-pyroxene andesite somewhat like the rock of Sheep Mtn area except that it has smaller phenocrysts and has hornblende in most of the bodies. The body about Sheep Mtn is a low dome composed of dark flows and chaotic breccia and brecciated flows of pyroxene andesite with conspicuous tabular feldspar. Little tuff breccia is present. The bodies of Sheep Mtn in NE. part of San Juan Mtns probably represent remnants of several volcanic piles. The rocks are all lighter-colored than those of the other two domes and are latite andesites. The rocks of Del Norte quad. and adjoining areas are much alike and are chiefly in thick flows extruded upon a mountainous topography with deep canyons. The common rock is rather dense and light gray to purple drab in color. It is made up nearly half of phenocrysts up to 3 cm or more across. White calcic andesine is chief phenocryst, but prisms of black hornblende, flakes of biotite, and grains of green augite are present in moderate amount. The groundmass is fine-textured and made up of small plagioclase laths in a spongelike intergrowth of orthoclase and quartz.

Sheep Mountain quartzite.

Pre-Cambrian (Belt series): Central western Montana (Missoula to Helena region).

C. H. Clapp and C. F. Deiss, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 683, figs. 2, 3). *Sheep Mtn fm.*—Consists of (descending): (1) 1,050 ft. of massive red and some white qtzite, with beds of clay galls near top, deep-red weathering; (2) 695 ft. of massive pink-white coarse-grained cross-bedded qtzite, with some beds of coarse-grained ss. in upper part, all beds weathering gray red; (3) 555 ft. of massive pink and white coarse-grained cross-bedded qtzite with numerous bands of clay galls near base. Top fm. of Missoula group. Rests conformably on Garnet Range fm. Thickness 2,300 ft. on upper slopes of Sheep Mtn, T. 15 N., R. 18 W., sec. 24, and T. 14 N., R. 17 W., sec. 30.

Sheep Pen sandstone.

See under *Sheep Pen Canyon fm.*

Sheep Pen Canyon formation.

Triassic (?): Northeastern New Mexico (Union County).

B. H. Parker, 1930 (Kans. Geol. Soc. 4th Ann. Field Conf., p. 132, Mimeo). *Sheep Pen Canyon fm.*—Tan to buff massive and thin-bedded ss., 0 to 68 ft. thick. Of Triassic (?) age. Uncon. underlies La Plata group and overlies Sloan Canyon fm. [Derivation of name not stated.]

B. H. Parker, 1933 (Jour. Geol., vol. 41, No. 1, pp. 40–43). *Sheep Pen ss.*—Buff to tan ss., thin-bedded to massive, uncon. underlying Exeter ss. and conformably overlying Sloan Canyon fm. At type loc., where it caps a small mesa in E½ NW¼ sec. 35, T. 32 N., R. 35 E., it is 68 ft. thick. In places completely removed by erosion. Named for Sheep Pen Canyon, which joins Cimarron Valley about ½ mi. NW. of type loc. Tentatively assigned to Triassic (?). Has been confused with Exeter ss.

†Sheep Rock conglomerate.

A name applied by J. P. Lesley (Am. Phil. Soc. Proc., vol. 12, pp. 492-496, 1873) to cgl. forming Sheep Rock, btw. Big Tom's Creek and Little Tom's Creek, E. of Gladeville (now called Wise), Wise Co., Va. This cgl. is a local area of Gladeville ss. as defined and mapped by M. R. Campbell in 1893. In attempting to follow this cgl. to the E. Lesley confused it with older cgls. of Lee fm. (See U. S. G. S. Bull. 111, p. 28, 1893.)

Sheffield formation.

Upper Devonian or Mississippian: Central northern Iowa.

C. L. Fenton, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 355–376). *Sheffield fm.*—Blue nonfossiliferous clayey shales, about 90 ft. thick. Uncon. or discon. underlies Hackberry stage. Exposed at Hackberry Grove but is unrelated to Hackberry stage, although included in that stage by Webster (1889) and Calvin (1897). Uncon. overlies Nora fm., which possibly belongs to Cedar Valley stage. Is Dev.

According to A. O. Thomas (Iowa Geol. Surv. vol. 30, p. 116, footnote, 1925) the shales at Sheffield, Franklin Co., are basal fm. of Kinderhook group, and not same as the Upper Dev. shales that underlie Cerro Gordo substage of Fenton. The name *Sheffield* being therefore considered by him inappropriate for the Upper Dev. sh., he replaced it with *Juniper Hill fm.*, while Van Tuyl, in same volume (pp. 52, 91, 101, 107) applied *Sheffield sh.* to the younger fm., which he tentatively included in Kinderhook group, but with statement that lower two-thirds (40 ft.) may prove to be Upper Dev.

R. C. Moore, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., fig. 1, p. 245), included these beds in Kinderhook group (Miss.), but L. R. Laudon (p. 246 of same rept, also 1931, Iowa Acad. Sci. Proc., vol. 37, p. 251) stated that fauna with little question is late Upper Dev. M. A. Stainbrook (p. 249 of 1935 publication cited) also refers *Sheffield fm.* to Upper Dev., places Juniper Hill btw. Cerro Gordo and Nora, and treats it as basal memb. of Lime Creek sh.

Named for exposures in vicinity of Sheffield, Franklin Co.

Sheffield gas sand.

Sheffield oil sand.

Drillers' terms, NW. Pa. Of Chemung age. The Sheffield gas sand is said to be same as *Hague gas sand* and lower than *Sheffield or Blue Jay oil sand*. Named for Sheffield, Warren Co. J. D. Sisler, 1933 (Pa. Geol. Surv., 4th, Bull. M_{19}, p. 28), says *Sheffield sand* probably corresponds to Cooper sand of Warren Co. and is in approx. strat. position of 2d Bradford sand of Bradford dist.

Sheguindah beds.

Upper Ordovician: Ontario (Manitoulin Island).

A. F. Foerste, 1912 (Ohio Nat., vol. 13, p. 43). *Sheguindah beds.*—At base clay shales (with no trace of ls.) about 43 ft. thick. At 43 ft. first trace of ls. was found, but ls. layers do not become common until 100 ft. above base; these upper lss. and interbedded clays contain typical Eden fauna. Underlie Wekwemikongsing beds (of Lorraine age) and rest on Collingwood fm. (of Trenton age). Exposed along road from Little Current to Sheguindah.

Shelburn formation.

Pennsylvanian: Southwestern Indiana.

E. R. Cumings, 1922 (Hdb. Ind. Geol. pt. 4, Sep. Pub. 21, chart and pp. 408, 525, 529). *Shelburn fm.*—Name proposed for interval from top of Indiana coal No. 7 to base of Merom ss. Includes Ditney fm. (dropped), Somerville ls., and all of Millersburg fm. (dropped) except coal No. 7. Discon. underlies Merom ss. and discon. overlies Petersburg fm. (redefined). Is of post-Allegheny age. Includes Busseron ss. (possibly=Anvil Rock ss. of Ky.) at base.

Named for Shelburn, Sullivan Co.

†Shelburne gneiss.

W. O. Crosby (Rept. on geol. map of Mass., Mass. Commission to Centennial Exposition, Boston, 1876, pp. 1–42) referred, in two places, to the gneiss at Shelburne Falls, Mass., as *Shelburne gneiss*, but there is no subsequent record of the use of this name. According to B. K. Emerson (U. S. G. S. Bull. 597, 1917) the so-called "gneiss" at Shelburne Falls is Pelham granite.

Shelburne marble.

Lower (?) Cambrian: Northwestern Vermont (Chittenden County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 115). *Shelburne marble.*—Almost entirely marble, light-colored, for most part white, but also light buff or cream, bluish white, and various beds of mottled cream white or blue and white. A few thin beds of light-gray dol. occur in various parts of the fm. Thickness visible along Winooski River is about 200 ft., but upper limit is not there shown, and total is doubtless twice as great. Is overlain by Williston ls. No contacts are known btw. Shelburne marble and Milton dol., the next underlying fm., but it appears to be conformable. The Shelburne is believed to be younger than Highgate sl. The main belt of the marble and two much smaller parallel strips occur in town of Shelburne [Burlington quad.].

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 373, 375). *Shelburne marble* in Middlebury, Brandon, Proctor, and Danby is overlain by Williston ls., with great uncon. btw. them, which appears to be represented in St. Albans region by St. Albans sl., Mill River cgl., and Highgate sl. The marble contains no fossils so far as known, but it is uniform and is a regular unit in Lower Camb. succession of E. part of valley, where it grades downward into Clarendon Springs dol. In Burlington region it overlies Milton dol., which here consists of dol. cgl.

C. Schuchert, 1933 (Am. Jour. Sci., 5th, vol. 25, pp. 353–381), stated that Keith's so-called Milton dol. of central sequence is not true Milton dol. (Upper Camb.), but is Middle Camb., and he renamed it *Rugg Brook cgl.* The Upper Camb. age of true Milton dol. is now generally accepted. If the Shelburne marble, which Keith stated overlies true Milton dol., does in fact overlie that fm., it would be Upper Camb. instead of Lower Camb.

†Shelby limestone.

Middle Devonian: Central Indiana.

A. F. Foerste, 1898 (Ind. Dept. Geol. and Nat. Res. 22d Ann. Rept., pp. 234–235, in a description of the rocks of Shelby Co. from Waldron to Geneva). *Shelby bed.*—Brownish or bluish dolomitic ls. 31 ft. thick, with 2 ft. of massive dark-brown ls. at base. Uncon. overlies Louisville ls. Assigned to Lower Dev. [Type loc. not stated, but the fm. appears to have been named for Shelby Co.]

E. M. Kindle, 1901 (Ind. Dept. Geol. and Nat. Res. 25th Ann. Rept., p. 536). *Shelby bed* of Foerste is same as Geneva ls. and should be abandoned for the older name.

†Shelby dolomite.

Silurian (Niagaran): Western New York.

J. M. Clarke and R. Ruedemann, 1903 (N. Y. State Mus. Mem. 5, pp. 9–13), gave following (downward) section of Lockport dol. along Oak Orchard Creek, from 0 to 1¾ mi. S. of Shelby village, in Shelby, the SW. Twp of Orleans Co.: (1) Second Guelph fauna, *upper Shelby dol.*, 8 to 10 ft.; (2) Lockport dolomites, 32 ft.; (3) first Guelph fauna, *lower Shelby dol.*, 3 ft.; (4) Lockport dolomites (largely covered), 62+ ft. "We are thus presented with conclusive evidence of an invasion of the Guelph fauna from the west into western N. Y., while the Lockport dolomites were being deposited and at about the middle of the period of their formation."

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19), excluded Guelph dol. from Lockport dol., and included *Upper Shelby* and *Lower Shelby* in Guelph.

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114), divided *Niagara fm.* (as he called it) in Rochester and Ontario Beach quads. as follows (descending):

Lockport dolomites with interbedded Guelph faunas 130± ft.:

1. Second Guelph fauna, *upper Shelby dol.*, 8–10 ft. Is top of section at Shelby but we are not prepared to say positively that it terminates the series everywhere in N. Y. Presence of Lockport species more pronounced in this upper fauna.
2. Lockport dolomites, 32 ft. Characteristic Lockport fauna, and no Guelph species.
3. First Guelph fauna, *lower Shelby dol.*, 3 ft. Is purer Guelph fauna.

Lockport dolomites, 62 ft. Characteristic Lockport fauna.

Rochester sh., 85 ft.

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348), divided Niagaran into (descending) (1) *Guelph dol.* (*Shelby*); (2) Lockport; (3) * * *

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 50–51), included *Upper Shelby dol.* and *Lower Shelby dol.* in Guelph dol. and excluded Guelph from Lockport dol. He stated: Shelby is to be regarded both as a faunistic and a lithologic Guelph element in the succession of the strata.

M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111), stated that *upper Shelby beds* of N. Y. belong to Guelph dol., which "includes beds from base of upper Shelby beds up," and which he treated as distinct from and overlying the Lockport dol.

E. O. Ulrich and R. S. Bassler, 1923 (Md. Geol. Surv. Sil. vol., p. 260). The terms *Lower Shelby* and *Upper Shelby dol.* used by Clarke and Ruedemann as designations for the two zones of Lockport dol. in which Guelph fauna is found in western N. Y. obviously were not intended as formally proposed names of distinct formational units or of members of the Lockport. In fact even the name *Lockport* as employed by these authors in work just cited [1903 reference above] refers to faunal content of the beds rather than to a definite formational unit.

The U. S. Geol. Survey includes the beds containing the Guelph fauna in Lockport dol.

See also *Guelph dol.*

Shelbyville morainic system.

Pleistocene (Wisconsin stage): Southern Indiana and southern Illinois. Shown in part on moraine map (pl. 32) in U. S. G. S. Mon. 53, and in part on moraine map in U. S. G. S. P. P. 106. Named for Shelbyville, Shelby Co., Ill.

Sheldon limestone. (In Calhoun sh.)

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 47). The ls. underlying Iowa Point sh. and overlying Jones Point sh. is not Meadow ls. (which belongs down in Stanton ls.), and is here named *Sheldon ls.* In Sand Point section, Cass Co., Nebr., it consists of 3½ ft. of massive bluish-gray fossiliferous ls. that weathers buff or brownish. It is middle memb. of Calhoun sh. [Derivation of name not stated.]

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.), transferred Sheldon ls. and underlying Jones Point sh. to Deer Creek ls. and restricted Calhoun sh. to the beds they had previously called *Iowa Point sh.* This change made Sheldon ls. the top bed of Deer Creek ls.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 11), divided *Calhoun sh. fm.* into (descending) Iowa Point sh., Sheldon ls., and Jones Point sh., and this classification was followed by R. C. Moore in his 1936 revised classification (Kans. Geol. Surv. Bull. 22, p. 48). But on pp. 187-194 Moore proposed to redefine Sheldon ls., Jones Point sh., and Ervine Creek ls. on a cyclothem basis, expanding *Sheldon* to include some beds now included in Ervine Creek, and transferring Jones Point to a part of the Ervine Creek. These proposed changes involve a redefinition of present lower bdy of Calhoun sh. and upper bdy of Deer Creek ls. Moore stated that Sheldon ls. was named for outcrops in Sheldon quarry, just E. of Nehawka, Nebr.

Shelikof formation.

Upper Jurassic: Southwestern Alaska (Shelikof Strait).

S. R. Capps, 1923 (U. S. G. S. Bull. 739, pp. 91, 97, map). *Shelikof fm.*—Upper part, 700 to 1,000 ft. of black sh. with some ls. lenses at top; lower part, a thick series of ss., with minor amounts of cgl. and sandy to calc. sh. Thickness of fm. 5,000 to 7,000 ft. Large Upper Jurassic fauna. Is prevailing rock fm. on NW. shore of Shelikof Strait, from Katmai Bay at least as far SW. as Kialagvik Bay, and in Cold Bay dist. it forms nearly all bold headlands and coastal mtns visible from the strait. Underlies Naknek fm. and uncon. overlies Kialagvik fm.

†Shell Bluff marl. (In Barnwell formation.)

†Shell Bluff group. (In Barnwell formation.)

Eocene (upper): Eastern Georgia and South Carolina.

T. A. Conrad, 1866 (Am. Jour. Sci., 2d, vol. 41, p. 96). *Shell Bluff group.*—Black lignite clay and gray sand, with fossils [listed]. Thickness 5 ft. Named for Shell Bluff, on Savannah River, where *Ostrea georgiana* is abundant.

T. W. Vaughan, 1911 (Ga. Geol. Surv. Bull. 26, p. 240), treated *Ostrea georgiana* zone at Shell Bluff, on Savannah River, as topmost bed of McBean fm., and referred the McBean and the overlying Barnwell sand to Claiborne group.

C. W. Cooke and H. K. Shearer, 1918 (U. S. G. S. P. P. 120C), showed that the faunas of Barnwell sand and of *Ostrea georgiana* zone are of Jackson age, restricted Claiborne group of Ga. and McBean fm. to the beds beneath *Ostrea georgiana* zone and above Wilcox fm., and included the paleontologic zone referred to in Barnwell fm. Cooke stated (orally) that the *Ostrea georgiana* zone is the †Shell Bluff group of Conrad. On p. 61 they give a section of beds exposed at Shell Bluff, where both Barnwell and McBean fms. are present, and where thickness of *Ostrea georgiana* zone is given as 30 ft. and thickness of overlying red argill. sands composing rest of Barnwell fm. at that locality is given as 35 ft. These are present approved definitions of Barnwell and McBean fms.

Named for a bluff on Savannah River in Burke Co., Ga., where *Ostrea georgiana* occurs in profusion. This bluff is several mi. NE. of village of Shell Bluff, Burke Co.

Shell Rock limestone.

Upper Devonian: Central northern Iowa.

A. O. Thomas, 1924 (Iowa Geol. Surv. vol. 29, pp. 411–412). In parts of Butler, Floyd, NE. Cerro Gordo, and counties to N. there come in recognizable fms. which are higher and faunally separable from the Cedar Valley. They are not thick, probably not exceeding 100 ft. in vertical extent. The general group of these is called *Shell Rock ls.*, from their typical development along Shell Rock River btw. Rockford and Nora Springs and on northward, also about Mason City and to N. and NW. The upper memb. of this group is Nora ls., whose sharp contact with basal blue sh. of Lime Creek stage may be seen on Lime Creek just W. of Rockford. Below the Nora at this point, and separated by a slight erosional uncon., is a dolomitic ls., the Mason City dol. of Calvin. It is suggested that eventually the Shell Rock may be made a stage with the Nora, Mason City, and possibly other horizons as substages.

C. L. Fenton and C. L. Webster, 1924 (Univ. Mich. Pub., Contr. Mus. Geol., vol. 1, map, frontispiece), restricted *Shell Rock* to beds below Nora ls. and above their Lower Cedar Valley, and divided it into (descending) *Pachyphyllum* zone, *Aulopora* sh., Bloody Run zone, Lithographic beds, and Mud-crack zone.

C. H. Belanski, 1927 (Am. Mid. Nat., vol. 10, No. 10), included Nora ls. in his *Shell Rock stage*, but redefined Nora so as to include in it some beds (First *Actinostroma* zone) previously included in Mason City substage. He divided his *Shell Rock stage* into (descending): (1) Nora substage (including Second *Actinostroma* zone, *Platyrachella* zone, First *Actinostroma* zone); (2) Rock Grove substage (*Schizophoria* zone and *Paracyclas* zone); (3) Mason City substage (*Lepidocentrus* zone, *Trigonotreta* zone, and *Aulopora* zone), and defined it as resting uncon. on Cedar Valley ls. [restricted usage of name].

L. R. Laudon, 1931 (Iowa Geol. Surv., vol. 35, p. 344). In north-central Iowa the *Shell Rock fm.* uncon. overlies Cedar Valley ls. and in N. part of north-central province it is uncon. overlain by Juniper Hill sh. In S. part of north-central province it is undoubtedly directly overlain by Sheffield fm. Consists of hard gray fossiliferous ls. and dol.

The Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, adopted Belanski's 1927 definitions of *Shellrock fm.* and Cedar Valley ls., in that they divided their Shellrock fm. into Nora, Rock Grove, and Mason City members, and showed it as uncon. on Cedar Valley ls. restricted. On p. 256 M. A. Stainbrook gives thickness of *Shellrock fm.* as 16 to 65 ft.

Named for development along Shell Rock River, as stated in original definition above.

Shelton granite gneiss.

Pre-Cambrian: Central southern Virginia and northern North Carolina.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). *Shelton granite gneiss.*—Pink muscovite granite gneiss. Mapped from S. of Danville northeastward nearly to Wren, Charlotte Co.

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, pp. 18–23, map). *Shelton granite gneiss facies of Columbia granite.*—Mylonitized granite which occurs in 2 zones [described] in central Va. and extends into N. C., where it is quarried near Shelton, for which it is named. Intrudes Wissahickon fm. Is pre-Camb.

Shelton sand.

A subsurface sand, of Penn. age. in Stephens Co., southern Okla., lying at 1,900 ft. depth in Empire pool, the Cantrell sand lying at 1,800 ft., and the Smith at 2,000 ft.

Shelton Cliff sandstone.

Pennsylvanian: Southwestern Indiana.

W. N. Logan, 1924 (Ind. Dept. Cons. Pub. 42, p. 16). [Mentions "two rather massive sss., the Merom or Inglefield ss. and the *Shelton Cliff ss.*," in description of "Post-Allegheny group" of SW. Ind.]

Shenandoah limestone.

Lower Cambrian to Middle Ordovician: Western Virginia and eastern West Virginia.

H. R. Geiger and A. Keith, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 157–163, pl. 4). *Shenandoah ls.*—Lss. [character and thickness not described] underlying Martinsburg sh. in Blue Ridge Mtns near Harpers Ferry, W. Va. Contains Chazy-Calciferous fossils. Shenandoah River, W. Va., is characterized by this ls.

N. H. Darton, 1892 (Am. Geol., vol. 10, p. 13). In Staunton, Va., region the *Shenandoah ls.* consists of great mass of impure mag. lss. below, grading upward through a series of cherty beds of no great thickness into several hundred ft. of light-colored, heavily bedded purer lss. Lower beds not fossiliferous; in cherty beds a few middle Ord. gastropods were found. Underlies Martinsburg sh.

A. Keith, 1894 (U. S. G. S. Harpers Ferry folio, No. 10, p. 3). *Shenandoah ls.*—In general a series of blue and gray lss. and dolomites, with occasional beds of mottled blue ls. Prevailing calc. character locally modified by series of slates and sandy shales interbedded with the ls., about 1,000 ft. below its top; these beds best exposed along Antietam Creek, where they become less calc. and assume reddish-purple color. Also contains bed of white marble, probably below the slaty ls. series. Lower Sil. fossils in upper part, Lower Camb. fossils in lower part. Forms the Great Shenandoah Valley and reaches from N. Y. to Ala. Underlies Martinsburg sh. and overlies Antietam ss.

The Shenandoah ls. of early repts is now subdivided, in most areas, into several fms. (see Pa., Va., and W. Va. charts), and where subdivided it has in some repts been called *Shenandoah group.* The fms. into which it has been differentiated in Pa. reach a max. thickness of 6,800 ft., in W. Va. more than 10,000 ft., and in Va. more than 12,000 ft.

Shenandoah Mountain granite.

Pre-Cambrian: Southeastern New York (Poughkeepsie quadrangle).

C. E. Gordon, 1911 (N. Y. State Mus. Bull. 148, pp. 11, 17–18). *Shenandoah Mtn granite* [in heading], *Shenandoah granite* [in table]. Coarse white granite, made up almost entirely of quartz and feldspar. Occurs on Shenandoah Mtn, at summit of steep NW. slope, along road from East Hook to Hortontown. Assigned to pre-Cambric. "Has earmarks of a plutonic rock and bears little evidence of gneissoid structure, so that if it is of Precambric age it must be thought of as having escaped any pronounced foliation."

Shenandoan.

A name proposed by A. W. Grabau (see Pan-Am. Geol., vol. 66, No. 1, 1936, p. 27) for the "retreatal Lower Ord. series, commonly called Canadian, or even Beekmantown, even though it lacks the distinctive Beekmantown fauna, except in so far as this has transgressed the barrier of the Albany axis, during the period of maximum expansion."

†Shenango series.

Pennsylvanian and Mississippian: Western Pennsylvania.

F. Platt, 1875 (2d Pa. Geol. Surv. Rept. H, pp. 1–9). *Shenango series* [in table], *Shenango River series* [in text].—Underlies cgl. No. XII (Seral) and overlies Catskill series. Includes Sharon coals and Tionesta coals, or "all coal measures underlying the cgl., and at base red sh." [The term "Seral cgl." as used in this rept applied to Homewood ss., top memb. of Pottsville fm., and the names *Shenango* and *Shenango River* covered the rest of Pottsville fm. and underlying Mauch Chunk and Pocono fms.]

Named for Shenango River, Mercer Co.

Shenango sandstone.

Mississippian: Northwestern Pennsylvania (Mercer County).

J. P. Lesley and I. C. White, 1879 (2d Pa. Geol. Surv. geol. map of Mercer Co.). *Shenango ss. (No. X?).*

J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_3, p. 25). *Shenango ss.* is underlain by brown and olive Chemung shales.

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3, pp. 59–61). *Shenango ss.*—Massive ss., coarse, brownish white, charged with nodular iron ore and fish remains. Thickness in Mercer Co. 15 ft. Underlies Shenango shales and overlies Crawford shales. Has been quarried at many places along Shenango River [in Mercer Co.]. [In Rept. Q_4, 1881, White gives thickness of 15 to 35 ft. in Erie and Crawford Counties, Pa.]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61), divided his *Shenango stage* (*Shenango monothem*) into Hempfield sh. memb. (new name to replace Shenango sh. of White) and Shenango ss. memb.

The U. S. Geol. Survey at present treats this ss. as a part of Burgoon ss., top fm. of Pocono group in NW. Pa.

Shenango shale.

Mississippian: Northwestern Pennsylvania (Mercer County).

I. C. White, 1880 (2d Pa. Geol. Surv. Rept. Q_3, pp. 59–60; name proposed by J. P. Lesley, footnote on p. 59). *Shenango shales.*—Interstratified sandy shales and flaggy sss., 36 to 50 ft. thick. Underlie Sharon cgl. and overlie Shenango ss. in Mercer Co. [Named for exposures on Shenango River, Mercer Co.]

Is part of Burgoon ss., top fm. of Pocono group of U. S. Geol. Survey classification. K. E. Caster (1934) renamed it *Hempfield sh. memb.*

†Shenango group.

Mississippian: Northwestern Pennsylvania and northeastern Ohio.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 66, 77–81). *Shenango group.*—In Erie and Crawford Counties, Pa., divided into Shenango sh. (above) and Shenango ss. (below).

Replaced by *Burgoon ss.*, top fm. of Pocono group of NW. Pa. K. E. Caster has renamed "Shenango sh.," *Hempfield sh. memb.*, and has proposed *Shenango stage* (*Shenango monothem*) to include the sh. and ss. of White. (See Bulls. Am. Pal., vol. 21, No. 71, 1934, pp. 138–139.)

Shenango stage.

See under †*Shenango group.*

Shenango monothem.

See under †*Shenango group.*

†Shenango River series.

See 1875 entry under *Shenango series.*

Shepard formation.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park) and southern British Columbia.

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 324). *Sheppard qtzite.*—Yellow ferruginous qtzite, 700± ft. thick. Rests on extrusive diabase flow, which overlies Siyeh ls. Is older than Kintla argillite. Forms crest of Lewis Range in vicinity of Mount Cleveland and Sheppard Glacier, Mont., btw. Belly River and central Flattop Mtn.

The U. S. Geog. Bd. has approved *Shepard* (instead of *Sheppard*).

Shepherdstown gravel.

Probably Pliocene: Southern Pennsylvania (along the Susquehanna) and northern West Virginia.

M. R. Campbell, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 3, pp. 558–573). Along the Susquehanna 2 distinct berms, seemingly representing the same cycles of erosion as those along the Potomac, were identified, and, as a matter of convenience, in this general region they will be called by the same names as the gravels which rest upon them. Thus, the uppermost berm is called *Bryn Mawr*, because that name has long been applied to gravel that rests upon it at town of Bryn Mawr, a few mi. NW. of Phila.; and the term *Shepherdstown* is here proposed for the gravel-covered berm that in this region lies normally 100 ft. below the Bryn Mawr and is well developed at Shepherdstown, W. Va., in Shenandoah Valley. The Bryn Mawr gravel is well developed on both sides of Susquehanna River mouth at elev. of 400 ft. The *Shepherdstown gravel* lies normally about 100 ft. below the Bryn Mawr. [Describes distribution.] The nearly continuous tracing of the Shepherdstown gravel seems to show beyond question that after deposition of Bryn Mawr gravel and before Shepherdstown gravel was laid down, an anticlinal uplift, the axis of which trends nearly at right angles to the river, elevated Bryn Mawr berm at Safe Harbor to 250 ft. above its former position, but there is no trace of such uplift in vicinity of Harrisburg, where these 2 gravel-bearing berms are separated by interval of only 100 ft. For a long time writer has had opinion the Shepherdstown gravel was deposited near close of Plio. and Bryn Mawr berm was probably formed in early Plio.

Sheppard quartzite.

See *Shepard fm.*, the geographic spelling adopted by U. S. Geog. Bd.

Sheppard granite.

Tertiary: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 8, 117°30' to 118°). *Sheppard granite.*—Biotite granite, stocks and dikes, of Tert. age, B. C. and Wash.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 315, 355). *Sheppard granite* forms small stock at head of Sheppard Creek, B. C. Cuts Rossland volcanic group, Pend D'Oreille schists, Trail cgl., and cgl. of Lake Mtn.

Sherbrooke limestone.

Upper Cambrian: British Columbia.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, p. 2). *Sherbrooke fm.*—Bluish-gray aren. dolomitic massive and thin-bedded to shaly lss., with a few oolitic layers and cherty inclusions. Thickness at Mount Bosworth, 1,360 ft. Top fm. of Upper Camb. Overlies Paget fm. Contains Upper Camb. fossils, passing at summit into Ord. Type loc. W. slopes of Mount Bosworth, overlooking Sherbrooke Lake, 5 mi. N. of Hector, on Canadian Pacific Ry, B. C.

†Sherbrookian series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). In descending order: Lss., 365 ft.; oolites, 200 ft.; and shales 350 ft. Underlies Chancellorian series and overlies Sawbackian series. Of Late Cambric age. [Apparently same as Sherbrooke fm.]

Sherburne flagstone member (of Portage formation).

Upper Devonian: Eastern New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 381). *Sherburne flagstone.*—Fine-quality flagstones, of various grades of thickness, alternating with greenish or olive-colored sh. Overlain by Ithaca group and underlain by black sh. [Geneseo] that rests on Tully ls. Named for occurrence near Sherburne, Chenango Co.

L. Vanuxem, 1842 (Geol. N. Y., pt. 3, pp. 171–174). Hall's name *Sherburne flags* changed to *Portage or Nunda group* [one of the several discarded uses of *Portage* and *Nunda*]. Underlies Ithaca sh. and overlies Genesee sl.

C. S. Prosser, 1893 (Am. Jour. Sci., 3d, vol. 46, pp. 212–230). *Sherburne flagstones* of Vanuxem are a mass of sss. in Chenango Valley above horizon of Tully ls., which are mostly nonfossiliferous and are synchronous with lower part of Portage as exposed farther W. They are not same as "Sherburne group" of Conrad.

J. M. Clarke and C. S. Prosser, 1897 (N. Y. State Geol. 15th Ann. Rept.), adopted *Sherburne sss.* (or *Sherburne flagstone*) for lower Portage beds btw. Ithaca group and Genesee sl., which Prosser stated are 250 ft. thick in Chenango Valley.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19), classified *Sherburne flagstone* as younger than Middlesex sh. and as = Cashaqua sh.

H. S. Williams, 1913 (U. S. G. S. P. P. 79). *Sherburne flagstone memb.*, basal memb. of Portage fm., is overlain by Ithaca sh. memb. of Portage and underlain by Genesee sh. Is characterized by *Reticularia laevis* zone at top. [According to Williams (1907) his Sherburne flagstone memb. is same as Sherburne flagstone of Vanuxem.]

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, No. 1, p. 69), correlated Sherburne with Cashaqua sh. [of Portage group].

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 121–122). Upper limit of Hamilton in central N. Y. is zone of *Hypothyridina venustula* (Hall), which is generally accepted as base of Upper Dev. This zone is at base of Tully ls., a thin wedge extending from E. side of Canandaigua Lake at least as far E. as village of Sherburne, on E. side of Chenango Valley. This ls. uncon. overlies the Hamilton. East of Sherburne the characteristic ls. has been replaced by *Sherburne ss.*, but the *Hypothyridina* zone still persists at base of the ss., marking top of the Hamilton as far E. as village of Mount Vision, in Otego Valley. It is evident lower part of the Sherburne at its type loc. and probably for considerable distance eastward is actually a clastic phase of the Tully.

W. Goldring, 1931 (N. Y. State Hdb. 10, p. 369), correlated Sherburne with Cashaqua, which overlies Middlesex sh. and is a part of Portage group. She included Sherburne in Portage group and showed it as overlying Genesee black sh., which name she restricted to basal memb. or Geneseo sh. of Chadwick.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, p. 351), placed Sherburne above the Tully.

G. A. Cooper, 1933 (Am. Jour. Sci., 5th, vol. 26, p. 544), placed Sherburne of Chenango Valley above Genesee. In 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 5–7) Cooper explained further regarding *Hypothyridina* zone; stated that "so far as known the whole Sherburne, including the part of it assignable to the Tully, is quite unfossiliferous;" and described lithology of *Sherburne fm.* in different areas.

G. H. Chadwick, Feb. 28, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2), correlated *Sherburne* with the Genesee, and stated (p. 310) that *Sherburne ss.* at type loc. embraces the sandy facies of the Geneseo [basal memb. of Genesee] and even the Tully.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 858, 862), correlated *Sherburne flagstone fm.* with upper and major part of the Genesee (i. e., with Standish, West River, and Genundewa), and stated that at Sherburne itself even the basal (Geneseo) memb. of the Genesee and the underlying Tully ls. "have changed into essentially a part of type Sherburne."

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 10, 56–62), removed *Spirifer (Reticularia) laevis* zone from top of Sherburne memb. and named it *Cornell memb.*

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 785, 803, 805, 807, 818, 825–830). The whole sequence of Tully, Geneseo, and *Sherburne* E. of Chenango Valley passes laterally into rocks carrying Ithaca fossils and formerly designated "Ithaca" but found to be mostly of pre-Ithaca age. [On p. 805 is section 3 mi. S. of Sherburne, showing Otselic memb. of Ithaca fm. resting on 180 ft. of *Sherburne fm.*, which rests on Geneseo fm.] Prosser measured the *Sherburne* at type section as 250 ft. thick, but from this 65 ft. (representing Tully and Geneseo) must be deducted. It is 230± ft. thick in Norwich and Morrisville quads (N. of Sherburne) and 210± ft. thick in Cazenovia and Tully quads. To E. it becomes more difficult to recognize. In Unadilla Valley it is impossible to separate Geneseo and Sherburne. Due to rapid infiltration of Ithaca species in the Sherburne E. of Chenango Valley, it is practically impossible to recognize the fm. and separate it from overlying Otselic memb. Therefore it is best to abandon *Sherburne*, also *Ithaca* E. of Unadilla Valley, and use in their place *Unadilla fm.*, proposed by Prosser. *Sherburne* will be useful for the unfossiliferous fine-grained sss. and dark shales btw. Geneseo sh. and Otselic memb. from Chenango Valley eastward. The confusion in stratigraphy of eastern N. Y. is largely result of misidentification of middle Hamilton ss. in Schoharie Valley as Sherburne fm. In that valley the true position of *Sherburne ss.* is probably 2,000 ft. higher than Prosser identified it.

†Sherburne group.

Devonian: New York.

T. A. Conrad, 1841 (N. Y. Geol. Surv. 5th Ann. Rept., p. 31). *Sherburne group* underlies Tully ls. and overlies shales near Apulia.

C. S. Prosser, 1893 (Am. Jour. Sci., 3d, vol. 46, pp. 212–230). "Sherburne group" of Conrad is not same as *Sherburne flagstones*.

Is a part of Hamilton (Middle Dev.).

†Sherburne shale.

Devonian (Middle): Central southern New York.

W. W. Mather, 1843 (Geol. N. Y., vol. 1). Erie div. includes[* * *] Ludlowville sh., Encrinal ls., Moscow sh., Apulia and *Sherburne shales*, and Cazenovia group. [*Sherburne sh.* not defined.]

Sherburne conglomerate.

Lower Cambrian: Southwestern Vermont (Rutland County) and southeastern Vermont (Windham County).

C. H. Richardson, 1929 (16th Rept. Vt. State Geol., pp. 208–246, table opp. p. 288). *Sherburne cgl.* (Lower Camb.) was discovered by author in 1892 and named by him [published?]. Flanked on W. by Algonkian gneiss and on E. by Camb. schists. Carries pebbles and boulders up to 1 ft. diam. of pre-Camb. qtzites, granites, and gneisses. A good outcrop is about 2 mi. SE. of north Sherburne [in Rutland quad. and Rutland Co.], at head of the narrow valley leading down to Sherburne. Is a basal cgl. Uncon. overlies Algonkian terranes.

Sheridan quartzite.

Pre-Cambrian: Yellowstone National Park.

W. H. Weed, 1896 (U. S. G. S. Yellowstone Nat. Park folio, No. 30). *Sheridan qtzite.*—Chiefly dense bluish-white qtzite. Found at only 3 places in the park. Best exposed on slopes of Mount Sheridan. Oldest fm. in the park. Assigned to Algonkian.

†Sheridan beds.

Pleistocene: Panhandle of Texas to South Dakota.

W. B. Scott, 1897 (Intr. to geol., pp. 532–533). Over the Great Plains, from S. Dak. to Tex., the surface fm. is a fine calc. sandy clay, which lies uncon. on eroded surfaces of older strata, from the Blanco to Cret. This fm. may be called *Sheridan stage* (*Equus beds*), from Sheridan Co., Nebr., where it is admirably shown, and is Pleist. in age, probably corresponding to one of Glacial stages, though by some it is regarded as Plio.

Geographic name is preoccupied, and U. S. Geol. Survey uses as a general designation the paleontologic term *Equus* zone.

A. L. Lugn, 1934 (Nebr. State Mus. vol. 1, Bull. 41, p. 355). There is some doubt that any of "Sheridan beds" is as old as Aftonian or Nebraskan.

Sheridan sandstone.

Silurian: Northeastern Maine (Aroostook County).

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21, 45, 47–49, 51). *Sheridan ss.* is a peculiar rock, looking like an ordinary ss. of various degrees of fineness and in its coarsest state a pebbly cgl. Color greenish gray to rather dull brown. When closely inspected it is found to be composed of soft and hard rocks, both rounded and angular—quartz and feldspar; jasper, sl., and argill. sh., green, red, and black; and fragments of fossils, corals, and crinoids, but particularly pieces of brachiopods of size large enough to recognize. Most conspicuous feature is the angular pieces of black sl., which at first suggest fragments of carbonaceous matter but are evidently fragments of the more ancient slates. Igneous materials also are associated with them, emphasizing their close association in origin with the tuffs and volcanic ash beds with which they are stratigraphically associated. Believed to be of about same age as Ashland shales and older than Ashland lss. Fauna presents affinities with both Clinton and Niagara of New York. Is regarded as younger than Aroostook ls. Named for exposures on Sheridan Plantation, S. of Aroostook River, Aroostook Co.

Sheridan formation.

Middle Ordovician: Northwestern Michigan (Iron River district).

R. C. Allen, 1910 (Mich. Geol. and Biol. Surv. Pub. 3, geol. ser. 2, p. 113). *Sheridan fm.*—Consists of (in what is believed to be descending order) coarse quartz ss., buff or red color, generally friable, 35 or 40 ft.; cgl. of unknown but not great thickness, composed of angular fragments of chert up to a couple of inches in diam. in matrix of same composition but finer-grained, and forming basal memb. of fm. on Sheridan Hill, Iron River dist.; nonmag. ls., of dove or buff color, flaggy, containing fossils correlated by Ulrich with Lowville of N. Y. Uncon. overlies Michigamme sl.

Sherman diorite.

Miocene: Yellowstone National Park, Wyoming.

A. Hague et al., 1904 (U. S. G. S. Mon. 32, Atlas, Canyon sheet). *Sherman diorite.*—Light-colored crystalline intrusive rock, exposed on Sulphur Creek in vicinity of Hot Springs, Canyon quad.

Derivation of name not stated and not apparent from map.

Sherman granite.

Pre-Cambrian: Southeastern Wyoming (Albany County) and northern Colorado.

E. Blackwelder, 1908 (Sci., n. s., vol. 27, pp. 778–788). *Sherman granite.*—Coarse red granite, essentially unaltered, except that it is deeply weathered. Probably Algonkian.

E. Blackwelder, 1910 (U. S. G. S. Laramie-Sherman folio, No. 173, p. 3). *Sherman granite.*—Coarse-grained massive granite, composed chiefly of pink feldspars, glassy quartz, and black hornblende mica, a spotted pink aspect being the result. Is pre-Camb. [Mapped over large area at and around Sherman.]

On 1935 geol. map of Colo. this granite was included in the newly established Front Range granite group.

Sherman marble.

Lower Cambrian (?): Southeastern Vermont (Windham County).

G. D. Hubbard, 1924 (14th Rept. Vt. State Geol., pp. 269–276 and map). *Sherman marble.*—[Describes several occurrences of marble in Readsboro and Whitingham Twps, and says:] Since in all these occurrences the marble dips outward from an axis beneath other layers, since all the marble in the area is quite similar, and since the rock succession above the marble is always the same, it seems reasonable to infer that the marble is continuous beneath other rocks from one area to another. And if it underlies thus a considerable portion of the southern part of our area, we also infer that it underlies the whole area. The marble is usually gray to white, coarse crystalline, granular, and does not hold together very well, but at Sherman some of it is very firm and would handle well. The friableness in other localities may be due to weathering. Other colors than gray and white are known. Pink tints occur in the old pit across the river from Sherman. Yellow bands occur at Sherman. Pink marble in beautiful tints is found in the extreme southwestern outcrops of the Whitingham area. The marble is usually medium-grained, but near the top some coarse beds appear, and where the graphite is coarse the calcite crystals are generally large too. The marble is rarely pure calcium carbonate, even for single layers and for short distances. Nearly every sample gives a feeble iron reaction. Dolomite is common. The fm. could well be called dolomitic, but in some places accessory minerals make up a very considerable part of the rock. At Sherman graphite is common, particularly in the lower layers exposed. It becomes obvious from the discussion of the last few pages that the marble varies visibly from place to place. Yet these are all within a narrow range and do not seem to indicate more than one formation. The thickest exposures are at Sherman, where fully 200 ft. can be seen, but we believe there is at least 600 ft. of the marbles. Is oldest rock in area studied. Is overlain by Whitingham schist. Is essentially=Bellowspipe ls. of Mass., which is assigned to Ord. by Emerson.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol, table opp. p. 288), assigned this fm. to Lower Camb., but without discussion, and correlated it with Plymouth marble.

Named for town of Sherman, on Hoosac Tunnel & Wilmington Railroad, Whitingham Twp, Windham Co., where it is most extensively exposed and worked.

Sherman Fall formation. (In Trenton group.)

Middle Ordovician: Central New York.

G. M. Kay, 1929 (Jour. Geol., vol. 37, No. 7, pp. 664–671; name suggested by J. J. Galloway). *Sherman Fall fm.*—Here defined as the "Prasopora beds" or Trenton restricted of Raymond, Johnston, and others. Includes about 105 ft. of thin-bedded lss. with shaly partings, extending to seam in cliff of upper High Fall about 20 ft. from top of fall. Comprises zones F to K of Raymond (Bull. Am. Pal.

No. 17, 1903) and zone A_3 and most of overlying zone A_4 of Prosser and Cumings. Named for Sherman Fall, in Trenton Falls gorge of West Canada Creek, Oneida Co., N. Y. Its base, a bed in which *Prasopora simulatrix orientalis* is abundant, lies immediately above a stratum of massive dark-blue ls. about 3 ft. thick that is conspicuous in side of gorge along path above Sherman Fall, the bed A_4 of Prosser and Cumings (N. Y. State Geol. 15th Ann. Rept., p. 615, 1897). Is younger than Hull fm. and older than Lower Cobourg.

See also G. M. Kay, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 225–244).

Sheroli formation.

Miocene: Costa Rica.

A. H. Redfield, 1923 (Econ. Geol., vol. 18, p. 364) and 1924 (Revista econ. San Salvador, año 11, No. 4, p. 176).

Sherwin glacial stage.

Pleistocene: Sierra Nevada, California.

E. Blackwelder, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 91–92) and 1931 (G. S. A. Bull., vol. 42, pp. 865–922). *Sherwin stage.*—Glacial till on E. slope of Sierra Nevada of a stage younger than McGee stage and older than Tahoe stage. Correlated with Kansan stage. Best developed in area N. of Sherwin Hill, NW. of Bishop, in Mount Morrison quad.

†Sherwood limestone.

Lower Cambrian: Central western Virginia.

H. D. Campbell, 1905 (Am. Jour. Sci., 4th, vol. 20, pp. 445–447). *Sherwood ls.*—Upper part consists of heavy beds of light-blue and gray mag. ls. with occasional beds of sh. and shaly ls. Basal several hundred ft. consist of white crystalline dol. Thickness of fm. 1,600 to 1,800 ft. Underlies Buena Vista sh. and rests on qtzites and shales. Named for exposures in James River at Sherwood, Va.

Same as Shady dol.

Shetlerville formation.

Mississippian: Southeastern Illinois and adjacent parts of Kentucky.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 281–290, and No. 5, pp. 395–416; also Ill. Geol. Surv. Bull. 41). *Shetlerville fm.*—Lss. interbedded with more or less calc. shales, but the ls. and sh. succession is not uniform from place to place, and the ls. layers also grade into shales horizontally, so that in places ls. may constitute nearly entire fm., while elsewhere shales may compose the greater part. The lss. are commonly crystalline, dark gray or blue, and usually more or less cross-bedded. The unweathered shales are chiefly blue, although thin layers of red sh. occur in places. The lss. weather yellowish or buff; the shales weather yellowish, buff, or ashy gray. Thickness of fm. 30± ft. Lithologically in strong contrast to underlying Ste. Genevieve ls., being much more shaly, much more irregularly bedded, and much less uniform in character. Is entirely foreign to any part of true Ste. Genevieve ls. as typically developed in Ste. Genevieve Co., Mo., although it has been included in the Ste. Genevieve, being a part of Ulrich's Ohara ls. memb. The Ohara memb. is a complex, of which Shetlerville fm. constitutes lower part of upper div., while the lower div. of the Ohara properly belongs to the Ste. Genevieve. The Shetlerville fm. rests uncon. on "Lower Ohara," and is uncon. overlain by Renault ls., which was also included in Ulrich's Ohara ls. The Shetlerville is faunally more closely related to overlying Renault than to underlying Ste. Genevieve ls.

S. Weller, 1921 (Ky. Geol. Surv., ser. 6, vol. 4, pp. 27, 30). *Shetlerville* better be considered as memb. of Renault, rather than as an entirely distinct fm., and it is so considered in this rept. Rests uncon. on underlying Ste. Genevieve ls.

E. O. Ulrich and C. Butts contend that all of Ohara ls. memb. is present at Ste. Genevieve, and that so-called "Upper Ohara" and Shetlerville of Weller belong to Ste. Genevieve ls., as well as so-called "Lower Ohara" and underlying beds. (See also under *Ste. Genevieve ls.*)

Named for Shetlerville, Hardin Co., Ill. Well exposed just E. of that town, btw. Rich and Melcher Hills.

Shickshock formation.

Ordovician (?): Quebec (Matapedia Valley).

G. W. Crickmay, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 368–385). *Shickshock fm.*—Interbedded volcanic rocks and arkosic qtzite. Forms summit of Shickshock Mtns from Lake Matapedia to Table Top Mtns. Type is section at Lake Matapedia. Overlies Quebec group. Is overlapped by Val Brillant fm. (Sil.). No fossils.

Shiloh marl member (of Kirkwood formation).

Miocene (upper): Southern New Jersey.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, pp. 40–44). *Shiloh marls.*—At Shiloh [Cumberland Co.] consist of (descending): Unfossiliferous "yellow marl," 2 ft.; uncon. on unfossiliferous "black marl," 2 to 3 ft.; uncon. on fossiliferous "shell marl," 8 to 10 ft. Assigned to Mio. Overlies barren black sand and underlies Quat.

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 141). *Shiloh marl.*—Gray, highly fossiliferous marl containing undoubted Mio. fossils. Occurs in limited area in Salem and Cumberland Counties. Rests on Alloway clay and underlies Cohansey sand.

W. B. Clark, H. B. Kümmel, and B. L. Miller, 1909 (U. S. G. S. Trenton folio, No. 167). *Shiloh marl memb. of Kirkwood fm.*—Brown clay and fine clayey gray sand containing great numbers of shells. Thickness 30 ft. Forms top memb. of Kirkwood fm. Underlies Cohansey sand, probably uncon. Overlies 80 to 90 ft. of clay (of chocolate to drab and locally black color) exposed to SW., about Woodstown and Alloway.

Shimer gypsum member (of Blaine gypsum).

Permian: Central southern Kansas and western Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 27, 28, 31). *Shimer gyp.*—Upper gyp. memb., 0 to 10 ft. thick, of Cave Creek fm. Separated from underlying Medicine Lodge gyp. by 7 to 10 ft. of clay sh. called *Jenkins clay*. Underlies Dog Creek shales.

C. N. Gould, 1902 (Okla Geol. Surv. 2d Bien. Rept., p. 49). *Shimer gyp. memb. of Blaine div.*—Top memb. of Blaine div. Thickness 15 to 18 ft. Overlies Altona dol. memb. of Blaine and underlies Dog Creek shales.

C. N. Gould later abandoned Altona dol. memb., and defined Shimer as separated from underlying Medicine Lodge gyp. by red shales (see 1906 and 1927 entries under *Altona dol. memb.*), but he did not explain to what bed his Altona dol. corresponded.

The correlation of the beds in Okla. that have been called Shimer gyp. with typical Shimer gyp. of Kans. has in recent years been seriously questioned. Some geologists believe that Shimer of Kans. is the Medicine Lodge of some areas in Okla., and that typical Medicine Lodge of Kans. is so-called Ferguson gyp. of Okla. (See 1931 entry under *Medicine Lodge gyp.*)

Named for Shimer Twp, Barber Co., Kans.

Shinarump conglomerate.

Triassic (Upper ?): Southwestern, southern, and southeastern Utah, northern Arizona, northwestern New Mexico, and southeastern Nevada.

G. K. Gilbert, 1875 (U. S. Geol. and Geog. Surv. W. 100th M., vol. 3, pp. 1–187). *Shinarump cgl.*—Underlies Upper Trias marls [Chinle fm.] and overlies Lower Trias marls [Moenkopi fm.] in western Utah and northern Ariz.

E. E. Howell, 1875 (U. S. Geol. and Geog. Surv. Terr. W. 100th M., vol. 3, pp 247–248, 270–273, 284). *Shinarump cgl.*—Yellow cgl. with silicified wood very abundant. Thickness 100 ft. in Pine Mtn, southern Utah; 50 ft. btw. Paria Settlement and Last Bluff, southern Utah. Overlain by variegated gypsiferous marl series of the Trias and underlain by chocolate and light-colored Trias shales. Occurs also in Virgen Range, Nev., near Toquerville, Utah, and from Pine Valley Mtns to Le Verken Creek, Utah.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns). *Shinarump cgl.*—A fine cgl. not easily recognized, toward N. about 20 ft. [thick]; to S. increases to 200 ft. Caps Shinarump Cliffs. Overlain and underlain by badland sss., with much gyp.; often argill., sometimes indurated sss.

The fm. overlying Shinarump cgl. is now known as *Chinle fm.*, and the fm. underlying it as *Moenkopi fm.* The cgl. is of Triassic age, but whether Upper or Middle Triassic is a debated question.

Type loc., Shinarump Cliffs, S. of Vermilion Cliffs, southern part of Kane Co., Utah.

†Shinarump group.

Triassic (Upper, Middle (?), and Lower): Utah, Arizona, northwestern New Mexico.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 53, 54, 68, 150, 152). *Shinarump group.*—Consists of: (1) *Upper Shinarump* (badland sss. with much gyp.; often argill.; sometimes indurated sss.); (2) *Shinarump cgl.* (a fine cgl. not easily recognized, about 20 ft. thick to N. and 200 ft. to S.; caps Shinarump Cliffs); (3) *Lower Shinarump* (badland sss. with much gyp.; sometimes argill.; in a few places indurated sss.; sometimes uncon. below, with a cgl. at base composed of rounded and angular fragments of Carbf. rocks). In Uinta Mtns the variegated beds both above and below Shinarump cgl. are seen in many places on either flank of the mtns. Thickness 1,800 ft. Underlies Vermilion Cliff group and uncon. overlies Upper Aubrey group (Carbf.). Named for Shinarump Cliffs [S. of Vermilion Cliffs, Kane Co., southern Utah].

The use of a name in two senses (for a group and for a fm. within that group) being contrary to practice of U. S. Geol. Survey, the Upper Shinarump of Powell in *southern* Utah and adjacent areas was renamed *Chinle fm.*, and his Lower Shinarump was renamed *Moenkopi fm.*, the name *Shinarump* being retained for the *cgl.*, which is of rather wide distribution. Powell's Shinarump group in *NE.* Utah appears to correspond to Woodside sh. and Thaynes ls. of SW. Wyo. But according to some geologists (A. R. Schultz, U. S. G. S. Bull. 702, 1920, and G. R. Mansfield, U. S. G. S. P. P. 152, 1927) the White Cliff group and Vermilion Cliff group of Powell in *NE.* Utah are the same beds, and the Ankareh sh. is included in upper part of †Shinarump group.

Shinarump clay.

Name applied by A. C. Lawson (Econ. Geol., vol. 8, 1913, p. 435) to the beds in southern Utah now known as *Chinle fm.* He defined his Shinarump clay as overlying Shinarump cgl. and underlying Vermilion Cliff ss.

Shinarumpian series.

A term applied by C. R. Keyes to Triassic deposits stated by him to be older than his Doloresian series and younger than his Documan series.

Shinersville conglomerate. (In Pottsville formation.)

Pennsylvanian: Northeastern Pennsylvania (Sullivan County).

F. Platt, 1880 (2d Pa. Geol. Surv. Rept. G_2, pp. 186–199). *Shinersville cgl.*—Very massive ss., mostly gray, occasionally bluish and spotted, and with numerous layers of regularly stratified white quartz pebbles. Thickness about 50 ft. Near Shinersville school house 30 to 40 ft. is exposed. Basal div. of Pottsville cgl. Rests on Mauch Chunk red sh.

Shinumo quartzite. (Of Unkar group.)

Pre-Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Shinumo qtzite.*—Hard, compact cross-bedded ss. and qtzite, usually of fine and even grain. Thickness 1,564 ft. Conformably underlies Dox ss. and conformably overlies Hakatai sh., all of which belong to Unkar group. Named for exposures in canyon of Shinumo Creek, Shinumo quad.

†Shirley stage.

Upper Jurassic: Southeastern Wyoming.

W. C. Knight, 1900 (Geol. Soc. Am. Bull., vol. 11, pp. 377–388). *Shirley stage.*—Marine beds consisting of bands of sh., ls., ss., and clay, a few ft. to 200 ft. thick. Middle Jurassic. Extends from SE. Wyo. to Black Hills and westward. Not known in southern Wyo. or northern Colo. Named for Shirley Mtns, SE. Wyo., on S. side of which it is well developed.

Same as *Sundance fm.*, which has priority.

Shiwits shale.

Permian: Northwestern Arizona (Mojave County).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 338). *Shiwits shales.*—The uppermost red sh. section of Supaian series, as exposed in canyon walls, especially around Shiwits Plateau, N. of Peach Springs, Mojave Co. Thickness 400 ft.

Shnabkaib shale member (of Moenkopi formation).

Lower Triassic: Southwestern Utah (Washington County) and northwestern Arizona.

H. Bassler and J. B. Reeside, Jr., 1921 (U. S. G. S. Bull. 726C, pp. 90, 92). *Shnabkaib sh. memb.*—Sandy sh. and soft ss., fine-grained, creamy white, with some pinkish layers and gyp. Thickness 360 to 630 ft. Lies 405 to 475 ft. below top of Moenkopi fm. and 400 to 435 ft. above Virgin ls. memb. of Moenkopi, this interval being occupied by brick-red ss. and sh. and reddish and light bluish-gray gyp. Named for striking isolated Shnabkaib Mesa, 2 mi. SE. of town of Washington, on NW. flank of Washington dome. [See also U. S. G. S. P. P. 129D, 1922.]

Shoal Creek limestone member (of McLeansboro formation).

Pennsylvanian: Central western and southwestern Illinois.

H. Engelmann, 1868 (Ill. Geol. Surv., vol. 3, pp. 148, 159–164, 175, 220). *Shoal Creek ls.*—Light-colored, grayish or bluish compact, close-textured ls., 4 to 15 ft. thick, in Coal Measures of Washington, Clinton, and Jefferson Counties, Ill. Overlain by Upper Sandstone Formation of Coal Measures (200 to 250 ft. thick) and underlain by Slaty Division of Coal Measures (15 to 50 ft. thick).

According to G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. Ser. Bull. 26, pp. 17–44), and 1926 (Ill. Acad. Sci. Trans., vol. 19, p. 257), *Shoal Creek ls.* lies 100± ft. above Carlinville ls., which lies higher than coal No. 8, and coal No. 8 lies 140 ft. above coal No. 7.

H. R. Wanless, 1931 (Geol. Soc. Am. Bull., vol. 42, p. 804), placed base of Shoal Creek ls. 100± ft. above top of Carlinville ls. and 35± ft. above coal No. 9.

G. E. Ekblaw, 1933 (Ill. Acad. Sci. Trans., vol. 25, pp. 143–145). The ls. called *Shoal Creek ls.* by Wallace Lee in U. S. G. S. Mount Olive-Gillespie folio, No. 220, 1926, appears to occupy same position as LaSalle ls., and it seems *LaSalle* may well be applied to it. It lies 52± ft. above the ls. that crops out extensively along Shoal Creek in Bond and Clinton Counties, which is unquestionably the one originally named Shoal Creek. The section was traced N. and it was found Worthen's local *Carlinville ls.* is identical with Shoal Creek ls. This lower ls. was called *Carlinville ls.* in folio cited. *Carlinville* should be abandoned.

J. R. Ball, 1934 (Ill. Acad. Sci. Trans., vol. 26, p. 97). "Carlinville" ls. is same as Shoal Creek ls.

See Ill. correlation chart compiled by M. G. Wilmarth, 1936.

Named for outcrops along Shoal Creek, Clinton Co.

†Shoal Creek limestone.

Lower Cretaceous (Comanche series): Central Texas.

R. T. Hill, 1889 (Am. Geol., vol. 3, p. 289; Am. Jour. Sci., 3d, vol. 38, p. 470; Tex. Geol. Surv. Bull. 4, pp. xiv, xxii). *Shoal Creek or Vola ls.*—Impure ls., 50 or 75 ft. thick. Top fm. of Washita div. and of Comanche series in Burnet and Travis Counties. Uncon. underlies Upper Cret. and overlies *Exogyra arietina* clays (Del Rio clay).

Preoccupied. Replaced by *Buda ls.*

Named for Shoal Creek at Austin.

Shoal Creek cyclical formation.

A name applied by H. R. Wanless (Geol. Soc. Am. Bull., vol. 42, 1931, pp. 801–812) to a part of McLeansboro fm. (Penn.) of central western Ill. Includes Shoal Creek ls. Derivation of name not stated.

Shoal Lake conglomerate.

Pre-Cambrian (lower Huronian): Western Ontario (Rainy Lake district).

C. K. Leith, Robt. Bell, W. G. Miller, F. D. Adams, A. C. Lane, C. R. Van Hise, 1905 (Jour. Geol., vol. 13, p. 95). *Cgl. known as Shoal Lake cgl.* holds numerous large well-rotted fragments of underlying rocks and forms base of sedimentary series. Exposed at Shoal Lake, Ont.

†Shoal River marl member. (In Shoal River formation.)

Miocene (middle): Northwestern Florida.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept., table opp. p. 50 and pp. 91, 104–106). *Shoal River marl memb. of Alum Bluff fm.*—Very fossiliferous greenish to gray sands, clays, and marls interbedded. Recently discovered by T. W. Vaughan (unpublished notes) in west Fla. Thickness about 50 ft. Lies stratigraphically about 30 ft. above Oak Grove sand memb. Included in upper part of Alum Bluff fm.

Later studies by Julia Gardner resulted in finding Shoal River fauna in all beds btw. top of Oak Grove sand and base of Choctawhatchee marl. The name *Shoal River fm.* was therefore adopted (U. S. G. S. P. P. 142, pp. 1–3, 1926), to include not only †Shoal River marl memb. of earlier repts but underlying and overlying beds carrying the Shoal River fauna. Named for exposures on Shoal River, Walton Co.

Shoal River formation. (In Alum Bluff group.)

Miocene (middle): Northwestern Florida and probably southeastern Alabama.

Julia Gardner, 1926 (U. S. G. S. P. P. 142, pp. 1–3). *Shoal River fm.*—Marls, clays, and sands, occurring stratigraphically above Oak Grove sand and underlying Choctawhatchee marl. Characterized by a distinctive fauna. Top fm. of Alum Bluff group. Includes "Shoal River marl memb." of Matson and others and underlying and overlying sands and clays containing same fauna.

Named for exposures on Shoal River, Walton Co., Fla., especially at Shell Bluff.

Shoemaker limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 33, 35, 173). *Shoemaker ls.*, 8 to 9 ft. thick, lies 6 to 7 ft. above base of Lawrence sh. memb. and 40 to 43 ft. below top of the Lawrence in vicinity of Nehawka, Cass Co. Has been eroded from the Platte exposures. Was erroneously correlated as Oreapolis bed by Condra and Bengston in Nebr. Acad. Sci., vol. 9, No. 2, p. 10, 1915. Named for Shoemaker farm and Shoemaker Bridge, about 3 mi. NW. of Nehawka, Nebr.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., p. 11). The so-called Lawrence sh. of Bull. 1 is Ladore sh.

This name does not appear in subsequent classifications and seems to have been dropped.

shoe-string sands.

A descriptive term popularly applied to the oil and gas sands of eastern Kans. whose length greatly exceeds their width.

Shohola formation.

Upper Devonian: Northeastern Pennsylvania (Wayne and Pike Counties).

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 585–587). Underlying the Damascus red sh. in Wayne and Pike Counties, particularly in Delaware

Valley, is a succession of continental beds here named *Shohola fm.*, from Shohola, on Delaware River near mouth of Lackawaxen Creek. The fm. consists of 2 members, Paupack ss. above and Barryville memb. below. Evidently the Barryville memb. corresponds to and is a thickened continuation of the beds below Paupack ss. which so puzzled I. C. White [and which he named *Paupack shales and ss.*]. The Barryville and Paupack members are grouped together as *Shohola fm.* because they fall naturally together btw. Damascus sh. above and Delaware River flags below. The fm. is of Chemung age except for at least upper part of Paupack ss., which is probably early Canadaway. The Shohola extends W. across Pike Co. The Paupack is lost, and the Barryville either thins or becomes dominantly red and merges with lower part of Damascus red beds and is not recognized beyond central Monroe Co., along Brodhead Creek.

Sholem Alechem limestone.

Pennsylvanian: Southwestern Oklahoma (Cotton County).

W. F. Cloud, 1930 (Okla. Geol. Surv. Bull. 40MM). *Sholem Alechem ls.*, 470± ft. thick in Cotton Co., is probably=lower ls. body of Hoxbar fm. and the ls. of upper part of Deese fm. Is not exposed. Rests uncon. on Honey Creek ls. or Wilberns fm. of Tex. [Fig. 2 shows it underlying Hoxbar fm. Derivation of name not stated.]

Shongalo greensand. (In Claiborne group.)

Eocene (middle): Northwestern Mississippi (Carroll County).

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 164–165). *Ferruginous greensand of Claiborne group—Shongalo greensand.*—The highly ferruginous sand occurring in railroad cut at Vaiden Station, near Shongalo, Carroll Co., and also in cuts btw. that place and Rockport; contains a considerable percentage of greensand grains.

Is a part of Winona sand memb. of Lisbon fm. (See geol. map, pl. 2, in U. S. G. S. W. S. P. 576, 1928.)

Shoofly formation.

Mississippian: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Shoo Fly beds.*—Thickness 8,600 ft. Contain a ls. which crops out on Clear Creek, about 2 mi. SE. of Shoo Fly Bridge. Probably either Triassic or Carbf., with slight presumption in favor of latter.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Shoo Fly fm.*—Mainly clay slates above and qtzite below. The slates are light to dark gray, generally dull but sometimes silky, and in places slightly micaceous and contain occasional films of gray or black flinty material as well as thin beds of ss. and fine cgl. of quartz pebbles. Here and there are traces of beds composed exclusively of volcanic fragments, some of which are clearly vesicular. Near middle are ls. lentils, some over 50 ft. thick. The qtzites that prevail in upper part are thin-bedded, somewhat slaty, and indistinctly schistose, with micaceous partings. Thickness 6,800± ft. Everywhere separated from underlying Arlington fm. by Taylor meta-andesite. Is older than Peale fm., but relations not determined.

Named for exposures in road btw. Shoo Fly Bridge and Spanish Creek, Taylorsville region.

Short Creek oolite member (of Boone limestone).

Mississippian (Warsaw): Southwestern Missouri, southeastern Kansas, and northeastern Oklahoma.

W. S. T. Smith and C. E. Siebenthal, 1907 (U. S. G. S. Joplin folio, No. 148). *Short Creek oolite memb (of Boone fm.).*—Thin but persistent bed of oolitic ls., 1½ to 8 ft. thick. Generally a single massive homogeneous bed, but in some places divides into 2 beds which may have slightly different characteristics. Lies about 100 ft. above Grand Falls chert memb. and about 100 ft. below Carterville fm. Named for exposures along Short Creek, a stream flowing westward btw. Galena and Empire in Cherokee Co., Kans.

C. E. Siebenthal, 1908 (U. S. G. S. Bull. 340, p. 190). *Short Creek oolite memb.* of Boone fm. occurs in E. half of Wyandotte quad. wherever its horizon is exposed, but W. of Spring and Neosho Rivers it usually pinches out or loses its oolitic character.

This oolite memb. is assigned to Warsaw epoch by R. C. Moore, 1928, also 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245).

Shoshone.

See 1901 entry under †*Popo Agie beds*.

†Shoshone group.

Upper Cretaceous and Eocene: New Mexico to Montana.

W. Cross, 1909 (Wash. Acad. Sci. Proc., vol. 11, pp. 27–45). *Shoshone group*.—Included, through misapprehension, by King and others in original Laramie, but because of uncon. should be separated. Map published by Bur. Ethnology illustrating distribution of great linguistic families of North American Indians shows dist. once occupied by Shoshonean family to embrace greater part of Rocky Mtn area with a part of Great Basin. The mtns were especially the land of Utes and Shoshones, two tribes of this family. With this broad derivation it is proposed to apply *Shoshone group* to the deposits which uncon. succeed Laramie and their equivalents and which are overlain by Fort Union or Wasatch beds, when they are present. Embraces lacustrine, fluviatile, or terrestrial deposits, composed of detritus from rising land area of Rocky Mtn province, formed btw. Laramie and Fort Union epochs. Embraces beds which have been called "Post-Laramie" or "Upper Laramie;" *Denver fm.* and *Arapahoe fm.* of Denver dist.; *Middle Park* and *Animas beds* of Colo.; the *Carbon* and *Evanston beds* of Wyo.; *Livingston beds* and *Hell Creek beds* of Mont.; and the Converse Co. "Ceratops beds" of Wyo.

Shoshone Falls andesite.

Miocene? (upper Miocene?): Southern Idaho (Twin Falls and Jerome Counties).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Shoshone Falls andesite*.—Purple and black massive vitreous porphyritic andesite, overlain by a deep-red soil 1± ft. thick. Thickness of fm. 200+ ft. Forms Shoshone Falls and Pillar Falls, in Twin Falls and Jerome Counties. Exposed along Snake River from foot of Twin Falls down as far as Perrine ranch, a distance of 6 mi. Uncon. underlies Pillar Falls mud flow, which fills irregularities in its surface, and rests uncon. on Paleozoic lss.

Shoshoni limestone.

Cambrian: Western Wyoming (Wind River Mountains).

See under *Bull Lake Creek shales*.

†Shot Pouch sandstone.

Mississippian: Western Kentucky.

See under *Tar Springs ss.*, 1856 item.

Shreveport gas sand.

A subsurface sand in NW. La. that is believed to lie at horizon of Nacatoch sand.

Shriver chert. (In Oriskany group.)

Lower Devonian: Central Pennsylvania to eastern West Virginia, western Maryland, and central western Virginia.

C. K. Swartz et al., 1913 (Md. Geol. Surv. Lower Devonian vol., p. 91 and table opp. p. 30). *Shriver chert memb.*—Dark siliceous sh. with much black impure chert in nodules or layers of nodules. Thickness 0 to 100 ft. Basal memb. of Oriskany fm. Underlies Ridgeley ss. and overlies Becraft memb. of Helderberg fm. Meager fauna. Named for Shriver Ridge, at Cumberland, Md.

Shublik formation.

Upper Triassic: Northern Alaska (Canning River region).

E. D. Leffingwell, 1919 (U. S. G. S. P. P. 109, pp. 103, 115, map). *Shublik fm.*—About 1,350 ft. of dark ls., sh., and ss., overlying Sadlerochit ss. (Penn.) and underlying Kingak sh. (Lower? Jurassic); probably conformable, but contacts not seen. Type loc. is at Shublik Island, on Canning River, at SW. corner of Shublik Mtns. Fauna is Upper Triassic.

Shulaps volcanics.

Triassic(?): British Columbia.

W. S. McCann, 1922 (Canada Geol. Surv. Mem. 130, p. 26).

Shulie formation.

Carboniferous: Nova Scotia.

W. A. Bell, 1913 (12th Int. Geol. Cong. Guidebook 1, p. 342). [In Canada Geol. Surv. Summ. Rept. 1912, p. 369, 1914, Bell assigned this fm. to Penn.]

Shultz limestone member (of Talpa formation).

Permian: Central Texas (Concho County).

W. Kramer, 1934 (A. A. P. G. Bull., vol. 18, No. 12, pp. 1579, 1582). Uppermost 50 ft. of Talpa fm. in Concho Co. contains 2 persistent ledge makers. The lower of these members is a 2-foot bed of yellow ls., lying 950 ft. above Coleman Junction ls. It is here called *Shultz memb.*, from ranch house of Mrs. Winifred Shultz, which is on the ledge formed by the outcrop (in NE¼ T. & N. O. R. R. Co. survey No. 127) 8 mi. SE. of Paint Rock. The upper ls. is top bed of Talpa fm. and here called *Hartgrove memb.* Has been traced across SE. part of Runnels Co. to point 9.3 mi. N. of SE. corner of that county.

Shumla sandstone.

Upper Devonian: Western New York (Chautauqua Co.).

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 25 and chart). *Shumla ss.* in Chautauqua Co. lies well up in Chemung fm. Is younger than Laona ss.

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1027-1029). *Shumla ss.* (*Hall*).—The sss. exposed at Shumla, 2½ mi. S. of Laona, are 260 to 280 ft. above Laona ss.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 85). Quarries in this [Shumla] ss. on the Canadaway at Shumla were mentioned by Hall (1843). The fm. as yet has not been traced outside of Chautauqua Co. [The compiler has not found that Hall used the name *Shumla ss.*]

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), and 1924 (N. Y. State Mus. Bull. 251, p. 151), applied *Westfield sh.* to beds btw. Laona ss. and Shumla ss. and *Northeast sh.* to beds overlying Shumla ss. This classification is also that of W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), who included all these beds in the Chumung. Chadwick, however, has transferred all of them to his Canadaway group, q. v.

Shunganunga shale.

Pennsylvanian: Northeastern Kansas.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 29). *Shunganunga sh.*—Very fossiliferous sh., 10 in. to 10 ft. thick, varying in color from dark olive to bluish or even jet black. Included in Upper Coal Measures of Shawnee Co. Underlies Wabaunsee fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 203, 206, 255). Beede applied †*Shunganunga sh.* to the few ft. of beds btw. top of Nodaway coal and base of Church ls., but there seems no good reason for recognizing this as a separate unit. It is included, without differentiation, in Severy sh., where Bachelor Creek ls. memb. of Howard ls. is absent.

Named for Shunganunga Creek, Shawnee Co.

†Shushitna slate.

A typographical error in U. S. G. S. Bull. 191, 1902, p. 374, for the fm. spelled *Sushitna sl.* in publication cited, but now spelled *Susitna sl.*

Shuswap series.

Pre-Cambrian: British Columbia and Yukon.

G. M. Dawson, 1890 (Canada Geol. Surv., n. s., vol. 4, pp. 29B, 31B).

Shuswap granites.

Pre-Cambrian: British Columbia.

C. [R.] Keyes, 1917 (Iowa Acad. Sci. Proc., vol. 24, p. 56).

†Shutesbury serpentine.

Name applied by B. K. Emerson (U. S. G. S. Mon. 29, 1898, p. 55) to an exposure of serpentine 1 mi. S. of village of Shutesbury, Mass., and later discarded by him. Not mentioned in his U. S. G. S. Bull. 597, 1917.

Shutler formation.

Pleistocene and late Tertiary: Central northern Oregon.

E. T. Hodge, 1932 (Univ. Oreg. Pub. Suppl. to Geol. ser., vol. 1, No. 5, p. 6). Arlington lake beds occur N. of T. 2 S. and E. of Deschutes River and adjacent to Columbia River. The bdy of this fm. on E. side of Deschutes River, as shown on map, is arbitrary, since field evidence shows it is intergradational with Madras fm., and in fact beds of lacustrine origin occur btw. Deschutes River and T. 13 E. The name is not wholly distinctive of this fm. and in later publications we propose to call it *Shutler fm.*, because of its well-developed occurrence near Shutler post office, T. 2 N., R. 21 E. The fm. E. of Alkali Creek is made up of water-worn river gravels in its lower portion. These are overlain by the lake beds that occur from Alkali Creek westward to Deschutes River. The lake beds are in turn overlain by gravels that begin near Arlington and can be traced westward to The Dalles. The lake beds consist of beds of diatoms, volcanic ash, and silt. All of beds lie absolutely flat and uncon. upon Columbia River basalt. Pleist. fossils in older gravels; perhaps part of Arlington lake beds are Recent.

Siamo slate.

Pre-Cambrian (middle Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 554+). *Siamo sl.*—Most typical rock is a sl., but locally it passes into graywacke and often into a rock approaching qtzite. Thickness 1,250 ft. Conformably underlies Negaunee fm. and grades into underlying Ajibik qtzite. Named for exposures on Siamo Hill, just S. of W. part of Teal Lake. Assigned to Algonkian.

Siberia limestone. (In Chester group.)

Mississippian: Southern Indiana (Perry, Dubois, and Crawford Counties) and Breckinridge County, Kentucky.

C. A. Malott, 1920 (Sci., n. s., vol. 51, pp. 521–522) and 1925 (Ind. Acad. Sci. Proc. vol. 34, pp. 109–132). *Siberia ls.*—Coarse crystalline fossiliferous ls. in upper Chester. Frequently quite siliceous and is laminated or cross-bedded on weathered faces. Rarely seen in place. Usually thin, but in some sections is 10 to 20 ft. thick. Below it occurs a rather persistent yellow ls. ledge which frequently contains fossils. This yellow ledge may be considered a part of it, though it is usually separated from the main ledge by a few ft. of sh. The Siberia ls. normally is 175 ft. above Glen Dean ls., and lies from 32 to 33½ ft. above Wickcliff ss. It appears beneath Mansfield ss. in latitude of Schnellville and Wickcliff in Dubois and Crawford Counties and extends beyond Ohio River in Breckinridge Co., Ky. Named for exposures in vicinity of Siberia, Perry Co., Ind.

Sibley series.

Pre-Cambrian (Keweenawan): Western Ontario (Thunder Bay region).

T. L. Tanton, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 114, abstract). [See under *Kaministikwia group.*]

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned *Sibley clastics and ls.* of Thunder Bay region to Keweenawan.

Sicamous limestone.

Pre-Cambrian: British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 167). Included in Shuswap series.

Sicamous series.

A term employed by C. [R.] Keyes to cover rocks in Cordilleran region interpreted as having been formed during later part of Keewatin epoch. (See Iowa Acad. Sci. Proc., vol. 24, p. 56, 1917.)

Sicker series.

Jurassic: British Columbia (Vancouver Island).

C. H. Clapp and J. A. Allan, 1911 (Canada Geol. Surv. map 17A), and C. H. Clapp, 1912 (Canada Geol. Surv. Mem. 13, p. 71). Assigned to Jurassic or Triassic.

H. C. Cooke, 1917 (Canada Geol. Surv. Mem. 96, p. 125), and R. W. Goranson, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 76).

Sickle series.

Pre-Cambrian: Manitoba.

G. W. H. Norman, 1934 (Canada Geol. Surv. Summ. Rept. 1933, pt. C, No. 2347, p. 30).

Siderian.

Pre-Cambrian: General.

See under *Pelodian*.

Siebert tuff.

Miocene (upper): Central Nevada (Tonopah region).

J. E. Spurr, 1905 (U. S. G. S. P. P. 42, pp. 51–55, maps, etc.). ***Siebert tuff*** (*lake beds*).—White stratified tuffs that form conspicuous feature of geology near Tonopah. As a rule beautifully and uniformly bedded and composed of well-assorted material. Where beds of cgl. occur the pebbles are perfectly rounded. Since these sediments do not vary in character for thicknesses of several hundred ft., it is plain that they were laid down in a large body of standing water that lasted a considerable length of time. That this body was a lake is indicated by numerous general considerations derived from study of geology of surrounding region and by presence of numerous fresh-water Infusoria in some of strata. In contrast to general regular stratification, cross-bedded strata may occasionally be found. The lake came into existence at close of most active period of Tonopah rhyolite-dacite eruptions. Because of complex faulting max. thickness cannot be given, but on E. slope of Siebert Mtn an unbroken section of 600± ft. is exposed. As neither top nor bottom was seen it is likely the maximum is much more than 600 ft. Rests, in different places, on earlier andesite, on later andesite, on Fraction dacite breccia, and on Tonopah rhyolite-dacite, which is younger than the Fraction. Thin sheets of Tonopah rhyolite-dacite in places occur within the tuff series. Is uncon. overlain by basalt.

The Siebert tuff of Spurr is in good standing in Tonopah region, where is its type loc., but *Siebert fm.* in broad sense in which it was used in subsequent repts is now replaced by Esmeralda fm.

†Siebert formation.

Miocene (upper): Southern and central Nevada and southeastern California.

S. H. Ball, 1907 (U. S. G. S. Bull. 308, pp. 27, 32–34, map). *Siebert lake beds*.—Thick masses of sediments occur in majority of ranges of the area [SW. Nev. and Inyo Co., Calif.], and on lithologic and strat. grounds are correlated with Siebert lake beds, of Mio. age, at Tonopah, Nev., described by Spurr. These tuffaceous sss. and cgls., largely composed of rhyolitic material, reach an observed maximum (in Amargosa Range) of 1,150 ft. Are uncon. underlain by rhyolite and uncon. overlain by rhyolite. In southern Klondike Hills and Silver Peak Range the Siebert lake beds are interbedded, without erosional uncon., with rhyolites and siliceous latites and dacites. [As above defined and mapped Ball's Siebert lake beds include Fraction rhyolite breccia, which is not a part of Siebert tuff of Spurr.]

The Siebert fm. of F. L. Ransome (U. S. G. S. Bull. 303, 1907, and P. P. 66, 1909) in Goldfield dist., Nev., also included Fraction rhyolite breccia and is therefore a larger unit than Siebert tuff as originally defined by Spurr. This broad use of Siebert has been abandoned by U. S. Geol. Survey, being same as Esmeralda fm., the older name. (See H. G. Ferguson, 1924, U. S. G. S. Bull. 723, pp. 42–43.)

Sierra limestone.

Mississippian: Southwestern New Mexico (Sierra County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. 19, pp. 7-21). *Sierra ls.*—Compact, massively bedded gray lss., 50 ft. thick. Contains upper Burlington and lower Keokuk fauna. Overlies Lake Valley ls. [restricted] at Lake Valley. The latter ls. consists of 150 ft. of shaly, highly fossiliferous lss. containing a lower Burlington fauna. [Derivation of name not given.]

Sierra Blanca series.

Sierra Blanca coal measures.

Upper Cretaceous (Benton): Southern central New Mexico (Sierra Blanca region).

D. R. Semmes, 1920 (Am. Jour. Sci., 4th, vol. 50, pp. 415–420). *Sierra Blanca series.*—Interbedded sss., and sh., coal seams, an occasional ls., and, near base, a massive coarse-grained buff ss. (Dakota?). Thickness 1,500 to 2,500 ft. Regarded as Upper Cret., but may possibly be post-Laramie. The upper memb. is actually of post-Laramie age. The series sometimes rests on variegated shales, thin beds of ls., sss., and cgls., which are probably Morrison fm.

Probably named for Sierra Blanca, Lincoln and Otero Counties, in vicinity of which occurs a great thickness of Upper Cret. rocks (of Fox Hills, Pierre, Colorado, and Dakota age), underlain by Morrison fm.

G. H. Hansen, 1931 (Geo. Wash. Univ. Bull., Summaries of doctoral theses 1925–28, pp. 84–85). *Sierra Blanca coal measures.*—Yellow, gray, and brown clays intercalated btw. sss. and coal beds of variable thickness and quality. Thickness 600± ft. So different from underlying Tucson ss. that a strat. break might be supposed to exist btw. them, but no evidence of break was found. Believed to be of Benton age and not Montana, as once supposed. [Type loc. not given.]

Sierra Blanca limestone.

Eocene (upper): Southern California (southern part of Santa Ynez quadrangle, Santa Barbara County).

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 10, pp. 350, 352–354, pl. 46, and map). *Sierra Blanca ls.*—Remarkably pure massive, almost white foraminiferal ls., its upper 10 or 15 ft. grading into medium- to fairly coarse-grained gray ss. interbedded with gray sh. Thickness 0 to 200 ft. In Indian Canyon 200 ft. thick. Decreases in thickness to E. and disappears a little over 1 mi. W. of Mono Creek. Rests conformably on Mono sh. On S. side of San Rafael Mtns it is overlain by 25 ft. of massive maroon-gray to gray sh. of Eo. age. It is also uncon. overlain by Mio. strata. Is conspicuously exposed on S. side of Sierra Blanca Mtn, 1½ mi. SW. of Loma Pelona. Assigned to Eo.

M. F. Keenan, 1932 (San Diego Soc. Nat. Hist. Trans., vol. 7, No. 8, pp. 53–84), assigned these rocks to middle Eo., "older than Tejon restricted, and younger than Martinez."

Sierra de Cayey tuffs.

Cretaceous: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, p. 61).

Sierran.

Pliocene and Quaternary.

J. Le Conte, 1899 (Jour. Geol., vol. 7, pp. 525–544). *Sierran* proposed to replace *Ozarkian* (preoccupied), applied to a time of general uplift and erosion, longer than both the Glacial and the Champlain put together. In E. part of continent the Ozarkian grades into the Tert. In Sierra Nevada it is sharply marked off from the Tert. That it belongs to the Quat. is certain.

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 88–95). The term *Sierran* is not the equiv. and cannot properly replace the term *Ozarkian*. As I understand Le Conte, *Sierran* is derived from the canyons of Sierra Nevada region, and its definition may be given as the designation of that period during which these canyons were in process of formation. Under Le Conte's definition *Sierran* apparently covers at least part of the Ozarkian or preglacial portion of Pleist., and nearly all of the Glacial period as latter has been established in Eastern States and Europe. I have avoided applying *Ozarkian* in Calif. because, the Glacial period being so very imperfectly represented here, I could not distinguish the work of the Ozarkian from that of later time.

O. H. Hershey, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 3, pp. 1-29). Le Conte's Sierran period is divided into (descending):

Erosion epoch not named.

San Pedran epoch (deposition). May be approx.=Iowan.

Los Angelan epoch (erosion).

Red Bluff epoch (deposition).

Santa Claran epoch (erosion).

J. P. Smith, 1910 (Jour. Geol., vol. 18, No. 3, p. 227), divided Quat. of Calif. into (descending) Terrace epoch, Champlain epoch, and Sierran epoch (including Glacial and pre-Glacial).

J. E. Eaton, 1928 (A. A. P. G. Bull., vol. 12, p. 119), divided the Pleist. of Calif. into (descending) Champlain, Glacial, Sierran, and Pedroian.

Siesta formation.

Pliocene: Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, pp. 384-390 and map). *Siestan fm.*—Fresh-water cgls., sss., and shales, with lignites, clays, ls., chert, and tuff. Included in Upper Berkeleyan. Overlies in places Grizzly Peak andesite and underlies in places a fresh-water ls. memb. of Upper Berkeleyan.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Siesta fm.*—Lake beds. [Same lithology as above.] Thickness 200 ft. Underlies Bald Peak basalt and overlies Moraga fm. Is middle fm. of Berkeley group.

Named for development in Siesta Valley, Berkeley Hills.

†Siestan formation.

See *Siesta fm.*

Siggins sand.

A subsurface sand or sands in McLeansboro fm. (Penn.) of Siggins pool, Cumberland Co., SE. Ill. (See Ill. Geol. Surv. Bull. 54, index.)

Signal Hill formation.

Pre-Cambrian: Newfoundland.

J. B. Jukes, 1839 (Rept. on geol. Newfoundland), and 1840 (Edinburgh New Philos., Jour., vol. 29, p. 107). *Signal Hill ss. and cgl.* [Age not given.]

J. B. Jukes, 1843 (Gen. rept. geol. of Newfoundland, pp. 51+), assigned *Signal Hill ss.* to Algonkian, as did C. D. Walcott (Geol. Soc. Am. Bull., vol. 10, 1889, p. 219) and later writers.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geology of Newfoundland, No. 4). *Signal Hill fm.*—Red sss. with cgls. and slates. No fossils. Upper fm. of Huronian. Uncon. underlies Random fm. (Keweenawan) and overlies Avalonian fm. (Huronian). [Derivation of name not stated.]

Signal Mountain formation.

Upper Cambrian: Southeastern Oklahoma (Wichita and Arbuckle Mountains).

E. O. Ulrich, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 742-747). *Signal Mtn fm.* is named for exposures in sec. 8, T. 2 N., R. 12 W., about 1 mi. S. of Signal Mtn, one of prominent peaks at E. end of Wichita Range. Signal Mtn itself is a pre-Camb. hill, but the beds to which the name is here applied are in plain sight of it, and no other good name is available. In this section Signal Mtn fm. overlies Fort Sill fm., the base being marked by a clastic zone, about 35 ft. thick, consisting of calc. ss. with abundant green glauconite grains. This is followed by a zone of flat-pebble cgls. about 20 ft. thick, which in turn is overlain by about 130 ft. of thin-bedded, more or less coarsely crystalline gray and yellowish-gray ls. separated by thin sh. partings. Glauconite grains are fairly abundant throughout the fm., and this aids in separating it from the underlying Fort Sill, in which very few grains occur. Also, the ls. is much more crystalline than that of the Fort Sill. It contains following well-marked faunal zones (ascending): (1) *Elkia* zone, which lies about 25 ft. above thick top ls. beds of Fort Sill fm.; was not seen in section S. of Signal Mtn, but may fall in sandy beds which mark base of fm. there. (2) *Stenopilus* zone, which occurs just above the sandy basal ls. in sections S. and SE. of Signal Mtn. (3) *Saukinae* zone, which lies 30± ft. above *Stenopilus* zone in Signal Mtn region and ranges upward through about 50 ft. of strata, but on N. side of Wichita uplift, where the fm. is much thicker, this zone comes in at a somewhat higher level and extends through about 100 ft. of beds. It contains the largest and most widely distributed fauna of the fm. (4) *Eurekia* zone, which lies about 50 ft. above most fossiliferous layers of *Saukinae* zone in sections S. of Signal Mtn and about 100 ft. above base of fm. (5) *Euptychaspis* zone, the 5th and highest zone, is characterized by small species of *Euptychaspis;* occupies uppermost 50 ft. of fm. The Fort Sill and Signal Mtn fms. occur in base of Arbuckle ls. in both Arbuckle and Wichita uplifts. In Wichita Mtns the Fort Sill is everywhere succeeded by Signal Mtn fm., but in the Arbuckles 100 to 600 ft. of Royer marble wedges in btw. them.

See also under *Arbuckle group*, Decker, 1933.

Silica shale. (In Traverse formation.)

Middle Devonian: Northwestern Ohio (Lucas County).

G. A. Stewart, 1927 (Ohio Geol. Surv., 4th ser., Bull. 32, pp. 5–9). *Silica sh.*—Bluish-gray sh., soft, highly calc.; disintegrates very rapidly on exposure; contains much iron pyrite. About 10 ft. thick in quarry of Sandusky Cement Co. ½ mi. N. of village of Silica, Lucas Co. Evidently thickens rapidly westward, where two test holes indicate its thickness may be 15 to 17 ft. More typical Hamilton fauna than any previously found in Ohio. Overlain by thick-bedded bluish-gray ls. and grades into underlying heavy blue ls., all of which are included in Traverse fm.

E. R. Pohl, 1930 (Tenn. Acad. Sci. Jour., vol. 5, pp. 60–62). "Silica sh." of Ohio is nothing more than southern extension of basal deposit of Long Lake stage (Bell sh.) [of northern Mich.].

†Siliceous group.

Descriptive term applied in early Tenn. repts to Fort Payne chert and Grainger sh.

†Siliceous limestone.

Descriptive term applied in early repts to ls. in western Pa., W. Va., and Md. later named *Loyalhanna ls.*

Sillery formation.

Ordovician or Cambrian: Quebec.

W. E. Logan, 1863 (Canada Geol. Surv. Rept. 1843–63, pp. 225–297). *Sillery fm.*—Lower Sil.; synonym Chazy (?); eastern Canada; included in Quebec group.

Some later Canadian writers refer this fm. to Ord. and others refer it to Camb. and to Dev.

†Silo sandstone.

Upper Cretaceous: Southeastern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79, p. 6). *Silo ss.*—Fine brown friable ss. and sandy clays, locally indurated by ferruginous cement, sh., and shaly ss. Thickness 200 to 500 ft. Top fm. of Cret. in Atoka quad. Overlies Bennington ls.

Same as Woodbine sand, older and better-established name.

Named for Silo, Bryan Co.

Silurian period (or system).

The time (and the rocks) of one of the Paleozoic periods (following the Ordovician period and preceding the Devonian period). In early geologic repts called "Upper Silurian," but "Lower Silurian" was replaced by *Ordovician system* in 1879, and *Silurian* is now restricted to post-Ordovician and pre-Devonian time and rocks. For definition see U. S. G. S. Bull. 769, pp. 80–81

Siluric.

A variant of Silurian employed by some geologists.

Siluronian.

A name proposed by A. W. Grabau (Pan-Am. Geol., vol. 66, No. 1, 1936, pp. 30, 31) "for the new system, composed of the old Upper Sil., a transgressive series, and the old Lower Dev. as a retreatal series, the two together forming a complete pulsation system." The Oriskany to be basal bed of Dev. system as Grabau would restrict it.

Silver shales.

Upper Devonian: Southwestern New Mexico (Grant County).

C. R. Keyes, 1908 (Am. Inst. Min. Engrs. Bi-Mon. Bull. 19, pp. 7-21). *Silver shales.*—Black argill. shales, nonfossiliferous, 100 ft. thick. Underlie Bella shales and uncon. overlie Santa Rita ls. (Sil.). Assigned to Dev. upon strat. position. Type loc., Silver City, Grant Co.

Appears to correspond to lower part of Percha sh.

Silver City granite.

Age (?): Southwestern Idaho (Silver City).

A. M. Piper and F. B. Laney, 1926 (Idaho Bur. Mines and Geol. Bull. 11, p. 15). [*Granodiorite or Silver City granite* is used in heading, but the rock is mapped simply as *Granodiorite*.]

Silver Creek limestone member (of Sellersburg limestone).

Middle Devonian (Hamilton): Southern Indiana and central northern Kentucky.

C. E. Siebenthal, 1901 (Ind. Dept. Geol. and Nat. Res. 25th Ann. Rept., p. 345). *Silver Creek Hydraulic ls.*—Homogeneous fine-grained bluish to drab argill. mag. ls. 0 to 16 ft. thick. Formerly included in Sellersburg ls. Overlain by what author calls Sellersburg ls. [upper part of Sellersburg as originally defined], and underlain by Jeffersonville ls.

C. Butts, 1915 (Ky. Geol. Surv., 4th ser., vol. 3, pt. 2, pp. 118, 120), divided Sellersburg ls. as originally defined by Kindle into Beechwood ls. memb. above (=Sellersburg ls. of Siebenthal, 1901) and *Silver Creek ls. memb.* below. This is now the generally accepted definition of Sellersburg ls. Contains Hamilton fossils.

Named for Silver Creek, Clark Co., Ind.

†Silver Creek shale.

Upper Devonian: Western New York (Chautauqua County).

D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, pp. 1019-1029). *Silver Creek light soft shales*, 112 ft. thick, underlie Dunkirk black sh. and overlie Angola soft shales with concretions in Lake Erie section of Portage group.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 76). *Hanover shales* (*nom. nov.*).—Name is from exposures in town of Hanover, Chautauqua Co., and is here used in place of *Silver Creek* (preoccupied). Excellent exposures in Walnut and Silver Creek Ravines. Equiv. to upper part of Hatch sh. and flags of eastern sections.

G. H. Chadwick, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 157). *Hanover shales* much younger than Hatch shales and=Wiscoy shales. Discon. overlie Angola shales and discon. underlie Dunkirk black sh.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [In this table Chadwick seems to have restricted *Hanover sh.*, because he gave following as succession in Chautauqua Co. (downward): Dunkirk sh.; Hanover sh.; *Pipe Creek sh.*; hiatus (?) equiv. to Nunda ss.; and Angola sh.; and correlated Hanover and Pipe Creek shales with Wiscoy sh.]

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 149). *Hanover sh.* (formerly *Silver Creek sh.*), is highest memb. of Portage group on Lake Erie. Has been traced continuously into Wiscoy sh. of Genesee Valley.

Silver Dyke breccia.

Tertiary: Central Montana (Little Belt Mountains).

P. A. Schafer, 1935 (Mont. Bur. Mines and Geol. Mem. 13, map of Neihart min. dist.) *Silver Dyke breccia.*—Brecciated granite porphyry and quartz porphyry with occasional fragments of gneiss. [Map shows it occurring W. of Silver Dyke mine, and as older than Carpenter Creek porphyry and younger than Snow Creek porphyry. On p. 51 is a "sketch map showing geol. and surface plant in vicinity of Silver Dyke mine," which maps "breccia" but without a name. Page 52 states: It is possible that the fracturing which accompanied the injection of the Carpenter Creek porphyry caused the brecciation of the brittle Snow Creek quartz porphyry.]

†Silverheels porphyry (also porphyrite).

Eocene: Northeastern part of Mosquito Range, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215–230) and 1886 (U. S. G. S. Mon. 12, pp. 83, 104–107). *Silverheels porphyry.*—Extremely fine-grained greenish-gray rock characterized by fine needles of decomposed hornblende and carrying quartz in small amount, two feldspars, and hornblende and biotite. [On p. 342 of Mon. 12 Whitman Cross describes the rock as *Silverheels porphyrite.*]

In U. S. G. S. P. P. 148, pl. 2, 1927, mapped with the other masses of Gray porphyry, without a distinctive name.

Named from fact it forms important intrusive sheets on Mount Silverheels, NE. of Alma.

Silver Hill formation.

Middle Cambrian: Central western Montana (Philipsburg region).

F. C. Calkins and W. H. Emmons, 1913 (U. S. G. S. P. P. 78). *Silver Hill fm.*—In descending order: (1) Calc. sh., strongly banded in brown, white, and green, interbedded with laminated ls., 90 ft.; (2) ls. with thin brown siliceous laminae, 120± ft.; (3) sh., dark green, not notably calc., with a 3-ft. sheet of dark intrusive igneous rock near base, 120 ft. Underlies Hasmark fm. and overlies Flathead qtzite. Named for Silver Hill, S. of Silver Lake, on whose steep E. face the best section is displayed.

Silver Hills facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, 1931, pp. 77, 94, 96) to a lithologic development of New Providence fm. in a part of southern Ind. and Jefferson Co., Ky.

Silver Hoard formation.

Carboniferous: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. B, p. 60) and 1920 (Canada Geol. Surv. Mem. 117, p. 15).

Silverhorn dolomite.

Middle Devonian: Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. and Met. Eng. Trans., No. 1647, p. 7) and 1932 (U. S. G. S. P. P. 171). *Silverhorn dol.*—A succession of varied dolomites with some beds of ls., and in upper part beds of qtzitic ss. with a capping qtzite 20 to 100 ft. thick; the whole not less than 3,000 ft. thick. In fault contact with Sil. ls. Conformably underlies West Range ls. (Upper Dev.). Fossils assigned to high Middle Dev. by E. Kirk. Named for exposures S. of old Silverhorn mining camp, 4 mi. NW. of Bristol Pass.

Silveria formation.

Pleistocene: Northwestern Illinois (Stephenson County).

O. H. Hershey, 1896 (Am. Jour. Sci., 4th, vol. 2, pp. 324–330). *Silveria fm.*—Blue and brown laminated silts, 100 ft. thick, called "Kansan Buried Loess" in previous paper. Neither preglacial nor interglacial. Separated from overlying Kansan drift by erosion interval. [According to F. Leverett (U. S. G. S. Mon. 38, pp. 111–118, 1899) this sand and silt is overlain by Illinoian drift and it appears to be underlain by Yarmouth soil.]

Named for extinct Lake Silveria, in Pecatonica Basin, Stephenson Co.

Silver King dolomite member.

Middle Cambrian: Southeastern California (San Bernardino Mountains).

J. C. Hazzard and J. F. Mason, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 2, pp. 236–237). *Silver King dol.*—Dark-gray to black medium- to coarse-grained dol., 200 to 250 ft. thick, lying in upper part of Bonanza King fm., 200 to 250± ft. below its top. Most distinctive and easily recognizable memb. of Bonanza King fm. in Providence Mtns. Named for Silver King mine, on E. side of Providence Mtns. Not present in Marble Mtns.

Silver Lake shale. (In Scranton shale.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 30). *Silver Lake sh.*—Olive-colored sh., not very fossiliferous, 15 to 35 ft. thick, containing a thin, very argill. ls. Included in Upper Coal Measures of Shawnee Co. [From statement on p. 28 appears to overlie Silver Lake coal and underlie Stanton ls.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 41, 58). *Silver Lake sh.*, named by Beede, is top unit of Scranton sh. Thickness 8 ft. in Nebr., increasing to 20 ft. or more a few mi. W. of Topeka, Kans. Overlies Rulo ls., beneath which is Silver Lake coal.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 214). *Silver Lake sh.* underlies Burlingame ls. and overlies Rulo ls. Can be traced practically continuously from Nebr. across eastern Kans. into northern Okla. Type loc. in vicinity of Silver Lake, Shawnee Co., Kans. [Moore discarded Scranton sh. and treated Silver Lake sh. as a fm. in his redefined Wabaunsee group.]

Silver Lake group.

Pliocene: Central southern Oregon.

T. Condon, 1902 (The two islands). *Silver Lake group*, Pliocene lake bed. Fossils.

†Silver Ledge porphyry.

Mississippian (upper): Central northern Utah (Mercur district).

A name applied by J. E. Spurr to an altered ls. containing the silver ores of Mercur dist., which occur in Great Blue ls.

Silver Mountain monzonite porphyry.

Eocene (?): Southeastern Colorado (Huerfano County).

R. C. Hills, 1900 (U. S. G. S. Walsenburg folio, No. 68). *Silver Mtn monzonite porphyry.*—Belongs to Silver Mtn center of eruption and is well represented in Huerfano Park quad., adjoining Walsenburg quad. on W.

Silver Peak group.

Lower Cambrian: Southwestern Nevada and Inyo County, California.

H. W. Turner, 1902 (Am. Geol., vol. 29, pp. 261–272). *Silver Peak fm.*—Lower Camb. rocks in mtns N. of Clayton Valley, Esmeralda Co., Nev., consisting of (ascending): (1) Massive dol.; (2) massive green qtzite; (3) knotted schists; (4) *Archeocyathus* ls. and green *Olenellus* sl. with dark ls. and some qtzite and thin-bedded sl. near top. Also exposed in Silver Peak Range, Esmeralda Co., Nev. Uncon. overlain by Upper Camb. Emigrant fm. Rests on Algonkian rocks. According to C. D. Walcott's division line btw. Camb. and Algonkian, items 1, 2, and 3 of section N. of Clayton Valley would belong to Algonkian, but they are here included in Lower Camb. [Thickness not given.]

The Silver Peak deposits are regarded as divisible into two or more fms., and hence have been called *Silver Peak group* and *Silver Peak "series."* They have been identified, with a thickness of 7,000 ft., by E. Kirk (U. S. G. S. P. P. 110, 1918) in Inyo Range, Calif. C. D. Walcott also identified them in Inyo Range in 1908.

Silver-pipe limestone.

Mississippian: Central New Mexico.

C. L. Herrick, 1904 (Am. Geol., vol. 33, pp. 310–312). [See under †*Graphic-Kelly ls.*]

Not a geographic name but miners' descriptive term.

Silver Plume granite.

Pre-Cambrian: Central northern Colorado (Georgetown quadrangle).

S. H. Ball, 1906 (Am. Jour. Sci., 4th, vol. 21, p. 389). *Silver Plume granite.*—Biotite granite, in stocks, dikes, and irregular masses; is a medium grained hypidiomorphic granular rock. Cuts all pre-Camb. fms. of Georgetown quad. except the pegmatite and associated granite and granite porphyry. Forms S. wall of Clear Creek canyon at mining town of Silver Plume.

For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

†Silver Reef sandstone.

A name locally applied in Washington Co., SW. Utah, to 25 ft. of variable coarse arkosic cross-bedded ss. banded with gray, white, and mauve, lying 260 ft. above base of Chinle fm. (Upper Triassic) at Virgin City, where it is said to be the same zone that in the Silver Reef, near Leeds, about 10 mi. W. of Virgin City, contains the fossil logs impregnated with silver minerals which in the eighties supported several flourishing enterprises. (See U. S. G. S. P. P. 129, p. 62, 1922.)

†Silver Terrace sandstone.

Jurassic (?): Western California (San Francisco).

R. Crandall, 1907 (Am. Phil. Soc. Proc., vol. 46, pp. 3–58). *Silver Terrace ss.*—Sss., with some shales, tuffs, and lignites. Thickness 500 ft. Forms Silver Terrace Hills, in E. part of San Francisco. Is older than Telegraph Hill ss. In places is overlain by the upper jasper bed. Is a part of the Franciscan.

A. C. Lawson (U. S. G. S. San Francisco folio, No. 193, 1914) mapped this ss. as *Marin ss.*

Silvertip conglomerate member.

Mississippian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 46 and passim). *Silvertip cgl. memb.*—Basal memb. of Madison ls. Consists of massive ls.-breccia cgl. with angular pebbles up to 4 or 5 inches long. On Pentagon Mtn the pebbles are of banded gray ls.; on Lone Butte they are of brown petroliferous ls. Matrix is light-gray, crystalline, argill., white-gray weathering ls. In general the pebbles are finer grained than the matrix, and some of them are slightly rounded. Is known to occur in only 3 areas—Lone Butte, Spotted Bear Mtn, and Pentagon Mtn. Thickness 140 ft. on Lone Butte, 23 on Spotted Bear Mtn. Underlies Saypo ls. memb. and discon. overlies Spotted Bear ls. memb. of Jefferson ls. (Middle Dev.). Named for Silvertip syncline, because it is thickest on Lone Butte, which lies nearly in center of the syncline.

Silverton volcanic series.

Miocene: Southwestern Colorado.

W. Cross, 1901 (U. S. G. S. Bull. 182, pp. 29–39). *Silverton series.*—Complex of andesitic flows and tuffs alternating with rhyolitic flows, flow breccia, and tuff. In Telluride quad. and at most places in Silverton quad. the lowest memb. is a rhyolitic flow or flow breccia of peculiar character. This complex as a whole contrasts markedly with underlying San Juan series (which is purely andesitic and entirely fragmental) and with overlying Potosi series (which is almost entirely rhyolitic). In Telluride folio was called "Intermediate series." Rests uncon. on San Juan series. Covers greater part of Silverton quad. Thickness 300 to 5,000 ft.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120), called these rocks *Silverton volcanic series,* and divided them into several units.

W. Cross and E. Howe, 1907 (U. S. G. S. Ouray folio, No. 153), introduced new name *Henson tuff* for uppermost fm. of Silverton volcanic series and stated that in Silverton folio the upper part of Henson tuff was included in overlying Potosi volcanic series and that lower part was included in the underlying pyroxene andesite, which was then called uppermost part of Silverton volcanic series.

Includes Henson tuff, Burns latite tuff, Eureka rhyolite, and Picayune volcanic group, also unnamed pyroxene andesite.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Silvies River beds.

Lower Jurassic: Southeastern Oregon.

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, p. 105). [Table showing *Silvies River beds*, Lower Jurassic sss. and red impure ls., 950 ft. thick. Younger than Eagle Creek beds (Upper Triassic) and older than Knoxville (?) fm. Probably named for Silvies River, Harney Co.]

W. D. Smith, 1924 (Univ. Oreg. Commonwealth Rev., vol. 6, No. 4, p. 74), repeated above table, in which *Silvies River beds, Lower Jurassic* appears.

Simi conglomerate.

Eocene (lower): Southern California (Ventura County).

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 15, No. 11, pp. 400–401 and map). *Simi cgl.*—A very persistent cgl. of well-rounded pebbles and boulders of all sizes up to 1 ft. diam., in matrix of coarse-grained arkosic ss. Occasionally, especially near top, there are lenticular beds of ss. varying in thickness from 6 in. to several ft. The pebbles are chiefly qtzite, but granite and rhyolite pebbles are abundant, and the fm. also contains pebbles of diorite, ss., gneiss, and schist. Thickness, few ft. to 800 ft. on W. side of the faults S. of Simi Valley, with max. of about 1,500 ft. E. of main fault. Is basal fm. of Martinez group (lower Eo.). Rests uncon. on Chico fm. Grades vertically and laterally into overlying Las Virgenes ss. Named for occurrence on flanks of Simi Hills, Ventura Co.

Similkameen beds.

Tertiary: British Columbia.

J. W. Dawson, 1890 (Canada Roy. Soc. Proc. and Trans., vol. 7, sec. 4, pp. 75–91). Included in Mio.

†Similkameen formation.

Cretaceous (Lower): Central northern Washington.

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137, map). *Similkameen fm.* (text heading); *Similkameen system* (map).—Mainly sss., shales, and lss.; 800 to 1,000 ft. of qtzite, cgls., and breccias at base. Total thickness 4,000 or 5,000 ft. These rocks appear to constitute a well-defined fm., which I propose to term provisionally *Similkameen fm.*, since it is exposed throughout a large part of elevated region drained by headwaters of Similkameen River.

Preoccupied in British Columbia. Replaced by *Pasayten fm.*

Similkameen granite.

Tertiary (?): British Columbia and central northern Washington (Okanogan batholith).

R. A. Daly, 1906 (Geol. Soc. Am. Bull., vol. 17, pp. 329–376). Possibly irrupted in late Mio. or even Plio. Trenched by deep valley of Similkameen River.

J. B. Umpleby, 1911 (Wash. Geol. Surv. Bull. 5, pp. 64–74), assigned this granite to *pre-Tert., preferably late Cret.*

†Simmons Bluff beds.

Pleistocene: Southern South Carolina (Charleston County).

W. H. Dall, 1897 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 336, published in 1897 as House Doc. 5, 55th Cong., 2d sess.). *Simmons Bluff beds.*—The Pleist. of Simmons Bluff, S. C., carries a rich and finely preserved marine fauna.

According to C. W. Cooke (personal communication, 1935) the beds exposed at Simmons Bluff, about 12 mi. below Rantowles, Charleston Co., are a facies of Pamlico fm.

Simms sand.

A subsurface sand assigned to upper part of McElroy memb. of Fayette ss. of eastern Tex. by O. L. Brace (A. A. P. G. Bull., vol. 15, No. 7, 1931, pp. 779–781).

Simojovel formation.

Tertiary: Mexico.

W. A. VerWiebe, 1925 (Pan-Am. Geol., vol. 44, p. 133). *Simijovel fm.*, Mexico, assigned to Tert.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 325). *Simojovel fm.*, Mexico, assigned to upper Mio.

Simon quartz keratophyre.

Middle Triassic: Central Nevada (Cedar Mountains).

A. Knopf, 1921 (U. S. G. S. Bull. 725H). *Simon quartz keratophyre* believed to have been erupted contemporaneously with Middle Triassic lss. Named for Simon mine.

Simon limestone.

Mississippian: Southeastern Arizona (Cochise County).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 243, 251, 338). *Simon lss.*—The basal Mississippian beds, carrying Chouteau fauna, as exposed in face of Chiricahua Mtns and overlooking San Simon bolson [NE. corner of Cochise Co.]. Thickness 300 ft.

†Simon sandstone.

A shortened form of *Mount Simon ss.*, employed by C. [R.] Keyes.

Simons syenite.

Pre-Cambrian: Long Lake quadrangle, Adirondack Mountains, New York.

H. P. Cushing, 1907 (N. Y. State Mus. 60th Ann. Rept., pt. 2, map only). "Red to green quartzose syenite, forming a granitic phase—*Simons syenite.*"

Exposed on shores of Simons Pond, Franklin Co.

Simons sand.

A subsurface sand in central eastern Okla., which is said to correlate with part of Tyner fm., of Ord. age.

Simonson dolomite.

Middle Devonian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421-432). *Simonson dol.*—Characteristic rock is dark- to medium-gray dol. in which individual grains are sufficiently large to be distinguished by unaided eye. Beds 1 to 2 ft. thick. Fine lamination is generally present, and commonly extremely irregular in detail. Two nonpersistent dol. cgls. occur within the fm., and a third, which persists throughout outcrop of fm., has been chosen to mark top bdy. Thickness 1,000 ft. Middle Dev. fossils. Grades into underlying Sevy dol. and is overlain by Guilmette fm. Named for exposures in Simonson Canyon, on W. side of Deep Creek Range, Gold Hill region.

See also U. S. G. S. P. P. 177, 1934, by Nolan.

Simpson group.

Lower and Middle Ordovician: Central southern Oklahoma (Arbuckle Mountains).

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Simpson fm.*—Sss. and fossiliferous ls., with interbedded greenish clay shales and marls separable into several quite distinct members. Thickness 1,600 ft. In Tishomingo quad. and in Arbuckle Mtns, where fm. is completely exposed, it varies in thickness from 1,200 to 2,000 ft. Underlies Viola ls. through transition, and overlies Arbuckle ls.

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). According to E. O. Ulrich the fauna of lower part of Simpson fm. has decided similarities to that of Chazy of N. Y. and Canada, and fauna of upper part bears close relations to that of upper div. of Stones River group in Tenn. and Ky., but certain species indicate age=Black River fauna of Minn., though it may be these forms appeared earlier in Tishomingo region.

J. A. Taff, 1904 (U. S. G. S. P. P. 31, p. 25). [Statements about fossils of Simpson fm. similar to 1903 above, except that there is no mention of Black River.]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), assigned *Simpson fm.* [restricted] wholly to Stones River (early Chazyan) and an older "unnamed epoch" (later named "Big Buffalo," etc.); allocated the overlying beds, of late Chazy and Black River age, to a new fm. which he called *Bromide;* and designated the uncon. overlying beds of Trenton age as *Viola ls.* According to F. C. Edson, 1927, the beds at Bromide type loc. were mapped by Taff as *Viola ls.* See under *Bromide fm.*

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 30), showed *Simpson fm.* as of upper, middle, and lower Chazy age, and as including at top "typical Bromide (of late Chazy age)," while the overlying beds of Black River age he "provisionally referred to Bromide fm."

F. C. Edson, 1927 (A. A. P. G. Bull., vol. 11, No. 9, pp. 967-975), suggested that *Simpson fm.* be divided into (descending): (1) Bromide group (all "post-Wilcox" beds, of lower Black River age, underlying Viola ls., of upper Black River and Richmond age); (2) "Wilcox" sand, of upper Chazy age; and (3) *Simpson fm.* [restricted], of lower Chazy or Stones River age.

E. O. Ulrich, in ms. chart prepared in April 1928 but first published (by C. E. Decker) in Dec. 1930 (A. A. P. G. Bull., vol. 14, p. 1495), divided Simpson fm. into (descending): (1) West Spring Creek with Criner memb. (of early Trenton and late Black River age); uncon. on (2) Bromide fm. (of Chazy age); and (3) Oil Creek fm. (also of Chazy age).

E. O. Ulrich in chart submitted at Dec. 1928 meeting of Geol. Soc. Am. in N. Y., but first published (by C. E. Decker, from ms. rept. by C. N. Gould) in Dec. 1930 (same reference as above), divided Simpson fm. into (descending) Bromide, Criner, Tulip Creek, McLish, Falls, Nebo, and Joins Ranch.

E. O. Ulrich, Feb., 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73), showed *Simpson fm.* as including at top the lower part of Bromide (which part he assigned to Black River) and divided the rest of the Simpson into several new but undefined fms., named (descending) Criner, Tulip Creek, Falls, McLish, Oil Creek, and Joins, all of Chazy age.

C. E. Decker, Dec. 1930 (A. A. P. G. Bull., vol. 76, art. 21, p. 1498), divided Simpson fm. into (descending) Bromide (including Criner), Tulip Creek, McLish (same as *Falls,* dropped), Oil Creek, and Joins fms.

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 11-13). The *Simpson* is here raised to a *group,* divided into 5 fms. (ascending), Joins, Oil Creek, McLish, Tulip Creek, and Bromide. These fms. represent 5 more or less complete sedimentary cycles with a basal sand at bottom of each of 4 upper ones and a cgl. at base of lowest one.

E. O. Ulrich, 1933 (Geol. Soc. Am. Bull., vol. 44, p. 105). *Simpson group* is divided into 8 fms.: Bromide fm. (correlates with Lowville); Criner fm.; Cool Creek fm.; Tulip Creek fm.; McLish and Falls fms., of middle Chazyan age; and Oil Creek and Joins fms., of lower Chazyan age.

C. E. Decker, 1933 (Tulsa Geol. Soc. Digest, pp. 55+), divided *Simpson group* into Bromide, Tulip Creek, McLish, Oil Creek, Joins, West Spring Creek (not defined), Alden ls. (not defined), and Cool Creek ls.

Named for former village of Simpson, just N. of Pontotoc, Johnston Co.

Simpson shale.

Devonian: Northwest Territories, Mackenzie, and Alberta.

A. E. Cameron, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 26).

Simpson sand.

A subsurface sand in Robberson field, central southern Okla., lying lower than Jackson sand and higher than Pugh sand. Assigned to Ord. in Okla. Geol. Surv. Bull. 40Q, 1928, p. 179.

Simsboro sand member (of Rockdale formation).

Eocene (Wilcox): Central and southern Texas (between Brazos and Frio Rivers).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 586, etc.). *Simsboro sand.*—Middle memb. of Rockdale fm. in central and southern Tex. Named by W. A. Reiter during his detailed work on the Wilcox in Mexia dist., from typical exposures at town of Simsboro, Freestone Co. Has been mapped by Reiter (letter Oct. 27, 1932) from near Rockdale, Milam Co., to Trinity River, and has been traced by other geologists over a still larger area. Consists of 240 to 300 ft. of gray soft sand containing fossil wood, lumps of water-rolled clay, seams and lentils of blue-gray clay (in some places chocolate brown), and a little lignite. Underlies Calvert Bluff clay memb. of Rockdale and overlies Butler clay memb.

Sinbad limestone member (of Moenkopi formation).

Lower Triassic: Central eastern Utah (San Rafael Swell).

J. B. Reeside, Jr., C. E. Dobbin, A. A. Baker, and E. T. McKnight (name proposed by Reeside and Gilluly), 1927 (A. A. P. G. Bull., vol. 11, No. 5, p. 797). In Green River Valley the Moenkopi fm. contains near middle (about 320 ft. above base) a thin marine ls. (*Sinbad ls. memb.*) near base of a thick zone of light greenish-gray sandy sh. Type Sinbad is in San Rafael Swell.

J. Gilluly and J. B. Reeside, Jr., 1928 (U. S. G. S. P. P. 150, table opp. p. 62, p. 65). On W. side of San Rafael Swell the Moenkopi fm. includes, about 200 ft. above base, a fairly persistent memb. of thick-bedded light-gray sandy ls. and ss., 40 to 150 ft. thick, here named *Sinbad ls. memb.*, from excellent exposures in Sinbad [Plateau].

Sinclair formation.

Ordovician: British Columbia.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 75, pp. 14, 34, 50).

Singleshot member (of Appekunny argillite).

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park).

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Singleshot memb.*—Basal memb. of Appekunny fm. Consists of 300 to 400 ft. of metargillites with interbedded thick qtzites and dolomitic sss. Colors range from brown through greenish and white to red. Mud cracks and coarse ripple marks common. Underlies Appistoki memb. of Grinnell fm. Overlies Altyn fm. Best seen on Singleshot Mtn. near St. Mary Lake, Glacier Nat. Park.

Sing Sing marble.

See under *Tuckahoe marble*.

Sinian system.

Term advocated by A. W. Grabau (Geol. Soc. Am. Bull., vol. 36, p. 175, 1925) "for those pre-Cambrian deposits which are but little altered." Is a modification of Von Richthofen's term *Sinian series*, most of which, according to Grabau, is pre-Camb. and continental, but the upper part of which is Camb. and principally marine.

Sinks Grove limestone. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 451, 484). *Sinks Grove ls.*—Blue hard, somewhat sandy and impure deposit, containing throughout a vast amount of black nodular carbonaceous chert which weathers gray. Marine fossils in matrix and in chert. Thickness 175 to 330 ft. Underlies Patton sh. and overlies Hillsdale ls.; all members of Greenbrier series [ls.]. Type loc. along Sinks Grove-Knobs road, in vicinity of Sinks Grove, Monroe Co. Also observed in Mercer Co., W. Va.; in Giles Co., Va.; and in Washington Co., Va., where it reaches 415 ft. in thickness but thins and disappears before Ky. and Tenn. lines are reached.

Siouan series.

A name applied by C. [R.] Keyes in 1912 (Iowa Acad. Sci. Proc., vol. 19, pp. 147–151) to include Sioux qtzite.

Sioux quartzite.

Pre-Cambrian (Huronian): Southeastern South Dakota, southwestern Minnesota, northwestern Iowa, and northeastern Nebraska.

C. A. White, 1870 (Iowa Geol. Surv. vol. 1, pp. 26, 167–171). *Sioux qtzite.*—Red ss. or qtzite outcropping in banks of Big Sioux River, Iowa [and S. Dak.]. Completely metamorphosed; very hard and compact; breaks with splintery fracture; color varies from bright red to deep red. Thickness 50 ft. Believed to be older than [so-called] Potsdam ss. Assigned to Huronian (?).

N. H. Winchell, 1873 (Minn. Geol. Nat. Hist. Surv. 1st Ann. Rept.), gave thickness at New Ulm as 350± ft.

J. E. Todd, 1900 (U. S. G. S. W. S. P. 34). *Sioux qtzite* (Algonkian), is 500+ ft. thick in SE. S. Dak. Chiefly red or purplish qtzite of intensely compact and durable character. Is frequently called *Sioux Falls "granite,"* from extensive exposures and numerous quarries in vicinity of Sioux Falls, S. Dak.

†Sioux Falls granite.

Popular term for *Sioux qtzite*, from extensive exposures and numerous quarries in vicinity of Sioux Falls, S. Dak.

Sir Donald formation.

Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 138).

Siskiyou terrane.

Pre-Cambrian (?): Northwestern California (Klamath Mountains).

N. E. A. Hinds, 1932 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 20, No. 11, pp. 375-410). While Abrams and Salmon fms. may be of different ages, they form a distinct strat. group in Klamath-Siskiyou region, hence I propose to consider them as members of a single terrane for which I suggest the name *Siskiyou*, from the wide exposure of these strata in Siskiyou Mtns. They are pre-Middle Dev. and probably pre-Sil.

N. E. A. Hinds, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1, 2, p. 84). Writer believes Siskiyou fms. are definitely pre-Sil. and probably pre-Camb. The Abrams and Salmon fms. are separated by an erosional uncon. Though of different ages they form a distinct strat. group, since they are much more highly metamorphosed than any of later fms. so far known from this region, and their degree of recrystallization is similar.

The U. S. Geol. Survey at present classifies Abrams schist and Salmon fm. as *pre-Camb.* (*?*).

Siskiyou granodiorite.

Jurassic: Northwestern California (Del Norte and Siskiyou Counties).

J. H. Maxson, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1, 2, Jan. and Apr., p. 131, map). *Siskiyou granodiorite.*—Coarse-grained plutonic rock containing green hornblende, biotite, sodic plagioclase, orthoclase and quartz, and, as accessory minerals, apatite and magnetite. Correlated with granodiorites of Sierra Nevada batholith, of late Jurassic age. Intrudes Preston diorite and serpentine and is intruded by Patrick greenstone, of supposed Cret. age.

Sisquoc formation.

Pliocene (lower): Southern California (Santa Maria district).

W. W. Porter II, 1932 (A. A. P. G. Bull., vol. 16, No. 2, pp. 135-143). *Sisquoc fm.* (*lower Plio.*).—Silts, sss., and diatomites, 1,150 to 1,190± ft. thick, divided into (descending): (1) In general 550 ft. of fine, friable, ordinarily ferruginous fossiliferous ss. interbedded with finer material, and with a very fossiliferous ss. near top; (2) two thin iron-stained cgl. stringers, which separate beds above from beds below; (3) 600± ft. of chiefly fine muddy, silty friable gray ss., with some beds of shaly diatomite containing fish remains, radiolarians, sponge spicules, and at one place volcanic glass; (4) at base 40 ft. of pebbly cgl. with ss. partly impregnated with dry oil or tar. In Purisima Hills is represented by upper part of the 2,300± ft. of diatomite exposed on Harris Grade road. Conformably underlies Foxen fm. (middle Plio.) and uncon. overlies Santa Margarita fm. (upper Mio.). Named for well-exposed section on Sisquoc ranch, on S. side of Sisquoc River, in Sisquoc grant.

Sitgreaves tuff.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). *Sitgreaves tuff.*—Cream-colored pumiceous tuff in thick beds; a flow. Thickness 0 to 300± ft. Overlies Meadow Creek trachyte. Named for Sitgreaves Pass.

Siwash series.

Carboniferous: British Columbia.

C. Camsell, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 109), and A. M. Bateman (p. 126 of same rept).

Sixmile granite.

Pre-Cambrian: Central Texas (Llano uplift).

H. B. Stenzel, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 144). Pre-Camb. granites intrusive into Valley Spring gneiss and Packsaddle schist are divided, on basis of lithology and structure, into: (1) *Sixmile granites* (the youngest), gray fine-grained granites; (2) *Oatman Creek granites*, gray medium-grained granites that form a small en échelon swarm of intrusive bodies SE. of Llano; (3) *Town Mtn granites* (the oldest), red coarse-grained granites. [Derivation of names not stated. But in 1935 (Univ. Tex. Bull. 3501, p. 116) Stenzel stated that Sixmile granite is quarried at Sixmile, near Llano, Tex.]

Six Mile shale member.

Upper Devonian: Central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). *Six Mile sh. memb.*, 50 to 80 ft. thick, is top memb. of Middlesex sh. fm. in Ithaca region. Probably of upper Middlesex age. Overlies Renwick sh. memb. [Derivation of name not stated.]

Siyeh limestone.

Pre-Cambrian (Belt series): Northwestern Montana (Glacier National Park), southwestern Alberta, and southeastern British Columbia.

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 323). *Siyeh ls.*—Chiefly ls. but interbedded with argillite. The ls. usually very massive, of mural aspect, dark blue or grayish, weathering buff. Often characterized by peculiar internal structures and large concentric growths. Indistinctly fossiliferous. Thickness 4,000± ft. Forms mass of Mount Siyeh, at head of Canyon Creek, a tributary from the S., which enters Swift Current Creek at Altyn. Constitutes upper part of all principal summits of Lewis Range N. of Mount Siyeh, including Mounts Gould, Wilbur, Merritt, and Cleveland. Extends W. into Livingston Range and forms massive peaks btw. Waterton and North Fork drainage lines. Is intruded by sheet of diorite 60 to 100 ft. thick. Rests conformably on Grinnell argillite and overlain by sheet of extrusive igneous rocks.

Skagit volcanic formation.

Tertiary or Cretaceous: Southwestern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv. Dept. Mines Mem. 38, map 15, 121° to 121°30'). [Mapped following two units (descending):

Skagit volcanic fm. (liparite tuff).
Skagit volcanic fm. (andesite flows and pyroclastic deposits).]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 528). *Skagit volcanic fm.*—Local accumulation of andesitic breccias, associated with flows and with more acid lava. Thickness 5,000+ ft. Extends from first summit W. of Skagit River to summit of Custer Ridge, the main divide of Skagit Range. Lies uncon. on Custer batholith and Hozomeen sediments. Of Olig. (?) age; may be Lower Cret.; probably not younger than Mio. [On p. 531 he described *Skagit harzburgite*, which cuts Custer gneiss.]

Skajit limestone.

Silurian: Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 238). *Skajit fm.*—Heavy-bedded ls. and mica schist, 4,000 ft. thick. The ls. is highly altered, finely crystalline, schistose, and often micaceous; some layers becoming more and more foliated grade into mica schist. Appears to underlie Totsen series, with uncon. [Now known to overlie †Totsen series, which is same as Birch Creek schist.] Tentatively assigned to Sil. on imperfect fossil evidence.

Named for Skajit Mtns, Endicott Range.

Skajit River beds.

Lower Cretaceous: Canada.

G. M. Dawson, 1889 (Am. Jour. Sci., 3d, vol. 38, p. 126).

A local facies of Kootenai fm.

Skaneateles shale. (In Hamilton group.)

Middle Devonian: Central and western New York.

L. Vanuxem, 1840 (N. Y. Geol. Surv. 4th Rept., p. 380). *Skaneateles shales.*—Highly fossiliferous shales underlying Hamilton group and overlying the upper shales of Marcellus, which are less highly colored than underlying deep black Marcellus shales. Cover N. end of both sides of Skaneateles Lake.

J. Hall, 1842 (Am. Jour. Sci., 1st, vol. 42, pp. 57–62). *Skaneateles sh.* underlies Ludlowville sh. and overlies Marcellus sh.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, pp. 66–67). The term *Skaneateles* as here applied refers to that bed of strata for which the name was originally used by Vanuxem. The fm. is recognized from east-central N. Y. to western limits of State. The term is from the lake of this name in Onondaga Co. Is basal subdivision of Hamilton beds. Underlies Ludlowville sh. (including Centerfield ls. at base) and overlies Cardiff sh. (top memb. of Marcellus beds).

D. D. Luther, 1914 (N. Y. State Mus. Bull. 172, pp. 6–30), treated Centerfield lss. as top memb. of Skaneateles sh.

See also *Shaffer sh.*

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 214–219). *Skaneateles fm.* [redefined].—In Chenango and Unadilla Valleys is divisible into (descending) Colgate, Berwyn, Pompey, Delphi, and Mottville members. To W. of Cayuga Lake all of the Skaneateles except Stafford ls. (here transferred from underlying Marcellus sh. to Skaneateles fm., as it is=Mottville memb. to E.) is here included under the new name *Levanna memb.* (which replaces *Shaffer sh.* of Clarke). The Skaneateles underlies Centerfield ls. memb. of Ludlowville fm. and overlies Marcellus sh. There are practically no exposures of the rock at N. end of Skaneateles Lake, but Vanuxem's 1842 rept. gave a clearer description of the fm. on Cayuga Lake, which justifies retention of name.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 369, 391, 392). *Skaneateles fm.* underlies Ludlowville sh., overlies Marcellus sh., and includes Stafford ls., supposed Cardiff sh., and *Skaneateles sh.* Extends from east-central N. Y. to extreme W. limits of State.

The U. S. Geol. Survey calls this fm. *Skaneateles sh.*, since it is chiefly sh., and includes in it the same beds included in it by N. Y. State Survey (Goldring, 1931).

Skeena sandstone.

Skeena series.

Skeena formation.

Lower Cretaceous: British Columbia.

G. M. Dawson, 1881 (Canada Geol. Surv. Rept. 1879–80, pp. 128, 129). *Skeena ss.*

W. W. Leach, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 64). *Skeena series.*

R. G. McConnell, 1913 (12th Int. Geol. Cong. Guidebook 10, p. 15) and 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 58). *Skeena fm.*

Most Canadian geologists now use *Skeena fm.*

Skelley limestone. (In Conemaugh formation.)

Pennsylvanian: Eastern Ohio.

D. D. Condit, 1912 (Ohio Geol. Surv., 4th ser., Bull. 17, p. 27). *Skelley ls.*—Ls. similar to older Ames ls., overlying Duquesne coal and underlying Birmingham sh. Occurs nearly everywhere in [eastern] Ohio except where replaced by massive ss. Included in Conemaugh fm.

Named for Skelley Station, on Pa. R. R., in Jefferson Co.

Skelt shale. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

D. B. Reger, 1920 (W. Va. Geol. Surv. Rept. Webster Co., p. 198). *Skelt sh.*—Dark-gray fissile sh., with marine fossils, 0 to 5 ft. thick. Underlies Guyandot ss. and is separated from underlying Sewell B coal by 2 ft. of ss. Exposed on N. side of Sugar Creek, ½ mi. E. of Skelt P. O.

Skelton shale. (Buried.)

Mississippian: North-central Kansas.

J. S. Barwick, 1928 (A. A. P. G. Bull., vol. 12, No. 2, p. 183). *Skelton sh.*—Unit No. 2 encountered in wells in Salina Basin, Kans. Not exposed. Thickness over most of basin 100 to 150 ft. In wide belt through Marion, McPherson, Rice, and Reno Counties it rests on Engle sh. (unit No. 4; not exposed), and the two have been penetrated in many wells. At S. end of basin it consists of 70± ft. of black fissile sh. that correlates with Chattanooga. To N. this black sh. thins or fingers out, and above it are patches of gray, green, and red shales and limes, which attain thickness of 150 ft. Named after Skelton No. 1 well of Danciger Oil & Refining Co., sec. 26, T. 15 S., R. 2 W., Saline Co., which entered this horizon at 3,085 to 3,205 ft. depth. Underlies "Mississippi lime" (unit No. 1) and overlies Younkin fm. (unit No. 3) where present.

†Skiatook shale.

Pennsylvanian: Northeastern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 34). *Skiatook sh.*—Chiefly sh., some ss. in upper part, and a ls. at about horizon of Hogshooter ls. Thickness 250 to 500 ft. Overlies Nowata sh. and underlies Dewey ls. Includes Lenapah ls. at base.

Now divided into (descending) Nellie Bly fm., Hogshooter ls., Coffeyville fm., and Lenapah ls.

Named for Skiatook, Tulsa Co.

Skidegate formation.

Cretaceous: British Columbia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 217).

Skinner sand.

A subsurface sand, of Penn. age and 20± ft. thick, in Okla. that lies 250 to 400± ft. below Oswego lime and is correlated with a part of Cherokee sh.

Skinners Eddy limestone. (In Catskill formation.)

Upper Devonian: Northeastern Pennsylvania (Wyoming County).

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G7, pp. 117, 118, pl. X). *Skinners Eddy ls.*—Brecciated ls., 2 ft. thick. Quarried on land of Mr. Kinney, about ⅓ mi. below Skinner's Eddy, on Tuscarora Creek, Braintree Twp, Wyoming Co. Included in Delaware flag series of Catskill series.

Skoki formation.

Ordovician: Alberta.

C. D. Walcott, 1928 (Smithsonian Misc. Coll., vol. 75, p. 217).

Skolai volcanics.

Triassic: Eastern Alaska (Skolai Range).

O. Rohn, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, pp. 429-430, pl. 52, map). *Skolai volcanics.*—Amygdaloidal basic volcanics of Skolai Range. Intermediate in age btw. Nikolai greenstone and recent basaltic lavas. Much younger than Nikolai greenstone.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, chart opp. p. 206), assigned these volcanics to Triassic.

Skonun formation.

Tertiary: British Columbia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 220).

Skrainka diabase.

Pre-Cambrian: Southeastern Missouri.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 253). *Skrainka terrane.*—Diabases. Younger than Iron Mtn and uncon. below Pilot Knob.

J. Bridge, 1930 (personal communication). Skrainka diabase of Keyes is considered to be probably Algonkian.

Named for old post office at Skrainka, SW. of Mine LaMotte Station, Madison Co.

Skull Creek shale member (of Graneros shale).

Upper Cretaceous: Northeastern Wyoming.

A. J. Collier, 1922 (U. S. G. S. Bull. 736, table opp. p. 76, p. 79, etc.). *Skull Creek sh. memb.*—Basal memb. of Graneros sh. in Osage oil field, Weston Co., Wyo. Mainly dark bluish-gray sh., about 200 ft. thick. Contains a few calc. concretions and near base some siliceous sh. Very few fossils. Is called Thermopolis sh. by drillers but represents only basal part of true Thermopolis sh. Is well exposed along Skull Creek SE. of Osage, btw. outcrops of Dakota ss. below and Newcastle ss. above.

Skull Hill formation.

Miocene: British Columbia.

W. L. Uglow, 1922 (Canada Geol. Surv. Summ. Rept. 1921, pt. A, p. 86).

Skunnemunk conglomerate.

Devonian (Upper): Northern New Jersey and southeastern New York.

N. H. Darton, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 367–394). *Skunnemunk cgl.*—Thickness 300 to 2,500 ft. Overlies Bellvale flags. Assigned to Dev. May represent Oneonta fm. or may be later and=coarse beds of Chemung age in southern Catskills, or it may be a purely local feature.

H. Ries, 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1, 4 mo.). In its typical development *Skunnemunk cgl.* is an aggregate of quartz and some sh. pebbles in matrix of reddish quartz and argill. material, local layers of red sl. interbedded in upper portions; also contains beds of pebbly qtzite and red quartzitic ss. Caps Bellvale and Skunnemunk Mtns, Orange Co., N. Y. Grades into underlying Bellvale flags. Assigned to Hamilton epoch.

H. B. Kümmel and S. Weller, 1902 (N. J. Geol. Surv. Ann. Rept. State Geol. 1901). *Skunnemunk cgl.* forms great mass of Bearfort Mtn, the southward continuation of Bellvale Mtn of N. Y., and also forms central part of Skunnemunk Mtn. In previous repts the cgl. of Bearfort Mtn was miscorrelated with Green Pond cgl.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 404). *Skunnemunk cgl.* is thought to represent Portage time with the upper beds as late as Catskill.

On U. S. G. S. *Schunemunk* topog. map the name of this mtn is spelled *Schunemunk*.

Skwentna group.

Jurassic(?): Southern Alaska (Cook Inlet region).

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 149–152, 180). *Skwentna series.*—Ancient volcanic rocks interstratified with tuffs and derived slates and some arkoses, all highly folded. First seen on Skwentna River 10 or 15 mi. above junction with Yentna River, then on right bank of the Skwentna some miles below mouth of Hayes River. On E. side of Tordrillo Mtns it conformably underlies Tordrillo series; on W. side it conformably underlies Terra Cotta series. Assigned to Jurassic(?).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, p. 234, table opp. p. 270). *Skwentna group* contains no fossils. From available evidence is probably Lower Jurassic. The overlying Tordrillo fm. is Middle Jurassic.

Sky Blue Quarry limestone.

Paleozoic (?): Southern California (Riverside County).

J. W. Daly, 1935 (Am. Min., vol. 20, No. 9, pp. 638–647, map). *Sky Blue Quarry ls.*—Except for development of blue calcite and more intense metamorphism near some of quartz monzonite dikes, this fm. is lithologically similar to Chino Quarry ls.; no evidence to show that the original sediments of these 2 fms. differed appreciably in chemical composition. Thickness 500± ft. Top fm. of Jurupa series. Contact with underlying Chino Quarry qtzite obscured by intrusives; may be uncon. Named for quarry at Crestmore.

Skyline formation.

Carboniferous: British Columbia.

S. J. Schofield, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. B, p. 60) and 1920 (Canada Geol. Surv. Mem. 117, p. 16).

Slate Hill shale.

Carboniferous: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 320, 329–330, 356, 364). *Slate Hill shales.*—Greenish shales with sandy layers and sss. near top. Composes upper part of Aquidneck series. Overlain by Purgatory cgl. Exposed at Slate Hill [Middletown Twp, Newport Co.].

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, map), mapped the rocks of Slate Hill as Rhode Island fm.

Slater sandstone member (of Mingo formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 40). *Slater ss. memb.*—Cliff-making ss., 0 to 100 ft. thick, in Mingo fm., lying 300 ft. below top of Mingo.

Named for Slater Fork of Catron Creek, Bell Co., Ky.

†Slatington shale.

Silurian: Southwestern Arkansas and southeastern Oklahoma.

A. H. Purdue, 1909 (Geol. Soc. Am. Bull., vol. 19, p. 557). *Slatington sh.*—Sh. uncon. overlying Blaylock ss. and underlying Missouri Mtn fm. [not Missouri Mtn sl. but a younger fm.]. Slatington sh. and Missouri Mtn fm. may possibly be Sil. [The rocks are same as those named *Missouri Mtn sl.* by Purdue later in 1909.]

Apparently named for Slatington, Montgomery Co., Ark.

Slave Point limestone.

Devonian: Northwest Territories, Mackenzie, and Alberta.

A. E. Cameron, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 26).

Slesse diorite.

Miocene(?): British Columbia and northern Washington.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 532).

Slickford sand.

A subsurface sand in New Providence fm. of Wayne Co., eastern Ky.

Slide Mountain series.

Mississippian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 18).

Slide Mountain conglomerate.

Upper Devonian: Eastern New York (Catskill Mountains).

G. H. Chadwick, 1933 (Am. Jour. Sci., 5th, vol. 26, pp. 480, 482, 483). *Slide Mtn cgl.*—White cgl. topping the reds on highest peaks [of the Catskills?]. Caps highest peak, Slide Mtn. Overlies Katsberg red beds. Possibly of Chautauquan age.

G. H. Chadwick, Feb. 1935 (Am. Jour. Sci., 5th, vol. 29, No. 170, p. 140). A cgl. constitutes 1,000 ft. and more of summit of Wittenberg, where it is best exposed, and others of the high central Catskills. It is easy to show by tracing that this *Wittenberg cgl.* is upper Enfield, =upper part of Hatch sh. of western N. Y., of Naples age. Above it, capping only the one highest pinnacle of the Catskills, is the thinner *Slide Mtn cgl.*, corresponding apparently to Grimes ss., basal bed of Chemung.

G. H. Chadwick, Nov. 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 859, 861, 862). Of Chemung rocks only the Cayuta or Catawissa reds appear to be represented E. of Delaware River in N. Y., and these only on the higher lands rising rapidly to the mtn tops and being present in the Catskills proper only as the white *Slide Mtn cgl.* capping the highest peak alone.

Slippery Rock sand.

A subsurface sand of Miss. age in western Pa. (Butler and Zelienople quads.), that is found in wells in gorge of Slippery Rock Creek.

Sloan Canyon formation.

Triassic(?): Northeastern New Mexico (Union County).

B. H. Parker, 1930 (Kans. Geol. Soc. 4th Ann. Field Conf., p. 132, Mimeo). *Sloan Canyon fm.*—Varicolored earthy and calc. shales with thin beds of gray marl and ss. Thickness 125 to 150 ft. Of Triassic(?) age. Overlies Dockum group and underlies Sheep Pen Canyon fm. [Derivation of name not stated.]

B. H. Parker, 1933 (Jour. Geol., vol. 41, No. 1, pp. 40–43). *Sloan Canyon fm.*—Pale, variegated argill. and calc. shales with thin layers of hard gray marl and a bed of red ss. near base. Estimated thickness 125 to 150 ft. Conformably underlies Sheep Pen ss. and overlies the red beds assigned by Darton to Dockum group. Typically exposed throughout lower part of valley of Sloan Canyon in east-central part of T. 31 N., R. 35 E., Union Co., N. Mex. Because of poor induration of the shales the basal contact is generally concealed, and consequently the true character of the lowermost 25 to 50 ft. of the deposit is not known. Contains numerous fragmental fish teeth and bones and, at one place, many tracks, probably of reptilian origin. On basis of strat. position the Sloan Canyon and overlying Sheep Pen fms. are referred to Triassic (?). Darton assigned this fm. and Exeter ss. to Morrison fm., but this does not seem tenable in light of pronounced angular uncon. that separates the Sloan Canyon beds and Exeter ss. and which involves complete removal by erosion of Sheep Pen ss. at several localities where the shales of Sloan Canyon fm. and Exeter ss. are in contact.

†Sloans Valley limestone. (In Chester group.)

Mississippian: Western Kentucky and southeastern Illinois.

A. D. Brokaw, 1916 (Ext. from Ill. Geol. Surv. Bull. 35) and 1917 (Ill. Geol. Surv. Bull. 35, p. 12, pl. 1). *Sloans Valley fm.*—Interbedded lss. and shales, 40 to 95 ft. thick, underlying Tar Springs ss. and overlying Hardinsburg ss. in parts of Saline, Johnson, Pope, and Williamson Counties, southern Ill.

S. St. Clair, 1917 (Ill. Geol. Surv. Bull. 35, p. 46, pl. 4). *Sloans Valley fm.*—Interbedded lss. and shales, 50 ft. thick, underlying Tar Springs fm. and overlying Hardinsburg fm., in parts of Williamson, Union, and Jackson Counties, Ill.

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41, pp. 191, 197). Glen Dean ls. was called *Sloans Valley fm.* by Brokaw and by St. Clair, from a locality in Pulaski Co., Ky. Glen Dean is preferable name. The Sloans Valley section is less well known than that of SE. Ill. and adjacent portions of Ky., and it is not unlikely the section includes much more than exact equiv. of the strata for which the name has been used in Ill.

Slocan series.

Carboniferous or Triassic: British Columbia.

C. V. Corless, 1902 (Canadian Min. Inst. Jour., vol. 5, p. 506). [Age not given.]

O. E. LeRoy, 1913 (12th Int. Geol. Cong. Guidebook 9, p. 63). Slocan series assigned to Carbf. (?).

M. F. Bancroft, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. B, pp. 29, 36) and 1920 (Summ. Rept. 1919, pt. B, p. 41), and S. J. Schofield, 1920 (Canada Geol. Surv. Mem. 117, p. 15), assigned these rocks to Carbf.; J. F. Walker, 1929 (Canada Geol. Surv. Summ. Rept. 1928, pt. A, p. 127), and C. E. Cairnes, 1934 (Canada Dept. Mines Geol. Surv. Mem. 173, No. 2358, p. 52), assigned them to Triassic.

Slollicum series.

Triassic: Central northern Washington and adjacent British Columbia.

C. H. Crickmay, 1930 (Geol. Mag., vol. 67, map, pp. 488, 489). *Slollicum series.*—Schists, argillites, and greenstones, 10,000 ft. thick. In B. C. underlies Harrison Lake fm. (Middle Jurassic). In Wash. underlies Paleocene. Overlies Triassic volcanics in both Wash. and B. C. Assigned to Triassic. [Derivation of name not stated and no geographic feature of that name shown on map.]

Sluss sand.

A subsurface sand in Butler Co., Kans., that is said to lie at approx. horizon of Stapleton zone.

Smalls Brook limestone.

Carboniferous: Nova Scotia.

H. M. Ami, 1899 (British Ass. Adv. Sci. Rept. 1899, p. 756).

Smelt Brook formation.

Carboniferous: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 212).

Smelter granite.

Jurassic: British Columbia and northern Washington.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 381).

Smethport oil sand.

Drillers' term for an oil-bearing sand, 26± ft. thick, in vicinity of Smethport, McKean Co., NW. Pa., which lies 360 ft. below Bradford oil sand. (See C. A. Ashburner, 1880, 2d Pa. Geol. Surv. Rept. R.)

†Smethport shale member (of Knapp formation).

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, pt. 1, p. 203). *Smethport sh. memb. of Knapp fm. (part of "Riceville," Knapp sh.)*—Basal memb. of Knapp fm. Includes Marvin Creek ls., *Syringothyris* zone (in upper Chagrin). Overlies Riceville fm. restricted. Was formerly included in Riceville. The *Syringothyris* zone is lower Smethport memb. (lower upper Riceville), and an unfailing guide throughout most of area.

In 1934 Caster replaced this name with *Kushequa sh. memb.*

Smethport magnafacies.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 27). Westward the Catskill magnafacies gives way to purple- and chocolate-weathering shales and sss. in which occur, as a normal feature, flat-pebble cgls., usually as local lenses, but in the later parvafacies some carry over into adjoining facies province to W. It is proposed that this *magnafacies* be known by name *Smethport*, from town of Smethport, McKean Co., Pa. The *Cattaraugus parvafacies* of Olean, N. Y., area is best-known parvafacies of Smethport magnafacies.

Smith sand.

A subsurface sand, 10 to 30 ft. thick, lying at or near base of Penn. section of Graham field, NW. part of Carter Co., southern Okla., and from 250 to 350 ft. below Sutherland oil sand. The name has also been applied to an apparently older sand lying in upper part of Cromwell sand (of basal Penn. or uppermost Miss. age) of central Okla.; and also to a Perm. sand in Pecos River region of western Tex., as explained under *Yates sand*.

†Smith Creek beds.

See under *†Smith River lake beds.*

Smithfield limestone member (of Marlboro formation).

Pre-Cambrian: Eastern Rhode Island.

E. Emmons 1843 (N. Y. Nat. Hist. Agric., vol. 1, pp. 90–91), mentioned the *Smithfield ls.* of R. I., which he believed to be same as the younger Stockbridge ls.

E. Emmons, 1846 (Agric. N. Y., vol. 1, pp. 90–93). *Smithfield ls.* lies in valley of Blackstone River about 10 mi. N. of Providence, R. I. It is white or clouded ls. enclosed in mag. sl.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 107–109). *Smithfield lss.*—Finely granular dolomitic crystalline aggregates, forming top div. in Blackstone series. Overlie Ashton schists. Owing to setting off of Lincoln from Smithfield in 1871, the areas of ls. formerly designated by this name are no longer in town of Smithfield. The areas of this rock are isolated, ovoidal in outline, and have no very systematic distribution.

B. K. Emerson and J. H. Perry, 1907 (U. S. G. S. Bull. 311, pp. 8, 11, 16–26, and map). *Smithfield ls. memb. of Marlboro fm.*—Generally pure white but in some places banded in dark gray or tinged yellow with iron or pink with manganese.

Varies from massive saccharoidal marbles of fine to above medium grain to rocks laminated through shearing. Thickness 0 to 150± ft. Is a subordinate memb. of Marlboro fm., and changes into tremolite schist, steatite, and serpentine.

Smith Fork glacial stage.

Pleistocene: Northeastern Utah.

W. H. Bradley, 1936 (U. S. G. S. P. P. 185). Youngest glacial stage in Uinta Mtns of NE. Utah (only). Probably of Wisconsin age. Named for long train of lateral moraines left by its glaciers in valley of East Fork of Smith Fork, Utah.

Smith Point formation.

Lower Cambrian: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geol. of Newfoundland, No. 4). *Smith Point fm.*—Red ls. with red sh., carrying *Hyolithes*, etc. Forms top fm. of Etcheminian series. Discon. overlain by Hanford fm., and underlain by Brigus fm. [Derivation of name not stated.]

†Smith River lake beds.

Miocene (middle): Central southern Montana (Little Belt Mountains region).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Smith River lake beds.*—Irregularly bedded sands and loosely cemented cgls., with beds of marl and volcanic dust. Deposited in lake that once filled valley of Smith River, btw. Little Belt and Big Belt Ranges. Rest uncon. on all older rocks. Contain middle Mio. fossils.

The stream for which these beds were named *Smith River* is now known as *Deep River*. (See *Deep River beds.*) The beds have also been called "Smith Creek beds."

Smiths Ferry sand.

Drillers' term for a sand in Pocono fm. of SW. Pa. and W. Va., lying lower than Papoose sand and higher than Murrysville sand.

†Smithville chert lentil. (In Stanley shale.)

Mississippian: Southeastern Oklahoma (McCurtain County).

H. D. Miser and C. W. Honess, 1927 (Okla. Geol. Surv. Bull. 44, p. 11). *Smithville chert lentil.*—Black chert, about 25 ft. thick, occurring in middle of Stanley sh. Crops out in northern McCurtain and southern Le Flore Counties. Until now has always been described and mapped (Okla. Geol. Surv. Circ. No. 3, pl. 1) as black chert of Stanley sh. Is of importance in mapping structure and calculating thicknesses of adjacent beds and is therefore named, for village of Smithville, E. of which, in T. 1 S., R. 26 E., Okla., there are typical exposures. Name proposed by Honess.

Smithville formation.

Lower Ordovician (Beekmantown): Northern Arkansas (Sharp and Lawrence Counties) and southeastern Missouri (?).

G. C. Branner, 1929 (geol. map of Ark.). *Smithville ls.*—Uncon. underlies Black Rock ls. and uncon. overlies Powell ls. in Ozark region. Thickness 0 to 200± ft. Assigned to Upper Canadian [which is Beekmantown of U. S. G. S.]. [Mapped at and around Smithville, Lawrence Co., Ark.]

H. S. McQueen, 1930 (Insoluble residues as a guide in stratigraphic studies, published March 1930; Reprint of App. I, 56th Bien. Rept., 1931, p. 25, pl. 1). [See under *Black Rock fm.*] Thickness of Smithville in SE. Mo. 0 to 120 ft.

E. T. McKnight, 1936 (U. S. G. S. Bull. 853, on Yellville quad., Ark.). *Smithville fm.*—Chiefly fine-grained gray mag. ls. or dol. that weathers drab or whitish, with minor amounts of ss. and blue-gray ls. Thickness in Sharp and Lawrence Counties, Ark., 200± ft. Absent in Yellville quad. Not studied in detail. Uncon. underlies Black Rock fm. The Black Rock and Smithville fms. resemble Everton fm. in lithology but are believed by E. O. Ulrich, on basis of fossil evidence, to occupy an interval btw. Everton fm. above and Powell dol. below and to be uncon. with Everton and with Powell.

Smithwick shale. (Of Bend group.)

Pennsylvanian (Pottsville): Central Texas.

S. Paige, 1911 (U. S. G. S. Bull. 450, p. 25). *Smithwick sh.*—Soft, very dark or nearly black carbonaceous sh., in which are included a number of ss. lentils. Thickness probably 400 ft. Overlies Marble Falls ls. and is overlapped by Cret. sediments in central Tex. mineral region. Named for old town of Smithwick, Burnet Co.

See also S. Paige, 1912 (U. S. G. S. Llano-Burnet folio, No. 183), and see under *Bend group*.

E. H. Sellards, 1933 (Univ. Tex. Bull 3232, p. 101). Type loc. of Smithwick fm. is at Smithwick, but the exposures at this place are sandy shales and coarse sss. with indeterminate plant fragments, the exposure suggesting Strawn rather than Smithwick. If these exposures prove to be Strawn, the name *Smithwick*, well established, will doubtless be retained, and Bend post office may be given as suitable type loc., the fm. being well exposed there throughout most of its entire thickness.

†Smithwick lime.

Drillers' term for a black ls. in lower part of Smithwick sh. (Penn.) of Tex. Also called "Caddo lime," "Breckenridge lime," and "False Black lime" by oil men. (See U. S. G. S. Bull. 736, p. 123, 1923.)

Smock sand.

A subsurface sand in Butler Co., Kans., that is said to lie at approx. position of Stapleton sand.

Smoky Hill chalk member (of Niobrara formation).

Smoky Hill marl member (of Niobrara formation).

Upper Cretaceous: Northwestern Kansas and eastern Colorado.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 51). *Smoky Hill chalk.*—Chalky and marly lss. and chalk composing upper fm. of Niobrara div. Overlies Osborne ls. (lower fm. of Niobrara div.) and underlies Lisbon shales of Fort Pierre div. Named for Smoky Hill River, Kans.

Top memb. of Niobrara fm. in Kans. Overlies Fort Hays ls. memb. of Niobrara and underlies Pierre sh. In eastern Colo. it is called *marl* memb. (instead of *chalk* memb.).

Smoky River series.

Upper Cretaceous: British Columbia.

G. M. Dawson, 1881 (Canada Geol. Surv. Rept. 1879–80, p. 15B). *Smoky River series;* included in Colorado group.

Snake Creek beds.

Miocene (upper) and Pliocene (lower): Western Nebraska and eastern Wyoming.

W. D. Matthew and H. J. Cook, 1909 (Am. Mus. Nat. Hist. Bull., vol. 26, art. 27, pp. 362–363). *Snake Creek beds.*—Clean sand, with gravel scattered through it. Contains bones, jaws, etc., of great variety of lower Plio. fossil mammals. Regarded as outlier of Ogalalla fm., known to Kans. geologists as "mortar beds." Lack calc. cement, but otherwise are very like the "mortar beds" of Republican River Valley. Overlie Sheep Creek beds (middle Mio.) with erosion uncon.

H. J. Cook, 1915 (Nebr. Geol. Surv. vol. 7, pt. 11, pp. 72–75). "Spoon Butte beds" of Peterson, which cap Spoon Butte, Wyo., are a cemented phase of *Snake Creek beds* (lower Plio.), and overlie Sheep Creek beds (middle Mio.).

H. F. Osborn, 1910 (Age of mammals, pp. 341, 353, 354, 355), J. C. Merriam, 1911 (Univ. Calif. Pub., Dept. Geol. Bull., vol. 6, No. 11, pp. 199–304), W. B. Scott, 1913 (History of land mammals of Western Hemisphere, pp. 17, 127, 222, 388), W. J. Sinclair, 1915 (Am. Phil. Soc. Proc., vol. 54, pp. 74–75) assigned these beds to lower Plio.

E. H. Barbour, 1915 (Am. Jour. Sci., 4th, vol. 39, p. 87, in a paper on Burge, Cherry Co., Nebr.). Snake River deposits border a stream variously termed Snake Creek and Snake River. Latter name is preferable, since it avoids confusion with Snake Creek and the Snake Creek beds of Sioux Co., to which the beds around Burge are equiv. [See also under *Snake River stage.*]

J. C. Merriam, 1917 (Univ. Calif. Pub., Dept. Geol. Bull., vol. 10, No. 22, pp. 435–443). It seems possible Snake River fauna represents more than one stage.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., n. s., vol. 2, pt. 1, pp. 23, 27, 28, 34), assigned these beds to upper Mio. and lower Plio., as did H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5, p. 44).

See also under *Valentine beds*.

Snake Hill formation.

Middle Ordovician (early Trenton): Eastern New York.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). Subdivisions of Trenton in east-central N. Y. (descending): Canajoharie sh., Dolgeville, *Snake Hill sh.*, and Basal Trenton.

J. M. Clarke, 1912 (N. Y. State Mus. Bull. 158, p. 21). *Snake Hill beds*.—Thick fm. of shales, grits, and cherts of lower Trenton age. Overlies Normanskill sh. Field work by R. Ruedemann.

R. Ruedemann, 1912 (N. Y. State Mus. Bull. 162). *Snake Hill beds*.—A belt of slates, grits, and sss. which in Hudson Valley extends btw. Canajoharie sh. and Normanskill sh., from both of which it is distinguished by its fauna, and from Canajoharie in character of the sh. and greater intercalation of aren. beds. Deposited in Levis Basin upon Normanskill sh. and brought to mouth of the Mohawk and in contact with Canajoharie sh. by overthrusting and compression of the shales of Levis Basin. The Snake Hill fauna occurs in lowest Mohawk Valley, where there appears to be an intermixture of Snake Hill beds with Canajoharie sh. But considering all the evidence the Snake Hill beds are believed to be older than Canajoharie sh. and deposited in a separate basin. Nowhere have they been observed btw. Canajoharie sh. and Glens Falls ls., on which Canajoharie rests.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 41). *Snake Hill beds (1912 Ruedemann)* are shales, grits, and sss. above Normanskill sh. in Levis trough and of Trenton age. Name is from the very fossiliferous beds at Snake Hill, on E. side of Saratoga Lake. Other fossiliferous exposures are at Green Island, opposite Troy, and at Mechanicville.

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 66–99, and map). *Snake Hill sh.*—Dark-gray to black, bluish, and greenish-gray argill. shales. Mainly on account of large and distinguishing faunas obtained around Albany, Green Island, and Cohoes, and especially at Snake Hill, on shore of Saratoga Lake, the beds have recently (1912) been considered a separate fm. by writer and named *Snake Hill beds*, from most fossiliferous outcrop. Lithologically similar to Normanskill beds, but lack strong development of grits and white beds as distinct divisions, though both are present in thinner intercalations; possess a cgl. with characters peculiar to itself. Probably rests on upper div. of Normanskill sh. and is youngest fm. in Levis Basin. [In chart on p. 140 shown to be of early Trenton and late Black River age and as uncon. overlying Rysedorph Hill cgl.]

In N. Y. State Mus. Bull. 227, 228, 1921, p. 101) Ruedemann described new fossils from *Snake Hill sh.* of Hudson River Valley, and stated that it is of lower and middle Trenton age.

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, pp. 412, 414), showed *Snake Hill sh.* as older than Schenectady, younger than Canajoharie sh., and of late Trenton age.

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285). [On p. 25 *Snake Hill sh.* is placed beneath Canajoharie sh.; on p. 27 it is correlated with Canajoharie sh.; on p. 131 Snake Hill is placed above Canajoharie and below Schenectady. The latter position is assigned to *Snake Hill sh.* by Ruedemann in 16th Int. Geol. Cong. Guidebook 1, 1933.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 286). *Snake Hill beds* are contemp. with Canajoharie.

†Snake Hills trap.

Name applied by N. H. Darton (U. S. G. S. Bull. 67, p. 55, 1890) to 200 ft. of intrusive "trap" (now called Palisade diabase) on Big and Little Snake Hills, W. of Bergen Hill, N. J.

Snake Ridge formation.

Upper Cretaceous: Mexico (Sonora).

See under *Cabullona group.*

Snake River basalt.

Tertiary and Quaternary (probably chiefly Pliocene, but includes Recent, Pleistocene, and Miocene basalt flows): Southern Idaho.

W. Lindgren, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, pl. 8), mapped *Snake River basalts* (*Pliocene*) from Nampa eastward to and beyond Lincoln Co., Idaho, and *Columbia lava fm.* (*Miocene*) across SW. Idaho, also in Washington and Wallowa Counties and around Hailey. In text heading and text, however, he did not use *Snake River basalt*, but simply called the younger rocks *Pliocene basalts.*

I. C. Russell, 1902 (U. S. G. S. Bull. 199, pp. 38+, 59+, map). *Snake River lava* is here proposed as general term by which to designate the basaltic rocks that underlie by far the larger part of Snake River Plains and to a great extent form their actual surfaces. It includes also the lava streams and associated cinder cones, etc., which have descended lateral valleys or adjacent mtn slopes and united with the sheets of similar material extruded from numerous craters on the plains. When this extensive fm. is studied in detail, it will, I judge, be found practicable to separate it into several distinct portions and to correlate some of these with sed. beds containing fossils and thus determine their precise geol. age. Estimated area covered by Snake River lava is in neighborhood of 20,000 sq. mi. [Mapped across southern Idaho from Nampa to S. half of Fremont Co., over large part of Bingham Co., and N. part of Bannock Co.] So far as now definitely known there is but one lava field in No. Am. of greater extent, namely, Columbia River lava. In Snake River Canyon below Shoshone Falls nearly 700 ft. of lava in horizontal sheets are exposed, but whether this is max. thickness cannot be told. As a rule the sheets of lava are relatively thin, averaging perhaps 50 to 80 ft., and widely extended. Is similar in all its features to Columbia River lava. The country separating these two areas of basaltic rock has not yet been geologically explored, and while it is possible a direct connection btw. them may be discovered, it seems more probable they are distinct and have somewhat different histories. It appears by far the greater part of Snake River lava is much younger, although its basal members seem to be of about same age. The principal part of Columbia River lava, as shown by fossil leaves in associated sediments, is Mio. The older part of Snake River lava, as indicated by relation to Payette fm., etc., is also Mio. Much reliance should not at present be placed in this correlation. The latest outpourings of molten rock over Snake River Plains occurred probably within recent times, and are perhaps not over 100 to 150 yrs old.

J. P. Buwalda, 1923 (Idaho Bur. Mines and Geol. Pam. 5). *Snake River lavas* either overlie or are interbedded with Idaho fm. and lie in central part of valley. They occur in thin sheets and in many cases appear very recent, having uneroded and fresh surfaces.

V. R. D. Kirkham, 1931 (Jour. Geol., vol. 39, No. 3, pp. 201–239). *Snake River basalt* is interbedded with upper members of Idaho fm. and Columbia River basalt (Mio.) discon. underlies Idaho fm.

H. T. Stearns (U. S. G. S. W. S. P. 774, in press) has mapped in detail a large part of area mapped in reconnaissance by Russell, and subdivided the basalts into many newly named fms. His work showed that Snake River basalt as defined and mapped by Russell included basalt flows of Mio., Plio., Pleist., and Recent age. The U. S. G. S. uses the old name *Snake River basalt* as a blanket term to cover undiff. basalt flows of these ages in southern Idaho.

Snake River stage.

Pliocene: Northwestern Nebraska (Cherry County).

E. H. Barbour, 1915 (Am. Jour. Sci., 4th, vol. 39, p. 87), described remains of a mastodon found near Burge, Cherry Co., in deposits "bordering a stream variously termed Snake Creek and Snake River," and stated: Latter name is preferable, since it avoids confusion with Snake Creek and the Snake Creek beds in Sioux Co. "The beds around Burge are equiv. to the well-known Snake Creek, and it might be sufficiently distinctive, as well as associative, to call these deposits the *Snake River stage.*"

Snake River series.

Permian (?): Northern Idaho (Orofino region).

V. R. D. Kirkham, 1927 (Idaho Bur. Mines and Geol. Pam. 24, pp. 3–6). *Snake River series (?)*.—Qtzite, cgl., sh., ss., impure ls., and highly altered schistose andesitic lavas and greenstone schist. Exposed in Clearwater River Canyon near Asahka. Appears on lithologic grounds to be an extension of Perm. rocks exposed in Snake and Salmon River Canyons farther W. and S. Relations to Belt series not clear.

Snaring formation.

Upper Cambrian: Alberta (Jasper Park).

P. E. Raymond, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 291, 292, 300). *Snaring fm.*—Yellow-weathering unfossiliferous dolomites, exposed along the Snaring about 1 mi. up the river from the bridge. Rests on sh. containing trilobites believed to be Upper Camb. [On p. 300 he seems to include the sh.] The Snaring is probably a shallow-water, near-shore equivalent of upper part of Lynx fm. of Mount Robson. Overlies Bosche ls. and sh. and underlies Mons dol. (Lower Ord.).

Snee sand.

Drillers' name, long in use, for a sand of Upper Dev. or early Carbf. age, in western Pa. Lies lower than Nineveh 30-foot sand. Considered same as Blue Monday sand.

Sneeds limestone lentil (of Everton limestone).

Lower Ordovician: Northern Arkansas.

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202). *Sneeds ls. lentil.*—Basal beds of Everton ls. in Hemmed-in Hollow, 2 mi. S. of Compton, Harrison quad. Typically exposed on Sneeds Creek. Underlies (uncon.) Kings River ss. memb. of Everton and uncon overlies Powell ls. Consists of sandy hard, compact dark-drab mag. ls. in thick layers; lowest layer contains many pebbles of underlying Powell ls. Greatest thickness 50 ft. Present only locally.

†Sneedville limestone.

Silurian (late): Eastern Tennessee.

J. M. Safford, 1856 (Geol. reconn. Tenn., 1st Rept., p. 157). *Sneedville ls.*—Band of gray ls. in eastern Tenn., 100 to 200 ft. thick, resting on variegated shales, with fine sss. and containing iron ore. Lies lower than Carbf. or Dev. black sl. Assigned to Dev.

Replaced by Hancock ls., later but better-established name, under which it has been mapped over large areas. Is of upper Cayuga age.

Named for Sneedville, Hancock Co.

Sneffels member (of San Juan tuff).

Tertiary (Miocene? or Oligocene?): Southwestern Colorado (Ouray district).

W. S. Burbank, 1930 (Colo. Sci. Soc. Proc., vol. 12, p. 187). *Sneffels memb. of San Juan tuff.*—Upper memb. of San Juan tuff in vicinity of Canyon Creek, Sneffels, and Ouray. Overlies Canyon Creek memb. of the San Juan and is uncon. overlain by Silverton volcanic series. Is characterized in lower part by uniform nature of lava fragments of which it is composed. These fragments are mostly of finely porphyritic lava containing numerous small phenocrysts of feldspar. Cgl. beds are much less common than in Canyon Creek memb. and are essentially absent in lower part. Thickness 1,500 to 2,000 ft. Becomes more heterogeneous in upper part as base of Silverton volcanic series is approached. On the whole the memb. is characterized by many light-colored beds of reddish or pinkish tone. At many places the breccia at base of Sneffels memb. is of reddish color. Ranging from 700 to 900 ft. below top of Sneffels memb. there is locally an andesitic flow, or several flows, interbedded in the memb., which range in thickness from 25 to 50 ft. These flows are of dark-gray or reddish color and characterized by amygdaloidal and scoriaceous tops.

Sniabar limestone.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 90, 97). [See under *Schubert Creek ls.* and *Swope fm.*] Named elsewhere in this Guidebook by Jewett.

J. M. Jewett, 1932 (pp. 99, 101, 103 of book cited above). *Sniabar ls.* will be proposed by N. D. Newell to replace "Hertha" as used for ls. at base of Kansas City fm. at Kansas City. It extends from Kansas City and beyond to near Linn-Bourbon Co. line. Thickness at Kansas City as much as 12 ft., but where present in Kans. it is generally less than 8 ft. Is memb. of Swope fm., underlying Elm Branch sh. and overlying Mound City sh.

J. M. Jewett, 1933 (Kans. Acad. Sci. Trans., vol. 36, p. 134). *Sniabar ls.* at Kansas City has long been called *Hertha*, but writer has found this ls. pinches out near Linn-Bourbon Co. line and that the Hertha is really the Bethany Falls. The Sniabar pinches out to S. Named for Sniabar Creek in Mo., E. of Kansas City.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 25). Lower memb. of Hertha ls., well developed in NE. Kans. and adjoining parts of Mo., is here termed *Sniabar ls.*, from exposures along Sniabar Creek, SE. part of Jackson Co., NW. Mo. It consists of thick-bedded ferruginous fine-grained ls., generally drab or gray when fresh, weathering brown. Uppermost part is granular. Generally consists of a single bed. Averages 6 ft. thick in Miami Co., Kans. Rather unfossiliferous. Upper memb. of Hertha is Schubert Creek ls. of Jewett. A characteristic exposure is ½ mi. N. of Knobtown, Jackson Co. Outcrops at 4 places [described] in Miami Co., but does not outcrop in Johnson Co. [See also under *Hertha ls.*, 1935 entry.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 80), discarded *Sniabar ls.*

Sni Mills limestone.

Pennsylvanian: Northeastern Kansas (Jackson County).

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, pp. 19, 20). *Sni Mills ls.*—Gray or thin band of calc. fossiliferous marl; "brecciated" and algal in thicker phase. Thickness 0 to 1 ft. In lower part of Bourbon fm., higher than Warrensburg ss. [Derivation of name not stated, but p. 18 mentions "Stop 2. Sni Mills."]

Snoqualmie granodiorite.

Miocene: Central Washington (Snoqualmie quadrangle).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139). *Snoqualmie granodiorite.*—Batholith of massive granodiorite and granite, exposed about headwaters of Snoqualmie River. Intrudes Guye fm. and Keechelus andesitic series, both of which are Mio. Age must be late Mio. or post-Mio.

Snowbank granite.

Pre-Cambrian (lower or middle Huronian): Northeastern Minnesota (Vermilion district).

N. H. Winchell, 1899 (Minn. Geol. Nat. Hist. Surv. Final Rept., vol. 4). *Snowbank Lake granite* is intrusive into upper Keewatin.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 136). *Snowbank granite* is confined to Snowbank Lake and vicinity. Varies from fine-grained to coarse-grained, the medium-grained facies being most abundant; porphyritic facies also occur. Mineralogically it varies from normal mica and hornblende granite to augite granite and syenite. Intrudes Ogishke cgl. and Knife Lake sl.

†Snowbank Lake granite.

Same as *Snowbank granite.*

Snowbird formation.

Lower Cambrian: Western North Carolina and eastern Tennessee.

A. Keith, 1904 (U. S. G. S. Asheville folio, No. 116, p. 5 and columnar section). *Snowbird fm.*—Mainly fine and coarse qtzite. With this are interstratified beds of cgl. and arkose and subordinate layers of gray and black sl. Some of qtzites contain much feldspar in small grains, while others contain little but quartz grains. Most beds are light-colored, white or gray, but there are considerable variations in this respect. Southwest of Max Patch Mtn the lower layers are dark bluish gray, due to presence of oxides of iron btw. the quartz grains. When considerably weathered the iron oxides give the rock a rusty-brown or red color. In vicinity of Stackhouse they are dark gray, and on waters of Shelton Laurel Creek the bluish-gray and black layers are of frequent occurrence. The arkose beds which lie at base of fm. are either light gray or reddish, varying with color of feldspar fragments. Thickness 0 to 5,000 ft. Basal fm. of Camb. system. Underlies Hiwassee sl. Rests on pre-Camb. crystalline rocks.

Named for development in Snowbird Mtn, on bdy btw. Cocke and Haywood Counties in Mount Guyot quad., N. C.

Snow Creek porphyry.

Early Tertiary(?): Central Montana (Neihart district, Cascade County).

P. A. Schafer, 1935 (Mont. Bur. Mines and Geol. Mem. 13, map, pp. 10-15). *Snow Creek (Neihart) rhyolite or quartz porphyry.*—The rock called *Neihart porphyry* by Weed forms large intrusive mass exposed continuously from vicinity of I. X. L. mine across lower end of Poverty Ridge, a short distance above junction of Snow and Carpenter Creeks, across Carpenter Creek near mouths of Hegener and Mackey Creeks, and extending to divide at heads of those creeks. Can be traced 3 mi. Crosscuts Pinto diorite and the gneiss. Is probably early Tert.

Snowdrift sandstone.

Pre-Cambrian: Northwest Territories, Canada.

C. Lausen, 1929 (Canadian Min. and Met. Bull. 202, p. 378).

Snow Fork limestone. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio.

E. Orton, 1878 (Ohio Geol. Surv., vol. 3, pp. 889, 897, pls. opp. pp. 889, 921). *Snow Fork ls.*—Buff ls. in Coal Measures, about 20 or 30 ft. above the great coal seam of Hocking Valley and stratigraphically btw. Norris and Hanging Rock lss.

Later repts state it is same as Norris and Lower Freeport lss.

Named for Snow Fork of Monday Creek, Hocking Co.

Snow Hill marl member (of Black Creek formation).

Upper Cretaceous: Coastal Plain of southern North Carolina and eastern South Carolina.

L. W. Stephenson, 1923 (N. C. Geol. and Econ. Surv. vol. 5, pt. 1, pp. 9-10). *Snow Hill calc. marl memb.*—Laminated sands and clays interstratified with layers or lenses of more or less calc. greensand and marine clay, some of which contain an abundant marine fauna, as at Snow Hill. Is largely a calc. deposit. Top memb. of Black Creek fm.

Named for exposures at Snow Hill, Greene Co., N. C.

†Snyder shale.

An abbreviated form of *Snyder Creek sh.*, employed by C. [R.] Keyes.

Snyder sands.

Subsurface sands of Chester (Miss.) age in Ind., the higher one (*Snyder shallow sand*) being correlated with Elwren ss. of Malott, and the lower one (*Snyder deep sand*) being correlated with Mooretown ss. of Cumings.

Snyder Creek shale.

Upper Devonian: Central Missouri.

J. A. Gallaher, 1900 (Mo. Geol. Surv. vol. 13, p. 153). *Snyder Creek shales.*—Shales overlying Western Hamilton or Callaway ls. and older than Genesee black sh. Limited almost exclusively to Callaway Co.

C. R. Keyes, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 285). *Snyder shales.*—Green and blue shales, 50 ft. thick, highly fossiliferous. Immediately underlie Chouteau ls. on Snyder Creek and overlie Callaway ls.

According to M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.), this sh. outcrops in Boone, Callaway, Montgomery, and Warren Counties.

E. B. Branson, 1923 (Mo. Bur. Geol. and Mines vol. 17, 2d ser., pp. 38–46). *Snyder Creek sh.* is overlain uncon. by Sylamore ss. over most of its extent, but Chouteau ls., Burlington ls., and Cherokee sh. are occasionally in contact with it.

Named for exposures on Snyder Creek (probably same as Craghead Creek), which flows through Snyder farm, Callaway Co.

Snyder Hill formation.

Permian: Southeastern Arizona (Whetstone Mountains).

A. A. Stoyanow, April 30, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 530–532, 536). *Snyder Hill fm.*—In Whetstone Mtns. above the ls. with Manzano fauna, are thin-bedded, very fossiliferous black ls. beds with wide array of gastropods, large and small. These black ls. beds are placed at base of Snyder Hill fm., on basis of their fauna. As defined at present the Snyder Hill fm. is a rather empirical unit. Its strat. position has been established as btw. beds containing Manzano fauna and beds containing fauna of memb. B of Kaibab fm. As yet no area has been located in which the entire Snyder Hill fm. is present. Thickness unknown, but estimated btw. 200 and 500 ft. Type loc. is Snyder Hill, an isolated hill, surrounded by Cret. deposits, 10± mi. SW. of Tucson. Base of fm. is not exposed there. Top beds in type loc. are gray lss. carrying silicified bryozoan reefs. [Assigned to Perm. and placed below Chiricahua ls.]

Snyderville shale. (In Oread limestone.)

Pennsylvanian: Southeastern Nebraska, eastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 32, 33, 38). *Snyderville sh.*, in Oread ls. memb., is largely argill.; in most exposures its upper part is bluish or grayish and lower part is reddish. Thickness 11 ft. in SE. Nebr., 15 to 17 ft. in NW. Mo., and 12 to 16 ft. in Kans. Underlies Leavenworth ls. and overlies Weeping Water ls. Named for exposures in Heebner Creek E. of Snyderville quarry, located btw. 3 and 4 mi. W. of Nehawka, Nebr.

Sobrante sandstone.

Miocene (lower): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Sobrante ss.*—Ss., somewhat variable in character, but prevailingly fine-grained and light-colored, though it shows local ferruginous staining. Some beds are gritty and some flaggy. Near base a bed of volcanic ash that ranges in thickness from a few in. to 20 or more ft. Is basal fm. of Monterey group. Thickness 400 ft. Underlies Claremont sh. and uncon. overlies Tejon fm. Named for exposures on Sobrante Ridge, Contra Costa Co.

In 1918 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 11, No. 2, pp. 54–111) B. L. Clark proposed to restrict *Sobrante ss.* to upper 80 to 100 ft. of Lawson's Sobrante ss., or to beds containing *Arca montereyana* fauna, and to transfer the lower (and uncon.) part to San Lorenzo (Olig.) or *Agasoma gravidum* zone.

Sockanosset sandstone.

Pennsylvanian: Eastern Rhode Island (Providence County).

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 159–163). *Sockanosset sss.*—Sss. and conglomeratic beds, well exposed in Sockanosset Ridge E. and W. of reservoir near Providence. Overlie Pawtucket shales, both of which are included in Cranston beds, and belong to Kingstown series of Foerste.

Socorran series.

A term applied by C. R. Keyes (Sci., n. s., vol. 23, p. 921) to 300 ft. of Miss. lss. in SW. N. Mex., said to underlie his Ladronesian series (shales) and to overlie Dev. lss.

Sodus shale member (of Clinton formation).

Silurian: Central and western New York.

J. M. Clarke, 1906 (N. Y. State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12). [See under *Irondequoit ls.*]

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114, pp. 5–35). *Sodus sh.*—Soft bright-green sh., 24 ft. thick, forming basal memb. of Clinton fm. in Rochester and Ontario Beach quads. Underlies Furnaceville ore and rests on Medina fm. [In Niagara quad. is 2½ to 6 ft. thick.]

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). The Furnaceville ore bed lies *in* and not *below* the Wolcott ls. [See further under *Furnaceville iron ore.*]

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 461–463), included *Sodus sh.* in Medina, but all published repts by other geologists include it in Clinton.

M. Y. Williams, 1914 (Canada Geol. Surv. Summ. Rept. 1913), stated that Wolcott ls. of Niagara escarpment rests successively on Sodus sh., Thorold ss., and Cabot Head sh.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Sodus sh.* restricted to beds as developed at type loc. of Sodus sh., which are shown to be younger than Sodus sh. of repts, the beds separating this redefined Sodus sh. from Thorold ss., being named (descending) Sterling Station ore, Reynales ls., Furnaceville ore, Bear Creek sh., Martville ss., and Maplewood sh. "Hartnagel defined this name as from town of Sodus [Wayne Co.], 'where this division is well shown in vicinity of Sodus Bay;' but, misled by Hall's error, he extended it to the basal or Maplewood sh. at Rochester." [Chadwick also stated that his Bear Creek and Maplewood shales are below water around Sodus Bay; that his restricted Sodus sh. is 18 ft. thick at Rochester and 55 ft. at Sodus; and that Hartnagel's Sodus sh. at Rochester is the much older Maplewood and Bear Creek shales. See further explanation under *Maplewood sh.*]

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 347), adopted Chadwick's 1918 classification of the Clinton of N. Y., but showed true Sodus sh. absent at Rochester.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 326, 327), placed *Sodus sh.* below Wolcott ls. and above Bear Creek sh.; included in it, at base, Sterling Station ore; stated it consists mainly of purple sh. with thin layers of highly fossiliferous pearly ls.; that it is absent at Rochester; and that it is 40 ft. thick at Wolcott, Wayne Co., 31 ft. at Lakeport, Oneida Co., and 55 ft. or more at Sodus, Wayne Co.

Soldado Rock formation.

Eocene: Trinidad.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 701).

Soldier Creek shale. (In Wabaunsee group.)

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 30). *Soldier Creek sh.*—Sh., very aren. and moderately fossiliferous, 40 ft. or less thick. Included in Upper Coal Measures of Shawnee Co. [From statement on p. 28 appears to underlie Wakarusa ls. and overlie Stanton ls. The ls. underlying Soldier Creek sh. has for several years been known to be Burlingame ls. (see Condra, Nebr. Geol. Surv., 2d ser., Bull. 1, 1927), which is much younger than Stanton ls.; and the Oct. 1932 revised classification chart of Penn. of Kans. and Nebr., by R. C. Moore and G. E. Condra, defined Soldier Creek sh. as basal bed of Humphrey sh., and as underlying Wakarusa ls. and overlying Burlingame ls.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10), dropped Humphrey sh. from his classification and stated that *Soldier Creek sh. fm.* underlies Wakarusa ls. fm. and overlies Burlingame ls. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 218–221). Soldier Creek sh. underlies Wakarusa ls. and overlies Burlingame ls. Beede's original *Wakarusa ls.* is unit here called *Reading ls.*, and Wakarusa ls. as now defined by usage, mainly by Condra, was included in upper part of Beede's "Stanton" (=Burlingame) ls. It is apparent, therefore, that name *Soldier Creek* is transferred to a sh. that lies below that originally signified. Present application of Auburn sh. is synonymous with Beede's Soldier Creek sh. The Soldier Creek sh. is a bluish-gray to bluish clayey to sandy or silty micaceous unit locally containing a little ss. and a thin coal in upper part. In a few places marine invertebrates occur at top. Thickness 15 to 25 ft. in southern Nebr. and part of northern Kans., but near Kansas River and southward for many mi. it is less than 6 ft. thick; in southern Kans. it is 12 to

18 ft. thick; minimum 2± ft. Type loc. not designated, but presumably it is on "Big and Little Soldier Creeks about 3 mi. from Silver Lake," Shawnee Co., Kans.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

†Soledad division.

Miocene (upper): Southern California (Los Angeles County).

O. H. Hershey, 1902 (Am. Geol., vol. 29, pp. 349–372). *Soledad div.*—Gravel and sand, chiefly granitic, with lava pebbles and cobbles less abundant than in Lang div., and finer and more evenly bedded. Supposed to be marine. Thickness 3,000 ft. Conformably underlies Saugus div. and conformably overlies Lang div.

W. S. W. Kew, 1924 (U. S. G. S. Bull. 753, p. 81). The "*Soledad div.*" of Hershey is now thought by writer to be equiv., in greater part at least, to upper part of Mint Canyon fm. (upper Mio.) of this rept.

Named for exposures in Soledad Canyon, near Saugus, Los Angeles Co.

Soledad beds.

Cretaceous: Mexico.

E. Harrmann, 1913 (Deutsche geol. Gesell. Zeitschr., Bd. 65, Monatsb. 1, p. 25).

Soledad group.

Miocene (lower) or Oligocene: Southern California (Los Angeles County).

D. S. Jordan, 1919 (Leland Stanford Jr. Univ. Pub., Univ. ser., Fossil fishes of southern Calif., pp. 3–5). *Soledad group.*—Sss. and shales; the sss. of pale-yellow color, also soft white sss. and rather fine white shaly ss. Considerably older than the diatomaceous deposits referred to Monterey, which are sometimes segregated under name *Puente*. The fish fauna is older than Monterey and of lowest Mio. or possibly Olig. age. Well developed about Soledad Pass, in extreme N. part of Los Angeles Co., about 40 mi. N. of Los Angeles.

Soledad volcanic conglomerate member (of Catahoula tuff).

Tertiary (lower Miocene or Oligocene): Southwestern Texas coastal plain.

T. L. Bailey, 1926 (Univ. Tex. Bull. 2645, pp. 65, 80–89, 178–179). *Soledad memb. of Gueydan fm.*—Interbedded friable grayish-pink trachyandesite or acid andesite tuffs, pumice-pebble cgls. or lapilli beds, coarse to fine volcanic cgls. and volcanic sss. and tuffaceous sss. Middle memb. of Gueydan fm. [Thicknesses in sections 33 and 55 ft.] Underlies, conformably, Chusa memb. of Gueydan fm. and overlies Fant memb. of Gueydan. Assigned to Olig. because it correlates with lower part of Catahoula ss. Named for fact Soledad Hills, in western Duval Co., are composed of this memb.

The *Gueydan fm.* is same as Catahoula tuff, and "Gueydan" has been discarded by both Tex. Geol. Survey and U. S. Geol. Survey.

Soledad rhyolite.

Tertiary (?): Southern New Mexico (Dona Ana County).

K. C. Dunham, 1935 (N. Mex. School Mines Bull. 11, pp. 53, 56). *Soledad rhyolite.*—Flows 2,500 ft. thick. Overlies Cueva rhyolite. Exposed in mtns adjacent to Soledad Canyon, its type loc. Covers greater part of the lava field and occupies surface area of 35± sq. mi. In absence of evidence assigned to Tert.

Soleduck formation.

Cretaceous (?): Northwestern Washington (Olympic Peninsula).

A. B. Reagan, 1909 (Kans. Acad. Sci. Trans., vol. 22, p. 161). *Soleduck fm.*—Hard gray ss. and flinty slates of N. slopes of the Olympics. At N. is mostly hard gray ss., but nearing the Soleduck, and btw. the tributaries of that stream it is chiefly flinty dark-colored sl., though soft carbonaceous shales are exposed on S. slope of ridge that separates main channel of Soleduck from its northern fork; the sl. weathers iron-rust color. From Soleduck Springs S. to top of Soleduck-Bogachiel divide the fm. is alternating very hard to soft sh. and ss. Thickness 20,000± ft. Rests uncon. on Bogachiel fm. No fossils, but believed to be Cret. [In this same publication Reagan mapped the *Pliocene plutonic rocks* as *Soleduck fm.*, thus using *Soleduck* in 2 senses.]

Soleduck formation.

Pliocene: Northwestern Washington (Olympic Peninsula).

A. B. Reagan, 1909 (Kans. Acad. Sci. Trans., vol. 22), mapped the Plio. plutonic rocks of Olympic Peninsula as *Soleduck fm.*, and also applied *Soleduck fm.* to a great thickness of ss. and sl. of Cret. (?) age in the same region.

Solen beds.

Miocene (?): Northwestern Oregon.

E. D. Cope, 1880 (Am. Nat., vol. 14, pp. 457–458, and Am. Phil. Soc. Proc., vol. 19, p. 62). *Solen beds.*—Extensive tertiary deposit rich in Mollusca, which is usually interrupted by the central elevations of the mountain axis. The unpublished notes of Prof. Condon, formerly State Geologist, refer them to upper Mio., under the name *Solen beds*. [Paleontologic name.]

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 321). Astoria group includes *Solen bed* of Condon.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 578, 601–605), correlate *Solen beds* of Condon with Empire fm., Astoria ss., and San Lorenzo or basal Astoria, which they assigned to Olig.

Solen limestone.

Middle (?) Devonian: Iowa.

See *Solon ls.*

Solitario slate.

Pre-Cambrian: Central northern New Mexico (Las Vegas region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 11). *Solitario slates.*—Extensive section of tilted Archeozoic beds lying above the main ls. exposed in Solitario Mtn. NW. of Las Vegas. Thickness 800 ft.

Solitario formation.

Upper Ordovician (?): Southwestern Texas (Solitario Peak).

W. A. J. M. Van der Gracht, 1931 (K. Akad. Wetensch. Amsterdam Verh., Afd. Natuurk, Deel 27, No. 3, table Vc, p. 64). The table of fms., furnished this author by C. L. Baker, describes "15 or 20 ft. of bright-green siliceous and clay shales" btw. the Maravillas and Caballos, which is designated as the "Solitario fm."

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 79). Overlying Maravillas chert in Solitario uplift is a green sh., the max. observed thickness of which does not exceed 25 or 50 ft. This sh., lying btw. these heavy cherts and the Dev. [?] novaculite, is but imperfectly exposed and as a rule is seen only as a grass-covered slope btw. these 2 fms. Best exposures seen were in fault blocks in SW. and NE. parts of the basin. A similar sh. of lesser thickness is locally present in Marathon uplift, btw. Maravillas chert and Caballos novaculite.

Solitude granite.

Pre-Cambrian: Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Solitude granite.*—Granite and muscovite granite. Intrudes Pinal schist, which is overlain by Apache group. One area lies at head of Solitude Gulch, Globe quad.

Solomon gypsum. (In Sumner group.)

Permian: Central Kansas.

G. P. Grimsley, 1899 (Univ. Geol. Surv. Kans., vol. 5, pp. 58–61). [On p. 58 Grimsley gave a geol. section at Solomon gyp. mine, Dickinson Co., showing 7 beds of gyp. separated by sh. or by ls. On p. 61 the text beneath the heading "Other exposures" begins with: The lower gyp. horizon which, for convenience of description, may be called *Solomon gyp.*, outcrops ¼ mi. S. of the Dillon mill, where 5 ft. of rock is exposed covered with 5 ft. of dirt. This locality is 2 mi. W. of Hope shaft and the rock is 10 ft. lower.]

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 717). "Solomon gyp." of Grimsley lies 100 ft. lower than "Greeley gyp." of Cragin, both occurring in lower part of Marion fm. At Hope, in SE. part of Dickinson Co., the Greeley gyp. and Hope gyp. occur, separated by 100 ft. of shales and lss.

I. Perrine, 1918 (A. A. P. G. Bull., vol. 2, pp. 73–90). Solomon gyp. of Dickinson Co. lies 100 ft. lower than Greeley gyp. of same Co.

Solomon schist.

Pre-Ordovician (?): Northwestern Alaska (Seward Peninsula).

P. S. Smith, 1910 (U. S. G. S. Bull. 433, pp. 50–53, etc., maps). *Solomon schist.*—Highly metamorphosed quartzose and calc. schists, with some interbedded lss. and numerous quartz veins. Of pre-Ord. (?) age. Oldest fm. in Solomon and Casadepaga quads. Underlies Sowik ls., probably uncon. Exposed along Solomon River.

Solomon Creek member (of Seguin formation).

Eocene (lower): Southeastern Texas.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 575, 576, 577). *Solomon Creek memb.*—Lower memb. of Seguin fm. Consists of gray laminated silty clay, fine, uniformly grained gray sand containing large flat, rough-surfaced calc. concretions from 1 to 12 ft. long and from a few in. to several ft. thick, and layers of silty carbonaceous clay containing plant remains, sulphur and gyp. crystals. Carries no lignite beds. Type loc. in Solomon's Creek, 6 mi. S. 25° W. of Elgin, Bastrop Co.

Solomon's Corner limestone.

Lower Ordovician (Beekmantown): Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 7).

Solon limestone.

Middle (?) Devonian: Central eastern Iowa.

W. H. Norton, 1897 (Iowa Geol. Surv., vol. 6, p. 148). *Solon substage.* [Only definition is use of name in table for basal part of Cedar Valley ls., underlying Mason City substage of Cedar Valley and overlying Wapsipinicon ls.]

C. [R.] Keyes (Iowa Acad. Sci. Proc., vol. 19, p. 149, 1912, and vol. 20, p. 206, 1913). *Solon terrane.*—Consists of 15 ft. of gray shaly ls. containing *Megistocrinus*, underlain by 10 ft. of compact bluish ls. containing *Phillipsastrea*. Overlain by Rapid ls. div. of Cedar Valley and underlain by Wapsipinicon ls. Included in Senecan.

Named for Solon, Johnson Co.

Solsberry formation.

Mississippian: Southwestern Indiana.

F. C. Greene, 1911 (Ind. Acad. Sci. Proc. for 1910, pp. 275, 281). *Solsberry fm.*—[Definition not clear, but seems to apply name to all Miss. rocks in western Monroe and eastern Greene Counties, above Mitchell ls. and uncon. underlying the Penn. As thus used it includes most of Chester group.]

Named for Solsberry, Greene Co.

Solsville member.

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 133, 219+). *Solsville memb. of Marcellus fm.*—Sandy sh., fine ss., and a calc. ss., 45 to 50 ft. thick, transitional into underlying Bridgewater sh. memb. of Marcellus in Chenango and Unadilla Valleys. Overlain by Pecksport memb. of Marcellus. Characterized by typical Hamilton fossils in an unusual assemblage. ["Common forms" are listed.] Forms ridges on sides of hills N. of Solsville [Madison Co.]. Type section is falls in Woods gully, 2 mi. NW. of Solsville. Also occurs in Reilly's quarry, 4 mi. NW. of Bridgewater. Not known W. of Pine Woods, Morrisville quad.

Somerset shale member (of Warsaw formation).

Mississippian: Southeastern Kentucky.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, pp. 89, 104). *Somerset sh. memb.*—Calc. sh. or shaly ls. with variable amount of highly fossiliferous ls. of usual Warsaw ("Harrodsburg") type intercalated in it in thick and thin layers. Thickness 10 to 50 ft.; 20 ft. at Somerset. Lies near top of Warsaw fm., but stratigraphically lower than Garrett Mill ss. memb. Is overlain by a few ft. of thick-bedded ls. containing Warsaw fossils, and above this ls. lies St. Louis ls. Named for Somerset, Pulaski Co., where it is well exposed in R. R. cut a short distance N. of R. R. station.

Somerset member. (In Pottsville formation.)

Pennsylvanian: Southern Illinois (Saline County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 311–312). *Somerset memb. of Carbondale fm.*—Those Penn. strata in southern Ill. which occur btw. Curlew ls. and Murphysboro or Davis coal, which were formerly included in Tradewater fm. Named for exposures in vicinity of Somerset, Saline Co. [The U. S. Geol. Survey draws top of Pottsville fm. at base of Murphysboro coal. These beds therefore belong to Pottsville fm. of most authors.]

Somerville limestone.

Pennsylvanian: Southwestern Indiana.

M. L. Fuller and G. H. Ashley, 1902 (U. S. G. S. Ditney folio, No. 84, p. 2). *Somerville fm.*—Ls., 30 ft. thick, with sh. memb. in middle. Overlain by Ditney fm. and underlain by Millersburg fm.

The Ind. Geol. Survey now includes these beds in Shelburn fm. (See Cumings, Hdb. Ind. Geol., pt. 4, Sep. Pub. 21.)

Named for Somerville, Gibson Co.

†Somerville slate.

Carboniferous or Devonian: Eastern Massachusetts.

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, geol. ser. vol. 8, No. 4, pp. 196–197). *Somerville sl.* is lithologically similar to recognized Camb. slates of the [Boston] region and markedly dissimilar to known Carbf. rocks of neighboring areas, especially to those of Narragansett Basin.

F. H. Lahee, 1914 (Am. Jour. Sci., 4th, vol. 37, p. 316). *Somerville slates*, 2,300 ft. thick, grade into underlying Squantum tillite of Roxbury cgl. through transition beds of shales or slates, sss., and cgls. 200 to 300 ft. thick.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks at and around Somerville as Cambridge sl., and the name "Somerville sl." has been discarded.

Somerville granite.

Pre-Cambrian: Northeastern Virginia (Fauquier County).

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30). *Somerville granite*, typically developed near Somerville. Is coarse-grained biotite-muscovite granite, massive, pegmatitic, of pre-Camb. or Camb. age, and closely related to Locust Grove granite.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.), mapped the granite at and around Somerville, Fauquier Co., as pre-Camb. and as intrusive into Glenarm series (Algonkian?).

Sonoma tuff.

Pliocene: Northern California (Sonoma County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 39–87). *Sonoma tuff.*—Andesitic in character and interbedded with thin flows of basalt, and with sss. and volcanic cgls. to W., where it is of fluviatile origin. To E. is interbedded with volcanic aggls. and breccias and is largely of aeolian origin. Rests conformably on Mark West andesite. Thickness 1,700 ft.

Probably named for exposures in Sonoma Mtns, Sonoma Co.

Sonoma group.

Sonoma volcanics.

Pliocene: Northern California (north of San Francisco Bay region).

R. E. Dickerson, 1922 (Calif. Acad. Sci. Proc., 4th ser., vol. 11, No. 19, with maps). *Sonoma group.*—Basalts, andesites, rhyolites, tuff-breccia, fine-grained tuff, and other aggls. Generalized section running N. from Adobe Fort to Petaluma Reservoir shows following sequence (descending): Basalt, tuff, basalt, cgl., basalt, *Neohipparion gidleyi* beds, and tuff, resting uncon. on Petaluma fm. Includes Sonoma tuff, Mark West andesite, and St. Helena rhyolite of Osmont. Is overlain by Millerton fm. In Pinole syncline is known as *Pinole tuff*. The tuffaceous facies of Sonoma group are represented as interbedded tuff members of marine Merced group.

R. R. Morse and T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 10, pp. 1437–1455). *Sonoma volcanics* overlie, with angular uncon., Petaluma fm. in Petaluma dist. and are probably = Merced fm. *Neohipparion gidleyi* occurs in Petaluma fm., and not in Sonoma group. [On map the Sonoma is assigned to *upper or middle Plio.;* but in text authors seem to incline to *middle Plio.*]

Named for typical exposures on W. flanks of Sonoma Mtns, Sonoma Co.

Sonora sandstone.

Mississippian: Southeastern and central eastern Iowa and northwestern Illinois (Carroll County).

C. R. Keyes, 1895 (Iowa Geol. Surv. vol. 3, pp. 320, 344–350). *Sonora ss.*—Sandy mag. ls., 8 ft. thick, forming top memb. of Augusta ls. in Lee Co., Iowa. Overlies Warsaw shales and underlies St. Louis ls. Named for Sonora quarries, on Ill. side of Miss. River., opp. Nashville and below Belfast.

According to F. M. Van Tuyl (Iowa Geol. Surv. vol. 30, 1925, p. 225) this is an aren. facies of Spergen fm., 20 ft. thick, and was formerly quarried extensively in Miss. River bluff 1 mi. S. of Sonora, Carroll Co., NW. Ill., where it underlies St. Louis ls. and overlies Warsaw sh.

Sonora shale.

Pennsylvanian: Missouri.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 252). *Sonora terrane.*—Shales, 100 ft. thick, underlying Cherokee sh. and overlying Chester in Mo.

Is basal part of Cherokee sh.

Derivation of name not stated.

Sonora formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 334).

Sonyea.

Upper Devonian: Western New York (Genesee River region).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 96, 98). To the combined Middlesex and Cashaqua, which are a natural unit, the name *Sonyea* is herein applied, from exposures on Cashaqua Creek at that place, near Portage. Overlain by Attica (combined Rhinestreet and Hatch), and all included in Nunda (Naples) group.

G. H. Chadwick, Feb. 28, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 314, 352). [See 1935 entry under *Ithaca sh. memb.*]

G. H. Chadwick, Dec. 1935 (letter dated Dec. 11). *Sonyea* was introduced to emphasize that Middlesex-Cashaqua constitute continuous sedimentation. Since these beds, instead of the Attica, now prove to be the Ithaca, the name has no lasting value save for a facies (parvafacies) of the Ithaca, and I have abandoned it.

Soo series.

Pre-Cambrian (early Huronian): Western Ontario.

R. G. McConnell, 1927 (Ont. Dept. Mines 35th Ann. Rept., pt. 2, p. 12). *Soo series,* pre-Camb., Ont.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned these rocks to early Huronian.

Sooke formation.

Miocene or Oligocene or both: Northwestern Washington and British Columbia (Vancouver Island).

J. C. Merriam, 1896 (Univ. Calif. Dept. Geol. Bull., vol. 2, pp. 105–108). *Sooke beds.*—The cliffs at mouth of St. Johns River and near Sooke, on S. coast of Vancouver Island, contain the Sooke fauna [listed], show considerable thickness of soft ss. with some cgl. In places the ss. is full of well-preserved fossils. Evidence indicates Sooke beds are middle Neocene and considerably later than Carmanah Point beds, whose fauna seems to be Mio.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 336–343). *Sooke beds* were named for Sooke Inlet, S. coast of Vancouver Island.

C. H. Clapp and J. A. Allan, 1911 (Canada Geol. Surv. map 17A), assigned Sooke fm. to *Olig.-Mio.*

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, p. 575). Occupying several disconnected areas along S. coast of Vancouver Island from Becher Bay W. to Sombrio River near Port San Juan, and perhaps farther, is the fm. termed *Sooke beds* by Merriam. Excepting type area btw. Muir and Coal Creeks, several mi. W. of Sooke, where drillings have shown the sediments to be more than 1,500 ft. thick, the beds comprise only a few ft. of basal cgl., usually less than height of the sea cliffs, which lies on Vancouver greenstone diorites. Is only local sediment, of Olig. age.

C. H. Clapp, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 50), assigned Sooke fm. to *Mio.*, and 1917 (Canada Geol. Surv. Mem. 96, p. 329) assigned it to *Mio. (?)*.

B. L. Clark and R. Arnold, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 303–308). *Sooke fm.* or *Agasoma acuminatum* beds underlies San Lorenzo fm. or *Molopophorus* zone, but fauna is probably only a facies of latter. Assigned to Olig.

H. C. Cooke, 1919 (Canada Geol. Surv. Mus. Bull. 30, p. 2), assigned Sooke fm. to Mio.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2) assigned Sooke fm. to Mio.

Sooke gabbro group.

Sooke intrusives.

Oligocene: British Columbia.

C. H. Clapp and J. A. Allan, 1911 (Canada Geol. Surv. map 17A) and C. H. Clapp, 1912 (Canada Geol. Surv. Mem. 13, p. 113).

Sooy conglomerate. (Buried.)

Pennsylvanian: Central Kansas.

F. C. Edson, 1935 (Tulsa Geol. Soc. Digest, May 7, 1934, pp. 30–32). The "Sooy" cgl. is widely distributed in western central Kans. but has no definite strat. position. Rests on beds ranging from pre-Camb. to upper Bendian, and is overlain by beds from Morrow to upper Lansing in age. It is an orogenic molasse deposit representing the 2 subphases of Wichita orogeny as well as several lower and middle Penn. orogenic periods. The "Sooy" cgl. and the Morrow-Atoka-Cherokee-Marmaton-Kansas City-lower Lansing groups represent, in part, simultaneous deposition of unlike sediments, although the "Sooy" is everywhere overlain by some part of the more marine group. The Gorham sand is a phase of it. It includes the weathered beds that overlie the "Chester," and I think the Welch chert. I place top of the "Sooy" at top of the red chert pebbles. It is more difficult to get the base. It contains a surprisingly small amount of Decorah sh. [On p. 31 I. H. Cram stated: If this cgl. was on the surface it would be a mappable unit and would be a fm.]

E. A. Koester, 1935 (A. A. P. G. Bull., vol. 19, No. 10, p. 1413). *Sooy cgl.* (named by Edson, Tulsa Geol. Soc. Digest, 1934) is a transgressive deposit, overlying rocks of pre-Camb. to Miss. age and underlying beds ranging in age from Cherokee in central Kans. to possible Perm. in NW. Kans. Name derived from one of first wells drilled in western Kans., in Barton Co. In its most common development it is a coarse cherty, partly sandy cgl. commonly cemented with red sh. Represents the first deposit of a transgressive sea. Locally contains several sand zones. Gorham sand is a near-shore phase of Sooy cgl.

†Sopchoppy limestone.

Miocene (lower): Northwestern Florida (Wakulla County).

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 119–122, 158, 334). *Sopchoppy ls.*—Very soft ls. containing numerous imprints of shells and many fragments of vertebrate ribs and other bones, also Conrad's orbitolite and about 30 species of shells, most of which are common to Chipola marl or *Orthaulax bed*. The horizon is probably not far from that of Chipola marl. Thickness unknown. Referred to Older Miocene.

Julia Gardner, 1926 (U. S. G. S. P. P. 142A, p. 2). "Sopchoppy ls." is nothing more than a shallow-water facies of Chipola fm.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept.). Hawthorn fm. restored to good standing and "Sopchoppy ls.," of Chipola age, included in it.

Named for exposures at Sopchoppy, Wakulla Co.

Sophie Mountain conglomerate.

Tertiary: British Columbia.

E. L. Bruce, 1917 (B. C. Dept. Mines Bull. 4, p. 5).

Sopris coal group. (In Vermejo formation.)

Upper Cretaceous: Eastern Colorado (Elmoro region).

R. C. Hills, 1899 (U. S. G. S. Elmoro folio, No. 58), applied *Sopris group* to 80 ft. of sh., shaly ss., and coal beds, lying 35 to 40 ft. above Engle [coal] group. Both of these coal groups belong to Vermejo fm. of present terminology.

Sorel sand.

Quaternary: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 225).

Soudan iron-formation.

Pre-Cambrian (Keewatin): Northeastern Minnesota (Vermilion district).

C. R. Van Hise and J. M. Clements, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 401–409, map). *Soudan fm.*—Iron-bearing; cherty iron carbonates, pyritic quartz rocks, ferruginous cherts, jaspilites, and ore bodies. Thickness 0 to 1,000 ft. Overlies Ely greenstone and is intruded by granite, greenstone, and porphyry. Named for occurrence on Soudan Hill, Vermilion dist.

The U. S. Geol. Survey has recently adopted *iron-formation* as a lithologic term.

Sougahatchee granite.

Age (?): Central eastern Alabama (Tallapoosa County).

G. I. Adams, 1933 (Jour. Geol., vol. 41, pp. 168–169). The basic rocks of the older intrusives of Dadeville belt are cut by granitic intrusives, the larger and more conspicuous areas of which are shown in a general way on the sketch map. The granite is here named *Sougahatchee granite*, from the creek near which it is exposed at many places in SW. border of Dadeville belt. Is much more gneissic than Pinckneyville granite.

Soulala formation.

Quaternary: Nicaragua.

O. H. Hershey, 1912 (Geol. Soc. Am. Bull., vol. 23, p. 507).

Soultan series.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 201). *Soultan series.*—Qtzites which with the uncon. overlying unnamed lavas and granites comprise Algomic period of Archeozoic era in Lake Superior region. [In 1917 (Iowa Acad. Sci. Proc., vol. 24, p. 56) Keyes removed these qtzites from his Algomic period and placed them in his underlying Huronic period.]

Derivation of name not stated.

Sour Dough limestone.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group*. Exposed in Sour Dough Canyon, in S. part of Panamint Range.]

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). *Sour Dough ls.*—Crystalline micaceous, aren. gray ls. with alternating white and gray stripes which in some places are corrugated. Thickness 50 to 60 ft. Basal fm. of Telescope group. Underlies Middle Park fm. and overlies Surprise fm., all of which are assigned to lower Paleozoic (?).

Souris Lignitic.

Upper Cretaceous: Canada.

G. M. Dawson, 1881 (Canada Geol. Surv. Rept. 1879–80, p. 128). Local name for Upper Cret. beds on Souris River that have been referred to Laramie fm.

†Sourland Mountain trap.

Name applied by N. H. Darton (U. S. G. S. Bull. 67, 1890) to the sheet of diabase on Sourland Mtn, N. J., which intrudes Brunswick and Lockatong fms., of Newark group (Upper Triassic). This local geographic name considered unnecessary and is not used by U. S. Geol. Survey.

South Ada limestone.

Miners' name for an ore-bearing ls., 8 ft. thick, in lower part of Oquirrh fm. (Penn.), Stockton dist., central northern Utah. Lies 18 ft. below their North Ada ls. and 230 ft. above their Maverick ls. Exposed in Ada claim. (See U. S. G. S. P. P. 173, 1932.)

South Amboy fire clay.

Economic term for a clay bed, 5 to 30 ft. thick, in Raritan fm. of NE. New Jersey. See G. H. Cook and J. C. Smock, 1877 (N. J. Geol. Surv. map of clay dist. of Middlesex Co.), and G. H. Cook, 1878 (N. J. Geol. Surv. Rept. on clays, p. 34). Named for occurrence at South Amboy.

South Bend limestone. (In Stanton limestone.)

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 23). *South Bend ls.*—Exposed in bed of Salt Creek SW. of C., B. & Q. station at Ashland, at track level near mouth of Salt Creek, in valley sides from Pawnee Creek to Louisville, and from State Fish Hatcheries to Meadow. Thickness 8 to 9 ft. Along railroad ½ mi. E. of Pawnee Creek it shows: Light-gray ls., 10 in.; light-colored sh. with calc. concretions, 1 ft. 3 in.; light-gray ls., 2 ft. 10 in.; light bluish gray sh., 1 ft. 10 in.; ls. with large flint nodules, 2 ft. 6 in. Lies 6 to 10 ft. above Louisville ls. and 16 to 18 ft. below Ashland ls. [Pl. 2 shows the ls. exposed in cliff at South Bend, Cass Co.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 41, 58). *South Bend ls.*, 9 ft. thick, is in lower part of Scranton sh. It overlies Rock Lake sh. and underlies Plattford sh. Named for exposures just N. of South Bend.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 13, 27, 32). In Ashland section what was supposed to be *South Bend ls.* is Iatan ls. The South Bend ls. underlies Weston sh. and overlies Rock Lake sh. and is top bed of Stanton ls. memb. [This is definition adopted by R. C. Moore and Condra in their Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.]

South Bend sandstone and shale. (In Graham formation.)

Pennsylvanian: Central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 37; Univ. Tex. Bull. 2132, pp. 127–136). *South Bend ss. and sh.*—A memb. of Graham fm. (of Canyon group), underlying Gunsight ls. memb. and overlying Bunger ls. memb. Consists of light-gray fine-grained lenticular ripple-marked sss. and blue-gray sandy fossiliferous shales 50 to 110 ft. thick. Typically exposed at South Bend, Young Co. Thins to S.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 104, 113, 114). *South Bend* is preoccupied and now replaced by *Necessity sh.*

South Bosque marl.

Upper Cretaceous: Central Texas (McLennan County).

J. K. Prather, 1902 (Tex. Acad. Sci. Trans., vol. 4, pt. 2, No. 8). *South Bosque marl.*—Marl, of clay-yellow color, with a few thin beds of argill. ls. interbedded. Thickness 100 to 250 ft. Underlies Austin chalk and overlies Eagle Ford clay. Included in Austin chalk by R. T. Hill.

According to L. W. Stephenson (personal communication, June 1930) the beds referred to belong to upper part of Eagle Ford fm.

Named for exposures at South Bosque Station, McLennan Co.

South Britain conglomerate.

Upper Triassic: Western Connecticut.

W. H. Hobbs, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 40–43, 49–51, 63–64). *South Britain cgl.*—Coarse arkose cgl. with included layers of Newark system [group]. Found principally in village of South Britain, Conn.

South Butler amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs to Central Mine group. Is younger than Ogima amygdaloid and older than Butler amygdaloid. The mineralized part is the South Butler lode. Probably named for its occurrence S. of the Butler amygdaloid, in Ontonagon Co.

South Butler flow.

Includes South Butler amygdaloid and the underlying trap.

South Carrollton limestone.

Pennsylvanian: Western Kentucky.

C. J. Norwood, 1878 (Ky. Geol. Surv., 2d ser., vol. 4, pt. 7, pp. 296-301, 319). *South Carrollton ls.*—Somewhat mottled ls., having a somewhat ferruginous exterior, marked with dove, drab, or ashy-white splotches. On fractured surface seems mainly blue or dove-colored, changing at places to drab or chocolate brown. Thickness 3 to 13 ft. In vicinity of South Carrollton [Muhlenberg Co.] the surface of the ls. is usually thickly studded with large crinoid columns. Probably identical with Madisonville ls. Exposed in bluff ½ mi. NW. of South Carrollton.

Southerland sand.

See *Sutherland sand.*

†Southern drift.

Descriptive term used in early La. and Miss. repts for Plio. deposits now in part at least included in Citronelle fm.

†Southern Lignitic.

See under *†Grand Gulf group.*

Southern Belle quartzite.

Middle Cambrian: Southeastern Arizona (Santa Catalina Mountains).

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 476-477, 482). *Southern Belle qtzite* (Middle Camb.) consists of 26 ft. of cliff-forming massive white qtzite, underlying Abrigo fm. (Upper Camb.) and overlying Santa Catalina fm. in Peppersauce Canyon, Santa Catalina Mtns.

South Fork limestone.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, pp. 5, 10). Burlingame ls. fm. divided into (descending): (1) *South Fork ls.* (one massive bed, or 2 or 3 beds separated by sh., 2½ ft.); (2) Winnebago sh. (bluish, argill., some limy fossiliferous seams, 8 to 12 ft.); (3) Taylor Branch ls. (bluish gray, massive, weathering brownish, 2 to 4½ ft.). The South Fork lies high in hill ¾ mi. SW. of DuBois [Pawnee Co., SE. Nebr.], at W. side of South Fork Valley; type of the Winnebago is in Mo. River bluffs S. of mouth of Winnebago Creek, N. of Rulo, Richardson Co., Nebr.; the Taylor Branch is lowest heavy ls. at top of opening in clay pit S. of Taylor Branch, S. of Table Rock, Nebr. These members have been traced through Kans. to Okla.

Southgate member. (In Latonia shale.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and north-central Kentucky.

R. S. Bassler, 1906 (U. S. Nat. Mus. Proc., vol. 30, p. 9). *Southgate.*—Blue to yellow shales, 20 ft. thick, with fewer lss. than in rest of Eden. Comprises middle memb. of Eden. Overlain by McMicken memb. and underlain by Economy memb.

Is middle part of Latonia sh.

Named for Southgate, Campbell Co., Ky.

South Hampton granite.

Age (?): Southeastern New Hampshire (Rockingham County).

E. Hitchcock, 1823 (Am. Jour. Sci., 1st, vol. 6, pp. 3-6). In painting on the map what I have denominated *South Hampton granite* I have comprehended most of the Chesterfield and Goshen granite. Texture of South Hampton granite is rather coarse. It contains the South Hampton lead mine. [South Hampton is in Rockingham County, N. H.]

South Higgins moraine.

Pleistocene (Wisconsin stage): Northern central Michigan (Roscommon County).

W. A. Ver Wiebe, 1927 (Papers Mich. Acad. Sci., Arts, and Lett., vol. 7, p. 161). Lies just S. of Higgins Lake.

South Mapleton andesite.

Paleozoic: Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 113, 169, 173). *South Mapleton andesites.*—Andesites outcropping in 10 or 12 places in fields in S. part of Mapleton Twp, to N. and S. of Mapleton-Presque Isle road. They are either identical with or present only minor variations from the Edmunds Hill and Hobart Hill masses. Assigned to Paleozoic.

On 1933 geol. map of Maine, by A. Keith, the andesites of NE. Maine are assigned to Dev.

South Moat flows.

Devonian (?): Northern New Hampshire (North Conway quadrangle, White Mountains).

M. Billings, 1928 (Am. Acad. Arts and Sci. Proc., vol. 63, No. 3, map, pp. 72, 92). *South Moat flows.*—Flows of comendites (quartz porphyries) and trachyte included in Moat volcanics, the rest of Moat volcanics being Pequawket breccia. The comendites are typically exposed on South Moat Mtn. The trachyte is found as a distinct flow only on S. slopes of South Moat Mtn. The South Moat flows are same as quartz porphyry of Hitchcock. [On map *South Moat flows* is divided into 2 blocks, the upper one labeled *comendites* and the lower one *trachyte*. See also under *Moat volcanics.*]

South Mountain slates.

Cambrian: Southern Pennsylvania.

F. Platt, 1877 (2d Pa. Geol. Surv. Rept. H., p. xxiv), divided Camb. system of Pa. into (descending) *Potsdam ss. (No. 1)*, *South Mountain slates*, and *Blue Ridge cgls.*, etc.

South Mountain quartzite.

A name casually applied in some early repts to the Lower Camb. Chickies qtzite of South Mtn, Pa., and western Md. See C. D. Walcott, Am. Jour. Sci., 3d, vol. 47, pp. 37–41, 1894, and U. S. G. S. Bull. 134, p. 33, 1896.

South Mountain gneiss.

A name casually applied in some early Pa. Survey repts to the gneiss of South Mtn. Also called "Laurentian gneiss."

†South Mountain type.

A field name applied by E. S. Larsen to part of Fisher quartz latite on South Mtn, Platoro-Summitville region, Rio Grande Co., Colo. (See Colo. Geol. Surv. Bull. 13, 1917.)

†South Pass group.

Pliocene: Northwestern Wyoming.

T. B. Comstock, 1874 (Rept. of reconn. of NW. Wyo. made in 1873 by Wm. A. Jones, table opp. p. 103), applied *South Pass group* to Plio. deposits divided into volcanic rocks (above) and *Yellowstone Lake group* (below). In text he used *South Pass beds*. Neither *South Pass group* nor *Yellowstone Lake group* is defined, and both have been ignored by other geologists working in region.

South Pewabic amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. R. Marvine, 1873 (Mich. Geol. Surv. vol. 1, pt. 2, pp. 52, 76, 77 and chart).

Belongs to Ashbed group. Is younger than Pewabic cgl. and older than Ashbed amygdaloid. The mineralized part is the South Pewabic lode. Named for occurrence in old South Pewabic mine, in Houghton Co.

South Pewabic flow.

Includes South Pewabic amygdaloid and the underlying trap.

South Prairie formation.

Eocene: Western Washington (Puget Sound region).

B. Willis, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 424 to 430). [See under †*Pittsburg fm., Eocene*, 1898 and 1899 entries.]

South Saskatchewan gravels.

Late Tertiary or Quaternary.

R. G. McConnell, 1886 (Geol. and Nat. Hist. Surv. Canada Ann. Rept. 1885, vol. 1, p. 70C).

South Tunnel bed.

Silurian (Niagaran): Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 397, 402). *South Tunnel bed.*—Overlies Baker (Clinton) ls. and underlies Whites Bend (Laurel) ls. Thickness 0 to 12 ft. Included in Clifton ls. Same as Osgood shaly clay of Ind.

Named for South Tunnel, Sumner Co.

South Valley limestone.

Name used by J. P. Lesley on map 43, Pa. Geol. Surv. Rept. X, 1885.

†South Valley Hill slates and mica schists.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania.

C. E. Hall, 1881 (2d Pa. Geol. Surv. Rept. C_6, pp. 31+). These slates and schists form a prominent ridge flanking Chester County ls. on S. and called South Valley Hill, hence the name—*South Valley Hill slates and mica schists.*

Include Wissahickon fm. and part of Peters Creek schist.

Southward Bridge formation. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County) and northwestern Alabama.

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Southward Bridge fm.*—Consists of (descending): (1) Fossiliferous ls.; (2) thick sh. and ss.; (3) fossiliferous ls.; (4) thick sh. Thickness 80 ft. Underlies Forest Grove fm. and overlies Southward Spring ss. Exposed in bluffs of Bear Creek SE. of Southward Spring.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23), gave many details of fm., including thicknesses of subdivisions, as follows: Upper ls., 5½ ft.; lower ls., 2 to 4 ft.; interval btw. the lss., 45 to 50 ft.; and basal sh. or clay, 31± ft. Type loc., Southward Bridge, near old village of Mingo, at confluence of Bear Creek and Cedar Creek Valleys [which his map shows is in Ala.], where fm. is 82 ft. 7 in. thick.

Southward Pond formation. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County) and northwestern Alabama.

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Southward Pond fm.*—Of oolitic texture and at many places contains asphalt. Whole fm. fossiliferous. Thickness 80 to 100 ft. Consists of (descending): (1) Sh. or shaly ls.; (2) *Pond ls. "C,"* 1 or 2 ft.; (3) sh. or shaly ls.; (4) *Pond ls. "B,"* 1 or 2 ft.; (5) sh. or shaly ls.; (6) *Pond ls. "A,"* 5 to 15 ft.; (7) sh. or shaly ls. Underlies Southward Spring ss. and overlies Allsboro ss. Named for exposures around bluffs of Southward or Cypress Pond.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23), gave many details of this fm., and described the lss. as follows: *Pond ls. "C,"* 3± ft. of somewhat cross-bedded hard bluish-gray, coarsely crystalline fossiliferous ls.; *Pond ls. "B,"* 0 to 1 ft. of very fossiliferous crystalline ls.; *Pond ls. "A,"* 1 to 16½ ft. of massive, slightly reddish-gray oolitic or foraminiferal ls., everywhere asphaltic. Pond ls. "C" lies 10 to 12 ft. above Pond ls. "B," which lies 10 to 27½ ft. above Pond ls. "A." Latter lies 6 to 25 ft. above Allsboro ss. Fm. named for exposures in bluffs of Southward (or Cypress) Pond, at Southward homestead. The pond is perhaps an old meander of Bear Creek.

Southward Spring sandstone. (In Chester group.)

Mississippian: Northeastern Mississippi (Tishomingo County) and northwestern Alabama (?).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Southward Spring ss.*—Impure shaly ss., somewhat calc., underlying Southward Bridge fm. and overlying Southward Pond fm. Thickness 30± ft.; 15 ft. exposed at Southward Spring.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23), gave many details of fm. On p. 118 he says "Southward Spring ss. is well exposed at the spring south of the [Southward or Cypress] pond."

Sowik limestone.

Ordovician (?): Northwestern Alaska (Seward Peninsula).

P. S. Smith, 1910 (U. S. G. S. Bull. 433, pp. 50, 54+, maps). *Sowik ls.*—Massive bluish-white nondolomitic ls., 400 to 1,000 ft. thick. Overlies Solomon schist, probably uncon., and underlies Hurrah sl. The N. end of this ls. is near settlement of Sowik, whence name. Tentatively assigned to Ord. (?).

†Spadra shale.

Pennsylvanian (Allegheny): Western Arkansas coal field.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Spadra stage.*—Shales and sss., with several coal beds. Thickness 0 to 500 ft. Underlie Sebastian stage and overlie Norristown stage.

A. J. Collier, 1907 (U. S. G. S. Bull. 326). *Spadra sh.*—Sh. with ss. lenses. Thickness 350 to 500 ft. Overlies Hartshorne ss. and underlies Fort Smith fm. Includes Lower Hartshorne coal at base. Is basal fm. of McAlester group.

Named for Spadra, Johnson Co.

Has been discarded. See explanation under *McAlester fm.*

Spafford member.

Middle Devonian: Central New York (Skaneateles quadrangle).

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. **11, 50**). *Spafford memb. of Ludlowville fm.*—Relatively fine and very fossiliferous sh. overlying Ivy Point memb. and underlying *Spirifer tullius* zone (Owasco memb.) of the Ludlowville. Thickness 25± ft. Type section is in first ravine N. of Ivy (or Willow) Point on E. side of Skaneateles Lake, about ¾ mi. N. and slightly W. of Spafford Landing.

Spaniard limestone member (of Savanna sandstone).

Pennsylvanian: East-central Oklahoma.

S. W. Lowman, 1933 (Tulsa Geol. Soc. Digest, p. 31). *Spaniard ls.*—Occurs in midst of Savanna ss. of east-central Okla. Overlain by ss. of Rattlesnake Mtn and underlain by an unnamed ss. Named for a well-exposed outcrop in Spaniard Creek, S. of Muskogee, about center of N½ sec. 11, T. 13 N., R. 18 E.

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Spaniard ls. memb. of Savanna ss.* is 3 to 10 ft. thick, lies 40 to 50 ft. below Sam Creek ls. memb. of Savanna ss., and rests on Keota ss. memb. of the Savanna.

†Spanish formation.

Mississippian: Northern California (Lassen Peak region).

J. S. Diller, 1892 (prel. proof-sheet edition of U. S. G. S. Lassen Peak folio, No. 15). *Spanish fm.*—Chiefly qtzites and slates with occasional lenses of ls. Has yielded no fossils. Is younger than Caribou fm. and older than Arlington fm. Named for fact it surrounds N. end of Spanish Peak.

In published Lassen Peak folio (No. 15) these rocks are mapped and described as Calaveras fm.

Spann limestone member (of Pennington shale).

Mississippian: Southeastern Kentucky (Wayne County).

M. J. Munn, 1914 (U. S. G. S. Bull. 579, p. 33). *Spann ls. memb.*—Massive cherty geodic ls., 3 to 15 ft. thick, in middle of Pennington sh.

Named for Spann, Wayne Co.

Sparksville facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 172, etc., 1931) to a lithologic development of his Carwood fm. in a part of southern Ind.

Sparland cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to a middle portion of McLeansboro fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 7. Derivation of name not stated.

†Sparry limestone.

A descriptive term applied in early N. Y. repts (1) to lower part of Trenton ls. as now defined; (2) to Stockbridge ls. of eastern N. Y. and Mass.; and (3) to a ls. in Helderberg group. The term appears to have originated with E. Emmons (Agric. N. Y., vol. 1, 1843, pp. 72–74; or, possibly with A. Eaton, 1824. In some early N. Y. repts "Grey Sparry ls." was applied to Onondaga ls.

†Sparta sands.

Tertiary: Northern Louisiana.

T. W. Vaughan, 1895 (Am. Geol., vol. 15, p. 225). *Sparta sands.*—Deep quartz sands, sometimes with gravel. Is = the "Drift" of Hopkins and Lerch. Thickness 60–100 ft. Underlies Pleist. second bottoms and uncon. overlies Grand Gulf group of Hilgard.

T. W. Vaughan, 1896 (U. S. G. S. Bull. 142, pp. 25–26). *Sparta sands, age undetermined.*—These sands and gravels have been called drift by Hopkins and Lerch. In order not to venture an opinion as to their age, and not to attempt a correlation of all superficial upland sands and gravels of NW. La., I have proposed a local name and desire to include under it deposits of whose homogeny and contemporaneity there can be no reasonable doubt. Extending across central portion of La. are deep quartz sands, whose northern extent is as follows: They reach to T. 16 N., on Louisiana meridian; the bdy from there passes 2 mi. S. of Gansville, thence NW. to Sparta. From Sparta the bdy runs S. to NW. corner of Natchitoches Parish, and thence it is formed by Black Lake Bayou and Black Lake, to mouth of that lake. West of Red River the line runs from Victoria by Fort Jessup and S. to mouth of Bayou Toreau. Except a narrow strip along Ouachita River, nearly all of region btw. the fluviatile deposits of Red and Ouachita Rivers is covered by these sands, which overlap both Lower Claiborne and Grand Gulf, extending entirely across the Jackson and Vicksburg. The material is usually almost pure quartz sands, sometimes with reddish coloring matter. In Grand Parish there is a great deal of quartz gravel. In southern gravelly portion transported fossils have been found. The sands and gravel of this fm. range in thickness from a trifling veneer to 60 and sometimes to 100 ft. Along the contact with the Eocene as seen near Provencal, there is some clay at base. These deposits rest with a distinct uncon. upon the older rocks. Named for good development near Sparta, Bienville Parish.

According to W. C. Spooner (A. A. P. G. Bull., vol. 10, No. 3, p. 326, 1926) the Sparta sands of Vaughan as above defined included Sparta sand of Spooner, 1926, "as well as portions of Catahoula ss. of Oligocene [Mio. ?] age, and Citronelle fm. of Pliocene age."

Sparta shale.

Upper Cambrian: Southwestern Wisconsin (Monroe County).

W. D. Shipton, 1916 (Iowa Acad. Sci. Proc., vol. 23, pp. 142–145). *Sparta sh.*—In Sparta quad. the Mendota is missing and a new Camb. memb. is recognizable. It consists of layers of argill. ss. alternating with thin fissile aren. and calc. layers, all with more than 50 per cent of sand; the aren. beds are mostly thin, but a few reach 2 ft. in thickness; the more limy layers are rarely more than 1 inch thick; the layers apparently become more calc. near contact with overlying Madison ss.; the fissile shales vary in color, some are of a green color, due to disseminated grains of glauconite. Thickness 200 ft. Faunally there is difference btw. the Mendota and Sparta beds. It is possible that Sparta beds may be=Franconia fm. of Ulrich (Bull. 35 Wis. Surv.), but since no description of Franconia beds has been published it is impossible to make definite statement to that effect. Winchell recognized the St. Lawrence and associated shaly beds as having total thickness of 200 ft. Those beds are probably=Sparta memb., which overlies Dresbach ss., 820 to 879 ft. thick.

Sparta sand. (In Claiborne group.)

Eocene (middle): Northwestern Louisiana and northeastern Texas.

W. C. Spooner, 1926 (A. A. P. G. Bull., vol. 10, No. 1, p. 7, and No. 3, pp. 220, 224, 227, 237). *Sparta sand.*—Middle div. of Lower Claiborne or St. Maurice fm. as originally defined and heretofore used. Limited below by Cane River beds and above by lowest fossiliferous horizon of St. Maurice beds as here restricted. Thickness of Sparta sand 400 to 550 ft. Upper half contains a relatively greater amount of clay than lower half; massive sands alternate with beds of finely laminated sandy clay, in part lignitic and in many places containing fossil leaves; upper 50 ft. contains considerable lignitic material and some thin lignitic beds which are well exposed in vicinity of town of Bienville. Lower half is chiefly massive sand with interbedded subordinate members of laminated sandy clay; the sands are made up of quartz grains somewhat coarser than found in Wilcox fm. Fossils generally absent, but a few species of near-shore forms are found near middle of fm. The Sparta sand of Vaughan (U. S. G. S. Bull. 142, p. 25, 1896) included Sparta sand as here defined as well as parts of Catahoula ss. (of Olig. age) and Citronelle fm. (of Plio. age).

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Sparta sand memb. of Claiborne fm.* occurs below Crockett memb. and above Weches memb. as defined in this paper. Is thickest in La., being 450 ft. thick in Palmer Corporation Crichton No. 1 well in Webster Parish, thinning toward S. part of Sabine uplift and in Tex.

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, pp. 1347–1361). *Sparta sands*, of Cook Mtn fm., underlie Crockett fm. and overlie Mount Selman fm. Thickness 250 or 300 ft.

H. K. Shearer, 1930 (A. A. P. G. Bull., vol. 14, No. 4, pp. 433–450). *Sparta sand* is nonmarine.

In La. the Sparta sand was formerly treated as a memb. of St. Maurice fm. In Tex. it was for a time treated as basal memb. of Cook Mtn fm., but it is now treated as a distinct fm. by U. S. Geol. Survey, and St. Maurice fm. has been abandoned. A. Deussen, however (1934 and 1936), continues to include Sparta sand in Cook Mtn fm.

H. B. Stenzel, 1935 (Univ. Tex. Bull. 3501, pp. 267–279), restricted *Crockett* to upper part of Crockett as previously defined, and applied new name *Stone City beds* to lower part. He stated the latter interfinger with underlying Sparta sand.

Named for development near Sparta, Bienville Co., La.

Sparta sand.

A subsurface sand in Chester group (Miss.) of Randolph Co., Ill.

Spartanburg zone.

Pre-Cambrian: Northern South Carolina.

See *Anderson-Spartanburg zone.*

Named for exposures in Spartanburg Co.

Spavinaw granite.

Pre-Cambrian (?): Northeastern Oklahoma (Mayes County).

N. F. Drake, 1897 (Am. Phil. Soc. Proc., vol. 36, pp. 338–341). [Describes a dike, 1,200± ft. long by 50± ft. wide, on N. side of Spavinaw Creek, 6± mi. from its mouth and ¾ mi. W. of Spavinaw post office, and in one place (on p. 341) he casually refers to it as *Spavinaw granite.*]

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 54). *Spavinaw granite.*—Dark-red, mottled fine-grained granite, of unknown thickness and unknown age, but presumably pre-Camb. Outcrops where it crosses Spavinaw Creek below Tulsa waterworks dam, NE. part of Mayes Co. The exposure is about ¼ mi. long and in places 200 ft. wide. Has been regarded by Drake, Snider (Okla. Geol. Surv. Bull. 24, pp. 50–53, 1915), Hutchison (Okla. Geol. Surv. Bull. 2, p. 152, 1911), and others as a granite dike. Aurin, Clark, and Trager, however (A. A. P. G. Bull., vol. 5, 1921), consider it the top of a buried granite mtn now being uncovered by erosion.

Spearfish formation.

Triassic (?): Western South Dakota, Wyoming, and northwestern Nebraska.

N. H. Darton, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 387). *Spearfish fm.* (Red beds), of Triassic age, uncon. underlie Sundance fm. in Black Hills, S. Dak.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 516). *Spearfish fm.*—Red sandy clays or shales with gyp. beds, which sometimes are 30 ft. thick. Thickness of fm. in Black Hills 350 to 500 ft. Overlies Minnekahta ls. and uncon. underlies Sundance fm. Named for Spearfish, S. Dak.

Spearhead rhyolite.

Tertiary (Pliocene?): Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 71, etc.). *Spearhead rhyolite.*—Rhyolitic flows; the upper and thicker memb. is soft, porous pinkish-gray rhyolite containing so many fragments of pumice as to warrant name of "flow breccia;" the lower memb. is essentially same as upper memb. but of brown color. Thickness 20 to 80 ft. Conformably overlies Pozo fm. and underlies Rabbit Spring fm. [Mapped at and around Spearhead Point, Goldfield dist.]

Spechts Ferry member.

Middle Ordovician (late Black River): Northeastern Iowa, southwestern Wisconsin, southeastern Minnesota, and northwestern Illinois.

G. M. Kay, 1928 (Sci., n. s., vol. 67, p. 16). *Spechts Ferry memb.*—Basal memb. of Decorah fm. At type loc. (ravine SW. of C. M. & St. P. R. R. station of Spechts Ferry, Dubuque Co., Iowa, it consists of 8½ ft. of shales and interbedded lss. It includes the "glass rock" and overlying shales at top of typical Platteville. Fossils are of latest Black River (Watertown) age. Overlies Platteville ls. and underlies Guttenberg ls. memb. of Decorah fm. [See also Kay, Jour. Geol., vol. 37, No. 7, Oct.–Nov. 1929, pp. 639–671, where he stated this memb. corresponds to "*Rhinidictya* bed" and "*Stictoporella* bed" of Minn.]

G. M. Kay, 1931 (Jour. Geol., vol. 39, p. 370), redefined Spechts Ferry memb. by excluding the "glass rock," which he stated was found to be older than the 8½ ft. of shales with intercalated thin lss. in type section of the memb.

G. M. Kay and G. I. Atwater, 1935 (Am. Jour. Sci., 5th, vol. 29, Feb., p. 101), continued to include Spechts Ferry memb. in the Decorah and to classify it as of late Black River age and rest of Decorah as Trenton.

G. M. Kay, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, pp. 286–287), treated *Spechts Ferry memb.* as top memb. of Platteville; named the underlying (conformable) beds *McGregor memb.*; called the overlying beds *Guttenberg memb. of Decorah fm.*; included the "glass rock" in top of his McGregor memb.; and classified his Spechts Ferry memb. as of Black River age. He also further redefined the memb. by transferring to overlying Guttenberg memb. of Decorah "the 10-in. beds of ls. containing pyritic and phosphatic nodules originally considered as the top of the memb." On pp. 285, 288 he stated: Spechts Ferry memb. is stratigraphically and faunally more closely related to underlying members of Platteville fm. But northern extension of the memb., being succeeded by other more calc. shales with which it comprises a lithologic unit, it is *more convenient* to consider the Spechts Ferry as a lowest memb. of Decorah fm. in Minn. and northern Iowa. On p. 295 he showed an uncon. btw. his Guttenberg and Spechts Ferry members in Minn. and Ill.

C. A. Bays and G. O. Raasch, 1935 (pp. 297–299 of Conf. Rept cited above), removed from McGregor memb. of Kay its upper part and renamed these upper beds *Magnolia memb.* Their Magnolia memb. underlies Spechts Ferry memb. of Kay.

The Committee of 9th Ann. Conf. Rept. Kans. Geol. Soc., 1935, transferred these beds to Platteville ls., and restricted Decorah sh. to Ion and Guttenberg members of Kay. These changes have not yet been considered by U. S. Geol. Survey for its publications.

Speck Mountain limestone member (of Thrifty formation).

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 408). *Speck Mtn ls. bed.*—Massive dark rough-weathering ls., 3 to 5 ft. thick, well developed on top and to W. of Speck Mtn. Northeast of Rockwood consists of 5 ft. of hard massive white ls., and near Trickham of 2 to 4 ft. of white barren, rather friable ls. Memb. of Cisco div. Overlies Speck Mtn clay bed and underlies Lohn bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, p. 24; Univ. Tex. Bull. 2132, p. 158). *"Speck Mtn" ls.* of Drake, of Colorado River Valley, is same as Ivan ls. memb. of Thrifty fm. of Brazos River region. (Speck Mtn has long priority.)

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103). *Speck Mtn ls.* of Drake is in Thrifty fm. It underlies Lohn sh. and lies higher than Blach Ranch ls.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197, 198, 221), showed *Speck Mtn ls.* as top memb. of Graham fm. and as underlying Avis ss. and overlying Wayland sh. memb.

According to C. O. Nickell (rept in press), Speck Mtn ls. memb. of Brown and Coleman Counties underlies Lohn sh. memb. and lies above 32 to 51 ft. of sh. called "Speck Mtn clay" by Drake. All these members belong to Thrifty fm. The Speck Mtn ls. lies considerably higher than Avis ss., basal memb. of Thrifty fm. [This is definition adopted by U. S. Geol. Survey.]

Named for Speck Mtn, Coleman Co.

†Speck Mountain clay. (In Thrifty formation.)

Pennsylvanian: Central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 407). *Speck Mtn clay bed.*—Fossiliferous sandy clay, bluish, purplish, or slightly red, 25 ft. thick, with a little ss. and some carbonaceous shaly clay. Memb. of Cisco div. Overlies *Bellerophon* bed and underlies Speck Mtn ls. bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132). *Speck Mtn clay of Drake* is included in Thrifty fm. of Cisco group.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), included this bed in Thrifty fm.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+), included in Graham fm. of Colorado River region all beds up to top of Speck Mtn ls.

The present definition of U. S. Geol. Survey includes in Thrifty fm. of Colorado River region all beds from top of Chaffin ls. down to base of Bellerophon ls. of Drake.

Named for Speck Mtn, Coleman Co.

Speechley sand.

Drillers' term. Western Pa. and W. Va. Of Chemung age. Has been considered older than Warren Third sand and younger than Tiona sand. Named for Speechley farm, about 5 mi. NE. of Oil City, Venango Co., Pa. A sand btw. Speechley and Warren Third sand has been called *Speechley Stray sand.*

Speiser shale. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 232, 234). *Speiser sh.*, top div. of Garrison sh. memb., consists of (descending): (1) Greenish-blue sh. with small calc. bodies, 9± ft.; (2) argill. sh. in bluish and reddish bands, 10 ft.; (3) 2 beds of light-gray lss., separated by 4 to 5 ft. of sh., 7 to 8 ft.; (4) bluish or bluish-gray sh., with a thin band of maroon sh. near base, small calc. concretions in the grayish zones, 18 to 23 ft. Total thickness of Speiser sh. 47± ft. Overlies Sabetha ls. Named for Speiser Twp, Richardson Co., Nebr.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 23). Speiser sh. of Condra 1927 here divided into (descending) *Speiser sh. restricted*, Funston ls., and Blue Rapids sh. Thickness of Speiser sh. as now constituted increases southward from 18 or 19 ft. in Nebr. to 34 or 35 ft. in southern Kans. Type loc. is W½ sec. 35, T. 1 N., R. 13 E., Speiser Twp. Also well exposed 3½ mi. SE. of Randolph, Kans.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Spence shale member (of Ute limestone).

Middle Cambrian: Northeastern Utah and southeastern Idaho.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 5, 6, 8). *Spence sh.*—Argill. shales, 30 ft. thick W. of Liberty, Bear Lake Co., Idaho, and also in Blacksmith Fork, Cache Co., Utah. Basal memb. of Ute fm. Abundant Middle Camb. fauna. Type loc. Spence Gulch, a ravine running up into Danish Flat from Mill Canyon, about 5 mi. W.-SW. of Liberty, Bear Lake Co., Idaho.

The sh. memb. at base of Howell fm. of House Range, Utah, has been correlated by Walcott with Spence sh. memb. of Ute ls. of NE. Utah. (See pp. 183, 197 of vol. cited above.)

Spence Bridge volcanic group.

Jurassic or Cretaceous: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 119).

Spence Bridge series.

Tertiary: British Columbia.

D. D. Cairnes, 1923 (Canada Geol. Surv. Summ. Rept. 1922, pt. A, p. 93).

Spencer chert.

Upper Ordovician (Richmond): Central Missouri (Camden County).

G. H. Scherer, 1905 (Bradley Geol. Field Sta. Drury Coll. Bull., vol. 1, pt. 2, p. 59). Local outcrop, just N. of Decaturville Hotel, in road from Decaturville [Camden Co.] to Lebanon, of chert and ls. differing from any in dist. E. O. Ulrich, from certain fossils discovered, designates it as a cherty form of the Maquoketa, of Richmond fm., which Shepard has named *Spencer chert*.

E. M. Shepard (letter dated Jan. 29, 1916), stated that he never published this name but used it provisionally in carbon prints given to his students for field work.

Spergen limestone. (Of Meramec group.)

Mississippian: Southern Indiana, Illinois, western Kentucky, eastern Missouri, and Iowa.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines, 2d ser., vol. 2, p. 110) and 1905 (U. S. G. S. P. P. 36, pp. 28–30). *Spergen Hill ls.*—Generally massive layers of oolitic ls., of light- or dark-gray, buff, or drab color, with interbedded thinner layers of various kinds of ls. and occasionally thin seams of yellowish sh., occurring in Ind., Ill., western Ky., and eastern Mo. Thickness few ft. to 125 ft. Included in St. Louis ls. of previous repts. Overlain by St. Louis ls. [restricted] and underlain by Warsaw fm. Included in Meramec group.

Adopted instead of *Bedford ls.* (preoccupied) and *Salem ls.* (Cumings, 1901), because of long-established use of terms *Spergen Hill fauna* and *Spergen fauna*, to designate the fauna contained in this fm., and because the name had acquired a formational significance long before *Salem ls.* was introduced, e. g.: S. S. Lyon, 1860 (St. Louis Acad. Sci. Trans., vol. 1, p. 619), described strat. horizon in Ky. which he stated to be equiv. to "Spergen Hill" beds of Washington Co., Ind.; C. E. Siebenthal, 1897 (Ind. Dept. Geol. and Nat. Res. 21st Ann. Rept., p. 298), stated that the Bedford oolitic ls. had also been called *Spergen Hill ls.* by other writers; S. Weller, 1898 (Jour. Geol., vol. 6, p. 313), stated: "One of the best known of the St. Louis ls. faunas is that of the *Spergen Hill beds* in Indiana;" H. S. Williams, 1900 (Ark. Geol. Surv., vol. 5, p. 348), stated: "The age of the Spring Creek ls. is about equivalent to the Warsaw, St. Louis, or *Spergen Hill* formations." *Salem ls.*, however, is name used by Ind. and Ill. Geol. Surveys. The Spergen is middle fm. of Meramec group. It is overlain by Mitchell ls. in Ind. and by St. Louis ls. in Ill., eastern Mo., Iowa, and western Ky.; underlain by Warsaw sh. in Ill., Iowa, and eastern Mo., and by Warsaw (†Harrodsburg) ls. in Ind. and western Ky. It is opinion of C. Butts (Ky. Geol. Surv., ser. 6, vol. 7, pp. 119–120, 1922) that Spergen ls. of Ind. is only a local lithologic facies of Warsaw ls., but most geologists consider it a distinct geologic unit of equal rank with Warsaw, St. Louis, and other fms. W. H. Twenhofel, however (Ky. Geol. Surv., ser. 6, vol. 37, 1931), inclined to Butts' view.

Named for Spergen Hill, near railroad station of Harristown, a few mi. SE. of Salem, Washington Co., Ind.

†Spergen Hill limestone.

Same as *Spergen ls.*, which see.

Sphinx conglomerate.

Eocene: Central southern Montana (Three Forks quadrangle).

A. C. Peale, 1896 (U. S. G. S. Three Forks folio, No. 24). *Sphinx cgl.*—In Sphinx Mtn is a group of beds which once may have spread over an extensive area, although now occupying only about 2 sq. mi. This remnant consists of btw. 2,000 and 3,000 ft. of reddish sss. and coarse cgls. of ls. pebbles and boulders cemented with reddish sand; compose entire mass of the peak. Beds are horizontal and distinctly stratified. No fossils. Arbitrarily referred to Eocene, but are certainly younger [older] than Bozeman lake beds (Neocene) and older [younger] than Livingston fm. (Cret. ?).

Spickert Knob facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 77, 127, 1931) to a lithologic development of his Locust Point fm. in a part of southern Ind. "This Spickert Knob facies is that of the type loc. of the [Locust Point] fm. at Locust Point."

Spieden formation.

Lower Cretaceous: Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2, pp. 93, 113–118). *Spieden fm.*—Cgl., breccia, ss., sh., and argill. ls.; 85 percent cgls. Isolated outcrops, which apparently are confined to Spieden Island, Sentinel Island, and Sentinel Rock. Thickness 2,000+ ft. The cgls. differ from those of upper Cret. Nanaimo series in scarcity of boulders of granodiorite and other batholithic rocks. Fossils [described] identified by T. W. Stanton as lower Cret. and = upper part of Knoxville of Calif.

Spiral Creek formation.

Age (?): Greenland.

C. Teichert, 1933 (Meddelelser om Grönland, Bd. 95, No. 1, pp. 49, 74).

Spiro sandstone member (of Savanna sandstone).

Pennsylvanian: Eastern Oklahoma (Muskogee, LeFlore, and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Spiro ss. memb. of Savanna ss.*—Dark-brown ss., regularly bedded, blocky, fine to medium texture. Plant fossils. Thickness in Muskogee-Porum area 12 ft. Lies 50± ft. above Keota ss. memb. of Savanna ss. and 60± ft. below Cavanal coal in Muskogee-Porum area. Caps ridge in secs. 13 and 14, T. 9 N., R. 25 E., just N. and NE. of Spiro, LeFlore Co.

Spitzenberg conglomerate.

Triassic (?): Southeastern Pennsylvania (Berks County).

L. Whitcomb and J. A. Engel, 1934 (Pa. Acad. Sci. Proc., vol. 8, pp. 37–43). *Spitzenberg cgl.*—A peculiar cgl. that caps the conical hill in Berks Co. which, because of its shape, has been named the Spitzenberg. The cgl. is in form of a gently dipping spoon-shaped syncline, resting upon Martinsburg sh. Is different from all other rocks of region. Best exposure is at NE. end of ridge, where its cross-bedded character can be seen. Matrix is fairly coarse sand that weathers gray or red.

Split Creek shale and sandstone member.

Oligocene: Southeastern Alaska (Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 771–775). *Split Creek sh. and ss. memb.*—Basal memb. of Katalla fm. Consists of 800 ft. of ss. grading down into hard dark-colored, rather platy shales, 700 ft. of which are exposed. Exposed only in N. part of area, in drainage to Bering Lake, in very narrow belt along Bering River, and in N. part of ridge btw. Redwood Creek and Katalla River. [Origin of name not stated.] Assigned to upper Olig., on basis of correlation with similar fossiliferous rocks in Yakataga dist., which are assigned to upper Olig. by B. L. Clark. Conformably overlain by Burls Creek sh. memb. of Katalla fm.

The U. S. Geol. Survey classifies typical Katalla fm. as Mio. (?).

Split-Rock slate.

Pre-Cambrian: Northwestern Iowa.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 187; Sci., n. s., vol. 40, p. 144). Slates, 75 ft. thick, younger than Sioux qtzite and comprising top fm. of Animikean series.

Derivation of name not stated.

Split Rock.

See under *Adirondack anorthosyte.*

Spokane shale (also **formation**).

Pre-Cambrian (Belt series): Western central and central southern Montana (Helena to Little Belt Mountains).

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 199–215). *Spokane shales.*—Massive beds of deep-red siliceous shales, 1,500 ft. thick. Underlie Empire shales and overlie Greyson shales. Type loc. in Spokane Hills, 15 mi. E. of Helena, although base is not there exposed.

Spokane glaciation.

Pleistocene: Washington.

J. H. Bretz, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 580). *Spokane glaciation* introduced for ice sheet older than Wisconsin drift of Wash. Named for development of the till, striated erratic boulders, outwash material, and drainage channels in vicinity of Spokane, Wash.

Spokane clays.

A term loosely applied commercially in eastern Wash. to the kaolins and buff-burning clays in general vicinity of Spokane, some of which belong to Latah fm. (Mio.).

Spoon Butte beds.

Miocene (upper) and Pliocene (lower): Western Nebraska and eastern Wyoming.

O. A. Peterson, 1909 (Carnegie Mus. Mem., vol. 4, No. 3, pp. 74–77). *Spoon Butte beds.*—Hard stratum of pinkish-gray ss., 25 to 50 ft. thick. No fossils. Assigned to Plio (?) or Mio. May represent Ogallala fm. Named for Spoon Butte, Laramie Co., Wyo. Overlies upper Harrison beds (middle Mio.).

H. J. Cook, 1915 (Nebr. Geol. Surv. vol. 7, pt. 11, pp. 74–75). *Snake Creek beds* cap Spoon Butte, Wyo., where they overlie Sheep Creek beds. They were called "Harrison beds" by Peterson in 1906, and regarded by him as "upper Harrison beds." In 1909 he named them "Spoon Butte beds," and considered them younger than upper Harrison beds. These cemented beds are a phase of Snake Creek beds of Matthew and Cook.

Spoon River sandstone and shale. (In Pottsville formation.)

Pennsylvanian: Central western Illinois (Fulton County).

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 307–316), applied *Spoon River ss. and sh.* to basal part of Pottsville fm. in Fulton Co., or to beds underlying clay beneath Seville (No. 1) coal and uncon. overlying St. Louis ls. Derivation of name not stated.

H. R. Wanless, 1929 (Ill. Geol. Surv. Bull. 57). Basal 50 to 80 ft. of Pottsville fm. in Alexis quad., NW. Ill., is=Spoon River of Savage (1927), so named because well exposed along Spoon River [which is chiefly in Fulton Co.].

†Spot Pond granite.

A name that has been applied locally to a stock of Dedham granite in Boston region, Mass.

Spotted Bear limestone member.

Middle Devonian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 44 and passim). *Spotted Bear ls. memb.*—Top memb. of Jefferson ls. in Spotted Bear, Pentagon, and Monitor Mtns. Thickest (426 ft.) on Monitor Mtn; thinnest (282 ft.) on Pentagon Mtn; not known to be present in intervening area. Most striking feature is variety of lss. and shales that compose the memb. Consists of (descending): (1) 4 ft. of platy cream-white argill. ls. that weathers light buff; (2) 22 ft. of massive platy brown-gray crystalline ls. that weathers gray; (3) gray medium bedded ls. in upper and lower parts and massive argill. tan-gray finely crystalline ls., 61 ft.; (4) gray to tan-gray argill. crystalline ls. that weathers irregular gray in lower part and sugary gray in upper part, 114 ft.; (5) massive thin-bedded gray crystalline ls., 86 ft., thicker-bedded upward; weathers dull gray. Discon. underlies Silvertip cgl. memb. of Madison ls. and overlies Lone Butte ls. memb. of Jefferson ls. Well exposed btw. elevations of 6,880 and 7,005 ft. on NW. slope of Spotted Bear Mtn, in NE¼ sec. 26, T. 25 N., R. 15 W.

Sprakers.

Middle Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, No. 2104, p. 400). *Sprakers* introduced for lower middle Canajoharie or zone of *Diplograptus amplexicaulis* in Mohawk Valley.

Sprayan series.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). *Sprayan series.*—Shales, 1,400 ft. thick, composing all of Late Triassic of Alberta. The Triassic Spray fm. may be a compact provincial series; it may be composed of two or more distinct provincial series; or it may prove to be a composite fm. comprising two or more interlocking provincial series. If the Triassic section prove to be but a single provincial series, then the name Spray River may be shortened and given serial ending and be known as Sprayan series; otherwise, if there be really two or more series they should be so denominated, the title Sprayan then being properly restricted to one of the subdivisions of serial rank.

Named for exposure in Spray River gorge, 7 mi. above Banff, Alberta.

Spray River formation.

Triassic: British Columbia and Alberta.

E. M. Kindle, 1924 (Pan-Am. Geol., vol. 42, pp. 113–124).

Spring Branch limestone. (In Lecompton limestone.)

Pennsylvanian: Southeastern Nebraska (?), northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 44, 47). *Spring Branch ls.*, basal unit of Lecompton ls., is exposed in Mo. and Kans.; probably not exposed in Nebr. Massive above and chalky and friable below. Weathers yellowish or brownish. Thickness in Mo. and Kans. 4 to 8 ft. Underlies Doniphan sh. and overlies Kanwaka sh. memb. Named for exposures on Spring Branch N. of Big Springs, Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 163, footnote). The absence of Spring Branch and "Curzen" lss. in Nebr. has been recognized by Condra. Conclusion that Spring Branch ls. is absent in Nebr. may require modification when restudy of correlation of "Plattsmouth ls." section of Snyderville quarries and other places in Nebr. has been completed, for it is possible topmost part of "Plattsmouth" as previously identified may prove to be Spring Branch ls.

Spring Canyon tongue (of Star Point sandstone).

Upper Cretaceous: Central eastern Utah (Book Cliffs).

F. R. Clark, 1928 (U. S. G. S. Bull. 793). *Spring Canyon tongue.*—Massive ss., 150 to 200 ft. thick, forming top part of Star Point ss. (basal fm. of Mesaverde group in Wasatch Plateau and Book Cliffs). Interfingers with tongues of marine Mancos sh. Forms conspicuous white cliffs in Spring Canyon, N. part of Castlegate quad., Carbon Co.

Spring Canyon coal group. (In Blackhawk formation.)

Upper Cretaceous: Central eastern Utah (Book Cliffs).

F. R. Clark, 1928 (U. S. G. S. Bull. 793). *Spring Canyon coal group.*—A group of 2 to 5 coal beds, with accompanying beds of sh., etc., in part underlying and in part grading laterally into Aberdeen ss. memb. of Blackhawk fm. In places a thin tongue of Mancos sh. separates the coal group from underlying Star Point ss.

Spring Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 381). *Spring Creek bed.*—Bluish sandy clay, 300 ft. thick, with 50 ft. of ss. near middle. Memb. of Strawn div. Underlies Cottonwood Creek bed and overlies Brown Creek bed.

Named for Spring Creek, San Saba Co.

Spring Creek granite.

Pre-Cambrian: Eastern Colorado (Cripple Creek district).

W. Cross, 1895 (U. S. G. S. 16th Ann. Rept., pt. 2, p. 23). *Spring Creek variety.*—A peculiar variety of granite which occurs opposite Red Mtn. on Spring Creek, in Cripple Creek dist. The rock is of medium grain, has a more or less distinct porphyritic structure, and is marked by brilliant-red color, due to very heavy impregnation of all the feldspar by iron oxide. Quartz appears in small irregular grains abundantly disseminated through the mass. No other constituents are visible to naked eye. Biotite was probably an original constituent of this granite, but it has been decomposed and mainly replaced by muscovite. Fluorite occurs sparingly all through the granite.

W. Lindgren and F. L. Ransome, 1906 (U. S. G. S. P. P. 54). Age of *Spring Creek granite* with reference to other granites of Cripple Creek dist. is unknown [p. 20]. Pikes Peak granite is probably intrusive into Spring Creek granite [p. 23].

L. C. Graton, 1906 (U. S. G. S. P. P. 54). *Spring Creek granite.*—Bright red, even-grained. No evidence as to relative age. Occurs only on SW. half of Red Mtn and on hill to S. on opposite side of Spring Creek, Cripple Creek dist.

†Spring Creek limestone. (In Moorefield shale.)

Mississippian: Northern Arkansas.

H. S. Williams, 1895 (Am. Jour. Sci., 3d, vol. 49, pp. 94–101). *Spring Creek ls.*—Dark-colored ls. and associated calc. shales at Spring Creek, a few mi. W. of Batesville. Overlies Boone chert and underlies Batesville ss. Contains Warsaw, St. Louis, and Spergen Hill fossils. According to Ark. geologists, this interval is to W. occupied by Fayetteville sh. [miscorrelation].

S. Weller, 1898 (N. Y. Acad. Sci. Trans., vol. 16, pp. 279, 281). *Spring Creek ls. and sh.*—This fm. has heretofore been referred to Fayetteville [Moorefield] sh. by Ark. geologists. Since correlation of black shales and lss. of Batesville region with Fayetteville sh. is based wholly on stratigraphy, and as strat. column is somewhat dissimilar in the two regions, it is thought best to assign a distinctive name to the fm. in Batesville region, until investigation of faunas of two areas proves it to be wholly or in part = the more western fm. The Spring Creek ls. is typically developed on Spring Creek, 2 mi. W. of Batesville, and is a black fetid ls. abounding in fossils. East of Batesville, in vicinity of Moorefield, it is more shaly and attains thickness of 300 ft. Fauna is unique. Overlies Boone chert and underlies Batesville ss.

E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 102–104). A few mi. NW. of Batesville there is a local deposit of highly fossiliferous ls. and limy sh. which

H. S. Williams has called *Spring Creek ls.* Apparently this calc. fm. rests on Boone fm. and underlies Moorefield sh. (=Fayetteville sh. in part of Branner), while increase in argill. matter toward top of exposure probably indicates the calc. beds grade up into the sh. Though of small consequence areally, this calc. fm. is too important geologically to be entirely neglected in classification of Miss. rocks of Ark. Perhaps it is sufficiently accounted for by ranking it as a memb. of Moorefield fm.

The †Spring Creek ls. is 0 to 15 ft. thick and is now treated by U. S. Geol. Survey as basal part of Moorefield sh.

Named for Spring Creek, 2 mi. W. of Batesville, Independence Co.

†Spring Creek clays.

Lower Cretaceous (Comanche series): Central southern Kansas.

C. N. Gould, 1898 (Am. Jour. Sci., 4th; vol. 5, pp. 170–174). *Spring Creek clays.*—Bluish-white clay, with clay-ironstone concretions; 20 to 80 ft. thick. Underlies Greenleaf ss. and overlies Kiowa shales. Basal div. of Medicine beds.

Named for Spring Creek, 12 mi. W. of Belvidere, Kiowa Co.

This name was discarded by U. S. Geol. Survey in 1921, the bed (in Kiowa sh.) being regarded as so local as to have no strat. value.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9), revived the name (in the form *Spring Creek sh. memb. of Belvidere fm.*), as explained in 1924 entry under *Belvidere sh.*

Spring Creek erosion cycle.

Recent: Southeastern Idaho.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713, pp. 17, 71). *Spring Creek cycle*, a postglacial (Recent) erosion cycle in SE. Idaho. Named for Spring Creek, which rises and has its entire course in the Fort Hall bottoms.

Springer formation.

Pennsylvanian (Pottsville): Central southern Oklahoma.

W. L. Goldston, Jr., 1922 (A. A. P. G. Bull., vol. 6, No. 1). *Springer memb.*—Basal memb. of Glenn fm. Largely black and blue shales separated by thin beds of ss. and ls. The shales at base are black and soft. Near top blue predominates, but there are zones of black sh. several ft. thick. To N. of Ardmore it contains no calc. members, but there are 12 brownish or drab sss. ranging in thickness from a few ft. to 100+ ft., some of which grade into shales to S. and E. Around Criner Hills sss. are less important and numerous beds of thin brownish lss. occur. Thickness 4,000 to 6,000 ft. Town of Springer [Carter Co.] is in midst of this memb. Fossils listed. Rests conformably on Caney sh. and underlies Otterville ls. memb.

G. H. Girty and P. V. Roundy, 1923 (A. A. P. G. Bull., vol. 7, No. 3, pp. 331–347). Goldston's Springer memb. seems to us to include both pre-Glenn and post-Glenn beds. We are satisfied Springer beds were excluded from Glenn fm. as originally defined, and that they are part of Caney sh.; in places they probably included the Hoxbar.

H. D. Miser, 1925 (Okla. Geol. Surv. Bull. 35, p. 26, footnote). [See this entry under *Hoxbar fm.*]

S. Powers, 1927 (A. A. P. G. Bull., vol. 11, No. 10, pp. 1067–1085), mapped *Springer fm.* as underlying Glenn fm.

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, pp. 7–21). *Springer fm.*, 3,000 or more ft. thick, includes all beds below Jolliff ls. memb. of Dornick Hills fm. and above Caney sh. Its basal memb. is here named *Rod Club ss. memb.* On Miser's map of Okla. these rocks were included in Caney sh.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46). *Springer fm.*, 3,000 to 3,500 ft. thick, as here defined corresponds closely with Goldston's Springer memb. of Glenn fm. in its type area and elsewhere. It was included in Glenn fm. by Taff in Tishomingo folio, but was excluded by Girty, Roundy, and Miser. It underlies Jolliff memb. of Dornick Hills fm. and overlies Caney sh.

The present approved definition of Springer fm. is that it underlies Wapanucka ls. in the Ti Valley-Choctaw belt of Ouachita Mtns, Okla., and elsewhere it underlies Dornick Hills fm. It overlies Caney sh. (now restricted to beds of Miss. age). (See H. D. Miser, A. A. P. G. Bull., vol. 18, No. 8, 1934, pp. 971–1009.)

Springfield limestone.

Silurian (Niagaran): Southwestern Ohio.

E. Orton, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 271, 274–277, 301). *Springfield stone or Blue Cliff.*—Massive blue crinoidal lss., with some buff and drab beds and interstratified sh. or blue clay, and with 5 to 15 ft. of blue sh. at base. Thickness 20 to 45 ft. Overlain by Cedarville or Guelph ls. and underlain by West Union or Lower Cliff ls. (the yellow cliff). All included in Niagara group. Occurs in Highland Co. and northward. [In index this fm. is called *Springfield ls.*]

The foregoing definition of *Springfield ls.* was used in Ohio Geol. Surv. repts 1873, 1874, 1884, 1888, 1893, 1905, 1915, and 1916, and, so far as known, is still followed by that Survey. In 1917 A. F. Foerste introduced *Euphemia dol.* for the beds underlying *Springfield dol.*, as he called the fm., and included (ascending) Euphemia dol., Springfield dol., and Cedarville dol. in his Durbin fm. It appears that Foerste's *Springfield dol.* is only a part of Orton's *Springfield ls.*

A. F. Foerste, 1935 (Denison Univ. Bull., Jour. Sci. Lab., vol. 30, p. 155). *Springfield* was introduced by Orton in 1871. Type loc. was Springfield, Ohio, where this fm. has long been quarried W. of city, where the typical well-bedded fine-grained Springfield dol. is 10 ft. thick, the underlying dense but somewhat mottled rock being 4 ft. thick, giving 14 ft. for entire Springfield dol. section, which rests directly on Euphemia dol. It is overlain by Cedarville dol.

Springfield clay.

Pleistocene: Southwestern Ohio.

E. Orton, 1873 (Ohio Geol. Surv. vol. 1, pp. 431, 443). *Springfield clay.*—Fine-grained yellow glacial clay, in Hamilton, Montgomery, Clark, and probably Clermont Counties; 15 to 30 ft. thick. Overlies sand, gravel, and streaks of loam and underlies soil. Included in [Pleistocene] drift.

Named for Springfield, Clark Co.

Springfield conglomerate.

Cambrian (probably): Southeastern Vermont (Windsor County).

C. H. Richardson, 1931 (17th Rept. Vt. State Geol., pp. 200–201). *Springfield cgl.*—Introduction of this term is demanded by discovery, on W. side of Skitchewaug Mtn, of a new cgl. It lies on E. side of Spencer Hollow road, the nearest approach to which is a few rods E. of Spencer School House [1½ mi. E. of Springfield, Claremont quad.], where the cgl. outcrops. Pebbles range from fraction of in. to 6 in. diam. Most of them are quartz; a few of mica schist were seen. The matrix is mica schist, the mica mostly muscovite. The cgl. carries much secondary quartz in veinlets and stringers. In some outcrops the rock appears as quartz schist; in others as coarse-textured qtzite. Some pebbles are well rounded; others are stretched or elongated. Metamorphism intense. Highly folded and crumpled and dips in all directions. More field work needed to determine exact age and true strat. position. There is no evidence of anything Ord. in either pebbles or matrix, both of which appear to be Camb.

Spring Grove member (of Wapsipinicon limestone).

Middle Devonian: Eastern Iowa (Linn County).

A. C. Trowbridge, M. L. Thompson, and E. H. Scobey, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., figs. 1, 2, and pp. 36, 424). *Spring Grove memb. of Wapsipinicon ls.*—At Linwood quarry, Scott Co., consists of (descending): Stylolitic ls., 13 ft.; ss., 6 in.; ls., 3 ft.; covered, 10 ft.; mag. ls. 5 ft. Underlies Davenport memb. of Wapsipinicon ls. [In fig. 1 is shown as overlying Kenwood memb. of Wapsipinicon.]

M. A. Stainbrook, 1935 (pp. 251–252 of rept. cited above). *Spring Grove ls.*—Name here proposed for a terrane distinct from the Kenwood, with which it hitherto has been included. Type loc. is natural exposure in right bank of Wapsipinicon River in center of sec. 24, Spring Grove Twp, Linn Co. Entire thickness of 18 ft. is exposed, with 12 ft. of Kenwood below and 8 ft. of Davenport above. The ls. is subdolomitic, fine-grained, more or less massively bedded, but finely laminated. Has greater northward extent than any Dev. beds below. Outcrops in southern Winnishiek Co. (valley of Crane Creek), along E. Dev. border of Fayette Co., and in Linn and Cedar Counties. No fossils. Lies uncon. on Kenwood in Linn Co. and on Sil. in Fayette Co., and is uncon. below Davenport memb.

Spring Hill limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 97). [See under *Merriam ls.* On p. 46 *Spring Hill ls.* is described as consisting of 15 to 21½ ft. of gray even-bedded ls.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 71–73). *Spring Hill ls. memb.*—Upper memb. of Plattsburg ls. Lower half or less is even gray ls. containing brachiopods and bryozoans. Remainder is oolitic or granular and contains large molluscan element. Overlies Hickory Creek sh. memb. and underlies Vilas sh. Named for exposures at town of Spring Hill, in S. part of Johnson Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Springler Knob facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol. Pub. 98, pp. 76, 222, etc., 1931) to a lithologic development ("that of type loc. of the fm.") of his Edwardsville fm., in a part of southern Ind.

Spring Point greenstone. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). [*Spring Point greenstone* mentioned as a fm. in Casco Bay group. Not defined.]

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 170). *Spring Point greenstone.*—Gray to dark-green actinolite schist, in part thoroughly schistose and in part massive; chloritic schists; and some schistose rocks that still show their original coarsely and irregularly fragmental texture and contain secondary felts of small actinolite needles and small blebs of blue quartz. Is very probably volcanic material locally but conformably intercalated btw. Cape Elizabeth fm. below and Diamond Island sl. above. Included in Casco Bay group. Assigned to Penn. (?). Named for exposures at Spring Point, South Portland, Cumberland Co.

Spring River sandstone.

Pennsylvanian: Southwestern Missouri.

D. White, 1897 (Geol. Soc. Am. Bull., vol. 8, p. 288). *Spring River ss.* proposed by W. P. Jenney [unpublished ms.] for thin, very irregular ferruginous ss., which intervenes btw. the coal-bearing shales and the Eocarboniferous bottom. Regarded as equiv. to "Millstone grit."

Named for Spring River, Jasper Co.

†Spring Rock limestone.

Pennsylvanian: Eastern Kansas.

G. C. Swallow and F. Hawn, 1865 (Kans. Geol. Surv. Rept. on Miami Co., p. 9). *Spring Rock.*—Hard bluish-gray fine-grained ls., 2 to 4 ft. thick, containing many fossils and crystalline particles of calc spar. Forms bed 16 of geol. section of Miami Co.

In a later rept Swallow applied this term to his bed No. 162, and identified it at Beaver Creek, Marais des Cygnes, W. of Topeka, and at Lecompton, confusing it with several lss.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 204). Howard ls. is part of †Spring Rock ls. of Swallow, which is abandoned.

Named for fine springs which come to surface from crevices in the rock.

†Spring Rock series.

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., p. 21). *Spring Rock series.*—Series of lss., sss., and shales, 88 ft. 2 in. thick, including beds Nos. 158 to 166, inclusive, of geol. section of eastern Kans. Underlies Einstein ss. and overlies Well Rock series.

Not a definite unit, but confused with several divisions, being in places the same as his Well Rock series and in other places the same as his Cave Rock series.

Appears to be named for the Spring Rock (bed No. 162), the source of many fine springs.

†Springvale beds.

Mississippian: Southeastern Iowa.

H. F. Bain, 1895 (Am. Geol., vol. 15, p. 320). *Springvale beds.*—Blue, somewhat calc. sh., in places aren. and locally called ss.; 20 to 25 ft. thick; basal memb. of St. Louis fm. Underlie Verdi beds (middle [upper now] memb. of St. Louis) and overlie Augusta [Spergen] fm.

F. M. Van Tuyl (Iowa Geol. Surv. vol. 30, pp. 181, 231, 1925) stated that the beds at old Springvale mill belong in upper part of Keokuk ls., and he introduced *Croton ls.* for the beds which Bain defined as "Springvale beds."

Named for old Springvale mill, 5 mi. S. of Delta, Keokuk Co.

Springvale sandstone.

Middle Devonian: Ontario (Hagersville region).

C. R. Stauffer, 1913 (12th Int. Geol. Cong. Guidebook 4, pp. 83–85, 89). Lower portion of Onondaga ls. in region around Hagersville, Ont., is usually aren. and very cherty—in some places an aren. chert and in others a true ss., as at Springvale, where lower part of Onondaga assumes such marked resemblance to true Oriskany that it has often been confused with it. But fauna is in every case Onondaga. Because of decided lithologic difference from ordinary appearance of fm. to which they belong, the beds are here referred to as *Springvale ss.* Consists of 5½ to 8 ft. of coarse white to yellowish ss., lower part rather massive, upper layers somewhat irregular and seem to contain more fossils. Material doubtless reworked Oriskany ss. Rests uncon. on Oriskany ss. or on eroded Sil. surface.

Spring Valley limestone. (In McLeansboro formation.)

Pennsylvanian: Central western Illinois.

G. H. Cady, 1921 (Ill. Geol. Surv. Cooperative Min. Ser. Bull. 26, pp. 36, 38), stated on p. 38 that in N. part of 4th dist. of Ill. the *Spring Valley ls.* lies 150± ft. above No. 7 coal. His section on p. 36 shows it 10 to 15 ft. above coal No. 8, 100± ft. above Lonsdale ls., and 25± ft. below LaSalle ls. The section shows *Spring Valley ls.* to be about 5 ft. thick. [Derivation of name not stated. There is a town called Spring Valley in Bureau Co., but that Co. is N. of the counties he lists as comprising 4th dist.]

Springville shale.

Mississippian: Southwestern Illinois (Union County).

T. E. Savage, 1920 (Am. Jour. Sci., 4th, vol. 49, pp. 169–178). *Springville sh.*—Greenish sh. that weathers variegated and mottled in shades of brown and red. From mottled color Worthen called it "Calico sh." He considered it youngest Dev. fm. in southern Ill. Lower part of fm. contains fossils [listed] that ally it with early Miss. Rockford ls. of SW. Ind. Well exposed in bed and banks of a creek a short distance NW. of Springville, SE¼ sec. 13, T. 13 S., R. 1 W., hence name. Lies uncon. on Mountain Glen sh. [He described this fm. under Upper Dev. heading, but did not list it in his table of Dev. rocks.]

Sprout Brook limestone.

Pre-Cambrian: Southeastern New York (Westchester and Putnam Counties).

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378). Coarsely crystalline ls. or dol., equiv. to Inwood ls. of Manhattan Island, lies next above Lowerre qtzite. It is 200 to 800 ft. thick. [Throughout paper he calls the ls. *Inwood ls.*, but on p. 370, under description of Sprout Brook Valley (which lies in Westchester and Putnam Counties), he in several places calls it *Sprout Brook ls.*] "My interpretation is that the ls. of Sprout Brook is the Inwood ls." [On his cross section he calls the ls. at Sprout Brook the Inwood ls.]

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68). Inwood ls. correlates with Cockeysville marble, of Glenarm series (Algonkian).

"Algonkian" has recently (1934) been discarded as a time term, and Inwood ls. is now classified by U. S. Geol. Survey simply as pre-Camb.

Spurwink limestone. (In Casco Bay group.)

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 198). [*Spurwink ls.* mentioned as a fm. of Casco Bay group. Not defined.]

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 171). *Spurwink ls.*—Thin interlaminated lenses of fine-grained white and light-bluish crystalline ls., fine-grained dark-gray calc. mica schist, and fine gray siliceous mica phyllite. Is pyritiferous, in places richly so. Thickness about 200 ft. Belongs to Casco Bay group. Conformably overlies Scarboro phyllite, and conformably underlies Jewell phyllite. Assigned to Penn. (?). Named for exposures on Spurwink River, in Scarboro and Cape Elizabeth, Cumberland Co.

Squam granite.

Early Carboniferous: Northeastern Massachusetts.

C. H. Clapp, 1910 (Igneous rocks of Essex Co., Mass., pp. 9, 10, 12).

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 195 and map). Small masses of granite intrusive into Quincy granite along Squam River and in Danvers have been called *Squam granite* by Clapp. The rock is apparently related to main granite mass, but is finer-grained and richer in mafic minerals. Its feldspar is mainly orthoclase or microcline.

C. H. Clapp, 1921 (U. S. G. S. Bull. 704, pp. 26, 91), described mineral constitution of *Squam granite*.

Squanjum marl.

Misprint (on p. 378 of U. S. G. S. Bull. 191) for *Squankum marl*.

†Squankum marl.

Eocene: Eastern New Jersey.

T. A. Conrad, 1869 (Am. Jour. Sci. 2d, vol. 47, pp. 363–364), in a description of Shark River, N. J., stated that the "Eocene greensand known by the name of Squankum marl" consists of 4 ft. of hard gray rock underlain by an unknown thickness of loose greensand; that it contains few organic remains; and that it is overlain by Mio. marl.

The 1912 geol. map of N. J., issued by N. J. Geol. Surv., maps the beds around Squankum, Monmouth Co., as Kirkwood fm. (Mio.), with Cohansey sand (Mio.?) 2 or 3 mi. away. These fms. are of Mio. age, but Shark River marl, which consists of greensand with slight admixture of argill. materials, is of Eo. age.

Squantum tillite member (of Roxbury conglomerate).

Devonian or Carboniferous: Eastern Massachusetts (Boston Basin).

R. W. Sayles, 1914 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 56, pp. 141–170). *Squantum tillite.*—Tillite; contains a gravel bed in places 15 to 30 ft. thick. Underlies Cambridge sl. and overlies a lower sl. which rests on Roxbury cgl. proper at Squantum Head.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 57). *Squantum tillite memb. of Roxbury cgl.*—Cgl. and tillite, with some interbedded ss. and sl. Thickness appears to range from 50 to 600 ft. or more. Grades into overlying Cambridge sl. and overlies Dorchester sh. memb. of Roxbury cgl., possibly uncon. Named for peninsula of Squantum, in Quincy.

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 102, 106), excluded *Squantum tillite* from Roxbury cgl. and assigned both to Permian.

L. La Forge, 1932 (U. S. G. S. Bull. 839), treated *Squantum tillite* as top memb. of Roxbury cgl., which he assigned to Dev. or Carbf.

†Squantum slates.

A name applied by F. H. Lahee (Am. Jour. Sci., 4th, vol. 37, p. 316, 1914) to the slates overlying Squantum tillite in Boston Basin, Mass., which are the Cambridge sl.

Square Lake limestone.

Lower Devonian (Helderbergian): Northeastern Maine (Aroostook County).

H. S. Williams, 1900 (U. S. G. S. Bull. 165, pp. 21, 22, 26, 30–33, 51, 54–78). *Square Lake ls.*—Gray fragmental ls., chiefly fragments of corals, crinoids, and more or less perfect fossil shells. Contains Lower Helderberg fauna and is older than Chapman ss. Named for exposures on W. shore of Square Lake (or Sedgwick Lake), Aroostook Co.

Squaw sand.

Drillers' name for two sands in upper part of Pocono fm. (Miss.) of SW. Pa. and W. Va. The higher one (*Squaw No. 1 sand*) is in W. Va. said to lie higher than Big Injun sand, but in SW. Pa. the name *Squaw No. 1 sand* has been applied to a sand in the Big Injun (Burgoon ss. memb.). The lower sand (*Squaw No. 2 sand*) lies lower than Big Injun and higher than Papoose sand, and is correlated by Pa. Geol. Surv. with Sharpsville ss. memb. of Cuyahoga fm. (See G. H. Ashley and J. D. Sisler, Pa. Geol. Surv., 4th ser., Bull. M_{10}, p. 6.)

Squaw sand.

A subsurface sand of early Penn. (Cherokee) age in central northern Okla., lying lower than Bartlesville sand and correlated with Taneha and Tucker sands.

Squaw Bay limestone.

Middle Devonian: Northeastern Michigan (Thunder Bay region).

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526). *Traverse group* subdivided [as shown in 1935 entry under *Traverse fm.*]. *Squaw Bay ls.*—Brown ls., some beds dolomitic; contains *Styliolina* and upper Dev. goniatites. Thickness exposed 3 ft.; nearby wells indicate probable total of 12 ft. Underlies Antrim black sh.; separated from underlying Partridge Point fm. by 3-foot covered interval. Type loc., Squaw Bay shore line of Partridge Point, center S. line of sec. 11, T. 30 N., R. 8 E., Alpena Co. "This fm. probably should be excluded from Traverse group."

Squirrel sand.

A subsurface sand, of Penn. age and 0 to 138± ft. thick, in NE. Okla. that lies in upper part of Cherokee sh. and is correlated with Prue and Perryman sands. In western Mo. the term has been used by drillers (see F. C. Greene, Mo. Bur. Geol. Mines, 57th Bien. Rept., App. 2, 1933, pp. 14, 16) for upper 100 ft. of Cherokee sh., being thus called because of manner in which the sand "jumps around" in well logs. The Squirrel sand of drillers in SE. Kans. occurs in upper part of Cherokee sh. and is regarded as probably approx.=the Squirrel sand of drillers of Okla. It outcrops in SE. Kans.

†Squirrel Creek formation.

Eocene: Southern Texas (Medina County).

R. A. Liddle, 1921 (Univ. Tex. Bull. 1860, p. 77, map, and columnar section). *Squirrel Creek fm.*—Impure gray and yellow gray lss.; medium hard; very glauconitic in places, no glauconite in other places; distinguished from underlying Elstone fm. by presence of brown calcite crystals and concretions. Thickness 75 to 100 ft. Upper fm. of Midway group in Medina Co. Uncon. underlies Buttsgin fm. Named for its largest exposure on E. and W. branches of Squirrel Creek above old Capt. Smith ranch house.

G. H. Chadwick, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 117). Extended field work has shown that Elstone and Squirrel Creek fms. have been inverted, the Elstone actually being the higher, and there is possibly a third memb. present locally above the Elstone glauconitic ls.

Julia Gardner (personal communication, July 1930). See under †*Elstone fm.*

Squirrel Gulch latite.

Tertiary: Southern Colorado (Bonanza district, Saguache County).

W. S. Burbank, 1932 (U. S. G. S. P. P. 169). *Squirrel Gulch latite.*—Massive flows of hornblende-biotite latite, 300 to 500 ft. thick. Underlies Porphyry Peak rhyolite and overlies Bonanza latite. Most prominent development occurs at upper part of Squirrel Creek and in N.-S. ridges W. of Kerber Creek in sec. 23.

Stacy dolomite member (of Gatesburg formation).

Upper Cambrian: Central Pennsylvania (Blair County).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 527, 534, 537). *Stacy dol. memb.*—Coarse thick-bedded steely blue ls., without qtzite. Basal memb. of Gatesburg fm. Overlies Warrior ls. Named for Stacy Hill, a knob 4 mi. slightly W. of S. of Williamsburg, Blair Co. [Thickness 500 ft. Exposed on summit and W. side of Stacy Knob.]

Stadler sand.

A term that has been locally applied to Newburg sand, which occurs about 200 ft. above base of Niagara ls. in Cleveland region, Ohio. Newburg has priority as well as usage. The sand has supplied gas to plant of Stadler Rendering & Fertilizing Co. on Cuyahoga River, just N. of mouth of Big Creek. (See also under *Newburg sand.*)

Staff limestone member (of Graford formation).

Pennsylvanian: Central northern Texas (Brazos River region).

F. Reeves, 1922 (U. S. G. S. Bull. 736E, p. 120). *Staff ls. memb. of Graford fm.*—Lies 159 ft. below Adams Branch ls. memb. Upper half weathers in gray fragments; lower part is massive, hard, and yellow. Thickness 10 ft. Outcrops near Staff, Eastland Co.

Stafford limestone member (of Skaneateles shale).

Middle Devonian: Western and central New York.

J. M. Clarke, 1894 (N. Y. State Mus. 47th Ann. Rept., pp. 342, 351). At 823 ft. depth in Livonia salt shaft, at Livonia, Livingston Co., occurs 2 ft. of compact grayish or chocolate-colored ls., somewhat bituminous, shaly at top, which I have named *Stafford ls.*, from its excellent development at Stafford, Genesee Co. Hamilton fossils very abundant [listed]. It persists from Livonia eastward probably not less than 50 mi. In the shaft section, as at all its observed outcrops, it bears a Hamilton fauna with a few Marcellus species. From this horizon upward there are no more lss. in the Marcellus section. The Stafford ls. rests on 28 ft. of compact black, very bituminous but not heavy-bedded shales [the fossils of which are listed].

I. P. Bishop, 1897 (N. Y. State Geol. 15th Ann. Rept., vol. 1, p. 314). *Stafford ls.* lies in midst of the jet-black Marcellus shales, 20 ft. above Corniferous [Onondaga] ls.

F. J. H. Merrill, 1898 (N. Y. State Mus. Bull. 4, No. 19). *Stafford ls.* is a thin ls. about 40 ft. above base of Marcellus sh. Extends from central N. Y. to Lake Erie. Well exposed at Stafford, Genesee Co.

Has sometimes been called *Manlius ls.*, because well exposed 2 mi. W. of village of Manlius (D. D. Luther, 1899), but is much younger than true Manlius ls., which is Sil. Thicknesses given range from 2 ft. to 8 ft. 4 in.; distances above Onondaga ls. vary from zero to 159 ft.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 215–216). *Stafford ls.* is basal memb. of Skaneateles fm. It is a gray ls. that weathers chocolate brown; in places is quite shaly, in other places highly calc. and massive. At Stafford [Genesee Co.] it is 3 ft. thick; at Lancaster 8½ ft.; at Lake Erie 15 ft. The upper 2 ft. of the Stafford at Lancaster is like typical Stafford, but presents considerable variations in fauna and lithology from the 6½ ft. below it, which should probably be placed in underlying Oatka Creek memb. of Marcellus. The beds above the Stafford are here named *Levanna memb.* of Skaneateles fm. The Stafford is considered=Mottville memb. [See under *Mottville memb.*]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *Stafford ls.* is basal bed of Skaneateles sh. [On p. 391 she stated it has recently been proved to be=Mottville ls.]

The U. S. Geol. Survey has adopted the definition of Skaneateles sh. that includes in it the Stafford ls. of N. Y. repts.

Stafford Store quartz monzonite.

Post-Ordovician: Northeastern Virginia (Stafford County).

J. T. Lonsdale, 1927 (Va. Geol. Surv. Bull. 30, p. 40), described geographic distribution and petrography of *Stafford Store quartz monzonite*, "which is typically developed near Stafford Store post office, Stafford Co."

Staghorn Point submember.

Middle Devonian: Central New York (Skaneateles quadrangle).

B. Smith, 1935 (N. Y. State Mus. Bull. 300, pp. 46–47). About 50 ft. above Centerfield ls. occurs the lower coral bed or reef of Otisco memb. of Ludlowville sh. and the hard and coarsely bedded platform on which the coral bed rests. This coral bed is 3 or 3½ ft. thick but may thin to almost nothing. The platform on which it rests is 5 or 10 ft. thick. Both are beautifully displayed in vicinity of Staghorn Point, on E. side of Skaneateles Lake, about 1⅕ mi. NW. from Spafford Landing. The term *Staghorn Point submember* is here proposed for the coral bed or reef typically shown just S. of Staghorn Point.

†Staked Plains formation.

Pliocene: Northwestern Texas.

R. T. Hill, 1890 (Am. Ass. Adv. Sci. Proc., vol. 38, p. 243). The Staked Plains are shown to be an extensive mesa, which was an interior baselevel in late Tert. or early Quat. time. Its surface is covered by a fresh-water lacustrine sediment, consisting of loam and gravel, for which name *Staked Plains fm.* is proposed.

These blanket deposits of the Staked Plains or Llano Estacado are now called *Ogallala fm.* (*Plio.*). (See 1937 geol. map of Tex.)

Stalk group.

Pre-Cambrian: Canada (Northwest Territories).

C. Lausen, 1929 (Canadian Min. and Met. Bull. 202, p. 379).

Stalnaker sand.

A subsurface sand, of Penn. age, in southern Kans. and northern Okla., lying at about 2,050 ft. depth in Udall pool, Cowley Co., Kans.; also produces in E. part of adjoining Sumner Co., Kans. Correlated with top part of Lansing group. Believed to be same as Tonkawa sand. In Mervine pool, Kay Co., Okla., it is 22 ft. thick and lies at 1,800 ft. depth, the Endicott lying at 1,500 ft. and the Burbank at 3,100 ft.

Stamford granite gneiss.

Pre-Cambrian: Southwestern Vermont (Bennington County) and western Massachusetts.

C. H. Hitchcock, 1861 (Rept. geol. Vt., vol. 2, p. 601). Climbing the great hill W. of Stamford monstrous boulders of granite appear, and presently the granite itself, which contains blue hyaline quartz. So peculiar is this granite that it has been called *Stamford granite* in our notes. It may be eruptive. Extends btw. 3 and 4 mi. to E. part of Pownal.

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, pl. 97). *Stamford gneiss*, pre-Camb., underlies Vermont fm. in western Mass.

J. E. Wolff, 1894 (U. S. G. S. Mon. 23, pp. 45–48). *Stamford gneiss* (*the "Stamford granite" of Vt. geol. rept.*).—Coarse banded granitoid gneiss. Underlies Vermont fm.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 151, and map). *Stamford granite gneiss.*—Described by Pumpelly and Wolff (U. S. G. S. Mon. 23, p. 45, 1894). Forms core of Hoosac Mtn proper. Was named for exposures at Stamford, Vt.

Intrudes Mount Holly gneiss. (L. M. Prindle and E. B. Knopf, Am. Jour. Sci., 5th, vol. 24, Oct. 1932.)

Stamper zone.

Drillers' name for 110± ft. of sandy dol. of Ord. age in Oklahoma City field, NE. Okla., containing fossils that correlate it with Joins fm. Underlies Kinter ss. of drillers and overlies beds identified as Arbuckle ls. Basal 0 to 40 ft. consists of gray and white mottled coarsely crystalline soft to hard ls., in places partly or completely dolomitic, which are called *Stamper ls.* (See A. A. P. G. Bull., vol. 16, No. 10, pp. 967+.) Derivation of name not known.

Stamper limestone.

See under *Stamper zone.*

Stanbridge slate.

Middle and Upper (?) Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 7).

Standish flagstone. (In Genesee group.)

Upper Devonian: West-central New York.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63, p. 29). *Standish flags and shales.*—Thin uneven bluish-gray flags and olive shales 15 ft. thick, overlying West River sh. and underlying Middlesex black shales of Portage group. Top div. of Genesee beds or group. Seems entitled to designation because it marks a transition from argill. shales of West River beds into aren. sedimentation characterizing for most part the mass of Portage strata. Not persistent for any great distance from Canandaigua and Naples quads. Fauna sparse and chiefly that of beds below.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 73). *Standish flags and shales* named for Standish Gully, town of Italy, Yates Co. Is a local fm. not recognized E. of Yates Co. and to W. thins to disappearance in Genesee Valley. Top div. of Genesee beds.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included *Standish sh.* and underlying West River sh. and Genundewa ls. in Portage group, and restricted Genesee to its basal memb., or the Geneseo sh. of Chadwick.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2), included Standish and underlying beds in *Genesee group.*

The U. S. Geol. Survey has adopted *Standish flagstone* as the name of this unit, and includes it in Genesee group.

†Standley shale.

Mississippian: Eastern Oklahoma.

See *Stanley sh.*

Standpipe sandstone. (In Elmdale formation.)

Pennsylvanian: Central northern Oklahoma (Pawnee County).

F. C. Greene, 1928 (Okla. Geol. Surv. Bull. 40CC). "Standpipe ss." lies 5 to 8 ft. below Neva ls. in Pawnee Co.

Standpipe limestone member (of Clear Fork formation).

Permian: Central northern Texas (Taylor County).

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, p. 27, pl. 1). *Standpipe ls.*—Dark-gray fossiliferous ls., 1 to 3 ft. thick, forming top memb. of Wichita-Albany. Type loc. is the lime outcropping at base of hill upon which is located the standpipe in E. part of Abilene, Taylor Co. Is used in unpublished rept of W. A. Riney.

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, No. 8, pl. 9, pp. 948, 949). *Standpipe ls.*—Lies 125 ft. above Lytle ls., in lower part of Clear Fork fm. Is noticeable chiefly on account of its outcrop in SW. part of city of Abilene. Is of local extent.

Stanford conglomerate.

Probably late Tertiary: Central northern Montana (Fort Benton quadrangle).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Stanford cgl.*—Cgl. found in the very prominent hills rising above the flat prairie near that town. The road E. of Stanford crosses a flat bench covered with this cgl. Thickness 0 to 100 ft. Uncon. overlies Montana fm. (Upper Cret.). Of Pleist. or Tert. age.

This gravel is now considered by W. C. Alden to probably be=Flaxville gravel, which is considered to be of upper Mio. or Plio. age.

Stanhope sand.

A subsurface sand in Stanhope pool, secs. 15 and 22, T. 26 S., R. 8 E., Kans. Lies in or on top of Mississippi lime.

Staniukovich shale.

Lower Cretaceous: Southwestern Alaska (Alaska Peninsula).

W. W. Atwood, 1911 (U. S. G. S. Bull. 467, pp. 25, 38, etc.). *Staniukovich sh.*—Shales and thin sss., 1,000+ ft. thick, conformably underlying Herendeen ls. (Lower Cret.) and overlying Naknek fm. (Upper Jurassic). Exposed on Herendeen Bay, also on Staniukovich Mtn. and E. to Port Moller. Is Lower Cret.

Stanley shale.

Pennsylvanian (Pottsville): Central southern and southeastern Oklahoma and western Arkansas.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Standley sh.*—Upper part bluish and greenish fissile green shales and massive and thin-bedded friable drab sss.; lower part siliceous and cherty fissile sh. Thickness 6,100 ft. Underlies Jackfork ss. and overlies Talihini chert.

A. H. Purdue, 1909 (Ark. Geol. Surv. Slates of Ark.). *Stanley sh.*—Greenish clay sh., with, locally, black sl. near base and greenish qtzitic ss.; frequently a cgl. at base. Thickness 6,000 ft. Uncon. overlies Fork Mtn sl., 0 to 125 ft. thick. [Stanley sh. as used in this rept included Hot Springs ss. of Hot Springs area. This definition of Stanley sh. (to exclude †Fork Mtn sl.) was also used by Purdue in U. S. G. S. Bull. 586, 1914.]

H. D. Miser, 1917 (U. S. G. S. Bull. 660, p. 66). Some sh. at base of Stanley sh. has in places been altered to sl., to which name "Fork Mtn sl." has been earlier applied. In Caddo Gap and DeQueen quads. Ark. and Okla., the Stanley rests uncon. on Arkansas novaculite and underlies Jackfork ss.

Age of Stanley sh. was changed to Penn. in 1934. (See H. D. Miser, A. A. P. G. Bull., vol. 18, No. 8, 1934.)

Named for Stanley, Pushmataha Co., Okla.

Stanstead granite.

Post-Devonian (?): Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11).

Stanton limestone. (In Lansing group, Kansas.)

Stanton limestone member (of Lansing formation, in Missouri).

Pennsylvanian: Northwestern Missouri, southwestern Iowa, southeastern Nebraska, eastern Kansas, and northeastern Oklahoma.

G. C. Swallow and F. Hawn, 1865 (Kans. Geol. Surv. Rept. on Miami Co., p. 6). *Stanton ls.*—Lss., 28 ft. thick, forming bed No. 7 of geol. section of Miami Co., Kans. At top thick beds of soft light-gray mag. ls. full of small brown ferruginous spots; in middle harder, regular beds of medium thickness; at bottom bluish-gray ls., weathering brown and separating into angular fragments by plane or conchoidal fractures. Overlain by 9 ft. of sh. and ss., and underlain by 15 to 28 ft. of ss., which passes into shales and fire clays at top and bottom, and rests on Cave ls.

E. Haworth and J. Bennett, 1908 (Kans. Acad. Sci. Trans., vol. 21, pt. 1, pp. 71–85). Stanton ls. of Swallow overlies Vilas sh. and underlies LeRoy sh. Is same as Piqua ls. of Adams.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13) and 1917 (U. S. G. S. Leavenworth-Smithville folio). *Stanton ls.* is top memb. of Lansing fm. Overlies Vilas sh. memb. and underlies Weston sh. memb. of Douglas fm.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 76). Swallow's original Stanton is equiv. to ls. now called *Plattsburg ls.* Usage has transferred application of name *Stanton* to the ls. next above the Plattsburg; and accordingly as used in this rept *Stanton* now applies to 3 ls. and 2 sh. members, all named, that are exact equiv. of Stanton of Hinds and Greene in Leavenworth-Smithville area. Stanton is top fm. of Lansing group.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 131–132). Swallow's original Stanton ls. is ls. now called *Plattsburg ls.* The name *Stanton* has been shifted by usage to ls. next above that exposed at Swallow's type loc. As now defined it overlies Vilas sh., underlies Weston sh., and is uppermost fm. of Lansing group. It is typically exposed in road cuts near SE. cor. sec. 3, T. 13 S., R. 21 E., and adjacent area along Captain Creek. Thickness 20 to 100+ ft.

†Stanton limestone series.

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., p. 20). *Stanton ls. series.*—Series of lss., sss., and shales, 74 ft. thick, including beds Nos. 151 to 155, inclusive, of geol. section of eastern Kans. Includes at top Stanton ls., 6 to 28 ft. thick. Underlain by Cave Rock series (of which Cave ls. is top bed) and overlain by Chocolate ls. series.

Preoccupied by Stanton ls. memb. of Lansing fm. Included Stanton ls. and Vilas sh. members of Lansing fm.

Probably named for its topmost memb., the Stanton ls.

Stanton sand.

Drillers' name for a Sil. sand in Ky.

Stapleton zone.

Name applied to lowest producing zone in Eldorado field, Butler Co., Kans., which lies at 2,350 to 2,750 ft. depth. According to J. R. Reeves (A. A. P. G. Structure symposium, vol. 2, 1929, p. 166) these rocks are in the Ord., either in Viola ls., Siliceous lime, or St. Peter ss.

Star limestone.

Carboniferous: British Columbia.

S. J. Schofield, 1920 (Canada Geol. Surv. Mem. 117, p. 15). Included in Slocan series.

†Staran series.

Triassic (Upper?): Humboldt County, Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52, 59). The great *Star Peak ls.*, or *Staran series*, of Humboldt Mtns. reported to be more than 5,000 ft. thick [thickness assigned by Keyes, 3,000 ft.], appears to fade out long before reaching southern and eastern confines of State. Uncon. below Jurassic Lovelockian series and above Koipatoan series. Of late Triassic age.

Named for exposures in Star Peak Mtn, Humboldt Co.

Starbird formation.

Devonian: British Columbia.

J. F. Walker, 1926 (Canada Geol. Surv. Mem. 148, p. 35).

Stark shale.

Pennsylvanian: Eastern Kansas, western Missouri, and southwestern Iowa.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 91, 97). [See under *Dennis fm.* Derivation of name not stated.]

J. M. Jewett, 1932 (pp. 99, 102, 103 of book cited above). *Stark sh.* is proposed for the sh. above Canville ls. and below Winterset ls. Its lower part is dark or black and carbonaceous, and upper part is commonly yellow, although the yellow upper part is not persistent. Traced by writer from Kansas City, Mo., to Dennis, Labette Co., Kans. Is easily distinguished from Galesburg sh. by means of the black sh.

at its base, even though Canville ls. be not present, as is case at Kansas City. Thickness 8 to 11 ft.

J. M. Jewett, 1933 (Kans. Acad. Sci. Trans., vol. 36, p. 133). Type loc. of Stark sh. is near Stark, Neosho Co., Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 92). N. of point in Linn Co. where Canville ls. disappears, Stark sh. memb. of Dennis fm. rests on Galesburg sh., but because lower part of Stark memb. is black fissile sh. (1 to 3 ft. thick) it is easy to separate Stark and Galesburg shales. In southern Kans., where Canville is missing, the absence of black platy sh. at horizon of Stark memb. makes it impossible to recognize Stark sh., and upper bdy of Galesburg sh. is extended up to base of Winterset ls. The upper part of Stark sh. consists of gray or buff calc. clay sh. 2 to 5 ft. thick. At Kansas City total thickness of Stark sh. is 4 ft. Jewett is author of name.

Starmount limestone.

Middle Cambrian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, pp. 434, 435). *Starmount ls.*—Mostly argill.; 600 ft. thick. Corresponds in character and position to Meagher ls. of Little Belt section, but positive identification with Meagher ls. is impossible, hence local name. Upper (and major) part is more massively bedded and of darker color, mottled, and contains less silica and clay than lower 250 ft., which consists of light-gray thin-bedded argill. ls. Underlies Hobo Gulch fm. and overlies an intrusive granite porphyry that is believed to be intruded into and to conceal a sh. that corresponds to Wolsey sh. of Little Belt section. Named for Starmount mine, Elkhorn min. dist.

Probably same as Meagher ls.

Star Peak formation.

Upper and Middle Triassic: Northwestern and northern Nevada.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, map V) and 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 267–278, 544). *Star Peak group.*—Upper 10,000 ft. of Triassic section in West Humboldt Range. In descending order: (1) Pure qtzite, 2,200 to 2,800 ft.; (2) ls., 1,000± ft.; (3) pure thinly bedded qtzite, 800 to 1,000 ft.; (4) heavy ferruginous lss., 2,000 ft.; (5) black slates, 250 ft.; (6) slaty qtzite, 1,250 ft.; dark carbonaceous ls., 1,500 ft. Rests conformably on Koipato group. Named for development at Star Peak Mtn.

Star Point sandstone. (Of Mesaverde group.)

Upper Cretaceous: Central eastern Utah (Wasatch Plateau and Book Cliffs).

E. M. Spieker and J. B. Reeside, Jr., 1925 (Geol. Soc. Am. Bull., vol. 36, p. 442). *Star Point ss.*—Basal fm. of Mesaverde group. Thickness 200 to 450 ft. in Wasatch Plateau. Conformably underlies Blackhawk fm. and grades into underlying marine Mancos sh. It really represents the retreating or closing phase of Mancos sea and is more closely allied in origin with the Mancos than with the Mesaverde type of rocks but is included in Mesaverde in conformity with accepted practice of giving that name to the sss. of Montana age immediately overlying Mancos sh. Star Point, a prominent headland of Wasatch Plateau SW. of Price, is formed by this ss.

F. R. Clark, 1928 (U. S. G. S. Bull. 793). *Star Point ss.* consists of non-coal-bearing medium-grained buff sss. separated by tongues of marine Mancos sh., into which it grades laterally in part and in part overlies. The 3 larger tongues of Star Point ss. are named (descending) Spring Canyon tongue, Storrs tongue, and, at base, Panther tongue.

Starr conglomerate.

Starrs conglomerate.

Lower Cambrian: Southeastern Tennessee.

C. W. Hayes, 1895 (U. S. G. S. Cleveland folio, No. 20, p. 2). *Starr cgl.* in text (*Starrs cgl. on map*).—Cgl., usually quite coarse and containing many large feldspar pebbles. Thickness 0 to 660 ft. Is middle memb. of Sandsuck sh.

Named for exposure near Starr Mtn, Monroe Co.

Starrucca shale. (In Catskill or Chemung formation.)

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. G_5, pp. 59, 70, 73). *Starucca olive shales.*—Olive or greenish shales containing many thin sss. and in places topped by a massive ss. Thickness 105 ft. in Susquehanna and Wayne Counties. Underlie New Milford red sh. and overlie Chemung sh. Form basal div. of Catskill fm. Well exposed along Jefferson Branch R. R. above Starucca Bridge, also near mouth of Starucca Creek. [In 1882 (2d Pa. Geol. Surv. Rept. G_6) I. C. White gave thickness of *Starrucca shales and sss.* in Pike and Monroe Counties as 600 ft., and stated that they may be = upper part of Chemung fm. instead of Catskill.]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, p. 1206). [See 1935 entry under *Delaware River flags.* Willard drops this name, stating it is only upper part of Trimmers Rock ss., the type loc. of which is in Perry Co.]

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 591). Beneath New Milford fm. in Susquehanna Co. is the fully marine Chemung, the Cayuta fm., the designation being extended upward to include Starrucca sh. of I. C. White, which writer does not differentiate from rest of Chemung.

In some early repts spelled *Starucca.* The spelling adopted by U. S. Geog. Bd. is *Starrucca.*

Starrucca sandstone.

Upper Devonian: Northeastern Pennsylvania.

C. S. Prosser, 1894 (U. S. G. S. Bull. 120, p. 78). *Starucca ss.*—Greenish gray massive sss., 600 ft. thick, underlying New Milford sh. and overlying Chemung of I. C. White in eastern Pa.

Occupies same interval as Starucca sh. of I. White. (The approved spelling is *Starrucca.*)

Starucca shale and sandstone.

Upper Devonian: Northeastern Pennsylvania.

See *Starrucca,* the spelling approved by U. S. Geog. Bd.

†State line serpentine.

Pre-Cambrian: Southeastern Pennsylvania and northeastern Maryland. (See F. D. Chester, 1889, 2d Pa. Geol. Surv. Ann. Rept. 1887, pp. 93–105.) Named for fact it occurs fully 16 mi. along bdy. btw. Pa. and Md. Is later than Glenarm series.

Staten Island serpentine.

Pre-Cambrian (?): Southeastern New York (Staten Island).

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). *Staten Island serpentine* clearly intrusive into Fordham gneiss, Inwood ls., and Manhattan schist.

C. P. Berkey and J. R. Healy, 1912 (Columbia Univ. Contr., vol. 20, pp. 1907–1912). *Staten Island or Hoboken serpentine.*—An intrusive which forms the elevated portion of Staten Island and the Knob at Castle Point, in Hoboken. In all cases it is probably more closely associated with Manhattan schist [pre-Camb.] than with any other important fm. Age undet.

State Quarry limestone.

Upper Devonian: Central eastern Iowa.

S. Calvin, 1897 (Iowa Acad. Sci., Proc., vol. 4, pp. 16–21). *State Quarry ls.*—Light-gray fossiliferous lss., 0 to 40 ft. thick, uncon. overlying Cedar Valley ls. in Johnson Co. Included in Upper Dev.

Regarded by some authors as contemp. in whole or part with Lime Creek sh., but E. O. Ulrich (1911) says it is much younger than Lime Creek sh. and of Cheming and Portage age.

Named for State quarry (or North Bend quarries), Penn Twp, Johnson Co.

†State Road conglomerate.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 257). One of cgls. at base of Mesnard qtzite is especially interesting, in that it was the first in which the clear evidence of uncon. was found. This contact is N. of Mud Lake and along an old road known as the State road, and the cgl. has sometimes been called "State Road cgl."

Staunton formation.

Pennsylvanian: Southwestern Indiana.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, chart and pp. 408, 525, 529). *Staunton fm.*—Name proposed for interval btw. top of coal No. 4 and top of coal No. 2 of Ind. Formerly included in Brazil fm. Rests discon. on Brazil fm. as here restricted and is discon. overlain by Petersburg fm. as here expanded. Of Allegheny age.

Named for Staunton, Clay Co.

Stayton lavas.

Miocene: Northwestern Oregon and central northern Oregon (Cascade Mountains region).

T. P. Thayer, 1933 (Pan-Am. Geol., vol. 59, No. 4, p. 317). *Stayton lavas.*—Basaltic, 400± ft. thick, correlated with Miocene Columbia basalts. Form Salem Hills, SW. of Salem, Oreg. Lie on eroded surface of gently folded Illahe fm. (lower-middle Olig.). To E. the lavas flatten and form the shallow Stayton Basin, about 12 mi. wide. East of the basin they rise gently into the Cascades, with conspicuous dip slopes, disappear under the conformably overlying *Fern Ridge tuffs*, and rest uncon. on Mehama volcanics.

Steamboat limestone.

Middle (?) Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 37 and passim). *Steamboat ls.*—At type loc. (on E. and N. sides of Steamboat Mtn) can be divided into 3 natural zones (descending): (1) Extremely massive tan-gray thick-bedded crumbly ls. with much yellow clay disseminated throughout, 40 ft.; (2) interbedded green-gray micaceous calc. sandy shales and tan argill. gray-weathering lss. with much buff clay in flakes, bands, and nodules, the upper 22 ft. composed solely of green calc. platy sh., 115 ft.; (3) thick-bedded massive gray and tan-gray fine-grained ls. with nodules and flakes of buff clay, 70 ft. Underlies Pagoda oolite and overlies Dearborn ls.

Steamboat Mountain type (of diorite porphyry).

Name applied by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, p. 515, 1900) to the rock that "forms the great laccolith of Steamboat Mtn," Little Belt Mtns, central southern Mont.

Stearns shale. (In Council Grove group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 230, 233, 234, 235, 237). *Stearns sh.*, in Garrison sh. memb. of Council Grove fm., consists of (descending): (1) Grayish calc. sh., 1½ to 2 ft.; (2) bluish-gray argill. crumbly sh., 4 to 6 ft.; (3) chocolate or reddish crumbly argill. sh., 5 to 8 ft.; (4) light-gray limy, loosely indurated sh., 2+ ft. Total thickness 14 to 18 ft. Overlies Morrill ls. and underlies Eiss ls. Named for exposure S. of Stearns School, NE. of Humboldt, Nebr.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 18). *Stearns sh.* is 17 to 18 ft. thick in Nebr. and about 8 ft. in southern Kans. Section at type loc. is now obscured, but the sh. is typically exposed along a N.-S. road 6 mi. S. and ½ mi. E. of Humboldt, Nebr.

G. E. Condra and R. C. Moore in 1932 included this sh. in the Garrison, but Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 7) treated it as distinct fm. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

Steele shale. (Of Montana group.)

Upper Cretaceous (Pierre): Eastern and central Wyoming.

In April 1909 the names to be used in U. S. G. S. Laramie-Sherman folio (No. 173), by N. H. Darton and C. E. Siebenthal, were given consideration by Com. on Geol. Names of U. S. Geol. Survey. The Cret. rocks as mapped in the western or Laramie quad. of this folio were divided by the authors into (descending): (1) An upper ss. of Pierre age, (2) a sh. of Pierre age, (3) the Niobrara ls., (4) the Benton sh., and (5) the Cloverly fm. Other Survey geologists, who had for several years worked in the coal fields of adjacent areas in southern and central Wyo., were satisfied that the upper ss. of Pierre age in Laramie Basin represented Mesaverde fm. of adjacent areas to W., and they had for some time had in contemplation the introduction of a suitable Wyo. name for the underlying sh. of Pierre age. They at this time presented for it the name *Steele sh.*, from Fort Steele, in the adjacent county (Carbon) on the W. The correlation of the rocks of Pierre age in Laramie quad. with Mesaverde fm. and the proposed Steele sh. to the W. was considered acceptable to all these workers, including Mr. Darton. The Laramie-Sherman folio was the first of these repts to be published (1910). Therefore in it occurs the following original definition of Steele sh.: The *Steele sh.* consists of about 3,000 ft. of dark sh. with some thin beds of ss. and numerous nodular concretions, mostly sandy. Believed to represent Steele sh., whose type loc. is Fort Steele, on North Platte River. Grades into overlying Mesaverde fm. and rests on Niobrara ls. Is basal fm. of Montana group in this area.

The Steele sh. in its type region was described by C. F. Bowen (U. S. G. S. P. P. 108, 1918, p. 229) as consisting of 4,000± ft. of dark-gray fossiliferous marine sh. with intercalated beds of ss. and shaly ss., some of which form conspicuous ledges near top of fm.; the shale containing concretions of calc. ss., dark ls., and white calcite. Underlies Mesaverde fm. and overlies Niobrara fm.

Subsequently (1920) Mesaverde fossils were obtained from thick sandy beds that were included in upper part of Steele sh. as mapped in Laramie Basin. The division line btw. Mesaverde fm. and Steele sh. in that area is therefore now placed somewhat lower than in 1910.

Steele Valley granodiorite.

Late Jurassic (?): Southern California (Riverside County).

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, map, pp. 491, 502). Late Jurassic (?) intrusive occurring in Steele Valley, S. part of Perris-Elsinore area, Riverside Co.

Steens basalt.

See under *Steens Mtn basalt.*

Steens Mountain formation.

Pliocene: Southeastern Oregon (Steens Mountain).

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Steens Mtn fm.*—Basalt and rhyolite dikes, 10 to more than 50 ft. thick, typically exposed on Steens Mtn, Harney Co.

†Steens Mountain basalt.

Miocene: Southeastern Oregon (Steens Mountain).

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, pp. 7–130, 101). *Steens Mtn basalt.*—Extensive series of thin flows of light-gray holocrystalline olivine basalt, 3,000+ ft. thick. Overlies Steens Mtn andesitic series. In general the evidence indicates this basalt is definitely younger than Columbia River flows and occurred either late in Mio. or early in Plio. Exposed almost continuously for 100 mi. on E. scarp of Steens and Pueblo Mtns.

The U. S. Geol. Survey has shortened this name to *Steens basalt*, which it classifies as Mio.

Steens Mountain andesitic series.

Tertiary (late): Southeastern Oregon (Steens Mountain).

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, pp. 7–130, 74). *Steens Mtn andesitic series.*—To N. of Alvord Creek, on E. slope of Steens Mtn, it consists of (descending): (1) Upper andesitic series accompanied by extensive breccias; (2) great andesite flow, 500 to 900± ft.; (3) thin bed of coarse andesitic tuffs, 10 to 20 ft.; (4) basic andesitic flow, very like that 100 ft. below top of underlying Alvord Creek beds, 200+ ft. Underlies *Steens Mtn basalt*. [Appears to be regarded as late Mio. or early Plio.]

Steep Rock series (or group).

Pre-Cambrian (lower Huronian): Ontario.

H. L. Smyth, 1891 (Am. Jour. Sci., 3d, vol. 42, pp. 319–331).

Steep Rock Lake series.

Pre-Cambrian: Ontario.

J. E. Gill and J. E. Hawley, 1931 (Jour. Geol., vol. 39, p. 656).

See *Steep Rock series*.

Stehekin physiographic stage.

Recent: Central Washington (Cascade Range).

B. Willis, 1903 (U. S. G. S. P. P. 19). Type loc. Stehekin sources and valley.

Steilacoom gravel.

Pleistocene (Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Steilacoom fm.*—Chiefly coarse gravel, sometimes washed clean, elsewhere mingled with coarse sand, usually stratified or cross stratified. Type, the Steilacoom Plains, which extend for many mi. S. and SW. from Tacoma. G. O. Smith, my associate, describes the deposits, in ms., as of glacial origin and a peculiar type of washed plains, which was submerged during retreat of the ice. Writer agrees with this conception.

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54). *Steilacoom gravels* differ from Gale sands in their prevailing coarseness.

Stein sand.

A subsurface sand in Chester group (Miss.) of Marion Co. Ill.

Stellarton formation.

Carboniferous: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 211).

Stennett limestone. (In Shawnee formation.)

Pennsylvanian: Southwestern Iowa.

S. W. Beyer and I. A. Williams, 1907 (Iowa Geol. Surv. vol. 17, p. 480). A sixth ls. horizon far above the strata of the Bethany may for present purposes be designated *Stennett ls*. It is typically developed at Stennett, Montgomery Co., and is believed to be present in adjoining counties.

G. L. Smith, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 276). The Mo. Geol. Surv. has correlated Forbes ls. with Deer Creek ls. of Kans., and uses this term for Forbes ls. As Iowa outcrops of this ls. are upwards of 100 mi. distant from type section of Forbes ls., it is by no means certain they represent same horizon. Under these circumstances, the Mo. Geol. Surv. having abandoned use of term Forbes, it is proposed that this ls. be named *Stennett ls*. Until the different fms. of Iowa have been actually traced in the field to those of Kans. it is preferable that they be designated by local names rather than by those of fms. several hundred mi. distant.

Stensgar dolomite member.

Paleozoic: Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 57; map). *Stensgar dol. memb. of Deer Trail argillite.*—Dolomitic ls., typically slightly banded to massive grayish-white to pure-white crystalline ls. containing large and varying quantities of mag. carbonate. In some places the rock becomes an impure magnesite. The dolomitic phases are usually pinkish, bluish, and reddish gray, depending on iron content. Lies in apparent conformity on Deer Trail argillite and is overlain by beds of Deer Trail argillite. [Type loc. not stated, but map shows it occurs near Stensgar Mtn.]

Stephen formation.

Middle Cambrian: British Columbia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 198). The Camb. strata of Mount Stephen, near Field, along line of Canadian Pacific Ry. are highly fossiliferous, and that locality proves to be one of best in world for collecting Neo-Camb. trilobites, which occur at about 11,000 ft. altitude. The designation *Stephen fm.* is suggested for the trilobitic beds of sh. and ls. with *Ogygopsis klotzi, Zacanthoides spinosus, Ptychoparia cordillerae* and associated fauna.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 2, 3). *Stephen fm.*—Bluish-gray and greenish-gray ls. and sh. band about 2,700 ft. up above r. r. track on N. and E. sides of Mount Stephen, above Field, on Canadian Pacific Ry. B. C. The lss. and the shales are calc. and siliceous. Thickness in Mount Bosworth section 640 ft.; on Mount Stephen 562 ft., with 150 ft. of local development of *Ogygopsis* shales at summit. Middle Camb. fossils; *Ogygopsis* fauna of Mount Stephen and fauna below in the thin-bedded dark bluish-gray ls. Underlies Eldon fm. and overlies Cathedral fm.

Stephens lime.

A subsurface unit, of Penn. age, in Fisher Co., north-central Tex., lying at 3,000 ft. depth.

Stephensian series.

Cambrian: Alberta.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 289). Shales and lss., aggregating 775 ft. in thickness, underlying Eldonian series and overlying Cathedralian series. [Apparently same as *Stephen fm.*]

†Stephensport bed. (In Chester group.)

Mississippian: Northwestern Kentucky and southwestern Indiana.

A. F. Foerste, 1910 (Ky. Geol. Surv. Rept. Prog. 1908 and 1909, p. 84). *Stephensport bed.*—Chiefly two ls. horizons, separated by an intermediate clay horizon, which near middle may be replaced by shaly or even by massive ss. layers. Thickness 96 ft. Underlies Tar Springs ss. and overlies Garfield ss. in Meade and Breckinridge Counties.

This name has also been proposed in a broader sense, for beds extending from top of Glen Dean ls. to base of Cypress ss. (See separate item.)

Named for Stephensport, Breckinridge Co., Ky.

Stephensport (broad usage). (In Chester group.)

Mississippian: Southern Indiana and Illinois and western Kentucky.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 514, footnote). *Stephensport* suggested to Professor Weller in 1920 for the middle Chester, including all rocks btw. top of Glen Dean ls. and base of Cypress ss., but Weller preferred to use *middle Chester* for the present.

Derivation of name not stated, but probably Stephensport, Breckinridge Co., Ky.

Stepovak series.

Eocene: Southwestern Alaska (Stepovak Bay, Alaska Peninsula).

C. Palache, 1904 (Harriman Alaska Expedition, vol. 4, p. 74). *Stepovak series.*—Marine sediments occupying most of area studied about Chicagof Cove, Stepovak

Bay, and containing abundant lower Eo. fossils. Folded and faulted. Upper beds are soft shales, sss., and grits, with some thin beds of ls. and some chert bands. Lower part consists of coarse breccias or aggls. and fine tuffs of igneous material.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, p. 240). Stepovak series of Palache is probably older than Kenai series.

Steptoean series.

A term applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53) and 1924 (Pan-Am. Geol., vol. 41, p. 78), to uppermost part of Pogonip ls. of Nev. Named for development in Egan Mtns, which face Steptoe Valley, NE. Nev.

Sterling granite gneiss.

Late Carboniferous or post-Carboniferous: Eastern Connecticut and western Rhode Island.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 131–134–136, 152, 154, 155, and map). *Sterling granite gneiss.*—Made up of two distinct types—a porphyritic gneiss with abundance of biotite along foliation planes, and an aplite or a granite gneiss practically free from mica. The porphyritic type is always highly gneissoid and the phenocrysts, which are of pink feldspar, are drawn out into lenticular forms. The aplitic type is probably a later intrusion than the porphyritic and normal types. General color of the granite gneiss is pink to red, although in some regions, where exposed in fresh cuts and quarries, it is light to medium gray. It is the "red Westerly" granite of the trade, and is quarried at Westerly, R. I. Intrudes Putman gneiss and is intruded by pegmatites and by Westerly granite (the "gray Westerly" of the trade). Covers most of Sterling Twp, Conn.

See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 23–24, 35–38, 119–135, and map).

Sterling Station iron ore.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). A 4-inch seam of ore 8 ft. above principal ore bed (Furnaceville) at Sterling Station [Cayuga Co.]. Not known to outcrop elsewhere, but appears in several wells. Underlies true [restricted] Sodus sh. [Lies in lower part of Clinton fm.]

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., p. 347), placed *Sterling Station ore* in lower part of Sodus sh., with a thin ls. separating it from underlying Bear Creek sh. This is position assigned to this ore by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10).

Steussy shale member (of Millsap Lake formation).

Pennsylvanian: North-central Texas.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 106, 107), from ms. of rept. by G. Scott and J. M. Armstrong, on geol. of Parker Co. (See under *Millsap Lake fm.*) Type loc. not stated.

Stevens series.

Paleozoic (?): Northeastern Washington (Stevens County).

C. E. Weaver, 1920 (Wash. Geol. Surv. Bull. 20, p. 49, map). *Stevens series.*—The metamorphosed sed. rocks of Stevens Co., which are divided into 11 apparently conformable members (descending): Mission argillites (including Northport ls.), 12,000± ft.; Clugston ls., 1,200± ft.; Colville qtzite, 5,000± ft.; Old Dominion ls., 1,500± ft.; Chewelah argillite, 4,000± ft.; Addy qtzite, 8,000± ft.; Deer Trail argillite (including Stensgar dol. memb.), 3,000± ft.; Eagle Mtn qtzite, 1,200± ft.; and Deer Lake argillite, 4,000± ft. Also includes the following additional named units, the relations of which to one another remain undetermined: Deep Lake argillite, 2,500± ft.; Republican Creek ls., 1,200± ft.; Lead Point argillite, 2,200± ft.; Red Top ls., 1,000± ft.; Fish Creek argillite, 1,500± ft.; Cedar Creek argillite, 2,500± ft.; and Boundary argillite, 4,000± ft. The series has been invaded and in many places greatly disturbed by batholithic masses of granite, syenite, and granodiorite. Is entirely unfossiliferous. The middle and lower members may represent middle and lower part of Paleozoic; the upper members are=Pend Oreille group of B. C. and possibly are upper Paleozoic. [On p. 114 author says upper part of Stevens series may be Mesozoic.]

Stevens Creek slates.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1908 (Repts and resolutions of General Assembly of S. C., regular sess. commencing Jan. 14, 1908, vol. 1, pp. 648–651; also S. C. Geol. Surv., ser. 4, Bull. 2, pp. 414–417, 1908). *Steven's Creek slates.*—Slates heretofore designated "Clay Slates," in which schistosity and slaty cleavage are highly developed. These slates were derived from basic igneous porphyries. Sericite schists and quartz monzonite schists are also included but chiefly along the boundaries.

Probably named for exposures on Stevens Creek, Edgefield Co.

Stevens Creek limestone. (In Borden group.)

Mississippian: Southeastern Indiana.

C. A. Malott, 1922 (Ind. Dept. Cons. Pub. 21, pt. 2, p. 193), in a section across Mitchell plain and Norman and Crawford uplands shows *Stevens Creek ls. lentil in Borden series* as exposed in middle of the Borden in Stevens Creek and in Brummets Creek, Norman upland, Monroe Co.

P. B. Stockdale, 1928 (Ohio Acad. Sci. Proc., vol. 8, pt. 4, p. 177). In vicinity of Borden the Borden group consists of (descending): Alternating layers of ss. and sandy sh., 40 ft.; lenticular ls. up to 5 ft. thick, named *Steven's Creek ls.* by C. A. Malott; massive ss., 100 ft.; sandy sh., 250 ft.; and pure sh., 150 ft.

P. B. Stockdale, 1930 (Ind. Acad. Sci. Proc., vol. 39, pp. 213–214). *Floyds Knob fm.*—Study of Borden rocks throughout unglaciated area of southern Ind. and incidental observation in adjacent parts of Ky. revealed a persistent unit in upper part of Borden group which has served as vital key to subdividing the rocks and to properly associating uppermost Borden fms. with overlying Harrodsburg and Salem lss. The name *Floyds Knob fm.* is being suggested for this fm. It exhibits several lithologic facies, the most common being ls. that is itself of differing traits from place to place. For this ls. facies the name *Goss Mill ls. facies* is being suggested. Thickness is commonly 3 to 4 ft., but at a few places it is as much as 8 ft. or more. Various Ind. workers have referred to the different ls. facies of Floyds Knob fm. as "Stevens Creek ls.," although the name has never been formally proposed in the literature. Preemption of the term by *Stevens Creek slates* of S. C. and confusion in interpretation of different beds which have been referred to same horizon in N. part of unglaciated area preclude continuation of "Stevens Creek." Floyds Knob fm. will be fully described in rept. for publication by Ind. Dept. Cons., Div. of Geol.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 54, 77, 194, 195, 215, 263, etc.). The ls. here named *Floyds Knob fm.* is an excellent key fm. It has often been spoken of as the "Stevens Creek ls." by Ind. workers, although the name has never been definitely proposed. No name has been specifically proposed in the literature for Floyds Knob fm. Most early Ind. workers entirely overlooked the fm.; some described it as merely a local lenticular occurrence of ls. within the "Knobstone ss." Among several students of Ind. geology the Floyds Knob fm. has been referred to as the "Stevens Creek ls.," as an outcome of usage begun by Malott, who suspected the significance and extent of the fm. The only published mention of this term, however, is in connection with a diagram showing a section across Monroe Co., where the bed is labeled *Stevens Creek ls. lentil* (Malott, 1922, p. 193). Glen Lee accepted Malott's designation by referring to it in his unpublished rept. as "Stephen's Creek ls." (Lee, 1924, p. 72 [of unpublished thesis]). In earlier times Ind. Univ. geologists, particularly Cumings and Beede, often spoke of the "Stobo lens," located in SE¼ sec. 33, T. 9 N., R. 1 E., and NE¼ sec. 4, T. 8 N., R. 1 E., near the old Stobo post office, 6½ mi. E. of Bloomington, and suspected the ls. as probably having a widespread distribution. However, the ls. quarry near old Stobo is in a crinoid bioherm, the bottom of the quarry being at a stratigraphic position some 25 to 30 ft. higher than the horizon, which is extensively traceable farther S. If it were entirely acceptable the writer would welcome the adoption of Malott's term "Stevens Creek" for the name of the fm. The term, however, is preempted. In 1908 Sloan applied "Steven's Creek slates" to an Archean deposit in S. C. Continuous field tracing has disclosed a number of points against desirability of *Stevens Creek*. The name was selected from a stream tributary to Salt Creek, flowing S. across west-center T. 9 N., R. 1 E., into north-center T. 8 N., R. 1 E., Monroe Co. Along much of valley of this stream the stratigraphy at and above horizon of Floyds Knob fm. is complicated and confusing. In many places, as at Stobo, crinoidal beds in bioherms occur quite far above horizon in question. At other places no definite ls. bed exists, but a zone of shaly, cherty rock, in some places calc., extending at places many ft. up into Edwardsville fm. is present. The name *Stevens Creek ls.* has been applied to a hard brown siliceous ls. bed, 2 to 5 ft. thick, which lies 25 ft. above base of true Floyds Knob fm., which farther S. has also been referred to as *Stevens Creek ls.* Both Floyds Knob ls. and the calc. memb. 25 ft. higher crop out in several places in Brown Co., to E. The upper bed, which is common to valley of Stevens Creek, is of much more limited and uncertain areal extent than the lower ls. bed to the S. The name *Stevens Creek ls.* is therefore abandoned, and replaced by *Floyds Knob fm.*, selected from a locality in which there is no possible confusion.

Stevenson limestone.

Carboniferous: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 47, 50). Included in Redtop fm.

Stewart andesites.

Devonian: New Brunswick.

W. V. Howard, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 477).

Stewart sand.

A subsurface sand in Kootenai fm. of Cutbank dist., Glacier Co., NW. Mont. According to J. G. Bartram (Geol. of nat. gas, A. A. P. G., 1935, pp. 257, 267) this sand is now called *Sunburst sand.*

Stewarts Landing facies.

Name applied by P. B. Stockdale (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76, 228, etc., 1931) to a lithologic development of his Edwardsville fm. in a part of southern Ind. and Jefferson Co., Ky.

†Stewartsville group.

Eocene: Western California.

B. L. Clark, 1918 (Geol. Soc. Am. Bull., vol. 29, p. 94).

Synonym of *Meganos*; printed through inadvertence.

Stewartville dolomite.

Middle Ordovician: Southeastern Minnesota, northeastern Iowa, and northwestern Illinois.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27). *Stewartville dol.* (*Maclurea bed*).—Uncon. overlies Prosser ls. and is uncon. overlain by Wykoff ls.=part of upper part of Galena dol.

R. S. Bassler, 1911 (U. S. Nat. Mus. Bull. 77, pp. 25–27). *Stewartville dol.*—Porous soft yellowish dol. and mottled mag. ls. (*Maclurea* bed) containing the *Maclurina manitobensis* fauna, 0 to 100 ft. thick; underlain by 0 to 20 ft. of unfossiliferous sandy mudstone. Overlies Prosser ls. Is top fm. of Trenton group.

Probably named for exposures at or near Stewartville, Olmsted Co., Minn.

A. C. Trowbridge, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 27). *Stewartville div.* of Galena dol. can be seen in Jo Daviess Co., Ill.

Stiles phyllite.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 400). *Stiles phyllite.*—Almost wholly sl. or phyllite, with fairly numerous thin beds of qtzite. Whole fm., including qtzite beds, has rather plain greenish aspect due to secondary chlorite. Weathers greenish gray or whitish gray. Much quartz in thin lenses and veins, especially in its eastern areas, where it is most metamorphosed. Occupies broad band along E. side of Taconic Range, curving westward and southwestward around end of the range. Thickness estimated at 400 or 500 ft. at N., and possibly twice that along E. side of range. Named for occurrence at Stiles Mtn [4 mi. SW. of Brandon, in Brandon quad.]. Underlies Hubbardton sl. and is rather sharply distinct from underlying Brezee phyllite.

†Stillwater sandstone. (In Conemaugh formation.)

Pennsylvanian: Eastern Ohio.

J. S. Newberry, 1874 (Ohio Geol. Surv. vol. 2, pl. opp. p. 81, p. 131). *Stillwater ss.*—Consists of ss., often cgl., 0 to 50 ft. thick, near base of Lower Barren Measures. Underlain by gray sh. and overlain by red and gray shales.

Same as Buffalo ss. memb. of Conemaugh fm.

Named for Big Stillwater Creek, Tuscarawas Co.

Stillwater formation.

Permian: Central and northern Oklahoma.

C. N. Gould, 1901 (Kans. Acad. Sci. Trans., vol. 17, p. 181). *Stillwater ss.*—Several hundred ft. of gray and brown sss. and shales below the Harper or Cimarron series. May eventually be proved to be but a southern continuation of the Sumner.

F. L. Aurin, H. G. Officer, and C. N. Gould, 1926 (A. A. P. G. Bull., vol. 10, pp. 786-799). *Stillwater fm.*—A series of red and gray sss. and red shales exposed in a zone extending N. and S. across east-central Okla. Ranges in thickness from 540 ft. in southern Kans. and northern Okla. to probably 800 ft. in east-central Okla. Occupies strat. interval btw. top of Herington ls. of Kans., or its southern equiv., and base of Cottonwood ls., or its southern equiv., thus corresponding to most of Marion fm. and all of Chase and Council Grove groups of Kans. Is basal fm. of Enid group. The Kans. subdivisions begin to lose their identity in region of Arkansas River in southern Osage, NE. Noble, and Pawnee Counties, Okla. By the time the color-change line has been reached the lss. are thinning rapidly and are being replaced by sss., while the shales begin to change their color from gray to red. Still farther S. the lss. disappear and entire fm. consists of alternating beds of red shales and red and gray sss. This is typical Stillwater, as exposed at Stillwater, Payne Co.

Stillwater formation.

Oligocene or Miocene: Southeastern Alaska (Controller Bay region).

G. C. Martin, 1908 (U. S. G. S. Bull. 335, pp. 24, 30). *Stillwater fm.*—Sh. and ss., without characteristic beds, so far as known. Thickness 1,000± ft. Underlies Kushtaka fm., probably conformably, and overlies Katalla fm. Occupies entire valley of Stillwater Creek and extends for some distance up valleys of Trout and Clear creeks.

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, p. 771). Little seems to be known regarding Stillwater fm. of Martin, which occurs to N. of Bering Lake.

Stillwater complex.

Pre-Cambrian: Montana.

J. W. Peoples, 1933 (Pan-Am. Geol., vol. 60, p. 152). In the pre-Camb. *Stillwater complex* of Mont. the rock facies consist of a norite (interpreted as a basal chill facies) on S. adjoined successively on N. by ultrabasic rocks 2,500 ft. thick, and then by banded noritic anorthositic facies. By analogy with *Bushveld complex* this may be interpreted as gravity stratification. Overlain uncon. by Camb. sediments. [Definitions of *Stillwater* and *Bushveld* are incomplete.]

Stine shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, pp. 83, 84, 89). *Stine sh.*—Blue, gray, and reddish sh. and 2 or 3 ls. seams, the lower one about 1 ft. thick, somewhat aren. and forming rounded blocks. Thickness 7 to 18 ft. in Nebr. and 12 to 14 ft. in NE. Kans. The sh. below the ls. layer is very fossiliferous. Underlies Houchen Creek ls. and overlies Americus ls. Included in Elmdale sh. Named for exposures in slopes S. of Stine, Nemaha Co., Nebr.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.), gave the following as correct strat. succession of subdivisions of this Admire sh. (descending): Oaks sh., Houchen Creek ls., Stine sh., Five Point ls., West Branch sh., Falls City ls., Hawxby sh., Aspinwall ls., and Towle sh. This classification not only transfers Houchen Creek ls. and Stine sh. from Elmdale sh. to Admire sh., but changes name of the ls. underlying Stine sh. to Five Point ls.

G. E. Condra, 1935. (See under *Hamlin sh.*)

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 50), adopted this name as defined by Condra and assigned the bed to Perm.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Stirling quartzite.

Lower Cambrian: Southeastern Nevada.

T. B. Nolan, 1928 (Am. Jour. Sci., 5th, vol. 17, pp. 461–472). *Stirling qtzite.*—Largely thick-bedded pink and gray qtzite containing local lenses of pebbles (chiefly of white vein quartz but with smaller proportion of red jasper); in many places interbedded with thin zones of sl. or mica schist. Thickness 3,700 ft. Grades into overlying Wood Canyon fm. and rests on Johnnie fm. Named for exposures on Mount Stirling, about 5 mi. E. of Johnnie mine, Spring Mtns, Clark Co.

Stissing dolomite.

Middle (?) and Lower Cambrian: Southeastern New York (Dutchess County).

C. D. Walcott, 1891 (U. S. G. S. Bull. 81, p. 360). [In this table Walcott mentions, among the Middle Camb. (Acadian) rocks:] "Limestones of Dutchess County, New York (*Stissing*), and central portions of Tennessee and Alabama sections (Coosa)."

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 26). *Stissing ls.* (*1891 Walcott*).—The name is from Stissing Mtn, in northern Dutchess Co. The beds to which this name is applied overlie *Olenellus* beds and contain fauna which is correlated by Walcott with Middle Cambric of Rocky Mtn province. It therefore represents the *Paradoxides* horizon but is without the *Paradoxides* of Atlantic sections.

E. B. Knopf, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 429–458). *Stissing dol.*—Consists of (descending): (1) Fine-grained sparkling gray dol. that contains considerable black chert and several fossil species; (2) shales and shaly dol., 40 ft.; (3) 60 ft. of heavy-bedded fine-grained white dol. with some sericite developed on bedding planes and joint planes, and 2 species of fossils. Overlies, probably discon., basal ("Poughquag") qtzite on S. and E. slopes of Stissing Mtn. Discon. underlies Hoyt dol. Total thickness 200± ft. Of Lower and Middle (?) Camb. age.

†Stissing quartzite.

Cambrian (?): Eastern New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, chart), showed *Stissing qtzite* as underlying *Potsdam ss. and sh.* and overlying *Georgia slates*, and in table on p. 9 he showed it as underlying *Georgia slates*, and as being basal fm. of Camb. In both table and chart included in Lower Camb. Is probably same as Cheshire (†Poughquag) qtzite, of Lower Camb. age, which is present on S. and E. slopes of Stissing Mtn, Dutchess Co.

Above is only record of *Stissing qtzite.*

Stobo limestone lens. (In Borden group.)

Mississippian: Southwestern Indiana (Monroe County).

A. B. Reagan, 1904 (Ind. Acad. Sci. Proc. 1903, p. 214). *Stobo ls. lens.*—On the whole the Knobstone fm. is nonfossiliferous. At intervals, however, as at Stobo post office [Monroe Co.], there are intercalated lenticular beds of ls. and calc. septaria with rich faunas, which consist of (descending): (1) Hard rough gray crinoidal ls., 1 ft.; (2) hard gray ls. with few fossils, 15 ft.; (3) hard gray ls. with rusty particles and crinoid stems, 5 ft.; (4) soft blue sandy sh., 10+ ft. Lies 90 to 99 ft. below top of Knobstone fm.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 194, 263, 265, etc.). [Abandons *Stobo ls.* and renames it *Floyds Knob ls.*] In earlier times Ind. Univ. geologists, particularly Cumings and Beede, often spoke of the "Stobo lens" located in SE¼ sec. 33, T. 9 N., R. 1 E., and NE¼ sec. 4, T. 8 N., R. 1 E., near old Stobo post office, 6½ mi. E. of Bloomington, and suspected the ls. as probably of widespread distribution. They generally considered it as correlative of the ls. fm. under question [Floyds Knob ls.] found farther S. and at other places in Monroe Co. However, the ls. quarry near old Stobo is in a crinoid bioherm, the bottom of quarry being some 25 to 30 ft. higher than the horizon which is extensively traceable farther S. Along hillsides and in ravines on W. side of Salt Creek valley, in N. center sec. 15 and SW¼ sec. 10, T. 8 N., R. 1 E., 2 to 2½ mi. SE. of old Stobo post office, the Floyds Knob fm. is represented by the usual calc. shaly zone, buff at weathered exposures, some 5 ft. thick, with Cutright ss. memb. of the Edwardsville a few ft. above. [On p. 265 he gives a section "slightly W. of old Stobo post office" in which thickness of Floyds Knob fm. is given as 15 ft. See also under *Stevens Creek ls.*]

Stockbridge limestone.

Cambrian and Ordovician: Western Massachusetts and Connecticut, southwestern Vermont, and eastern New York.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. of 2d dist., pp. 135–164). A coarse granular ls. of various colors, which I have denominated the *Stockbridge ls.*, taking its name from a well-known locality, one which has furnished to different parts of the Union a large proportion of the white and clouded marbles which have been so extensively employed for building and other purposes in construction. I have applied this name to all those varieties of ls. which are associated with those masses that are usually known in market as the Stockbridge marbles. Is second bed of ls. in Taconic system, being separated from underlying first bed of ls. by mag. sl. and from overlying third bed of ls. by granular quartz rock.

J. D. Dana, 1872 (Am. Jour. Sci., 3d, vol. 3, pp. 179–186, 250–256). *Stockbridge ls.*, the great metamorphic ls. of Green Mtn range. Is same as the Eolian of Vt. and extends southward and somewhat westward through Salisbury, Conn., and Dover and Pawling in Dutchess Co., N. Y., and continues for 7 or 8 mi. S. of Pawling. [Casually calls it *Pawling ls.* and *Poughquag ls.*] Generally admitted to be Lower Sil. and to represent more or less of time from Calciferous to Trenton periods. Chazy is probably present in it. It alternates with and is overlain by aren. mica schist. Is uncon. underlain by the qtzite of Green Mtn region [casually called *Green Mtn qtzite* and *Poughquag qtzite*].

T. N. Dale, 1891 (Am. Geol., vol. 8, pp. 1–7). *Stockbridge ls.* consists of 1,200 to 1,400 ft. of crystalline ls., in places a dol., quartzose or micaceous, more rarely feldspathic, rarely fossiliferous. In Mount Greylock, Mass., underlies Berkshire schist and overlies Vermont fm. (qtzite).

T. N. Dale, 1893 (U. S. G. S. 13th Ann. Rept., pt. 2, pp. 301–340). In Rensselaer grit plateau of eastern N. Y. the *Stockbridge ls.* conformably underlies Berkshire schist and is 1,000 to 1,400 ft. thick. Upper part is now generally admitted to be of Trenton, Chazy, and Calciferous age, while at least 470 ft. of lower part is Camb.

F. J. H. Merrill, 1901 (geol. map of N. Y.). [The "Cambro-Silurian metamorphosed crystalline ls." of SE. N. Y. is called *Stockbridge ls.* on map; and in accompanying N. Y. State Mus. Bull. 56, table opposite p. 34, 1901, the *Stockbridge ls.* of the map is shown to be=Trenton ls., Chazy ls., Beekmantown, Potsdam and Acadian.]

F. J. H. Merrill, 1904 (N. Y. State Geol. 23d Ann. Rept., pp. 195–198 and map; also N. Y. State Mus. 57th Ann. Rept.). The rocks of Beekman and Pawling Twps. Dutchess Co., N. Y. are mapped as (descending) Hudson schist, *Stockbridge ls.*, and Poughquag qtzite.

See also under *Barnegat ls.* and †*Poughquag ls.*

The present definition of Stockbridge ls. is a fm. of metamorphosed lss., underlying Berkshire (†Hudson) schist, overlying Cheshire (†Poughquag) qtzite, and comprising the metamorphosed equivalents of lss. of Mohawk and Champlain Valleys that range in age from Lower Camb. to Trenton, both inclusive. (See also †*Eolian ls.* and *Dorset ls.*, names that have been applied in SW. Vt.)

Named for prominent development and quarries around Stockbridge and West Stockbridge, in western Mass.

Stockholm band.

Name applied by A. C. Spencer, 1908 (U. S. G. S. Franklin Furnace folio, No. 161), to a part of Pochuck gneiss in Stockholm area of this quad.

Stockton limestone. (In Kanawha formation.)
Stockton cement bed.

Pennsylvanian: Southern West Virginia.

See under *Cannelton ls.* (1885).

Stockton formation. (In Newark group.)

Upper Triassic: New Jersey and southeastern Pennsylvania.

H. B. Kümmel, 1897 (N. J. Geol. Surv. Ann. Rept. State Geol. 1896, pp. 35–40, and Jour. Geol., vol. 5, pp. 543–544). *Stockton series.*—Interbedded coarse, more or less disintegrated arkose cgls.; yellow micaceous, feldspathic sss.; qtzite cgls.; brown-red sss. or freestones; and soft red argill. shales. The cgls. and yellow sss. prevail near bottom and the brown-red sss. near top. Thickness 2,300 to 6,700± ft. Underlies Lockatong series [fm.] and uncon. overlies older crystalline rocks. Is basal fm. of Newark system [group]. Exposed in quarries near Stockton [Hunterdon Co.], N. J.

Stockton shale. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, pp. 326–327). The plants of *Stockton fossiliferous sh.*, the roof sh. of Stockton coal in Kanawha Valley, are pronounced by D. White to belong to Allegheny fm. and to a position not higher than Clarion group. Writer, however, correlates Stockton sh. with Uffington sh. [For many years the Stockton coal and overlying sh., 4 to 50 ft. thick, have been included in Kanawha fm. in all repts of W. Va. Geol. Surv., their strat. position being given as beneath Kanawha black flint. According to D. White (Geol. Soc. Am. Bull., vol. 2, pp. 168–9) the Stockton coal lies 30 to 50 ft. beneath Black flint. The Stockton coal was so named because it was mined by Mr. Stockton.]

Stockton slate. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, pp. 152, 409–410). *Stockton sl., also Cannelton (Stockton) sh.*—Black sl., 15 ft. thick, with marine fossils, underlying Stockton ls. and overlying 2 ft. of black sl. containing fossil plants, or, where that is absent, resting on a coal bed.

Stockwether limestone member (of Pueblo formation).

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 417). *Stockwether bed.*—Mostly hard, rather brittle, rough-weathering gray, containing yellowish or light-colored chert nodules. Thickness 15 to 25 ft. Memb. of Cisco div. Overlies Coon Mtn bed and is separated from overlying Camp Colorado ls. by bed No. 13 (40 to 75 ft. of clay, mostly reddish).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 172, 174, and charts). *Stockwether ls. memb. of Pueblo fm.*—Overlies Camp Creek sh. memb. of Pueblo fm. and is separated from overlying Camp Colorado ls. memb. of Pueblo by sh. bed No. 13 of Drake. The Coon Mtn bed of Drake is largely Cretaceous. Named for Stockwether ranch, on Bull Creek, Coleman Co.

Wallace Lee and C. O. Nickell (ms. ready for publication by Tex. Geol. Survey) define *Stockwether ls. memb. of Pueblo fm.* as overlying Coon Mtn ss. memb., which rests on Camp Creek sh. memb. of Pueblo fm. This is approved definition of U. S. Geol. Survey.

†Stokes sandstone. (In Cheyenne sandstone.)

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 367). *Stokes ss.*—Leaf-bearing beds, comprising upper part of Elk Creek beds and consisting of a few ft. of more constantly aren. and consolidated sediments than lower part (Lanphier beds) of Elk Creek beds. Underlain by Lanphier beds and overlain by Champion shell bed.

Named for Stokes Draw, which proceeds from foot of Stokes Hill and S. of Lanphier Draw, in SE. corner of Kiowa Co.

This name was discarded by U. S. Geol. Survey in 1921, the beds being a local development of Cheyenne ss. and considered to be without strat. value.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9, p. 13), in summarizing Cragin's classification of Cheyenne ss., used *Stokes Hill ss.* (instead of *Stokes ss.*) for the upper part of Cragin's Elk Creek beds, and described the *Stokes Hill ss.* as a yellow medium-grained ss., a few ft. thick, that "was named from Stokes or Black Hill, a few mi. W. of Sun City."

Stokes sand.

A subsurface sand in top of Kansas City group in Eldorado oil field, Kans. Is correlated with Layton sand to S.

Stokes Hill sandstone.

Lower Cretaceous (Comanche series): Central southern Kansas. See 1924 entry under †*Stokes ss.*

Stollmeyer oil zone.

Stollmeyer Cruse shale.

Tertiary: Trinidad.

G. A. Macready, 1920 (Am. Inst. Min. and Met. Engrs. Trans. [preprint 1017], p. 9).

Stonebreaker limestone member (of Buck Creek formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

K. C. Heald, 1918 (U. S. G. S. Bull. 686K, pp. 130–131). *Stonebreaker ls.*—A series of thin lss. with intervening shales. The lss. are hard, tough, and sparingly fossiliferous. Weathered surface is light gray with many blotches of limonite yellow. Thickness 16 ft. In SE. corner of T. 27 N., R. 7 E., it lies 250± ft. below Foraker ls. The ls. has been more fully described by writer in U. S. G. S. Bull. 691C, 1918.

K. C. Heald, 1918 (U. S. G. S. Bull. 691C, pp. 61–64). *Stonebreaker ls.*, the highest prominent ls. above the "red lime" in NW. part of Pawhuska quad., lies 45± ft. below top of ss. B, the interval being filled with sh. with 2 or 3 thin beds of ls. The Stonebreaker is 2 to 16 ft. thick. Fresh surface is dark blue to light gray, with ocher-yellow limonite stains. Weathered surface is strongly stained with limonite, giving it a dirty-yellow blotched appearance. In NW. part of area there appears to be one bed, but in S. part, to W. of Parsons Switch, there are two beds, with an intermediate sh., all aggregating 12 ft. Named for Stonebreaker ranch [Pawhuska quad.], where it is well exposed.

H. T. Beckwith, 1928 (Okla. Geol. Surv. Bull. 40T). *Stonebreaker ls. memb. of Buck Creek fm.* lies 80 to 90 ft. below top of the Buck Creek in Osage Co., and higher than *Cryptozoon*-bearing ls. memb. It is 4 to 16 ft. thick in N. part of county and 50 or more in S. part of county. As it increases in thickness to S. it changes in appearance and character to some extent. In N. part of county it consists of one to three light- to dark-gray beds separated by rather thin sh. intervals. In S. part of county it consists of three distinct beds separated by a greater thickness of sandy sh. and sh. with some persistent ledges of ss.; some lss. are 10 ft. or more thick, are usually of lighter color, weather out differently, and are softer; the middle bed is thickest.

Stone City beds. (In Claiborne group.)

Eocene: Eastern Texas (Burleson, Brazos, and Leon Counties).

H. B. Stenzel, 1935 (Univ. Tex. Bull. 3501, pp. 267–279). *Crockett fm.* restricted to beds discon. above the marine Moseley ls., and the 85 ft. of underlying fossiliferous, partly marine beds down to top of Sparta sand in Stone City section, Burleson Co., are here named *Stone City beds*. They include Moseley ls. at top and Eaton lentil (marine) of Renick, and interfinger with underlying Sparta sand. How far they can be traced depends on detailed mapping. They have already been traced through Burleson, Brazos, and Leon Counties to Trinity River.

Stone Corral.

Permian: Central Kansas uplift.

E. A. Koester, 1935 (A. A. P. G. Bull., vol. 19, No. 10, p. 1410), used *Stone Corral* in table, where it is placed in lower part of Cimarron, but whether it is at base is not shown. No explanation of meaning of name is given.

Stonefort limestone member (of Tradewater formation).

Pennsylvanian: Southeastern Illinois (Saline and Williamson Counties).

L. G. Henbest, 1928 (Jour. Pal., vol. 2, pp. 70–71). *Stonefort ls. memb. of Tradewater fm.*—A fossiliferous ls., 2 to 3 ft. thick, lying 100± ft. below No. 2 coal (at base of Carbondale fm.), and 50± ft. above Bald Knob coal, in Saline and Williamson Counties, Ill., and probably extending into Ky. Fossils listed.

Named for exposures near Stonefort P. O. and station, Saline Co., Ill.

Stoneham oil sand.

Drillers' term for an oil sand forming basal memb. of Warren oil sand group in western Pa., which is Fourth sand at Stoneham, Warren Co. (See J. F. Carll, 1880, 2d Pa. Geol. Surv. Rept. I₃, p. 161. He also called it *Stoneham ss.*)

Stonehenge limestone member (of Beekmantown limestone).

Lower Ordovician: Central and central southern Pennsylvania, western Maryland, and northwestern Virginia.

G. W. Stose, 1908 (Jour. Geol., vol. 16, p. 703). Near base of Beekmantown ls. siliceous banded beds and large "edgewise" cgl. closely resembling underlying Conococheague ls. have been separated as a transition phase under name *Stonehenge memb. of the Beekmantown.*

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170). Thickness of *Stonehenge ls. memb. of Beekmantown ls.* is 485 ft. Exposed at Stonehenge, Franklin Co., Pa. Basal memb. of Beekmantown ls.

In central Pa. (Bellefonte and Hollidaysburg regions) the Beekmantown is treated as a *group*, divided (descending) into Bellefonte dol., Axemann ls., Nittany dol., and Stonehenge ls., the latter 0 to 702 ft. thick, and resting on Larke dol. and on Mines dol.

Stonehouse formation.

Silurian: Nova Scotia.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 203).

Stoner limestone. (In Stanton limestone.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 26, 27, 31, 33, 34, 36, 37). *Louisville ls.* is preoccupied hence *Stoner ls.* is proposed for this unit to include also Kiewitz sh. and so-called Du Bois ls. Thickness 14 to 16 ft. 8 in. Type loc. on Stoner farm, located NW. of South Bend, Cass Co., Nebr. Underlies Rock Lake sh. and overlies Eudora sh.

R. C. Moore does not use this name in Kans. See 1936 entry under *Olathe ls.*

Stones River group (also **Stones River limestone**).

Lower Ordovician (Chazy): Tennessee, northeastern Mississippi, western Virginia, western Maryland, northeastern West Virginia, and southern Pennsylvania.

J. M. Safford, 1851 (Am. Jour. Sci., 2d, vol. 12, pp. 353, 354–356). *Stones River group.*—Fossiliferous lss., 240 to 260 ft. thick, divided for convenience into three members, named (ascending) *Stones River beds, Lower Lebanon* [Lebanon of later repts] *ls.*, and *Upper Lebanon* [Carters] *ls.* The basal or Stones River beds are 75 ft. thick, blue and brownish-blue lss., mostly fine-grained and thick-bedded, some strata abounding in dark flinty layers. Lower Lebanon ls., 50 to 60 ft. thick, highly fossiliferous thin-bedded sky-blue lss., coarsely crystalline and abounding in calc. remains, sometimes separated by seams of argill. matter; grades into Upper Lebanon ls., which consists of 110 to 130 ft. of grayish, sometimes brownish, and blue thick-bedded lss., becoming thin-bedded and interstratified with occasional seams of clay in upper 15 or 20 ft. Underlies Nashville group. Oldest rocks in Middle Tenn.

Is of Chazy age. In central Tenn. now includes (descending) Lebanon, Ridley, Pierce, and Murfreesboro lss. The Lowville age of "Upper

Lebanon" or Carters ls. has been established by R. S. Bassler, E. O. Ulrich, and C. Butts, and that fm. is now excluded from Stones River group. In eastern Tenn. and western Va. the Stones River group is now divided by E. O. Ulrich and C. Butts into (descending) Lenoir ls., Mosheim ls., and Murfreesboro ls. Where not divided the Stones River rocks are called *Stones River ls.*

Named for exposures on Stone River, vicinity of Nashville, Tenn. Although the river is now called *Stone River*, the name of the deposits is firmly entrenched in the literature as *Stones River.*

†Stones River beds.

A name applied by Safford in 1851 to the part of Stones River group underlying Lebanon ls. and later subdivided into Ridley, Pierce, and Murfreesboro lss. See under *Stones River group.*

Stone's Switch sand.

Eocene (Jackson): Southeastern Texas (McMullen to Gonzales Counties).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1302, 1314, etc.). *Stone's Switch sand.*—Massive indurated qtzitic ss., 12 to 20 ft. thick, in Whitsett fm. as here defined. Name suggested by Sam Houston, who has traced it from King's Hills, McMullen Co., to E. part of Gonzales Co., where it is covered by overlap of Catahoula fm. Is quarried about 3 mi. S. of Campbellton, on J. Bowers survey. A railroad switch at this quarry was named Stone's Switch. Lies stratigraphically above Falls City sh. and below Dubose sands and clays, all zones in Whitsett fm.

Stonewall limestone.

Silurian: Manitoba.

E. M. Kindle, 1914 (Canada Geol. Surv. Summ. Rept. 1912, p. 249).

Stonewall quartz diorite.

Jurassic: Southern California (Cuyamaca region, San Diego County).

F. S. Hudson, 1922 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 13, No. 6, pp. 181, 191–193, map). *Stonewall quartz diorite.*—Named after Stonewall Peak, which is composed of this rock, which intrudes Julian schist.

Stonington gneiss.

Pre-Pennsylvanian: Southeastern Connecticut.

L. H. Martin, 1925 (Conn. Geol. and Nat. Hist. Surv. Bull. 33). *Stonington gneiss.*—Oldest igneous rock of Stonington region, because it is cut by all others. Is pre-Penn. and younger than the pre-Camb. schists.

Stonington beds.

Upper Ordovician (Richmond): Northern Michigan (Delta County).

R. C. Hussey, 1926 (Mich. Univ. Mus. Geol. Contr., vol. 2, No. 8, pp. 113–150). *Stonington beds.*—Middle division of Upper Ordovician Richmond fm. of Mich. Divided into Ogontz memb. above and Bay de Noc memb. below, both of which outcrop 1 mi. N. of Stonington P. O., on E. side of Little Bay de Noc. Rests discon. on Bill's Creek beds and is overlain by Big Hill beds.

Stony Brook beds. (In Chemung formation.)

Upper Devonian: Northeastern Pennsylvania.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7, pp. 68–73, 216–217). *Stony Brook beds.*—A series of olive-green sandy shales and shaly sss. filled with typical Chemung fossils. Occur in upper part of Chemung. Finely exposed at cutting along road where it crosses Stony Brook, Orange Twp, Columbia Co., and where it is 50 ft. thick.

Stonybrook quartzite.

Pre-Cambrian: Eastern Massachusetts (Boston Basin).

Walter E. Hobbs, 1899 (Am. Geol., vol. 23, p. 110). *Stonybrook qtzite,* 500± ft. thick. Becomes exceedingly fine-grained in upper part, and it may yet be found necessary to separate this portion as a siliceous mag. sl. Grades into overlying Kendall Green sl. Rests on Archean granite. Named for locality where best exposed [Stonybrook, Middlesex Co.].

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the rocks at and around Stonybrook as Westboro qtzite.

Stony Creek granite gneiss.

Pre-Triassic: Central southern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 147, 152, and map). *Stony Creek granite gneiss.*—Medium- to coarse-grained rock, composed largely of flesh-colored to pink orthoclase crystals, with subordinate white albite, small gray quartz grains, muscovite, and biotite. Is cut by Westerly granite and intrudes Mamacoke gneiss.

Named for occurrence at Stony Creek, a town in Branford Twp.

Stony Gap sandstone member (of Hinton formation).

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 298, 371). *Stony Gap ss.*—Light gray or white, massive, coarse, extremely hard and quartzitic, but without pebbles. Thickness 35 to 120 ft. Underlies Lower Bellepoint sh. Is basal memb. of Hinton group [fm.]. Replaces Hinton ss. of Stevenson, which conflicts with Hinton group [fm.]. Type loc. at village of Stony Gap, Mercer Co., on both sides of Bluefield-Princeton road. Can be traced through Tazewell, Russell, Scott, Wise, and Lee Counties, Va., to Cumberland Gap.

Stony Hills formation.

Permian: Southern Kansas and western Oklahoma.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 358, 363). *Stony Hills fm.*—Name suggested as more appropriate, for reasons stated, than Dog Creek fm. or sh., which in central Okla. becomes laminated with dolomites, which form a considerable part of its thickness, a large body of dol., called Chapman dol., forming its upper memb.

Same as Dog Creek sh., older name.

Named for Stony Hills, E. of Watonga, Blaine Co., Okla.

Stony Lonesome bed.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 334, 337–339). Further confusion has resulted from identification of that "Berea" bed (of Stony Lonesome, E. of Warren) by Ver Wiebe (and by Butts) with "Venango first oil sand." The Venango first sand is Woodcock ss. and not Berea (nor yet the Corry). Caster agrees with others in thinking the *Stony Lonesome bed* continuous with Pithole grit, the Corry ss., and, finally, with true Berea grit of Ohio, a correlation which writer formerly accepted without question, having seen no faunal lists. The Stony Lonesome bed rests (nearly) upon Knapp cgl., while the Pithole and Corry beds lie at different (sh.) intervals above the correlative Cussewago ss. [He listed the "fauna of the thin Stony Lonesome ('Berea') bed, Ver Wiebe's 'Venango first oil sand,' that rests almost directly upon Knapp cgl. in Warren region and may, indeed, be but the topmost stratum of Knapp fm."] Referred to Upper Dev.

G. H. Chadwick, 1935 (letter dated Dec. 11). *Stony Lonesome* has no standing. It was simply a convenience.

Stony Mountain formation.

Ordovician: Manitoba.

D. B. Dowling, 1901 (Canada Geol. Surv. Ann. Rept., n. s., vol. 11, p. 46F). *Stony Mtn fm.*, Ord., Canada.

Many subsequent Canada Geol. Surv. Repts, by Dowling, Malcolm, Wallace, and others, assign *Stony Mtn fm.* (and *Stony Mtn group*) to Ord.

A. K. Miller, 1930 (Am. Jour. Sci., 5th, vol. 20, p. 211), correlated Stony Mtn fm. of Manitoba with upper part of Bighorn dol., of Richmond age.

Stony Mountain shales.

Devonian: Manitoba.

R. C. Wallace, 1925 (Geological fms. of Manitoba, Nat. Hist. Soc. of Manitoba, p. 18), as listed by J. M. Nickles, assigned *Stony Mtn shales* of Manitoba to Devonian.

Stony Mountain limestone.

A. F. Foerste and T. E. Savage, 1927 (Denison Univ. Bull., Sci. Lab. Jour., vol. 22, p. 7), as listed by J. M. Nickles, assigned *Stony Mtn. ls.* of Manitoba to Ord.

Stony Point shale.

Middle (?) Ordovician: Northeastern New York and western Vermont (northern part of Champlain Basin).

R. Ruedemann, 1921 (N. Y. State Mus. Bull. 227, 228, pp. 112, 115–116). There is but one outcrop of sh. btw. Willsboro Point and Canadian bdy line, that at Stony Point, 1½ mi. S. of Rouses Point [Clinton Co.]. Fossils indicate it is older than Utica sh. and probably of late Trenton age. The black Ord. so-called "Utica" shales of Champlain Basin consist in the S. entirely of Canajoharie sh., and in the N. prevailingly of Stony Point sh. In the middle they may meet, the Stony Point sh. resting on Canajoharie sh. on Grand Isle and in Vt. portion of northern part of basin, while on N. Y. side the Canajoharie sh. is replaced by Cumberland Head sh., which places itself btw. lower div. of true Trenton ls. and the black Stony Point sh.

Storm King granite.

Pre-Cambrian: Southeastern New York (Putnam and Orange Counties).

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 364 and 377). *Storm King granite* has large development in Storm King [Putnam and Orange Counties] and Crows Nest Mtns and in Breakneck Ridge along N. border of the Highlands. Is intrusive into Fordham gneiss. Assigned to Pre-cambric.

C. P. Berkey, 1911 (N. Y. State Mus. Bull. 146). *Storm King Mtn gneissoid granite* (also *Storm King gneissoid granite*).—Is a rather acid coarse-grained reddish granite with considerable gneissoid structure. Constitutes whole of Storm King Mtn and larger part of Crows Nest on W. side of the Hudson; also forms chief rock of Bull Hill and Breakneck Ridge.

C. P. Berkey and Marion Rice, 1921 (N. Y. State Mus. Bull. 225, 226, map and passim). *Storm King granite.*—Medium- to coarse-grained, rather dark-colored, slightly greenish and sometimes greasy looking, with marked but crude gneissoid structure. Feldspars gray or red, quartz gray, and there is a strong black streaking of hornblende or augite. Biotite not abundant. Garnet in marginal portions. Intrusive into Grenville series.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68), classified this granite as of post-Glenarm pre-Camb. age.

Storm King Mountain gneissoid granite.

See under *Storm King granite.*

Stormville conglomerate.

Lower Devonian: Northeastern Pennsylvania (Monroe County).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 76, 132–133). *Stormville cgl.*—A calcareo-siliceous fossiliferous bed containing many quartz pebbles; 15 ft. thick. Underlies Stormville shales and overlies Stormville ls. in vicinity of Stormville, Monroe Co. All included in Lower Helderberg.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7), extended this name to several counties to NW. of Pike and Monroe Counties, and gave thickness of 4 to 7 ft.

Stormville hydraulic cement bed.

Stormville water lime.

Lower Devonian: Northeastern Pennsylvania.

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 136–137). *Stormville hydraulic cement bed* (also *Stormville water lime*).—A bed of water lime, usually pale buff, 5 to 10 ft. thick. Breaks with peculiar earthy fracture characteristic of hydraulic lss. No fossils. Underlies Stormville ls. and overlies Decker Ferry ls.

Stormville limestone.

Lower Devonian: Northeastern Pennsylvania (Monroe County).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 76, 133–135). *Stormville ls.*—Cherty, sandy massive lss., very fossiliferous, usually of gray color; 75 to 100 ft. thick. Underlies Stormville cgl. and overlies Stormville hydraulic cement bed. All included in Lower Helderberg.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7), extended this name to several counties NW. of Pike and Monroe Counties and gave thickness of 100 to 150 ft.

Stormville shale.

Lower Devonian: Northeastern Pennsylvania (Pike and Monroe Counties).

I. C. White, 1882 (2d Pa. Geol. Surv. Rept. G_6, pp. 76, 131–132). *Stormville shales.*—Limy fossiliferous ash-colored, often cherty shales, with a massive cherty ls. 10 ft. thick at base. Thickness 160 ft. Top fm. of Lower Helderberg in section from N. line of Monroe Co. to Delaware Water Gap. Underlies Oriskany ss. and overlies Stormville cgl. Well exposed in S. face of Walpack ridge just N. of village of Stormville, Monroe Co.

I. C. White, 1883 (2d Pa. Geol. Surv. Rept. G_7), extended this name to several counties to NW. of Pike and Monroe Counties, and gave thickness of 2 to 125 ft. In 1885 (2d Pa. Geol. Surv. Rept. T_3) White carried name *Stormville shales* over into Huntingdon Co., and applied it to 200 to 250 ft. of "dark-gray and black limy shales, with some sandy shales in places," underlying Oriskany ss. and overlying Lewistown ls. In U. S. G. S. Hollidaysburg-Huntingdon folio (No. 227) these beds are designated *Shriver ls.* and the overlying ss. is called *Ridgeley ss.*, the two composing the Oriskany group of that area.

Named for exposures at Stormville, Monroe Co.

Stormville sandstone.

Lower Devonian: Northeastern Pennsylvania (Monroe and Pike Counties) and northern New Jersey.

S. Weller, 1900 (N. J. Geol. Surv. Ann. Rept. State Geol. 1899, pp. 3–46), described *Stormville ss.* of Walpack Ridge, Sussex Co., N. J., and stated that it is intercalated btw. Coeymans and New Scotland lss. Also that, according to 2d Pa. Geol. Surv. Rept. G_6, pp. 132, 133, Stormville ss. becomes more and more conspicuous to S. and gradually replaces remaining members of New Scotland beds and superjacent strata.

Appears to be same as Stormville cgl. of 2d Pa. Geol. Surv. Rept. G_6, 1882, pp. 132–133.

Storrs tongue (of Star Point sandstone).

Upper Cretaceous: Central eastern Utah (Book Cliffs).

F. R. Clark, 1928 (U. S. G. S. Bull. 793). *Storrs tongue.*—Thick-bedded and thin-bedded ss. and sandy sh., 0–15 ft. thick, extending laterally from main mass of Star Point ss. into beds of marine Mancos sh. Lies lower than Spring Canyon tongue of Star Point ss. and higher than Panther tongue of Star Point ss. Forms prominent cliff at Storrs, Castlegate quad., Carbon Co.

Stovall limestone. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 49). *Stovall ls.*—Basal memb. of Winfield fm. Dark gray, granular, and quite fossiliferous. Is cherty from Nebr. to N. of Winfield, Kans., in a thickness increasing southward from 2± ft. to 4 ft. or more. It is noncherty at Winfield, beyond which it soon thins out southward, not reaching Arkansas City, Kans. We have followed it from Winfield, Kans., to Odell and Krider, Nebr. Overlies Gage sh. memb. of Doyle fm. and underlies Grant sh. memb. of Winfield fm. Type loc. in bluffs of Doyle Creek Valley SE. of Stovall elevator and farm, 7 mi. SW. of Florence, Kans.

Straight Cliffs sandstone.

Upper Cretaceous (uppermost Colorado): Central southern Utah (Kaiparowits Plateau).

H. E. Gregory and R. C. Moore, 1931 (U. S. G. S. P. P. 164). *Straight Cliffs ss.*—Very massive beds of light-yellowish or buff-brown fine- to medium-grained ss. Most of the hard massive beds are 3 to 10 ft. thick, but some exceed 60 ft. In several parts of Kaiparowits Plateau region contains workable beds of coal. In some districts thin streaks of carbonaceous sh. and poor coal occur almost from bottom to top of fm., but in other districts there is no coal. The chief coal zone is in middle third of fm., where beds 15 to 20 ft. thick occur. Thickness 900 to 1,250 ft. Conformably overlies Tropic sh. and conformably underlies Wahweap ss. The long line of nearly rectilinear cliffs fronting toward Escalante Valley is made by this fm. and suggests the name *Straight Cliffs*, which has been applied to it.

Straight Ridge sandstone member (of Pottsville formation).

Pennsylvanian: Central Alabama.

C. Butts, 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221). Resistant ss., 50 to 100 ft. thick, underlying Straight Ridge coal in Coosa coal field. Is a memb. of Pottsville fm. Lies 800± ft. above Wolf Ridge ss. memb. of Pottsville. Named for fact it forms Straight Ridge, which extends along W. side and S. end of Yellowleaf Basin, in Vandiver quad.

Stranger formation.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Stranger ss. and sh.* (new name), underlies Haskell ls. and uncon. overlies Lansing group redefined. Included in Douglas group redefined.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 93, 96). [See under *Douglas fm.*, Moore, 1932. On p. 46 *Stranger fm.* is described as consisting of 15+ ft. of buff soft cross-bedded ss. underlain by 1 ft. of brown ls. cgl. On p. 49 a thickness of 80 ft. is assigned to Stranger fm., the lower 40 ft. being massive buff cross-bedded soft ss. and the upper 40 ft. sh., ss., and coal beds.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 79–80). At base of Virgil series is fm. here called *Stranger fm.*, after Stranger Creek, near Tonganoxie, Kans.; typically exposed along E. side of sec. 3, T. 12 S., R. 21 E. It appears to be series of more or less disconnected channel deposits of ss. and sandy sh. extending from Leavenworth, Kans., S. into Okla. It is proposed to place upper limit of the Stranger at base of the thin ls. that underlies Lawrence sh. at Lawrence, Kans. This ls. has for many years been incorrectly called *Iatan ls.* It was later named *Haskell ls.* by Moore. Hinds and Greene (1915) showed true Iatan is a much older ls. From 8 to 10 ft. below Haskell ls. is Sibley coal. The marine sh. separating Haskell ls. and this coal has been named *Vinland sh.* by J. M. Patterson, in unpublished thesis. The dominantly sandy and nonmarine beds from top of Sibley coal to base of Stranger fm. were termed *Tonganoxie* by Patterson. The Stranger fm. is uncon. on various parts of Pedee and Lansing groups.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, 147). *Stranger fm.* as first defined embraced nonmarine channel ss. at base of Virgil series and shaly beds up to base of Haskell ls. This div. is not a natural one. Upper bdy was arbitrarily selected. A more desirable top bdy is hiatus at base of Ireland ss. Detailed observations show this uncon. is commonly, if not invariably, at or near top of Haskell ls. in NE. Kans., so that redefinition of Lawrence sh. at Lawrence, Kans., is not necessary. In southern Kans. the marine Robbins sh. occurs btw. Haskell ls. and uncon. at base of Ireland ss., and Lawrence sh. is restricted to beds above this uncon. Newell is author of name.

Stratford formation.

Pennsylvanian: Central southern Oklahoma.

G. D. Morgan, 1924 (Bureau of Geol. [Okla.] Bull. 2, pp. 137–140, pls. 3, 27, and map). *Stratford fm.*—At base is a series of lss., which constitute Hart ls. memb. Above this memb. is an undet. thickness largely composed of dark-colored shales. No suitable upper limit for Stratford fm. occurs in Stonewall quad., and since the region farther W. has not been investigated, none is here suggested. About

400 ft. of fm. is exposed in Stonewall quad. The shales contain a few sss., some of which are arkosic. Overlies Vanoss fm. Believed to underlie Konawa fm., but latter may prove to be in part=Stratford fm. Is part of Pontotoc terrane [group]. Included in Permian, but NE. from the point at which Stratford fm. is thought to be overlapped by Konawa fm. the Penn.-Perm. line is taken to be represented by base of Konawa fm.

Named for exposures at and around Stratford, Garvin Co.

Straven conglomerate member (of Pottsville formation).

Pennsylvanian: Central Alabama.

C. Butts, 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221). A very coarse cgl., 40 ft. thick, in upper part of Pottsville fm. in Cahaba coal field. Rests on Thompson coal. Named for Straven, Shelby Co., in Montevallo quad.

Straven coal group.

Pennsylvanian: Central Alabama.

A group of three coal beds in Pottsville fm. of Cahaba coal field, the lowest bed lying 940± ft. above Thompson coal, and the three beds occurring within a vertical section of 100± ft. May be=Dogwood coal group. Includes Upper Straven, Middle Straven, and Lower Straven coals.

Straw Hollow diorite.

Late Carboniferous or post-Carboniferous: Northeastern Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 219-220 and map). *Straw Hollow diorite.*—The rock of the great dike at type loc. at Straw Hollow, in Northboro, is porphyritic and contains saussuritized plagioclase phenocrysts nearly an in. long. Some other masses of rock are mapped with Straw Hollow diorite.

Strawn formation (also **group**).

Pennsylvanian (Allegheny): Central and northern Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvi). *Milburn-Strawn series.*—Alternating clays and shales and thin-bedded lss., with fire clay and coal, overlying Richland-Gordon sss. and underlying Brownwood-Ranger series.

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 361-398). *Strawn div.*—Shales, sss., and cgls., 3,000 ft. thick, uncon. overlying Millsap div. and underlying Canyon div. Top of coal No. 1, when present, is base.

In 1893 (Tex. Geol. Surv. 4th Ann. Rept. pt. 1) Cummins and N. F. Drake transferred "Millsap div." to the Strawn, and stated that it rested uncon. on Bend div. The U. S. Geol. Survey abandoned "Millsap" (conflict) in 1912, and has since included these beds in the Strawn, as have nearly all geologists since 1893. F. B. Plummer, however, in 1919 (A. A. P. G. Bull., vol. 3, pp. 132-145) excluded †Millsap from the Strawn and stated (under heading *Millsap div.*): Although in 1912 the Tex. Geol. Surv. dropped name Millsap for the lower series of lss. and shales beneath the typical Strawn sands and cgls., it now seems best to restore this name, as the 3 lower lss. are found to contain a fauna quite different from overlying Strawn beds.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 18-42, and Univ. Tex. Bull. 2132), divided *Strawn group* into Mineral Wells fm. (above) and Millsap fm. (below, including all beds beneath coal No. 1), but stated that fauna of latter beds, although not large, appears to be more closely related to that of Bend group than to that of Mineral Wells fm., and is sufficiently distinct to justify recognition of Millsap as a distinct fm. of Strawn group. R. C. Moore, 1929 (A. A. P. G. Bull., vol. 13, p. 888), continued to recognize Millsap as a distinct fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 105, 109), revised the definition of the Strawn by including in it, at the top, the Capps ls., and he divided it into Mineral Wells fm. restricted, Garner fm., and Millsap Lake fm. (=†Millsap of previous repts). This definition was adopted by U. S. Geol. Survey in 1935.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501), drew top of Strawn at *base* of Capps ls. and Rochelle cgl., both of which they included in Graford fm.

As now generally recognized the Strawn group underlies Canyon group and uncon. overlies Smithwick sh., and it is now classified by U. S. Geol. Survey as of Allegheny age.

Named for Strawn, Palo Pinto Co.

†Strawn limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 110). *Strawn ls.*—Ls., 6 ft. thick, in sh. interval btw. Burlington or Garnett ls. and Wyckoff ls. in section along Neosho River from Indian Territory to White City, Kans.

Preoccupied. Replaced by *Deer Creek ls.*, according to H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13), but according to R. C. Moore (Kans. Geol. Surv. Bull. 22, 1936, p. 172) this ls. is same as Lecompton ls.

Named for Strawn, Coffey Co.

Street Road limestone.

Cambrian: Southeastern Pennsylvania.

T. D. Rand, 1900 (Phila. Acad. Nat. Sci. Proc. 1900, pt. 1). *Street Road ls.* is Camb. according to Mr. Walcott.

Streetsville member.

Upper Ordovician (Richmond): Ontario.

W. S. Dyer, 1925 (Ont. Dept. Mines 32d Ann. Rept., pt. 7, p. 122).

Strelna formation.

Mississippian: Southeastern Alaska (Copper River region).

F. H. Moffit and J. B. Mertie, Jr., 1923 (U. S. G. S. Bull. 745, pp. 18–19, 21–28, table opp. p. 28, map). *Strelna fm.*—Basal fm. in Kotsina-Kuskulana dist. Is a complex of bedded lavas and tuffs intercalated with sed. beds and cut by basic intrusives. The rocks are chiefly stratified tuff beds and dense fine-grained basalt, with minor chert, argillite, sh., and ls. Thickness 7,000 to 8,000, possibly 10,000 ft. Underlies Nikolai greenstone [Permian], probably conformably. Named for occurrence in valley of Strelna Creek. The poorly preserved fossils indicate Miss. age, according to G. H. Girty, and suggest correlation with Lisburne ls.

Strickler limestone. (In Sumner group.)

Permian: Northeastern Kansas.

R. C. Moore, 1936. [See under *Donegal ls.*]

†Stringtown shale.

Lower and Middle (?) Ordovician: Southeastern Oklahoma (Atoka, Latimer, and Pushmataha Counties).

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Stringtown sh.*—Upper part black fissile cherty sh.; lower part greenish fissile friable shales with occasional inclusions of calc. cone-in-cone and ironstone concretions. Thickness 600 ft. Underlies Talihina chert. Base not defined. [In Ark. the name has been used in a restricted sense.]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 677). *Stringtown sh.* contains Normanskill fossils at 3 horizons. [U. S. Geol. Survey classifies Normanskill as of Chazy and Middle (?) Ord. age.]

B. F. Wallis, 1915 (Okla. Geol. Surv. Bull. 23, pp. 23–31). Talihina chert and most of Stringtown sh. were deposited in Ouachita Mtns while Viola ls. was being deposited in Arbuckle Mtns. Basal part of Stringtown is of Black River age and corresponds to upper part of Simpson fm.

C. W. Shannon and L. E. Trout, 1915 (Okla. Geol. Surv. Bull. 19, pt. 1, pp. 131–133). *Stringtown sh.* contains Upper Ord. fossils [?] in upper part. [On p. 429 of pt. 2 of Bull. 19 Shannon shows basal part of Stringtown sh. to be of Black River age.]

H. D. Miser, 1918 (U. S. G. S. Bull. 660, p. 67). The use of *Stringtown sh.* has been discontinued in this area [Caddo Gap and DeQueen quads., Ark.-Okla.] because the beds to which it has been applied do not form a mappable unit distinct from rest of sh. above Blakely ss.; because the graptolites supposed to be characteristic of it have apparently been found well down in underlying sh.; and because, according to E. O. Ulrich, the limits and character of Stringtown sh. at type loc. in Okla. are in doubt. With recognition of Blakely ss. as distinct fm., and failure to separate the Stringtown, it became necessary to give a new name (Womble sh.) to whole interval btw. Blakely ss. [below] and Bigfork chert [above].

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 34). *Stringtown sh.* is Lower Ord. and correlates with upper part of Simpson fm., Womble and Blakely sss., and St. Peter ("Burgen") ss.

H. D. Miser, 1926 (Okla. geol. map), placed Stringtown sh. opposite Womble schistose ss., Blakely ss., Mazarn sh., and St. Peter ("Burgen") ss.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45). *Stringtown or Womble sh.* underlies Bigfork chert, overlies Blakely ss., and is of basal Black River and upper Chazy (Blount) age.

The U. S. Geol. Survey has now replaced this name with *Womble sh.*, which affords a better type loc. and which contains in its upper part beds similar, lithologically and faunally, to Stringtown sh. (See paper by T. A. Hendricks, M. M. Knechtel, and J. Bridge, in A. A. P. G. Bull., vol. 21, No. 1, 1937, pp. 1–29.)

Named for Stringtown, Atoka Co.

Striped Peak formation.

Pre-Cambrian (Belt series): Northeastern Idaho and northwestern Montana (Coeur d'Alene district and Cabinet Mountains).

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, pp. 277–285). *Striped Peak fm.*—Siliceous sss., generally flaggy to shaly; mostly green and purple; ripple marks, sun cracks, etc. Thickness 1,000+ ft. Upper Algonkian fm. in Coeur d'Alene dist. Overlies Wallace fm. Largest areas occur near Striped Peak, Idaho, whence the name. Description of general geology of region is based almost wholly on work of F. C. Calkins.

Strites Pond formation.

Upper Cambrian: Quebec.

Name applied by H. W. McGerrigle (17th Rept. Vt. State Geol., pp. 182, 185, 1931) to A_2 of Logan's section of Philipsburg series of Quebec. McGerrigle mapped his *Strites Pond fm.* in small area in N. part of St. Albans quad., NW. Vt., stating that it extended about 4 mi. into that State. Logan described A_2 as consisting of 100 ft. of white and dove-gray pure compact lss. McGerrigle gave thickness as 400 ft. (See 1931 entry under *Philipsburg series.*) T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 6), classified this fm. as Ord., but paleontologists of U. S. Geol. Survey draw top of Camb. at top of this fm.

†Stromatopora beds.

A paleontologic name applied in some reports to Manlius ls. of N. Y.

†Strong flint. (In Chase group.)

Permian: Central Kansas.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 771–786, 799). *Strong flint.*—Two beds of light-gray ls. containing an abundance of flint in layers, separated by 18 ft. of massive light-gray or whitish ls. Total thickness 35 to 45 ft. Basal memb. of Chase fm. Overlain by shales in Chase fm. and underlain by Neosho fm.

Said to be same as Wreford ls., older name.

Named for Strong, Chase Co.

†Strong City beds.

Permian: Central Kansas.

L. C. Wooster, 1905 (The Carbf. rock system of eastern Kans.). *Strong City beds.*—Includes Strong flints or Wreford ls. and underlying Crusher Hill alternating shales and lss. Overlie Elmdale beds and underlie Cedar Point or Matfield shales. Elmdale beds as here used extends from top of Americus ls. to 12 ft. above Cottonwood ls., or to what appears to be top of Florena sh. memb. of Garrison fm.

Probably named for Strong, Chase Co.

Stuart shale.

Pennsylvanian: Central southern, central, and central eastern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Stuart sh.*—Blue and black clay sh., 90 to 280 ft. thick, with 10 to 50 ft. of ss. near center. Underlies Senora fm. and overlies Thurman ss.

Named for Stuart, Hughes Co., which is located on outcrop of fm.

Stull shale. (In Kanwaka shale.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). *Stull sh.* applied to top memb. of Kanwaka sh. in eastern Kans. Overlies Clay Creek ls. [Derivation of name not stated. On p. 52 *Stull sh.* is described as 26 ft. thick, of which upper 5 ft. consists of dark-bluish and yellow sh., clay, and sand, the middle 11 ft. of light yellowish-brown soft, partly cross-bedded ss., and the lower 10 ft. of bluish to yellowish sh., clay, and micaceous sand.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 171), more fully described this sh.; gave its thickness as 30± ft. near Stull and 45 ft. near Atchison; and stated type loc. is SE. cor. sec. 26, T. 12 S., R. 18 E., near village of Stull, Douglas Co., Kans.

Stump sandstone.

Upper Jurassic: Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98, pp. 76, 81). *Stump ss.*—Mainly thin-bedded gray to greenish-gray fine-grained sss. that weather into platy fragments about 1 in. thick. Near base are some beds of compact calc. ss., locally 6 ft. thick. At base is bed of grit or coarse-grained ss. containing marine Jurassic fossils. The Stump is usually resistant to weathering. Thickness 200 to 600 ft. Underlies Gannett group (Cret.?) and overlies Preuss ss. (Jurassic). Named for Stump Peak, at head of north fork of Stump Creek, about center of T. 6 S., R. 45 E. Boise meridian.

Stuntz conglomerate member (of Knife Lake slate).

Pre-Cambrian (pre-Huronian): Northeastern Minnesota (Vermilion district).

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept., p. 350). *Stuntz cgl., porodyte and porphyrel.*—Is older than Ogishke cgl. Named for exposures in vicinity of Stuntz Bay of Vermilion Lake.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 129, 131). The porphyry cgl. phase of Ogishke cgl. is confined mainly to area about Stuntz Bay. In the past it has been known as "Stuntz" cgl.

†Stuntz Island agglomerate.

A term applied by N. H. Winchell and H. V. Winchell in 1890 (Minn. Geol. Nat. Hist. Surv. Bull. 6) to a facies of Ogishke cgl.

Sturgeon quartzite.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Crystal Falls and other districts).

H. L. Smyth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 105+). *Sturgeon qtzite.*—Mainly coarse vitreous qtzite, of light-gray color. Also includes sheared qtzites or micaceous quartz schists. Thickness probably 430 to 500 ft. Underlies Randville dol. Is lowest memb. of Algonkian and rests on Archean granites and gneisses. Named for exposures along Sturgeon River.

Sturgis moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Sturgis, St. Joseph Co.

Sturm limestone. (In Lawrence shale.)

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 6, 33). *Sturm ls.*—Light-colored bluish impure ls. that weathers into nodular pellet-like forms. Thickness 6± ft. Is in Andrew (Lawrence) sh. Lies 4 ft. above Nebawka ls. and 6 ft. below Oreapolis ls. Exposed along North Branch of Weeping Water Creek btw. 2 and 4 mi. N. of Nebawka, with several good exposures near Sturm's school house, sec. 12, T. 10 N., R. 12 E. It is in bed of Weeping Water Creek 2 mi. W.-NW. of Nebawka, where it is marked by a ford in the creek.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 34), stated that Nehawka ls. is Iatan ls., but no mention is made of Sturm ls., and the name appears to have been dropped from the list of geol. units in Nebr. If Nehawka ls. is Iatan ls., the Sturm ls. is a bed in Lawrence sh.

Stuver series.

Mississippian: Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 240). *Stuver series.*—Chiefly hard flinty cgl. and qtzite, some sl. and sh. Exposed thickness 2,000 ft. Underlies Lisburne series (Dev.), and therefore tentatively assigned to pre-Dev.

Named for Mount Stuver, E. of Anaktuvuk River. Is now considered to be a part of Noatak fm. (Miss.).

†Styliola limestone.

†Styliolina limestone.

Paleontologic names applied in some early repts to ls. later named *Genundewa.*

sub-Aftonian drift (Pleistocene).

A name that has sometimes been applied to the oldest or Nebraskan glacial drift, because it underlies the Aftonian interglacial deposits.

sub-Blairsville red shale member (of Chemung formation).

Upper Devonian: Western Pennsylvania.

M. R. Campbell, 1904 (U. S. G. S. Latrobe folio, No. 110). *Sub-Blairsville sh. memb. of Chemung fm.*—Red sh. and ss., 320 to 450 ft. thick, lying on mass of sh. and ss. assigned to Chemung fm. Is 930 to 1,070 ft. below top of Pocono ss. and separated from the higher red sh. of the Pocono (Patton sh. memb.) by a variable mass of sh. and ss. The sub-Blairsville bed is not known at surface W. of Allegheny Front but presumably underlies entire region.

Named for occurrence in wells in vicinity of Blairsville, Indiana Co.

†sub-Carboniferous.

A name applied in many early repts to *Mississippian series.* As first used (by D. D. Owen) it included beds extending to base of Sil. lss. In some early repts called "Subcarboniferous."

†sub-Clarksville sand.

Upper Cretaceous (Gulf series): Southwestern Arkansas and northeastern Texas.

A. C. Veatch, 1906 (U. S. G. S. P. P. 46, pp. 24–25, and table opp. p. 16). *Sub-Clarksville sand.*—Sand bed which in Clarksville and Paris wells occurs near base of Brownstown (Taylor) fm. and to E. is found at top of Bingen sand. Does not outcrop in southern Ark. except as it may be represented as littoral deposits in upper part of Bingen sand. Thickness 50 to 100 ft.

Formerly considered to be same as Blossom sand but now considered by L. W. Stephenson to be probably older and of Eagle Ford or Woodbine age. Named for development in wells at Clarksville, Red River Co., Tex.

Subconglomerate measures.

A descriptive term applied in early Pa. Geol. Surv. repts. to the Miss. rocks of western Pa.

†sub-Olean conglomerate.

Devonian or Carboniferous: Southwestern New York and northwestern Pennsylvania.

C. A. Ashburner, 1880 (2d Pa. Geol. Surv. Rept. G_4, pp. 104–105). *Sub-Olean cgl. and ss. (Middle Pocono, No. X).*—Thickness 60 ft. Older than Olean cgl. (basal bed of Pottsville cgl.), and separated from it by 70 ft. of shales and sss.

Replaced by Knapp fm.

Sucarnoochee clay. (In Midway group.)

Eocene (lower): Southwestern Alabama.

E. A. Smith, 1892 (Sketch of geol. of Ala., pam. of 36 pp., Birmingham, Ala., Roberts & Son). *Sucarnochee clay* (also *Sucarnochee or Black Bluff group*).—Series of black clays, 100 ft. thick, well exposed at Black Bluff, on Sucarnochee River [Creek], and therefore called by latter name. Underlies Naheola series and overlies Clayton or Rutledge ls.

In present classification is middle fm. of Midway group, underlying Naheola fm. and overlying Clayton fm. Is same as Porters Creek clay, and of marine origin.

Named for exposures on Sucarnoochee Creek (the spelling adopted by U. S. Geog. Bd.) at Black Bluff, Sumter Co.

†Sudburian.

†Sudbury series.

Synonymous terms applied by A. P. Coleman to post-Laurentian rocks that form lower part of Huronian series (broad sense in which Huronian has been used by U. S. Geol. Survey for many years). For definition see U. S. G. S. Bull. 769, pp. 125–127.

Sudbury marble.

Lower Ordovician (Chazy): Southwestern Vermont (Rutland County).

Used in commercial sense as far back as 1861 (A. D. Hager, Rept. Geol. Vt., vol. 2).

A. Wing, 1877 (Am. Jour. Sci., 3d, vol. 13, pp. 334–347, 404–419). *Sudbury ls.* [heading] of western Vt. contains Trenton fossils. [He also said †Sparry ls. is of Trenton age.]

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 368). *Sudbury marble.*—For most part snow white, but contains a few beds of fine cream-colored dol. Outcrops in town of Sudbury, at NW. end of Taconic Range. No fossils, but appears to be of Chazy age. Rests on Beekmantown ls. and underlies ls. of Trenton age, being only separated from the latter by a heavy bed of gray dol.

Sudbury norite.

Pre-Cambrian: Ontario.

W. G. Miller, 1913 (12th Int. Geol. Cong. Guidebook 7, p. 7).

†Suffolk porphyry.

See *Praysville porphyry*.

Sugar Creek shale. (In Bethany Falls limestone.)

Pennsylvanian: Vicinity of Kansas City, Mo.-Kans.

C. O. Dunbar and G. E. Condra, 1932 (Nebr. Geol. Surv. Bull. 5, 2d ser., p. 17). published a table (table C) listing in one column "current nomenclature" in vicinity of Kansas City, and in the opp. column "Revised correlation by R. C. Moore, 1931," which showed Bethany Falls ls. of "current nomenclature" divided by R. C. Moore's "revised classification" into (descending) Swope ls., *Sugar Creek sh.*, and Middle Creek ls.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). introduced *Swope fm.* to include all beds from top of Bethany Falls ls. (restriction of R. C. Moore's 1931 definition) "to base of Schubert Creek ls. (called 'Hertha' by Hinds and Greene)." His restricted Bethany Falls ls. occupied position of Swope ls. of his 1931 classification, and the sh. separating this ls. from underlying Middle Creek ls. he named *Hushpuckney sh.*, and apparently abandoned his Sugar Creek sh.

Sugar Hill quartz monzonite.

Late Devonian or late Carboniferous: Northwestern New Hampshire (Moosilauke quadrangle).

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., Moosilauke map, p. 28). *Sugar Hill quartz monzonite.*—Medium-grained, pink, locally gneissic; late Dev. or late Carbf. Assigned to New Hampshire magma series. [Mapped on Ore Hill, 2± mi. SE. of Sugar Hill.]

Sugarloaf arkose. (In Newark group.)

Upper Triassic: Central Massachusetts and Connecticut.

B. K. Emerson, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 452). *Sugarloaf arkose*, or the feldspathic ss. and cgl. (shoreward rocks) of the Triassic of Mass. Thickness 700 to 3,000 ft.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; see also U. S. G. S. Mon. 29). [See 1898 entry under *Longmeadow ss.*]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 91–100). *Sugarloaf arkose.*—Coarse buff to pale-red ss., which in many places becomes so coarse that it can be called a cgl. Made up largely of debris of the granite and coarse pegmatite veins of high ground on W. or of Amherst-Leverett region on E. In central part of Mass. it extends from Conn. River westward, including the isolated area in Amherst village, and farther S. it occupies whole width of plain W. of Holyoke Range. All except possibly basal part is synchronous with Mount Toby cgl. to E. Is basal fm. of Newark group to W. Underlies Longmeadow ss. Talcott diabase of Conn. was deposited in early part of Sugarloaf time. Named for occurrence at Sugarloaf Mtn.

Sugarloaf sandstone.

Lower Cambrian: Central northern Maryland (Frederick County).

C. R. Keyes, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 306, 320–322). *Sugarloaf ss.* of Sugarloaf Mtn, Md., is seemingly identical with Catoctin ss.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Rept., vol. 1, p. 165). In Md. hills of qtzite appear, and at last a bold high ridge of qtzite called Sugarloaf Mtn. The *Sugarloaf ss.* (*qtzite*) is described as an unmistakable sedimentary rock. To E. of Sugarloaf is the great phyllite country of alternate belts of hydro-mica and chlorite sl., and these seem to be of later age than Sugarloaf ss., which is correlated with Chikis qtzite.

Sugarloaf metaquartzite.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 620, 623, 635). *Sugarloaf metaqtzite.*—Chiefly dense fine-grained vitreous metaqtzite of extreme purity and dull-white color, and without partings. Some parts characterized by distinctly bluish color quite unlike that of any other terrane in dist. Another common color is brownish white. Near top a few thin beds of fine cgl. of well-worn quartz pebbles in a matrix partly cemented with crystalline hematite. Thickness exposed varies from thin wedge to 1,900 ft. Underlies Nash marble series, but contact not seen. Conformably overlies Lookout schist. Exposed on NE. side of Sugarloaf Peak and elsewhere. Assigned to early Algonkian.

Sugar Loaf dacites.

Devonian: New Brunswick.

M. V. Howard, 1926 (Geol. Soc. Am. Bull., vol. 37, p. 484).

Sugar Loaf basalt.

Latest Pleistocene or Recent: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Sugar Loaf volcanics.*—Columnar-jointed basalt, nodular basalt, vesicular spatter, *aa* clinker, etc., erupted from Sugar Loaf Crater. Included in uppermost part of Honolulu volcanic series [q. v.]. Occurs at Honolulu.

Sugar Run sand.

Drillers' name for a subsurface sand in Bradford dist., NW. Pa., lying btw. Bradford First and Bradford Second sands and 525 ft. above Bradford Third sand.

†Suisun marble.

Age (?): Western California (Solano County).

J. D. Whitney, 1865 (Calif. Geol. Surv. vol. 1, p. 104). North of Suisun commences another series of hills, which has received the name "Pelevo Hills," at their SE. end, but which extend NW. and become merged in the chain known as "Vacca Mtns," the name given to the ridges here bounding Sacramento Valley on W. side. The Pelevo Hills are made up of Cret. strata. The well-known "Suisun marble" occurs in these sss., and is evidently a deposit from calc. springs. It is a deep brownish-yellow color with banded structure.

A local deposit of travertine of unknown age, according to F. L. Ransome.

Suitcase sand.

A subsurface sand, of Penn. age, 0 to 200 (?) ft. thick, in Burbank field, central northern Okla., that is correlated with part of Ochelata fm. It lies lower than Tonkawa sand and higher than Layton sand.

Sujeh formation.

Pre-Cambrian: British Columbia.

S. J. Schofield, 1915 (Canada Geol. Surv. Mem. 76, p. 33). Included in Purcell series.

Sukonk beds.

A misprint (on p. 382 of U. S. G. S. Bull. 191) for *Seekonk beds*.

Sukunka member.

Upper Cretaceous: British Columbia.

E. M. Spieker, 1922 (A. A. P. G. Bull., vol. 6, No. 2, pp. 112–126). Included in Dunvegan fm.

Sullivan formation.

Upper Cambrian: Alberta and British Columbia.

C. D. Walcott, 1920 (Smithsonian Misc. Coll., vol. 72, No. 1, p. 15). *Sullivan fm.*, Camb., Alberta. [Walcott fully defined this fm. in Smithsonian Misc. Coll., vol. 67, No. 8, p. 461, Mar. 5, 1923, when he assigned it to Upper Camb. Thickness 1,440 ft. Underlies Lyell fm. and overlies Arctomys fm.]

†Sullivanian series.

Cambrian: Alberta.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, pp. 285, 288). *Sullivanian series.*—In descending order: Oolites, 335–350 ft. thick; lss. or dol. 325–600 ft. thick; and shales (Bosworth?), 1,100–1,200 ft. thick. [On p. 288 the shales are excluded from Sullivanian series, under name "Bosworthian series."] Lies stratigraphically and uncon. below Sawbackian series and above Bosworthian series in Banff, Alberta. Of late Cambric age. Includes Paget oolites (above) and Thompson dolomites (below).

Sulphur Canyon sandstone bed. (In Price River formation.)

Upper Cretaceous: Central eastern Utah (Book Cliffs).

D. J. Fisher, 1935 (U. S. G. S. Bull. 852). *Sulphur Canyon ss. bed.*—Massive to medium-bedded ledge-making ss., buff to gray except for a white upper part. Weathers into blocky forms due to joints. Thickness 0 to 25 ft. Included in Neslen coal-bearing memb. of Price River fm. in E. part of Book Cliffs field. Lies 15± ft. above Thompsons Canyon ss. bed, and 0 to 14± ft. below Chesterfield coal zone. Is older than Bluecastle ss. bed to W. Named for Sulphur Canyon, T. 9 S., R. 100 W., Utah. Traced from Buck Canyon to Colo. line.

†Sulphur Creek group.

Upper Cretaceous (Colorado): Southwestern Wyoming, northwestern Colorado, and northeastern Utah (Uinta Mountains region).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 50, 154). *Sulphur Creek group.*—Black shales, occasionally friable sss., with carbonaceous shales and lignitic coal. Thickness 2,000 ft. In hills near Hilliard, Wyo., Sulphur Creek cuts through them for several miles. Underlies Salt Wells group and overlies Henrys Fork group.

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed Sulphur Creek group of Powell as=lower part of Hilliard fm. and of Niobrara and Benton age.

Sulphur Springs formation. (In Kinderhook group.)

Mississippian: Central eastern Missouri and southwestern Illinois.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 110). *Sulphur Springs fm.*—Basal fm. of Kinderhook group in area about Glen Park and Sulphur Springs, Mo. Consists of Bushberg ss. memb. (10 ft. thick) at top; Glen Park ls. memb. (oolitic ls. 5 ft. thick) in middle; and, at base, 0 to 15 ft. of sh. of either earliest Kinderhook or Dev. age. Underlain by Grand Tower ls.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 29), showed *Sulphur Springs fm.* uncon. below Fern Glen fm. and in places resting on Louisiana ls.

M. E. Wilson, 1922 (Mo. Bur. Geol. and Mines vol. 16, 2d ser.). Glen Park ls. memb. of Sulphur Springs fm. is correlated by Weller with upper part of Louisiana ls.

R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser., pp. 133–136, 140). *Sulphur Springs fm.* is exposed only in Ste. Genevieve and Jefferson Counties, Mo. The lower sh. memb. has not been definitely recognized except at Sulphur Springs. Fauna of Bushberg ss. memb. is essentially same as fauna of Glen Park ls. memb. The Glen Park ls. uncon. overlies Louisiana ls. in Calhoun Co., Ill. The Louisiana contains no species in common with the Glen Park. The Fern Glen fm. discon. overlies the Sulphur Springs. Lithologically and stratigraphically the Sulphur Springs fm. is closely related to Sylamore ss. of central and SW. Mo. and northern Ark., and may be correlated with it as a homotaxial equivalent. [In chart on p. 282 he showed Sulphur Springs fm. as younger than Louisiana ls. This chart showed following downward succession in Jersey and Calhoun Counties, SW. Ill.: Hannibal fm., Glen Park ls., Louisiana ls., Saverton sh., Grassy Creek sh., Dev.; and he gave same succession for western Ill. and NE. Mo. in Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, p. 245. In southern Ill. and SE. Mo. he showed (9th Conf., p. 245) Glen Park uncon. below Fern Glen and uncon. above Chattanooga. Ulrich applied *Glen Park ls. memb.* to 5 ft. of oolitic ls., which appears to be a smaller unit than Glen Park of Moore.]

S. Weller and S. St. Clair, 1928 (Mo. Bur. Geol. and Mines vol. 22, 2d ser., pp. 155–161, 165, 301). In Ste. Genevieve Co., Mo., the *Sulphur Springs fm.* is uncon. overlain by Fern Glen fm. It is everywhere uncon. underlain by Ord. It now occurs in patches only. The upper black sh. memb., 0 to 10 ft. thick, is similar lithologically to Chattanooga sh. The only fossil it contains is *Sporangites*, similar to those in the Chattanooga, but Sulphur Springs fm. is probably younger than typical manifestation of this fm. On basis of fauna at Hamburg, Ill., the Glen Park ls. has been correlated with some portion (upper part) of Louisiana ls., and this correlation may be accepted as including the whole of Sulphur Springs fm.

Named for exposures at Sulphur Springs, Jefferson Co., Mo.

Sultan limestone.

Devonian: Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 13, etc.). *Sultan ls.*—Lithologically divided into 3 members (descending): (1) Crystal Pass ls. memb., 150 to 260 ft.; (2) Valentine ls. memb., 75 to 380 ft.; (3) Ironside dol. memb., 5 to 125 ft. Most of fossils [listed] came from lower memb.; but some from middle memb.; no fossils in upper memb. According to E. Kirk the fossils are late Middle Dev. or early Upper Dev. Is overlain by Monte Cristo ls. (Miss.) and underlain by Goodsprings dol. (Dev.? to Upper Camb.). Well exposed in neighborhood of Sultan mine, Goodsprings quad. [Mr. Hewett sent an advance copy of his Goodsprings section and of the names he proposed to apply to the fms. to W. S. Glock, who in 1929 (Am. Jour. Sci., 5th, vol. 17, pp. 326 to 339) described the *Sultan ls.* in east-central part of Spring Mtn Range, Goodsprings quad.]

Sumas diorite.

Jurassic (?): Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines, Mem. 38, map 17, 1912). [Mapped *Sumas diorite* on NW. shore of Sumas Lake, which lies W. of 122° and N. of Int. Bdy.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 526). *Sumas granite* and *Sumas diorite* compose part of Sumas Mtn [B. C.(?)]. The diorite is the older. Both are Jurassic (?). May be contemp. with Custer granite gneiss.

Sumas granite.

See 1913 entry under *Sumas diorite*.

Summer formation.

Recent: Central southern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Summer fm.*—Varying thickness of sands and gravels, occurring as alluvial fans, etc. Type loc. on E. side of Summer Lake, Lake Co.

†Summerfield limestone. (In Conemaugh formation.)

Pennsylvanian: Eastern Ohio.

D. D. Condit, 1912 (Ohio Geol. Surv., 4th ser., Bull. 17, pp. 20, 23). *Summerfield ls.*—Nonmarine ls., 50 to 65 ft. below Pittsburg coal. Usually consists of soft gray, buff, or brownish amorphous ls. interbedded with clay. Probably = Lower Pittsburg ls. of Pa. and W. Va. Over much of southern Jefferson Co. the ls. is replaced by ss. or cgl. Included in Conemaugh fm.

Same as Lower Pittsburgh ls. memb., older name.

Named for Summerfield, Noble Co.

Summerhill sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania (Cambria County).

C. Butts, 1905 (U. S. G. S. Ebensburg folio, No. 133). *Summerhill ss.*—Generally laminated, but in places partly heavy bedded. Outcrops in bold ledge, about 50 ft. thick, high in bluff E. of Summerhill [Cambria Co.]. The Catholic Church at Wilmore is built on this ss. Varies in thickness from 30 to 60 ft. Included in Conemaugh fm. Its top is about 60 ft. below Wilmore ss. and it lies about 100 ft. above Ebensburg [Morgantown] ss.

Summerville formation. (In San Rafael group.)

Upper Jurassic: Southeastern Utah and southwestern Colorado.

J. Gilluly and J. B. Reeside, Jr., 1926 (U. S. G. S. Press Bull. 6064, March 30, 1926). [Name adopted at joint conference of J. Gilluly, J. B. Reeside, Jr., R. C. Moore, and H. E. Gregory, from area specially studied by Messrs. Gilluly and Reeside.] *Summerville fm.*—Thin-bedded chocolate-colored sss., earthy red-brown ss. and shales, some gyp., and in some sections a little ls. Thickness 125 to 331 ft. Top fm. of San Rafael group. Conformably overlies Curtis fm. and uncon. underlies Morrison fm.

Named for exposures at Summerville Point, just SE. of head of Summerville Wash, in N. end of San Rafael Swell, SE. Utah.

For additional details see U. S. G. S. P. P. 150, 1928 (by J. Gilluly and J. B. Reeside, Jr.), and U. S. G. S. P. P. 183, 1936 (by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.).

†Summit limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania (Lawrence and Beaver Counties).

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_5, pp. 25–26). *Summit ls.*—Slaty and slab-like ls. 5 ft. thick. Separated from underlying Brush Creek coal by 3 ft. of fire clay. Underlying beds concealed for 50 ft., down to Upper Freeport coal. Named for Summit cut on P. F. W. & C. R. R. in NW. part of Beaver Co.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2, p. 320). *Brush Creek (Summit) ls.*—Slaty dove-colored ls. charged with calcite. Underlies Brush Creek fire clay. Occurs in high knobs of Perry Twp, Lawrence Co.

Now considered same as Mahoning ls., the older name.

Summit limestone. (In Cherokee shale.)

Pennsylvanian: Northeastern Missouri.

W J McGee, 1892 (St. Louis Acad. Sci. Trans., vol. 5, p. 331). *Summit ls.*, 2 ft. thick, occurs at top of Lower Coal Measures in Macon Co. Separated from underlying Summit coal by 3 ft. of sh. or clay. Overlain by drift.

†Summit series. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania (Clarion County).

E. V. d'Invilliers, 1895 (2d Pa. Geol. Surv. vol. 3, pt. 2, p. 2377). In northern part of Clarion Co. the Clarion group is the "Summit series."

Summit type (of granite).

Pre-Cambrian: Eastern Colorado (Pikes Peak).

E. B. Mathews, 1900 (Jour. Geol., vol. 8, pp. 214–240). *Summit type of granite* shows very constant texture closely allied to that of granite porphyry. Confined to small area about Summit and down W. slope of highest part of Pikes Peak. Is younger than Pikes Peak type and older than Cripple Creek type.

Summit series.

A term applied by R. A. Daly (Canada Dept. Int., Rept. Chief Ast. 1910, vol. 2, pp. 47, 141, 178, 194, 1913) to rocks of the Selkirk Range, southern British Columbia, at 49th par., which he correlated with the pre-Camb. Belt series of Mont. and Idaho and with "a vast thickness of conformably overlying strata which may represent the whole Paleozoic succession up to and including the Sil." "Named for Summit Creek, Selkirk Mtns, along which a great part of the series is exposed." Divided into (descending): Lone Star fm., 2,000 ft.; Beehive fm., 7,000 ft.; Ripple fm., 1,650 ft.; Dewdney fm., 2,000 ft.; Wolf fm., 2,900 ft.; Monk fm., 5,500± ft.; Irene volcanics, 6,000 ft.; and Irene cgl., 5,000± ft. He correlated (p. 178) his Lone Star fm. with fms. in Idaho and Mont. which are of both Camb. and pre-Camb. age. But the rocks appear to belong chiefly if not wholly to Belt series of U. S. Geol. Survey.

†Summitville andesite. (Of Potosi volcanic series.)

Miocene: Southwestern Colorado.

E. S. Larsen, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 35–38). *Summitville andesite.*—Augite andesite flows and interbedded breccias and aggls. of like material. Thickness, 2,400+ ft. Included in Potosi volcanic series of Platoro-Summitville quad. Probably belongs to *Sheep Mtn fm.* Underlies Alboroto fm. and overlies Treasure Mtn latite. Named for extensive development in vicinity of Summitville, Rio Grande Co.

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718), gave thickness of this andesite as 3,000+ ft. in Platoro-Summitville dist. and reported its absence in Creede dist.

Later work by E. S. Larsen proved that the rocks around Summitville underlie, instead of overlie, Treasure Mtn latite, and that they belong to Conejos andesite. He therefore abandoned "Summitville," and applied *Sheep Mtn andesite* to the rocks underlying Alboroto quartz latite and overlying Treasure Mtn latite.

Summum sandstone. (In Carbondale formation.)

See under *Marietta.*

Summum cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to middle part of Carbondale fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated, but there is a village of that name in Fulton Co., Ill.

Sumner group.

Permian: Eastern Kansas and northern Oklahoma.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 9, 48). *Sumner div.*—Largely shales, but with some interbedded lss. Thickness 600 to 800 ft. Upper div. of Big Blue series. Divided into Wellington shales above and Geuda salt measures below. Overlies Chase lss. and underlies, probably uncon., Cimarron series.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, pp. 703–737). *Sumner stage* includes Wellington shales above and Marion fm. below, and rests on Winfield fm.

This definition was adopted by E. Haworth and J. Bennett in 1908 (Kans. Univ. Geol. Surv., vol. 9). J. W. Beede, 1909 (Jour. Geol., vol. 17, pp. 710–729), divided the Perm. rocks above Winfield ls. into Wellington stage above and Marion stage below, and included Luta ls. in his Marion stage.

R. C. Moore and W. P. Haynes, 1917 (Kans. Geol. Surv. Bull. 3), and R. C. Moore 1920 (Kans. Geol. Surv. Bull. 6, pt. 2), used *Big Blue group* to include Wellington fm. at top and Cottonwood ls. at base.

The U. S. Geol. Survey adopted *Sumner group* in 1910, to include Wellington fm. at top and Luta ls. at base, and this definition has since been followed generally. But R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), excluded Luta ls. from Sumner group and transferred it to Chase group. This modification has not been considered by U. S. Geol. Survey for its publications.

Named for Sumner Co., Kans.

†Sumpter epoch.

†Sumter epoch.

Pliocene and Miocene: Eastern South Carolina.

J. D. Dana, 1863 (Man. Geol., pp. 506, 511, 522, 798). *Sumter epoch.*—Includes Plio. and Mio. deposits of S. C. [which are now divided into several fms.].

The name has also been spelled *Sumpter*.

Named for development in Sumter dist., Sumter Co.

†Sunbeam monzonite.

Tertiary (post-Eocene): Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pls. 75, 77, pp. 644, 656–657). [*Sunbeam monzonite* as mapped included two types of rocks—a monzonite and a monzonite porphyry—which were mapped separately in U. S. G. S. P. P. 107, 1919.]

Named for Sunbeam mine.

Sunburst sand.

A subsurface gray ss., 5 to 50 ft. thick, forming basal part of Kootenai fm. (Lower Cret.) in Kevin-Sunburst oil field of Toole Co., central northern Mont. Lies at depth of about 1,550 ft.

Sunbury shale.

Mississippian: Ohio and northeastern Kentucky.

L. E. Hicks, 1878 (Am. Jour. Sci., 3d, vol. 16, pp. 216, 220). *Sunbury black sl.*—Black bituminous sh., 10 to 15 ft. thick, overlying Sunbury Calciferous Sandrock, 90 to 100 ft. thick, and underlying Raccoon shales [Cuyahoga fm.]. Included in Waverly group.

Underlies Cuyahoga fm. and overlies Berea ss., according to definition in use for many years.

Named for Sunbury, Delaware Co., Ohio.

†Sunbury Calciferous sandrock.

Mississippian and Devonian (?): Central Ohio.

L. E. Hicks, 1878 (Am. Jour. Sci., 3d, vol. 16, pp. 216, 220–222). *Sunbury Calciferous Sandrock.*—Shaly ss., compact ss. (somewhat calc.), and at bottom a few ft. of alternating shales and siliceous lss. Thickness 90 to 100 ft. Underlain by Huron sh. and overlain by Sunbury black sl. Near junction with underlying Huron sh. is stratum of calciferous sandrock, lying in huge rough concretionary masses, underlain by blue shales interstratified with thin layers of siliceous ls., the lowest of which rests directly on Huron sh. Included in Waverly group. [As thus defined includes equivalents of Berea ss., Bedford sh., Cleveland sh., and Chagrin sh. (?).]

Named for Sunbury, Delaware Co.

†Sun City marble.

Popular name for Medicine Lodge gyp. where quarried at Sun City, Barber Co., Kans.

Sundance formation.

Upper Jurassic: Southwestern South Dakota, Wyoming (widespread except southwestern Wyoming), central southern Montana (Stillwater to Rosebud Counties region), northwestern Nebraska, and central northern Colorado (as far S. as Loveland).

N. H. Darton, 1899 (Geol. Soc. Am. Bull., vol. 10, pp. 387–393). *Sundance fm.*—Green shales and thin-bedded sss., 60 to 400 ft. thick, underlying Unkpapa ss. and uncon. overlying Spearfish fm. (Red beds) in Black Hills. Marine Jurassic fossils abundant.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 520). *Sundance fm.* consists of dark-drab or green shales and buff or reddish sss. alternating, with 25 ft. of massive red ss. at base.

N. H. Darton and C. C. O'Harra, 1909 (U. S. G. S. Belle Fourche folio, No. 164, p. 3). Type loc. of *Sundance fm.* is above Sundance, not far SE. of Belle Fourche quad., S. Dak.

Sunday quartzite.

Pre-Cambrian (lower Huronian): Northwestern Michigan and northwestern Wisconsin (Penokee-Gogebic district).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pp. 225, 227, chart opp. p. 598, 605). *Sunday qtzite.*—Mainly qtzite, at least 150 ft. thick, with basal cgl. from a few in. to 10 ft. thick. Grades into overlying Bad River ls. Rests uncon. on Archean. May be same as Mesnard qtzite of Marquette dist. Named for two exposures E. of Sunday Lake, one a short distance E. of Little Presque Isle River and the other near Newport mine.

†Sunday Lake quartzite.

A name applied in some repts to *Sunday qtzite* of Penokee-Gogebic dist., Mich.

Sunderland formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

G. B. Shattuck, 1901 (Johns Hopkins Univ. Circ., vol. 20, No. 152, pp. 73–75). *Sunderland fm.*—Ice-borne boulders, gravel, sand, and loam, which change their mutual distribution both vertically and horizontally, after manner of shore deposits. They are frequently much altered and decayed and have been derived from fms. occurring in immediate vicinity, as well as from those found far W. in the mtns. In southern Md. the base of Sunderland terrace lies at about 90 ft., but rises gradually toward NW., until at Charlotte Hall (St. Marys Co., Md.) the surface of the bench is at 170 ft. Is next younger than Lafayette fm. and uncon. underlies Wicomico fm. Is extensively developed throughout Prince George's, Charles, St. Marys, and Calvert Counties, and numerous outliers exist on other parts of western shore from Herring Bay to Elkton, but continuity of fm. in this part of Md. has been destroyed. It is developed as an unmistakable terrane butting up against Piedmont Plateau or lapping around edges of the Lafayette. The scarp line at Charlotte Hall is part of the ancient sea cliff of Sunderland sea. Is basal fm. of Columbia group. The name is derived from hamlet of Sunderland, on the divide, in Calvert Co.

G. B. Shattuck, 1902 (Md. Geol. Surv. Cecil Co. Rept., p. 170). *Sunderland fm.* is a wave-built terrace, composed of clay, loam, sand, and gravel, 0 to 90 ft. thick. Base lies at about 90 ft. and upper limit at 160 to 180 ft.

M. R. Campbell, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 825–852). *Sunderland fm.* is not marine, but consists of two different fluviatile deposits, one deposited by Patuxent River and the other by Potomac River, and the two are not of same age. The hamlet of Sunderland is within the area deposited by Patuxent River. The name Sunderland should be abandoned as a fm. name.

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, Dec. 19), proposed to limit Wicomico to 95-foot level, *Sunderland* to 160-ft. level, Coharie to 215-foot level, and Brandywine to 270-ft. level. Later (16th Int. Geol. Cong. Guidebooks 5 and 12, 1932) Cooke fixed elev. of Sunderland fm. at 170 ft. The terrace fms. of Columbia group (including the Sunderland) now recognized by Cooke from Del. to southern Ga., and probably into Fla., are enumerated herein under *Columbia group*. Cooke regards all the fms. as chiefly marine terrace deposits.

Sunlight intrusives.

Miocene: Yellowstone National Park, Wyoming.

A. Hague et al., 1899 (U. S. G. S. Absaroka folio, No. 52) and 1904 (U. S. G. S. Mon. 32, Atlas). Cuts the early basic breccia.

Sunloch metagabbro.

Tertiary: British Columbia.

V. Dolmage, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 25).

Sunnybrook sand.

An oil-bearing sand in base of Hermitage fm. (of early Trenton age) of western Tenn., is known as *Lower Sunnybrook sand*, and a sand of Upper Ord. age is designated *Upper Sunnybrook sand*. The same names are used for two creviced lss. in Lexington fm. (of Trenton age) in Wayne Co., Ky.

Sunnyside limestone.

Carboniferous or Triassic: British Columbia.

C. Camsell, 1910 (Canada Geol. Surv. Mem. 2, pp. 47, 54). Assigned to Carbf. Included in Nickel Plate fm.

H. S. Bostock, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. A, pp. 207, 208). *Sunnyside ls.* assigned to Triassic.

†Sunrise series.

†Sunrise group.

Paleozoic and Mesozoic: Southern Alaska.

W. C. Mendenhall, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 305–307). About min. dist. of Turnagain Arm and vicinity, of which Sunrise City is center, is a series of metamorphic gold-bearing rocks to which name *Sunrise series* has been given. Wherever examined they consist of interbedded fine blue-black slates and dark-gray arkoses. Intruded by dikes. Outcrop all about W. waters of Prince William Sound, wherever the shores were examined. No fossils. Tentatively referred to upper Paleozoic.

Detailed mapping of type region showed that the rocks above described in this rapid reconn. rept included Paleozoic and Mesozoic beds, one more or less definite unit being of Upper Cret. age.

Sunrise formation.

Lower Jurassic: Southwestern Nevada (Tonopah and Hawthorne quadrangles).

S. W. Muller and H. G. Ferguson, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 241–252). *Sunrise fm.*—Shales, lss., and sss. of Lower Jurassic age, conformably underlying Dunlap fm. (Lower Jurassic) and conformably overlying Gabbs fm. (Upper Triassic). Thickness 0 to 1,200± ft. Named for Sunrise Flat, in Gabbs Valley Range. Type section is in upper part of New York Canyon, W. of Sunrise Flat.

Sunrise Springs series.

Tertiary or Pleistocene: Northeastern Arizona.

See 1932 entry under *Bidahochi fm.*

Sunset division. (In Arnheim formation.)

Upper Ordovician: Southwestern Ohio and north-central Kentucky.

A. F. Foerste, 1910 (Denison Univ. Sci. Lab. Bull. 16, p. 18). *Sunset div.*—Lower div. of Arnheim bed. On E. side of Cincinnati geanticline it is terminated by a layer containing *Platystrophia ponderosa*. Southward in Ky. this horizon consists of comparatively unfossiliferous argill. lss. containing comparatively few specimens of *Platystrophia*. Included in Richmond. Thickness 16 ft. Underlies Oregonia div. of Arnheim and overlies Mount Auburn beds (top div. of Maysville).

A. F. Foerste, 1912 (Ohio Nat., vol. 12, pp. 429–452). *Sunset div.* of Arnheim fm. differs lithologically from overlying Oregonia div. of Arnheim. Is included in Richmond only for reason that southward in Ky. it represents a period of diastrophic movement and is regarded as inaugurating a new period of sedimentation rather than closing a former period.

Named for Sunset, Fleming Co., Ky.

Sunset sandstone.

Lower Cretaceous: Alberta.

J. MacVicar, 1924 (Canada Geol. Surv. Summ. Rept. 1923, pt. B, p. 34). Assigned to Cret.

J. A. Allan and R. L. Rutherford, 1934 (Alberta Research Council Rept. 30, p. 32). Assigned to Lower Cret.

Sunshine Peak rhyolite.

Miocene: Southwestern Colorado (San Cristobal quadrangle).

E. S. Larsen, 1935 (U. S. G. S. Bull. 843). A local volcano poured out a considerable amount of this rhyolite on an irregular surface of Silverton volcanic series in NW. part of San Cristobal quad. and adjoining part of Uncompahgre quad. Named for exposures on Sunshine Peak, San Cristobal quad. Partly intrudes and partly uncon. overlies Picayune volcanic group. Confined to area about 12 mi. across. Has a uniform and distinctive character; is commonly dense, nearly white to quaker drab. Its intrusive portions carry many large inclusions of Picayune volcanic group. Assigned to Mio.

Supai formation. (Of Aubrey group.)

Permian and Pennsylvanian (?): Northern Arizona, southern Utah, southeastern Nevada.

N. H. Darton, 1910 (U. S. G. S. Bull. 435, pp. 21, 22, 25). *Supai fm.*—Name proposed for the red sss. and shales that constitute lower part of Aubrey group in northern Ariz. and form a definite strat. unit over wide area. In previous repts these rocks, together with the overlying gray ss. (herein named *Coconino ss.*), have usually been referred to as the "Aubrey ss. series." They are, however, distinct from the gray ss. throughout northern Ariz., but their separation from underlying Redwall ls. is not everywhere as clear as could be desired. Named for conspicuous exposures at Supai village, on Cataract Creek, northern Ariz. In Cataract Canyon and the side canyons near Supai settlement the fm. appears to be 1,400± ft. thick. At top are 400 ft. of red shales, in part sandy, with thin red ss. layers. The lower memb., about 1,000 ft. thick, consists of red sss. varying from coarse to fine and from slabby to cross-bedded, lying on about 75 ft. of red shales and soft red sss. Next below is Redwall ls., of which upper part is soft and contains some sh. partings. In Gilbert's section at mouth of Grand Canyon he included in top of Redwall ls. 510 ft. of alternating ss. and ls. which I believe belong to Supai fm.

L. F. Noble, 1922 (U. S. G. S. P. P. 131B, p. 64), removed from top of Supai fm. 267 to 317 ft. of deep brick-red sandy shales and fine-grained friable sss. (which he stated are uncon. on the underlying beds of the Supai) and named them *Hermit sh.* According to present definitions, therefore, the Supai fm. (restricted) is separated from overlying Coconino ss. by Hermit sh. In this same publication (pp. 54–60) Noble added to base of the Supai 200 to 510± ft. of red sandy sh., purplish and gray ls. with red chert, and reddish to buff calc. ss., of Penn. age, which Gilbert, Walcott, Darton, and other earlier writers had included in Redwall ls., but which Darton had suggested properly belong to Supai fm. Noble reported a probable uncon. btw. the Penn. and Miss. beds. Noble's definition is present approved definition of U. S. Geol. Survey.

In parts of southern Utah the gray Coconino ss. greatly thickens and occupies the time interval of a large part of the red Supai fm. See under *Coconino ss.* The Supai fm. as identified in SW. Utah and SE. Nev. probably includes the time equiv. of Hermit sh.

This fm. is now classified as Perm. and Penn. (?), because of its contained fossil plants, all of which were classified by D. White as of Perm. age. There is, however, a possibility some beds of Penn. age may be present in its basal part in some areas.

Supaian series.

A term employed by C. [R.] Keyes to designate the *Supai fm.* and supposedly contemp. deposits.

Superior amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Bohemian Range group, and is probably=Baltic amygdaloid. The mineralized part is the Superior lode. Named for occurrence in Superior mine, Houghton Co.

Superior flow.

Includes Superior amygdaloid and the underlying trap.

Superior sandstone.

An abbreviated form of *Lake Superior ss.* that is used by some geologists.

Superior drift.

A name that has been applied to red drift of Superior lobe of Labrador ice sheet (Wisconsin stage of Pleist.) in Superior Basin, Lake Superior region.

Superioran period.

Term introduced by C. [R.] Keyes. Same as his *Superioric period.*

Superioric period.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 201). Latest period of Proterozoic era in Lake Superior region. Includes Keweenawan lavas, Animikian slates, and the erosion interval separating them.

Superior West amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Bohemian Range group. Is first amygdaloid above or to W. of the Superior amygdaloid in Superior mine, Houghton Co. The mineralized part is the Superior West lode.

Superior West flow.

Includes Superior West amygdaloid and the underlying trap.

†Superjacent series.

A descriptive term used in a titular sense in folios and other early repts on Gold Belt region of northern Calif., to include the Cret., Tert., and Quat. deposits, in contradistinction to †Bedrock series, a term applied to underlying Jurassic, Triassic, and Carbf. fms.

Sur series.

Pre-Franciscan (possibly pre-Cambrian): Southern California (Southern Coast Ranges).

P. D. Trask, 1926 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 16, No. 6). *Sur series.*—The term *Santa Lucia series* was first applied to the crystalline complex of Santa Lucia Range by J. P. Smith in 1909 (Sci., n. s., vol. 30, p. 347). [Name used but not defined in publication cited.] The name *Santa Lucia*, however, had been previously applied by Lawson (1893) to the granite at N. end of Santa Lucia Range. It is very evident that the crystalline schists comprise a sed. series deposited prior to intrusion of the quartz diorite. At present both a series of sediments and the granite which intrudes them bear the same name. A new name should be applied to the schists, since, by priority, *Santa Lucia* should be given to the granite and quartz diorite. The name *Sur series* is proposed as a comprehensive name for the schist series of Southern Coast Ranges, which is particularly well developed along Sur River. Age unknown. No fossils have yet been found in this series. It is intruded by Santa Lucia quartz diorite, of pre-Chico age. It consists chiefly of sed. rocks now metamorphosed into qtzites, marbles, mica schists, paragneisses, and in part into injection gneiss. It includes the crystalline lss. that have been named *Gabilan ls.*

Surber sand.

A subsurface sand, of Penn. age, in Stephens Co., southern Okla., lying at 1,700 ft. depth in Empire pool, the Nigh sand lying at 1,600 ft. and the Cantrell at 1,800 ft.

Suretka conglomerate.

Tertiary: Costa Rica.

E. W. Berry, 1921 (U. S. Nat. Mus. Proc., vol. 59, p. 169).

†Surgent series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 106, 131–134, 272+, and vol. 2, p. 753) for Clinton "group" of N. Y. Divided into (descending) *Surgent red marl*, *Surgent upper ore sh.*, *Surgent ore ss.*, *Surgent lower ore sh.*, *Surgent upper sl.*, *Surgent iron ss.*, and *Surgent lower sl.*

Surprise formation.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930 (Econ. Geol., vol. 25, pp. 309–311 and map). *Surprise fm.*—A series of predominantly fine-textured flaggy or slaty rocks which occupy an irregular strip of country on W. side of Panamint Range. Prevailing rock types are cgl.-schist, actinolite schist, ottrelite schist, quartz-sericite schist, sl., phyllite, quartz-biotite-tourmaline schist, metamorphosed sss. and grits and a few beds of brown ls., and there exist all gradations and combinations of these rocks. Though bedding is not often seen, it is frequently suggested, and there can be no doubt as to sed. origin. Overlies Marvel dolomitic ls., usually with gradation from true ls. to true schist for a distance of 5 to 30 ft. Underlies Sour Dough dolomitic ls. (basal fm. of Telescope group) with noncon. Exposed along Surprise Canyon, S. part of Panamint Range. Assigned to lower Paleozoic (?).

F. M. Murphy, 1933 (Calif. State Div. Mines Rept. 28 of State Min., July–Oct. 1932, pp. 329–356). [Repeats 1930 definition, including (on p. 349 and on map) statement that Surprise fm. is separated from Telescope group by a noncon.; but in columnar section (on p. 336) he shows Surprise fm. as conformable with overlying Telescope group and the noncon. as in midst of Surprise fm. Gives rather detailed description of lithology.]

Sushitna slates.

Same as Susitna sl., the approved spelling.

Susitna slate.

Cretaceous and Jurassic (?): Southern Alaska (Cook Inlet region).

G. H. Eldridge, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 14–20, map). *Sushitna slates.*—Slates and schists, essentially qtzitic, varying from fine homogeneous rock to one of granular texture. Exposed up Sushitna River for 50± mi., from 15± mi. above mouth of the Chulitna to considerable distance above mouth of Indian Creek. [Thickness and age not given.]

The age of this fm. is now considered to be Cret. and Jurassic (?), and the river is now spelled *Susitna*.

Suslota limestone.

Carboniferous (upper): Central eastern Alaska (Mentasta Mountain region).

W. C. Mendenhall and F. C. Schrader, 1903 (U. S. G. S. P. P. 15, pp. 46–47). *Suslota series or Upper Carbf. ls.*—[In text called *Suslota ls.*] Medium- to heavy-bedded ls. intruded by igneous rocks. Occurs W. of Suslota Pass, where it plays prominent part in make-up of mtns.

†Susquehanna mica schist.

Pre-Cambrian: Northern Maryland.

W. B. Clark, E. B. Mathews, and E. W. Berry, 1918 (Md. Geol. Surv. vol. 10, table on p. 69). [Assigned to Camb.; not described.]

Same as Wissahickon fm. (pre-Camb.), according to E. B. Knopf (personal statement June 1922).

Susquehanna series.

G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108), proposed *Susquehanna series* as a geographic name for Upper Dev. series, to include Catskill to Tully, both inclusive.

Sutherland schistose complex.

Carboniferous (?): Southern British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines Mem. 38, map 9, 118° to 118°30'). *Sutherland schists.*—Phyllite, garnetiferous, epidotic, and actinolitic schists, etc.; Paleozoic (?). [Mapped on and around Sutherland Creek, B. C.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2). *Sutherland schistose complex.*—An intensely deformed series of lss., qtzites, and schists, sectioned by the railway line E. of Christina Lake. The oldest rocks are highly crystalline schists of sed. origin. With these are associated many irregular bands of gneissic gabbroid rocks, amphibolites, and sheared hornblende porphyrites; all greatly altered basic intrusives. Structurally characterized by utter confusion. No fossils. Possibly Carbf.

Sutherland oil sand.

A subsurface sand in lower part of Penn. section of Graham field, in NW. part of Carter Co., southern Okla., about 165 ft. below Bennett oil sand and 250 to 350 ft. above Smith sand. Thickness 20 to 40 ft.

Sutherland Falls marble.

Commercial name for a marble of Lower Ord. age in Rutland Co., SW. Vt. Mentioned, as a quarry term, as far back as 1861 (Rept. geol. Vt., vol. 2). Its outcrops are shown by G. W. Bain, 16th Int. Geol. Cong. Guidebook 1, 1933, fig. 19, p. 86. E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assign it to Chazy epoch. Sutherland Falls, on Otter Creek, at Proctor, drop 122 ft. Village of Proctor was known as Sutherland Falls until 1884, when it was incorporated as Proctor.

Sutter formation.

Eocene (?): Northern California (Marysville Buttes region, Sutter County).

R. E. Dickerson, 1916 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 9, pp. 404–406). *Sutter fm.*—Chiefly rhyolitic ash, rhyolitic tuff-breccia, thin flows of rhyolite, and cgl. containing rhyolitic and quartz pebbles. Thickness 500 to 600 ft. Rests with marked uncon. on Chico and on Tejon. Overlain uncon. by lava flows and mud flows that consist of andesitic material. Included in upper part of Ione fm. as mapped in Marysville folio of U. S. Geol. Survey, which also included Tejon and Chico rocks. Named for occurrence in Sutter Co., in what is now known as Marysville Buttes (formerly Sutter Buttes).

Howel Williams, 1929 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, pp. 112, 129+). *Sutter fm.*—Predominantly washed rhyolite tuffs below and andesite tuffs above, admixed with sands, clays, and gravels. Thickness 500 to 1,000+ ft.

Overlies Butte gravels and is overlain, with erosion uncon., by intrusive andesite porphyry. Assigned to Mio. and Plio (?). Dickerson's original description of Sutter beds calls for drastic revision. Essentially the Sutter fm. is detrital equiv. of the Tert. rhyolitic and andesidc deposits of Sierra Nevada, admixed with sediments that are the equivalents in age of the 6 auriferous gravels of the intervolcanic period of the Sierra. Although the Sierra was unquestionably the chief source of the Sutter beds, it is likely that part of the sediments was also derived from the Coast Ranges. Its volcanic materials appear to be entirely pyroclastic and free from lava flows, and there is nothing in the fm. to suggest a derivation from local vents, as Dickerson has supposed. The most notable and persistent feature of Sutter fm. is the regularity and prominence of its banding. Most complete and typical section is along West Butte Pass, adjacent to road bridge that lies due S. of South Butte.

W. Stalder, 1932 (A. A. P. G. Bull., vol. 16, No. 4, pp. 361–364). *Sutter fm.*, consisting of 1,000 or more ft. of sss., gravels, and clays, is probably Mio. or Plio.

†Sutton gneiss.

Pre-Cambrian: Central southern Massachusetts and northwestern Rhode Island.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). [*Sutton gneiss* is shown in strat. table of Worcester Co., Mass., as underlying Grafton qtzite and cgl. and overlying Northbridge gneiss.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped this rock as Northbridge granite gneiss and abandoned "Sutton gneiss," because, as stated in personal communication, Northbridge was better established and afforded a better type loc., Northbridge being in midst of the fm.

Named for exposures E. of Sutton, Worcester Co., Mass.

Sutton formation.

Jurassic and Triassic (?): British Columbia.

C. H. Clapp and J. A. Allan, 1911 (Canada Geol. Surv. map 17A), and C. H. Clapp, 1912 (Canada Geol. Surv. Mem. 13, p. 61).

Sutton limestone. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1917 (W. Va. Geol. Surv. Rept. Braxton and Clay Counties, p. 218). *Sutton ls.*—Calc. stratum, dark gray on fresh fracture, weathers yellowish gray; somewhat siliceous; 0 to 3 ft. thick. Lies 0 to 24 ft. below Upper Mahoning ss. and 0 to 15 ft. above Middle Mahoning ss. Exposed just E. of B. & O. R. R. station at Sutton, Braxton Co.

Sutton schists.

Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11).

Sutton Island series.

Cambrian or pre-Cambrian(?): Southeastern Maine (Mount Desert Island region).

N. S. Shaler, 1889 (U. S. G. S. 8th Ann. Rept., pt. 2, pp. 1037, 1041–1043, 1061, and map). *Sutton Island series.*—Highly metamorphosed dark-greenish and grayish thick flaggy clay slates, with qtzites, bedded felsites, and associated traps. This so-called series cannot be proved to be a continuous section. It consists of two divided portions, that which is found on Sutton's Island and that which appears on Cranberry Islands. Resembles similar deposits on Campobello and Deer Islands, in Passamaquoddy Bay. [See †*Campobello series.*] Is mapped across S. part of Mount Desert Island and on Sutton Island. No trace of fossils. The Sutton's Island group of rocks, though containing an abundance of volcanic material, shows no trace of the volcanic breccias which abound in the Cranberry series. Assigned to Camb. or pre-Camb. Named for development on Sutton Island, S. of Mount Desert Island.

On 1933 geol. map of Maine, by A. Keith, the rocks of Sutton Island appear to be mapped as "igneous, mainly Carbf."

Sutton Mountain series.

Sutton Mountain gneiss.

Pre-Cambrian: Southern Quebec and northwestern Vermont.

J. A. Dresser, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 210). *Sutton Mtn series*, pre-Camb., Quebec.

R. Harvie, Jr., 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 288). *Sutton Mtn series*, pre-Camb., Quebec.

S. B. Keith and G. W. Bain, 1932 (Econ. Geol., vol. 27, p. 174). *Sutton Mtn gneiss*, pre-Camb., occurs in Green Mtn geanticline, Vt. Light gray; distinct banded structure; greatly contorted locally.

Suwanee basalt flow.

See under *Laguna basalt flow*.

Suwannee limestone. (Of Vicksburg group.)

Oligocene (middle): Eastern Florida and south-central Georgia (Lowndes and Brooks Counties).

C. W. Cooke and W. C. Mansfield, 1936 (Geol. Soc. Am. Proc. 1935, pp. 71–72). *Suwannee ls.* is proposed for yellowish ls. typically exposed along Suwannee River in Fla., from Ellaville, where it uncon. overlies white ls. containing Vicksburg (Olig.) fossils, almost to White Springs, near which it lies uncon. below Hawthorn fm. (Mio.). Another large area of the ls., centering near Brooksville, Hernando Co., lies btw. Ocala ls. (Eo.) on N., and Tampa ls. (Mio.) on S. Most writers have regarded this ls. as part of Tampa ls. Writers think it is of late Vicksburg age and correlate it tentatively with Flint River fm. of Ga. and Chickasawhay marl memb. of Byram marl of Miss.

Swaggart sand.

A subsurface sand, of Penn. age, in central northern Okla., which is correlated with Tonkawa sand and with lower part of Nelagoney fm.

Swakane gneiss.

Pre-Ordovician: Central Washington (Entiat Mountains).

A. C. Waters, 1932 (Jour. Geol., vol. 40, No. 7, pp. 603–633). *Swakane gneiss.*—A complex of remarkably foliated, highly metamorphic rocks, in part sed. and in part igneous. Biotite gneiss predominates, but the fm. also includes granodiorite gneiss, amphibolite, amphibolite schist, marble, mica schist, and masses of serpentine. The most widespread sed. rock is a series of marble lenses and associated lime-silicate rocks which occur for most part in NW. cor. of area. Associated with the marble are belts of gneiss that show by their mineralogical composition that they are of sed. origin. Finest occurrence of Swakane gneiss is along canyon of Swakane Creek, for which it is named. Is oldest fm. in Entiat Mtns. Overlain uncon. by Swauk fm. (early Eo.) and intruded by Chelan batholith (probably late Jurassic). Peshastin fm. outcrops a few mi. SW. of this area. Warren S. Smith (Jour. Geol., vol. 24, 1916) correlates the Peshastin with a series of sed. rocks in Skykomish Basin to W. that contains definite Trenton fossils. On basis of comparative metamorphism the Swakane gneiss is therefore pre-Ord.

†Swallow limestone.

Pennsylvanian: Southeastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, pp. 104–105). *Swallow ls.*—First ls. system underlying Oswego ls., being a thin bed exposed about 7 mi. below Oswego. Named by Dr. Newlin on account of its having been described by Prof. Swallow in 1854. Included in Cherokee shales, unless it should prove to be more extensive in Cherokee Co. than now seems probable, in which case the term *Cherokee sh.* should be applied only to shales below Swallow ls.

Not a geographic name. The beds are included in Cherokee sh.

Swallow belt, terrane, or formations.

C. [R.] Keyes, 1933 (Pan-Am. Geol., vol. 59, pp. 132–135). *Permian* is inappropriate term for the Carbonic red-beds of Great Plains. For the miscellaneous collection of sediments or terranes now being called *Permian*, some such title as *Swallow* [nongeographic] *belt, terrane, or fms.*, or *Dumble beds* [nongeographic], might be adopted with great advantage. "Such course does not imply necessarily definite correlation, or specific geologic age, but merely pertains to the broad body of strata which pioneer who first brought the fms. as a whole into the attention of geologists." [Also uses *Swallowal or Dumblal group of strata* or *terrane*, pp. 135, 140.]

Swan Creek phosphate.

Upper Devonian or Mississippian: Western Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 136, 137, 138, 142). *Swan Creek phosphate.*—The phosphate rock of Swan Creek, Totty's Bend, and other localities in Lewis and Hickman Counties, Tenn., where it ranges in thickness from 10 to 50 in. or more; outside of this area it ranges from 1 in. to 10 in. One variety is dark bluish gray, fine-grained, weathering yellowish gray and then looking like ss. Another variety is lighter-colored and coarser and abounds in small spiral shells and other minute fossils. Sometimes it disintegrates and forms a white claylike substance. Contains very little ls. matter. Is closely associated with Hardin ss. and often apparently becomes the Hardin ss. Overlies Hardin ss. and underlies Dev. Chattanooga sh. [according to pp. 104 and 136].

The Hardin ss. is treated as a memb. of Chattanooga sh. According to E. O. Ulrich and C. W. Hayes (U. S. G. S. Columbia folio, No. 95) this phosphatic band is to SW. replaced by Hardin ss. memb.

Named for Swan Creek, Lewis and Hickman Counties.

Swan Creek limestone.

Upper Ordovician: Western Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 43-44). *Swan Creek ls.*—Cross-bedded, nearly unfossiliferous Ord. ls. in Tenn. River Valley. About 56 ft. thick. Of Lorraine age. Underlies Warren [Arnheim] ls. and overlies richly fossiliferous Lorraine ls. containing *Platystrophia lynx*.

Named for Swan Creek, Hickman Co.

Swan Creek sandstone.

Mississippian: Southwestern Illinois (Union County).

E. O. Ulrich, 1923 (Geol. Soc. Am. Bull., vol. 33, p. 831), stated that *Swan Creek ss.* was a field name applied by him to 20 ft. of ss. overlying the *Talarocrinus*-bearing zone in upper part of Ste. Genevieve ls. and corresponding to "some part of the Shetlerville." Exposed along Swan Creek, 1½ to 2½ mi. E. of Anna, Union Co.

Swandyke hornblende gneiss.

Pre-Cambrian: Central Colorado.

T. S. Lovering, 1935 (U. S. G. S. P. P. 178). *Swandyke hornblende gneiss.*—Chiefly hornblende gneiss, but subordinate quartz-biotite schists and gneisses and injection gneiss are common. Is a highly metamorphosed igneous rock intermediate btw. diorite and gabbro. In this quad. [Montezuma] it forms a thick sill-like mass in Idaho Springs fm., with which it is essentially conformable, in most places gradational, but areal relations shown on map suggest a large laccolithic mass or a thick surface flow intercalated in Idaho Springs fm.

On 1935 Colo. geol. map this fm. was included in Gunnison River series (comprising the oldest exposed rocks in Colo.) and assigned to *pre-Camb.*, the terms "Algonkian system" and "Archean system" having been discarded by U. S. Geol. Survey.

Swan Island moraine.

Pleistocene (Wisconsin): Southwestern Maine.

G. H. Stone, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 380). *Swan Island moraine.*—Probably a terminal moraine. Named for occurrence on Swan Island, in Kennebec River, S. of Richmond, Sagadahoc Co.

Swan Peak quartzite.

Lower Ordovician: Northeastern Utah and southeastern Idaho.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 407, 409). *Swan Peak qtzite.*—Fine-textured gray qtzite, 500 ft. thick. Chazy (?) fauna. Underlies (uncon.?) Fish Haven dol. and overlies Garden City ls.

Named for Swan Peak, Rich Co., Utah.

See also under †*Geneva qtzite.*

†Swan Pond granite.

Late Carboniferous or post-Carboniferous: Northeastern Massachusetts.

J. H. Sears, 1905 (Phys. geog., geol., min., and pal. of Essex Co., Mass., p. 141). Granite locally known as "Swan Pond granite," having its greatest development on shore of this pond.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the granite around Swan Pond as Andover granite.

Swan River beds.

Upper Cretaceous: Manitoba (Winnipeg region).

W. A. Johnston, 1934 (Canada Dept. Mines, Geol. Surv. Mem. 174, p. 12).

Swansea rhyolite.

Tertiary (late?): Central northern Utah (Tintic district).

G. W. Tower, Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, map). [Exposed in Swansea and South Swansea mines.]

†Swanton slate.

A name that has been loosely applied (J. B. Perry, Boston Soc. Nat. Hist. Proc., vol. 11, pp. 347+, 1868) to slates of Trenton, Upper Camb., and Lower Camb. ages, in NW. Vt. In 1869 (Am. Jour. Sci., 2d, vol. 47, pp. 341+) Perry used the term *Black slates or Swanton group*, 10,000–15,000 ft. thick; includes thin beds of ss. and ls. C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, No. 5, pp. 176–178), stated that Trenton ls. rests uncon. on *Swanton slates* at Highgate Springs, NW. Vt.

†Swanton marble.

A name applied in 5th Rept. Vt. State Geol., p. 133, 1906, to the Winooski marble at Swanton, Vt.

†Swanton conglomerate.

Lower Ordovician to Lower Cambrian: Northwestern Vermont (Franklin County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 118–126). *Swanton cgl.*—Largely coarse ls. cgl., with many beds of calc. gray ss., some calc. qtzite, and subordinate layers of dark-gray sl. The cgl. forms lenses of all sizes up to 30 ft. in thickness and ¾ mi. long. As a rule the rock consists of bluish-gray ls. matrix embedded with pebbles and great boulders of blue ls.; there are also many pebbles and boulders of fine white or bluish-white marble, gray calc. ss., sandy ls., gray dol., and a peculiar tough dark-gray dol. that weathers reddish brown; also a few small bits of black chert and pebbles of dark sl. The beds of this fm. begin about 8 mi. nearly S. of St. Albans and appear at many localities northward to and across Canada border. It is well shown in E. part of Swanton Twp. for which it is named. It is not continuous but forms disconnected lenses at base of Georgia sl., in which it was originally included. These lenses are common in towns of St. Albans, Swanton, and Highgate, and unusually good exposures occur about 1 mi. W. of Georgia Center. Heretofore included in Georgia sl., but notable aspect of the cgl. and its taxonomic value justify treating it as a distinct fm. It is separated from overlying Georgia sl. by a great uncon., and also from underlying Highgate sl. by a great uncon.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 377–379), divided the rocks of the central sequence of NW. Vt. into (descending): Georgia sl. (of

Beekmantown age); Corliss cgl. (of Beekmantown age); uncon.; Highgate sl. (of Upper Camb. age); Mill River cgl. (of Upper Camb. age); and several older fms. "In the original description of this region by writer the very strong resemblance of Mill River and Corliss cgls. led to their description as one fm.—the 'Swanton cgl.' Later detailed mapping and study showed that there were 2 cgls. and that the Mill River—the older one—was placed by thrust faulting S. of Highgate Center in position of the Corliss on top of Highgate sl., thus causing the confusion of the two." [The name *Swanton cgl.* has therefore been abandoned.]

Swarbrick formation.

Cambrian: Central Nevada (Tybo district).

H. G. Ferguson, 1933 (Nev. Univ. Bull., vol. 27, No. 3, pp. 13–25). *Swarbrick fm.*—Largely thin-bedded gray chert interbedded with thin bands of bluish gray ls., the lss. increasing toward top. Near top some sh. is interbedded with the chert. The uppermost chert horizons were included in this fm., so that as mapped the uppermost 200 or 300 ft. is in places dominantly sh. containing more or less chert. Thickness 2,500 to 3,000+ ft. Base not exposed. Oldest fm. in Tybo dist. Grades into overlying Tybo sh. No fossils. Forms hanging wall of ore-bearing fissure in Swarbrick prospect, in E. part of Tybo dist.

†Swartwood Tropidoleptus zone.

Term applied by H. S. Williams (Sci., n. s., vol. 24, pp. 365–372, 1906) to *Tropidoleptus* zone No. 3 of Cayuta sh. memb. of Chemung fm. in Ithaca region, N. Y., because of outcrop SW. of Swartwood.

The U. S. Geol. Survey does not apply geographic names to faunal zones, and Williams therefore withdrew the geographic name from his ms. of U. S. G. S. Watkins Glen-Catatonk folio, No. 169, 1909.

Swasey formation.

Middle Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 11). *Swasey fm.*—Bluish-gray oolitic and aren. lss. with some calc. and argill. shales. Thickness 238 ft. Overlies Dome fm. and underlies Wheeler fm. Type loc. is slopes of Swasey Peak.

Swastika sand (Archer County, Texas).

Same as Gose sand, both subsurface.

Swatara iron sandstone. (In Clinton formation.)

Silurian (Niagaran): Southeastern Pennsylvania (Lebanon County).

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 637, 638). *Swatara iron ss.*—Very massive iron ss., 120 ft. thick, lying 511 to 631 ft. above base of Rose Hill fm. (lower Clinton) in section E. of Swatara Creek, Swatara Gap, 11 mi. NW. of Lebanon, Pa. Overlain by 200± ft. of younger beds of Rose Hill fm. Lies lower in Rose Hill fm. than Center iron ss., whose base is 96 ft. below top of the Rose Hill.

Swauk formation.

Eocene: Central and central northern Washington.

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137). *Swauk ss.*—About Camas Land, to E. of Wenache Mtns and in Valley of Wenache in vicinity of Mission, Leavenworth, etc., consists largely of thick-bedded nearly white impure ss. with minor amounts of sandy sh. To S. of Wenache Mtns, in region drained by North and Middle Forks of Teanaway River and Swauk Creek, the fm. consists largely of thin-bedded yellowish arkose ss. and yellowish sandy sh. with 200 ft. of coarse cgl. at base. All deposited in a single Tert. lake or estuary. Thickness 6,000 to 8,000 ft. Fossil plants assigned to Eo. by F. H. Knowlton. Named for Swauk mining dist. [SW. of Camas Land], where it occurs. Is conformably overlain by Columbia [River] lava, and rests uncon. on schists, greenstones, serpentine, etc.

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Swauk fm.* underlies Teanaway basalt with slight uncon.

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Swauk fm.* was named for Swauk Creek, also for occurrence in Swauk mining dist.

Swearinger slate.

Upper Triassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Swearinger sl.*—Dark calc. slates with thin blue lss. and some siliceous layers. Thickness 200 ft. Includes *Halobia* bed, *Rhabdoceras* bed, and *Monotis* bed [zone of *Pseudomonotis subcircularis*]. Rests directly and uncon. on Carbf. Robinson fm. Believed to underlie Hosselkus ls.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Swearinger sl.*—Chiefly dark slaty sh., sometimes more or less calc. and at other times decidedly siliceous, but the thin beds of ls. or chert form only a small portion of whole mass. In the side of the sl. adjoining Hosselkus ls. thin lenticular beds of ls. become more abundant. They are generally dark, with irregular cherty or sandy layers, and are fossiliferous. Thickness 200 ft. Is underlain (not overlain, as originally supposed) by Hosselkus ls., with which it is conformable, but in places it rests on the older Robinson fm. Is overlapped by Trail fm. [Is approx = Brock sh.]

Named for fact that it occurs just above Swearinger's house, on N. side of Genesee Valley, Plumas Co.

Swede Pond quartzite.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199). *Swede Pond qtzite.*—Usually vitreous qtzite. Thickness 400 ft. Included in Grenville series. Where "soaked" by Laurentian granite it is called *Swede Pond gneiss* and *syntectic Swede Pond gneiss*. Is separated from overlying Catamount schist by 20 ft. of unnamed sandy ls. Overlies Paxon ls. Type loc. is Swede Pond, Hague Twp, Warren Co. On George W. Smith property, S. of Clintonville, it is divisible into Upper Swede Pond qtzite, 350 ft. thick, and Lower Swede Pond qtzite, 50 ft. thick, the two separated by Trout Pond ls., 50 ft. thick.

Swede Pond gneiss.

See under *Swede Pond qtzite.*

Sweeney sand.

Drillers' term for a sand in Gaines oil region, Tioga Co., northern Pa. Included in †Blossburg fm., a part of the Chemung. (See M. L. Fuller, U. S. G. S. 22d Ann. Rept., pt. 3, p. 593, 1902.)

†Sweetland shale.

An abbreviated form of *Sweetland Creek sh.* that is used by some geologists.

Sweetland Creek shale.

Upper Devonian or Mississippian: Southeastern Iowa and western Illinois (?).

J. A. Udden, 1899 (Jour. Geol., vol. 7, pp. 65–78). *Sweetland Creek beds.*—Olive-gray sh. with green bands, 0–48 ft. thick, uncon. overlying Cedar Valley ls. and uncon. underlying Coal Measures. Correlated with Dev. Black sh. of Interior.

Regarded by some geologists as contemp. in whole or part with Lime Creek sh., and by other geologists as younger than Lime Creek, also as possibly an outlier of basal Kinderhook. E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22), definitely classified it as post-Dev.; S. Weller (1920) suggested it is all Miss.; Van Tuyl (1925) suggested it is basal Kinderhook; T. E. Savage (1935) stated it is "considered by most geologists to be early Miss.;" R. C. Moore (1935) included it in Kinderhook group, and correlated it with Saverton and Grassy Creek shales of Mo.

Named for exposures on Sweetland Creek, Muscatine Co., Iowa. Some authors have extended this name into western Ill.

Sweetsburg slate.

Lower Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 10).

Sweetwater group.

Oligocene: Central Wyoming (Sweetwater Valley).

F. V. Hayden, 1871 (U. S. Geol. Surv. Terr. 4th Ann. Rept., p. 29). Fresh-water lake beds that cover entire Sweetwater Valley may be called *Sweetwater group*. Identical with upper part of Wind River deposits. Uncon. overlain by Plio. marls and sands.

F. M. Endlich, 1879 (U. S. Geol. and Geog. Surv. Terr. 11th Ann. Rept., pp. 110, 154–156). *Sweetwater group*.—Local deposit, in Sweetwater dist., consisting of brown indurated shales and marls, some sss. and cgl. near base. Thickness 1,200 to 1,400 ft. Assigned to Mio. Underlies Plio. Niobrara group and uncon. overlies Bridger group. Occurs all along Sweetwater River and continues N. to the hills opposite Seminoe Pass.

N. H. Darton, 1908 (Geol. Soc. Am. Bull., vol. 19, btw. pp. 403 and 463). Sweetwater fm. of Hayden Survey overlies Wasatch in Sweetwater Plateau. Strongly suggests the White River, into which it appears to merge in high plateau W. of Alcova. [On pl. 22 he mapped *Sweetwater fm.* over part of central Wyo.]

W. Granger, 1910 (Am. Mus. Nat. Hist. Bull., vol. 28, p. 241, footnote). Sweetwater of Hayden Survey is probably same as *Titanotherium* beds [Chadron fm., the lower part of White River group, Olig.].

The beds covering a large area along and adjacent to Sweetwater River were mapped as *White River group (Olig.)* on 1924 geol. map of Wyo.

Sweetwater dolomite.

Permian: Central northern Texas (Fisher and Nolan Counties).

A. M. Lloyd and W. C. Thompson, 1929 (A. A. P. G. Bull., vol. 13, p. 953, pl. 10). *Sweetwater dol.*—Thin, persistent dol., in places fine-grained and sandy and in places coarsely crystalline; 1 to 3 ft. thick. Strikes N. 30° W. through city of Sweetwater, and is named after its outcrop there. Directly underlies the Triassic in SW. Fisher Co. and northern Nolan Co.

M. G. Cheney, 1929 (Univ. Tex. Bull. 2913, p. 26), replaced this (preoccupied) name with *Claytonville dol.*, which E. H. Sellards (Univ. Tex. Bull. 3232, p. 167, 1933) also adopted, instead of Sweetwater (preoccupied), and included it in Peacock fm.

Sweetwater member.

Oligocene: Western Wyoming (Wind River Range).

C. M. Bauer, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 665–695). *Sweetwater memb. of White River group*.—Uncon. on Uinta fm., from head of Sand Draw SW. to S. end of Wind River Range, is a boulder bed, from a few ft. to 150 ft. thick, for most part unstratified and poorly sorted. One lens, 50 to 85 ft. thick, extending from Wagonbed Spring SW. for 2± mi., shows no sorting of material and no stratification. Base is visible all the way. Blocks of ss., cgl., tuff, and porphyry up to 10 or 12 ft. diam. are enclosed in matrix of finer material containing chert, granite, and schist pebbles. To NE. the boulders are smaller—3 to 4 ft. From head of Sand Draw toward SW. end of outcrop, granites, gneisses, and schists predominate. In high bluff NW. of Lone Butte the lower 20 to 40 ft. of the memb. consists almost wholly of well-rounded boulders of qtzite, schist, gneiss, and granite, 6 to 18 in. diam., and upper 30 to 60 ft. contains much fine material without stratification or sorting and a scattering of boulders (mostly of red and gray porphyries) from few in. to 2 or 3 ft. diam. Uplift, causing increased erosion, talus slides, and flood wash, accompanied by volcanism, is believed to have been responsible for formation of Sweetwater memb. From Wagonbed Spring SW. for nearly 1½ mi. the memb. is mainly aggl., standing up in cliff 65 to 85 ft. high. Along Sweetwater rim the memb. is overlain by consolidated gravel and sand beds of fluviatile origin, from a few ft. to 20 or 30 ft. thick, and belonging to White River group. The Sweetwater memb. is believed to be initial stage of White River group. [In table on p. 669 this memb. is placed below Brule and Chadron fms. of White River group (Olig.).] The boulder bed described in this paper as *Sweetwater memb. of White River group* is widespread. It occurs along Sweetwater escarpment from Lander-Rawlins road as far E. as Alcova, a distance of 80 mi. Writer believes it correlates with boulder bed on Green Mtn, S. of Sweetwater River, and it may correlate with Bishop cgl. of SW. Wyo.

Swenson gypsum member.

Permian: Central northern Texas (Stonewall and adjacent counties).

L. T. Patton, 1930 (Univ. Tex. Bull. 3027, pp. 45+). *Swenson gyp. memb.*—Basal memb. of Peacock fm. Named for exposures near town of Swenson, Stonewall Co. Forms prominent escarpment extending from S. border of county to near Swenson, where escarpment dies down and the gyp. bed disappears. On N. side of Salt Fork River a prominent gyp. bed appears that is correlated with Swenson gyp., although it is not believed that the two beds are continuous across area btw. Swenson and Salt Fork River. Believed that the two basins were separated by a bar at time of deposition of the gyp. beds. In many places the Swenson consists of two beds of gyp., each 5± ft. thick, separated by 5± ft. of sh. About 100 ft. above Swenson gyp. there occurs another rather prominent gyp. bed which may be called Oriana gyp. The Swenson is good key horizon in this and adjacent counties.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 168). *Swenson gyp. of Patton* is apparently same as Childress dol. and gyp. and is discarded. [On pp. 168 and 179 the Swenson gyp. is included in Peacock fm. and the Childress dol. and gyp. in underlying Blaine fm.]

Swenson sand.

A subsurface sand, of Penn. age, in central northern Okla., that has been correlated with Fort Scott ls. (Oswego lime) and also with Marland sand (Dev. or Miss.?). Named for Gus Swenson farm, Kay Co.

Swift Current beds.

Middle Ordovician: Ontario (Manitoulin Island).

A. F. Foerste, 1912 (Ohio Nat., vol. 13, pp. 38–39). *Swift Current beds.*—Chiefly whitish and reddish lss. containing fossils of Leray age. Thickness probably 50 ft. Rest on red clay shales of Lowville age, also, in places, on Huronian qtzites; are overlain by Cloche Island beds. Named for occurrence at Swift Current, the locality at which the railroad passes from the peninsula over the Cloche Island.

Swift Current formation.

Eocene: Saskatchewan.

F. H. McLearn et al., 1934 (Canada Geol. Surv. Summ. Rept. 1933, pt. B, p. 33).

Swift Water formation.

Probably Cambrian: Northwestern New Hampshire (Ammonoosuc region).

C. H. Hitchcock, 1874 (Am. Jour. Sci., 3d, vol. 7, pp. 468–476). *Swift Water series.*—Qtzites, sss., actinolite schist, hornblende schist, white mica schist, black sl. Thickness 2,500 to 4,400 ft. Seems to be more nearly related to overlying Helderberg series than any of other fms. [Name here used in paper describing region from Swiftwater and Woodville on S. to N. of Littleton, all in Grafton Co.]

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2, pp. 465, 658–675). *Swift Water series* assigned to lower part of Upper Huronian; placed below Lisbon group (also Upper Huronian) and above hornblende schist, basal Upper Huronian.

C. H. Hitchcock, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 461–482). *Lisbon-Swiftwater complex* may be Ord. In the State rept. the local name "Lisbon" was applied to the green schists and "Swiftwater" to an indefinite group of mica schists, slates, and cgls., both making parts of one whole. For convenience the double name may be used. The Lisbon rocks are green chloritic schists and sss., igneous diorites, granites, and protogenes, hydromica schists, qtzites, lss., cgls., etc. The Swiftwater rocks are mica schists, qtzites, hornblende schists, slates, argillitic and sericitic schists, and obscure cgls. The two groups were separated on published map, but further explorations indicate none of these rocks are restricted to any particular horizon. The Swiftwater series seems to underlie the other.

C. H. Hitchcock, 1905 (Geol. Littleton, N. H., Univ. Press, Cambridge), assigned *Swift Water schist series* to Sil. and the Lisbon to Lower Sil. or Camb.

F. H. Lahee, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 231–250). *Swiftwater series* is supposed to be = Lyman schists and associated rocks.

C. P. Ross, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 267–302). *Swift Water fm.*—Oldest fm. in Ammonoosuc mining dist. Is certainly pre-upper Sil. and probably Camb. Principally metamorphosed sss. and cgls., light or whitish; at one place a bed of black phyllite at top. Dips under Lisbon fm., of Camb. or Ord. age. Hitchcock's original distinction btw. the predominantly whitish Swift Water strata and the greenish Lisbon beds is adopted. No fossils. Surrounds village of Swift Water, Grafton Co.

M. Billings, 1933 (Am. Jour. Sci., 5th, vol. 25, p. 149), divided the rocks of Littleton and Moosilauke quads into *Littleton fm.* (Lower Dev.); *Fitch fm.* (middle Sil.); and 3 pre-Sil. fms., called (descending) *West Bath sl., Swiftwater-Lyman fm.*, and *Lisbon qtzite.* None of these fms. were described.

M. Billings, 1934 (Sci., vol. 79, pp. 55–56, Jan. 19, and Am. Jour. Sci., 5th, vol. 28, pp. 412–422, Dec.), divided the rocks of Littleton and Moosilauke quads into (descending) Littleton fm. (Lower Dev.); Fitch fm. (middle Sil.); Clough cgl. (Lower Sil.?); and 3 fms. of pre-Sil. (Upper Ord.?) age (descending), Partridge sl., Ammonoosuc volcanics, and Albee qtzite, thus dropping *Lisbon, Lyman*, and *Swift Water* from the nomenclature. The U. S. Geol. Survey has not yet had occasion to consider this revised classification.

Switchback limestone.

Upper or Middle Cambrian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 5, 39, and passim). *Switchback ls.*—In most places slightly calc., argill. fine-grained sandy gray to brown-gray dol. In Nannie Creek Basin region it consists of platy buff-gray siliceous dol., which gives ringing sound when struck. In other places, notably at type loc. near Pentagon Mtn, it consists of 100 ft. of massive, thick-bedded cream-gray sandy argill. mag. ls. underlain by 6 ft. of green-gray sh, and shaly ls. Minimum thickness of 20 ft. is in Dearborn region. Underlies Devils Glen dol. and overlies Gordon Mtn ls. Type loc. is upper-middle part of the cliffs which form E. side of peak 1 mi. S. 48° E. of Pentagon Mtn, in NE¼ sec. 23, T. 25 N., R. 12 W. Named for Switchback Pass, about ¼ mi. S. of these cliffs.

Swope limestone.

Swope formation.

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southeastern Nebraska.

C. O. Dunbar and G. E. Condra, 1932 (Nebr. Geol. Surv. Bull. 5, 2d ser., p. 17 and table C). Revised correlation by R. C. Moore, 1931 [unpublished?], divides Bethany Falls ls. in vicinity of Kansas City into (descending) *Swope ls.*, Sugar Creek sh., and Middle Creek ls.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). The beds from top of Bethany Falls ls. down to base of Schubert Creek ls. (which overlies Ladore sh. [restricted], clearly represent a single sedimentation cycle and are here named *Swope fm.* They are divided into (descending): Bethany Falls ls. [restriction of R. C. Moore's 1931 definition and replaces *Swope ls.* of his 1931 list of names], *Hushpuckney sh.* [=Sugar Creek sh.], *Middle Creek ls., Elm Branch sh., Sniabar ls., Mound City sh., Critzer ls., Tennison Creek sh.*, and *Schubert Creek ls.* (called "Hertha" by Hinds and Greene). [Derivation of names not stated.]

J. M. Jewett, 1932 (p. 100 of book cited above). Base of *Swope fm.* is variable, since the lower ls. members are less persistent than Bethany Falls ls., the upper memb. In all cases Swope fm. includes strata from top of Bethany Falls ls. as defined in repts of Mo. Geol. Surv. down to base of lowest lens of ls., which is a few ft. below the Bethany Falls and which is persistent over several mi. This excludes blue flaggy ls. beds which are present a few ft. below Swope fm. in southern Linn and northern Bourbon Counties.

N. D. Newell, May 15, 1935 (Kans. Geol. Surv. Bull. 21, pp. 26–29). *Swope ls.* is proposed by Moore and Newell for the persistent lss. and thin shales from top of Ladore sh. [restricted] to top of Bethany Falls ls. In Johnson and Miami Counties, NE. Kans., divided into (ascending) Middle Creek ls., Hushpuckney sh., and Bethany Falls ls. [On p. 26 he also stated that Ladore sh. of southern Kans. may include representatives of Middle Creek ls. and Hushpuckney sh. Named for Swope Park, Kansas City, Mo.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 37). Definition of *Swope fm.* is modified to exclude beds below Middle Creek ls., because nowhere else in Missouri series has a well-defined "lower" ls. (in terms of Shawnee cycle) been found. [On p. 78 Moore stated Swope ls. of his 1932 definition (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook) includes beds classed in his 1936 paper as Hertha ls., Ladore sh., and Bethany Falls ls.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Sybille tongue (of Phosphoria formation).

Permian: Central southern Wyoming (Laramie Basin).

H. D. Thomas, 1934 (A. A. P. G. Bull., vol. 18, No. 12, p. 1664). *Sybille tongue of Phosphoria fm.*—Fossiliferous ss., 21 ft. thick, lying in midst of Satanka sh., being 184 ft. above base of Satanka sh. and a similar distance below top of the Satanka. Its upper part is a massive medium-grained mottled pink and buff ss. containing great quantity of cylindrical gray chert nodules. This grades down and becomes a thin-bedded limy ss. containing maroon chert laminae and small angular gray-chert masses. Type loc. around Sybille anticline near Sybille Springs, in Laramie Basin. Seems to be absent in S. part of Laramie Basin. To N. and W. becomes more limy.

Sycamore sand. (In Travis Peak formation.)

Lower Cretaceous (Comanche series): Central Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 141, 142). *Sycamore sands.*—At base cgl. of well-rounded pebbles of Paleozoic ls., quartz, chert, granite, and schist, embedded in ferruginous yellow and red gritty sand; passes upward into angular cross-bedded sand, which becomes finer toward top until it reaches condition known as "pack sand." Thickness 50 ft. Basal memb. of Travis Peak fm. in Burnet Co. Underlies Cow Creek beds and overlies Carbf.

Named for exposures on Sycamore Creek, Burnet Co.

Sycamore limestone.

Mississippian (Kinderhook): Central southern Oklahoma (Arbuckle Mountains).

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Sycamore ls.*—Dense, even-textured bluish ls., which weathers to yellowish hues and is hard and tough. Thickness 0 to 160 ft. Overlies Woodford chert and underlies Caney sh. Increases in thickness to W.

According to E. O. Ulrich, C. Schuchert, and R. C. Moore the Sycamore fauna is of Kinderhook age.

Named for Sycamore Creek, Johnston Co., which crosses its outcrop in T. 3 S., R. 4 E.

Sycamore sandstone.

See *Sycamore Creek ss.*, Upper Dev., Ariz. Also see 1936 entry under *Jerome fm.*

Sycamore Creek sandstone.

Upper Devonian: Northeastern and central Arizona.

C. Lausen and E. D. Wilson, 1925 (Univ. Ariz., Ariz. Bur. Mines Bull. 120, pp. 7, 12–13). *Sycamore Creek ss.*—Name proposed by A. A. Stoyanow in unpublished ms. The fm. is generally dull reddish brown in color, although some buff-colored beds are present. Is made up of a coarse quartz sand cemented chiefly by oxides of iron and carbonate of lime. Cross-bedding is locally common, and then the stratification is not well defined. Traversed by numerous joints. Pebbly layers common. Is conformably overlain by thin-bedded flaggy lss. containing fossils identified by Stoyanow as Upper Dev. Occurs as isolated remnants S. and SE. of Payson, while to N. is a large area partly overlain by Redwall ls. Upper part has been largely removed by erosion, and where overlain by Redwall ls. [Miss.] the thickness is seldom over 150 ft. Contains fossil fishes identified by Stoyanow as undoubtedly Upper Dev. Rests uncon. on pre-Camb. diorite and in places on older rocks. On recent map of Ariz. is classified as Tapeats ss. (Upper Camb.).

A. A. Stoyanow, 1926 (Am. Jour. Sci., 5th, vol. 12, pp. 311–315). *Sycamore Creek fm.*—Three cliff-forming sss., separated by beds of reddish mottled ss., pink-white quartzitic ss., and compact pink ss.; some beds of gray ls. Thickness 125 to 324 ft. Best exposed at Sycamore Creek, a tributary of East Verde River. Assigned to Dev. Overlain by Dev. ls. Rests on granite.

In 1936 Stoyanow gave further description of this unit and changed its name to *Sycamore ss. memb. of Jerome fm.*, as explained under 1936 entry under *Jerome fm.*

Sykes sand.

A subsurface sand, of earliest Penn. or late Miss. age, in central Okla., which is correlated with basal part of Cromwell sand. According to Okla. Geol. Surv. Bull. 40Q. p. 180, 1928, the Sykes sand is of Penn. age and correlates with a part of Dutcher sand series.

Sykesville granite.

Pre-Cambrian: Northern Maryland (Carroll County).

A. I. Jonas, 1928 (Md. Geol. Surv. Carroll Co. geol. map). *Sykesville granite*, schistose biotite-quartz monzonite, of pre-Camb. age.

Sylacauga marble member (of Talladega slate).

Paleozoic or pre-Cambrian: Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 51). *Sylacauga marble memb. of Talladega sl.*—Fine-grained white or cream-tinted translucent rock, more or less clouded with green, due to layers of green phyllite. No dol. beds observed within the marble, but it undoubtedly is closely associated with large thicknesses of dol., which is believed to be of much later age than the marble. No fossils. Thickness at least 500 ft. Is in lower part of Talladega sl., probably 4,500± ft. above base. Overlain and underlain by phyllite, and is believed by Prouty to be same as Sawyer ls. memb. Prouty described the marble in Ala. Geol. Surv. Bull. 18, 1916, but did not apply name to it. He expressed opinion the marble is of various ages, from Upper Camb. (Conasauga) to Ord. (Chickamauga). Present writer believes it is all of same age and that it all lies in Talladega sl.

Named for exposures and quarries around Sylacauga, Talladega Co.

Sylamore sandstone member (of Chattanooga shale).

Devonian (?): Northern Arkansas, southwestern Missouri, and eastern Oklahoma.

R. A. F. Penrose, Jr., 1891 (Ark. Geol. Surv. Ann. Rept. 1890, vol. 1, pp. 113, 114). *Sylamore ss.*, proposed by J. C. Branner, in unpublished rept. for yellow, brown, or gray earthy ss., often containing green or black shaly layers, and sometimes merging into beds of same material. Frequently much iron-stained and sometimes contains small flat ferruginous concretions. Of irregular distribution. Thickness 0 to 30 or 40 ft. Supposed by Dr. Williams to be="Black sh." of Tenn. and elsewhere in Mississippi Basin. Underlies Boone chert and overlies St. Clair ls.

For many years the name *Sylamore fm.* was in some repts on Ark. geology used as defined above; in other repts it was said to underlie †Eureka sh., and in still other repts it was said to overlie †Eureka sh., the relations being confused by the fact that where "the ss. was present the overlying sh. seemed to be absent," and where "the sh. was present the ss. seemed to be absent," so that many repts stated that the ss. seemed to replace the sh. In 1905 (U. S. G. S. Fayetteville folio, No. 119) G. I. Adams and E. O. Ulrich defined *Sylamore ss. memb.* as basal memb. of Chattanooga sh., and as consisting of 0 to 75 ft. of white to light-brown friable ss. in massive beds, locally conglomeratic, with chert, ls., and phosphatic pebbles, and as overlain by 30 to 70 ft. of black carbonaceous fissile sh. forming the upper memb. of Chattanooga sh. They stated that the ss. is the ss. present at type loc. of †Key ss. and that the sh. is the sh. exposed at Noel, the type loc. of †Noel sh. Since 1905 the Sylamore has usually been described either as the basal memb. of Chattanooga sh. or as underlying †Eureka sh.

E. T. McKnight, 1935 (U. S. G. S. Bull. 853), described a ss. (0 to 18 ft. thick) underlying St. Joe ls. memb. of Boone fm. in Yellville quad., which he stated has been widely called *Sylamore ss.* in repts on northern Ark. but which he treated as basal memb. of Boone fm., because it appeared to be of Osage age. He stated: What Sylamore is at type loc. is unknown, as type loc. has not been visited for 40 yrs, when its strat. relations were uncertain. He also expressed belief that Sylamore of literature is "simply the basal ss. of an overlapping series of strata and that its age varies in different places."

Named for exposures on Sylamore Creek, Stone Co., central northern Ark.

Sylvan intrusives.

Late Tertiary: Yellowstone National Park.

W. H. Weed, 1896 (U. S. G. S. Yellowstone Nat. Park folio, No. 30). *Sylvan intrusives*.—Dike rocks varying from diorite to granite porphyry, breaking through late basic breccia near Sylvan Pass. Assigned to Neocene.

Sylvan shale.

Upper Ordovician (Richmond): Central southern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Sylvan sh.*—Soft greenish fissile sh., 50 ft. thick; increases to W., in Arbuckle Mtns, to nearly 300 ft. Underlies Hunton ls. and overlies Viola ls.

That the fm. is of Richmond age seems to be generally accepted.

Named for exposures near former village of Sylvan Johnston Co.

Sylvania sandstone.

Lower Devonian (Helderberg): Northwestern Ohio, Michigan, and western Ontario.

E. Orton, 1888 (Ohio Geol. Surv., vol. 6, pp. 4, 18). *Sylvania ss.*—Extremely pure glass sand, 20 or more ft. thick, in Lucas and Wood Counties, Ohio, and adjacent territory, also probably Monroe Co., Mich. Occurs in midst of Lower Helderberg or Waterlime, nearly or quite 200 ft. below Corniferous ls.

For many years Sylvania ss. was treated as middle part of †Monroe fm, all of which was supposed to be of Sil. age, but Sylvania ss. and overlying "Upper Monroe" are now classified by most if not all geologists as Lower Dev. (Helderbergian), and Sylvania ss. is now treated as a distinct fm., uncon. underlying Detroit River dol. and uncon. overlying Bass Islands dol. (Sil.). However, J. E. Carman, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 260, 264), states Sylvania ss. is conformable with overlying beds.

J. E. Carman, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 2, pp. 264–265). *Sylvania ss.* includes 2 phases, (1) a probably eolian deposit which has great development in SE. Mich. and is only slightly developed in NW. Ohio; (2) a reworked and water-laid phase, which is dominant type in NW. Ohio and which may show all gradations to pure dol. The water-laid phase grades conformably into overlying Detroit River dol., contains fossils of either Amherstberg or Lucas age, and is of different age at different places, being the marginal part of an encroaching sea. The eolian phase may represent not only Sylvania stage proper but also such part of Detroit River stage as is not here represented by marine deposits. Assigned to Dev. In spite of variable age relations of this ss. it is believed *Sylvania ss.* should be continued as the name of a lithologic unit in NW. Ohio.

Named for Sylvania, Lucas Co., Ohio.

Syracuse serpentine.

G. H. Williams, 1890 (Geol. Soc. Am. Bull., vol. 1, pp. 533–534), described *Syracuse serpentine* in James Street Hill, Syracuse, N. Y.

Syracuse salt member (of Salina formation).

Silurian (late): Western to east-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, pp. 18–19 and chart). *Syracuse salt* underlies Camillus sh. and overlies Verona sh. Included in Salina beds.

In later repts thicknesses of 35 to 300 ft. are given for this memb., which is stated to consist of alternating beds of rock salt and sh. underlying the Camillus and overlying the Vernon. (D. H. Newland and H. Leighton, N. Y. State Mus. Bull. 143, pp. 18–23, 1910.)

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 52). *Syracuse salt*.—While no outcrops of rock salt are known, this term is used to indicate the horizon of the salt beds as determined by the wells and shafts which penetrate the beds of rock salt [at Syracuse, N. Y.].

Is middle memb. of Salina fm.

Syrena formation. (Of Magdalena group.)

Pennsylvanian: Southwestern New Mexico (Santa Rita district).

A. C. Spencer and S. Paige, 1935 (U. S. G. S. Bull. 859). *Syrena fm.*—Lower memb. consists of 100 to 130 ft. of sh., with thin beds of ls. in lower part; upper memb. consists of 260 ft. of alternating ls. and sh. The lower memb. is locally called *Mountain Home sh.* by geologists of mining companies, in their company repts, and the upper memb. is called by them *Don ls.* Upper fm. of Magdalena group. The Syrena is overlain by Abo redbeds and underlain by Oswaldo fm. Named for Syrena patented mining claim 1± mi. S. of Hanover P. O.

Tabera formation.

Oligocene: Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Table Creek shale. (In Wabaunsee group.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, eastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 80). *Table Creek sh.*—Largely bluish gray and argill. to sandy; top part very sandy in Kans. Thickness in Nebr., Mo., and Iowa 25 to 45 ft.; increases to 50 ft. in Kans. S. of Kansas River. Nyman coal, in top part, persists in Iowa, Mo., Nebr., and at places in Kans. Named for outcrops on Table Creek at Nebraska City, Nebr. Underlies Dover ls. and overlies Maple Hill ls., all included in McKissick Grove sh. memb. of Wabaunsee fm.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 94, 96). Condra's name *Table Creek sh.*, which includes Nyman coal, is restricted to the sh. btw. the Jim Creek ls. above and Dover lss. below, and the sh. beneath the Dover (which formed basal part of Table Creek sh. as originally defined) is here named *French sh.* [On p. 58 thickness of Table Creek sh. restricted is given as 54 ft.]

R. C. Moore and G. E. Condra, Oct. 1932 (Revised classification chart of Kans. and Nebr.), transposed the names *French sh.* and *Table Creek sh. restricted*, by applying former name to the sh. *overlying* Dover ls. and the latter name to the sh. *underlying* Dover ls.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 10). *Table Creek sh.*, top memb. of McKissick sh. fm., underlies Dover ls. fm. and overlies Maple Hill ls. memb. of McKissick sh. fm.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), discarded McKissick Grove sh. and treated its subdivisions as fms. in Wabaunsee group. He stated (p. 239) that ls. called Jim Creek ls. in Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, 1932, is not true Jim Creek ls. but the younger Nebraska City ls. The Table Creek sh. as defined in 1932 rept therefore extended up to base of Nebraska City ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Table Head series.

Middle Ordovician: Newfoundland.

C. Schuchert and C. O. Dunbar, 1934 (Geol. Soc. Am. Mem. 1, pp. 63, 99).

†Table Mountain sandstone.

Permian: Central southern Oklahoma (Garvin County).

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 324 to 341). The most eastern exposure of Duncan ss. is on Table Mtn, in western Garvin Co., from which the name "Table Mountain ss." has been applied locally to this fm.

There is no other record of this name. Gould did not include it in his list of geologic names of Okla. (Okla. Geol. Surv. Bull. 35, Sept. 1925).

Table Mountain andesite.

Name applied by H. Williams (Calif. Univ. Dept. Geol. Sci. Bull., vol. 21, No. 8, 1932, diagram on p. 311) to the rocks shown as composing Table Mtn, NW. of Lassen Peak, Calif.

Table Mountain **formation**.

Late Tertiary or early Quaternary: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, p. 138, map). *Table Mtn fm.*—Moderately consolidated deposits of yellowish to reddish-brown gravels and sands of late Tert. or early Quat. age. Thickness 50 to 100 or more ft. Finely exposed in Table Mtn, 4 mi. NE. of Jacumba, southern Peninsular Range. Underlie Jacumba volcanics.

Table Rock granite.

Carboniferous (?): Northwestern South Carolina.

E. Sloan, 1907 (Summary of mineral resources of S. C., pp. 7, 8). [Name mentioned but fm. not defined.]

E. Sloan, 1908 (Catalogue of mineral localities of S. C.: S. C. Geol. Surv., ser. 4, Bull. 2, pp. 185, 411, 423, 425–426). *Table Rock granite.*—An intrusive granite, typically exhibited at Table Rock Mtn, and constituting predominant rock in portion of this zone NE. of Keowee River. It is a muscovite-bearing biotite granite which is not generally highly schistose, although in some of its probable exposures this feature is well developed. It comprises a medium fine-grained "pepper and salt" granite, varying to a coarse-grained gneissoid. While many exposures of Table Rock granite exhibit but slightly developed schistosity, it encloses areas of Carolina gneiss and Roan gneiss which are highly schistose and therefore assumedly much older; and while it appears in Saluda zone and in Chatooga zone, or on both sides of the Cambrian lss. and schists, it has not been observed breaking through the latter, yet in many of its aspects this Table Rock granite is quite fresh enough to represent a post-Carbf. intrusion. Therefore in so much as Carolina gneiss and Roan gneiss are prominently exhibited in Saluda zone the latter is placed with the Archean rocks, but in so much as the Table Rock intrusive granite is predominant rock over a large area, the Saluda zone is assigned to Archean with this qualification.

Named for development at Table Rock Mtn, Pickens Co.

Table Rock sandstone.

Upper Devonian: Western New York (Genesee River region).

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 2, pp. 96–98). [See under *Letchworth sh.* J. Hall (1840 Rept. N. Y. Geol. Surv., p. 391, and 1843 Rept.) mentioned a thin ss. that formed the *table rock* at top of lower Portage Falls, but he did not name the ss., and Chadwick's appears to be the original use of this name.]

†Tachatna series.

See *Takotna fm.*

Tackawasick limestone.

Middle Ordovician (Trenton): Eastern New York (Capital district).

R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, pp. 410, 414). *Tackawasick ls.*—Narrow band of Trenton shaly ls. found near E. edge of area in only a few outcrops. It appears as a band btw. Lower Camb. and Upper Dev. rocks (Rensselaer grits) and has evidently been overthrust far out of place. [On p. 414 he shows it as in part underlying Snake Hill sh. (of Trenton age) and in part equiv. to lower beds of the Snake Hill; and as uncon. overlying Rysedorph cgl.]

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285, p. 115). *Tackawasick ls. and sh.*—Occurs in E. trough of Capital dist., underlying Snake Hill sh. and overlying Rysedorph cgl. [On p. 25 he placed Rysedorph cgl. above Tackawasick.]

Tacoma delta.

Pleistocene: Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Tacoma delta.*—A complex mass of gravels exhibiting plunge structure and faults, forming a voluminous delta underlying city of Tacoma. A portion of the structure belongs to Vashon epoch; another part underlies Vashon till and probably was formed during Puyallup interglacial epoch. [Some geologists consider this epoch to be glacial.] The delta is attributed to outflow from a lake that covered Stellacoom plains as the ice retreated.

†Taconian.

Alternative name applied in some early repts to *†Taconic system*. Later C. Schuchert (Textbook of geol., 2d ed., vol. 2, p. 187, 1924) applied the name to the Lower Camb. (Waucoban) epoch, and used "Taconian series" to cover the Lower Camb. rocks of eastern North America. (See U. S. G. S. Bull. 769, p. 101.)

Taconian disturbance.

A term applied by C. Schuchert and C. O. Dunbar (Textbook geol., pt. 2, p. 65, 1933) to diastrophic movements of late Ord. and earliest Sil. time.

†Taconic slate.

Ordovician: New York.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. of 2d dist., pp. 135–164). A sl. which I have named *Taconic sl.*, and which is found at W. base of Taconic Range. It lies adjacent to the Lorrain or Hudson River shales, some varieties of which it resembles. Is dark sl., passing into light blue, often stained brown. It contains more alumina and less magnesia than the magnesian slates.

In early repts variously assigned to Sil., to Camb., and to pre-Camb.

†Taconic system.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. 2d dist., pp. 135–164, 429). "A group or system of rocks which belong evidently to a position between the primary of the Atlantic ranges of mountains and the New York system." [For fuller definition see book cited above or U. S. G. S. Bull. 769, pp. 101–102, 1925. Includes rocks ranging in age from Upper Ord. to Lower Camb.]

In early repts variously assigned to Camb., to Sil., and to pre-Camb.

Taconic limestone.

See 1862 entry under *†Eolian ls.*

Taconic revolution.

A period of uplift and folding extending from Lower Camb. to Upper Ord., during which low mtns were thrown up from Va. to Newfoundland. Named for Taconic Mtns, eastern N. Y.

Taft granite.

Probably Cretaceous: Yosemite National Park, California.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 122, map). Nonporphyritic biotite granite, of even, medium-coarse grain. Consists chiefly of white feldspar and smoky gray quartz in grains mostly about 5 mm diam. Younger than El Capitan granite.

Named for fact it composes Taft Point.

Taft sandstone member (of Boggy shale).

Pennsylvanian: Eastern Oklahoma (Muskogee County).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Taft ss. memb. of Boggy sh.*—Massive gray to light-brown ss.; small pebbles of quartz in T. 14 N. and large pebbles of ss., sh., and quartz in SW. corner of T. 15 N. The cgl. was not found N. of Arkansas River and hence may represent a shore phase of the memb. Thickness 50± ft. Lies 80 to 150 ft. above Inola ls. memb. of Boggy sh. Named for exposures S. of Taft, sec. 19, T. 15 N., R. 17 E.

Taggard limestone. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia and southwestern Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 450, 476). *Taggard ls.*—White, medium soft, pure, nearly always oolitic, 5 to 16 ft. thick. Few marine fossils. Underlies Upper Taggard sh. and overlies Lower Taggard sh.; all members of Greenbrier series [ls.]. Type loc. on Taggard Branch of Indian Creek, Monroe Co. Also observed in Mercer Co. To NE. it occurs at intervals in Greenbrier Valley as far N. as head of Tygart Valley River, in Randolph Co., W. Va. Was traced as far S. as Washington Co., Va.

Taggard shales. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 450, 476–479). *Upper Taggard sh.*—Red sh.; 0 to 15 ft. thick; with marine fossils; underlying Pickaway ls. and overlying Taggard ls. *Lower Taggard sh.*—Red or sandy sh.; 5 to 20 ft. thick; underlying Taggard ls. and overlying Patton ls. All members of Greenbrier series [ls.]. Type loc. of *Upper Taggard sh.* in road just N. of Taggard Branch of Indian Creek, 2.8 mi. SE. of Union, Monroe Co. Type loc. of *Lower Taggard sh.* on Taggard Branch of Indian Creek 2.8 mi. SE. of Union. Can be traced NE. to Pocahontas Co., but does not appear to be present in Mercer Co.

Tagish series.

Age (?): British Columbia (Windy Arm district).

R. G. McConnell, 1905 (Canada Geol. Surv. Summ. Rept. 1905, pp. 27–28).

Tah formation.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 335, 339).

†Tahkandit series.

Permian and Pennsylvanian (?): Yukon River region, Alaska.

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 169–174). *Tahkandit series.*—White or gray lss. alternating with carbonaceous shales and sometimes with cgls. Overlies Rampart series and underlies Mission Creek series. An erosion interval in some part of Tahkandit series is suspected. Probably includes rocks of Upper Carbf. to Dev. age.

This unit as defined included lss. of Perm. age (to which name *Tahkandit* was later restricted) and Nation River fm., of Penn. (?) age.

Tahkandit limestone.

Permian: Northeastern Alaska (Eagle-Circle district).

J. B. Mertie, Jr., 1930 (U. S. G. S. Bull. 816, p. 121). *Tahkandit ls.*—Essentially cream-colored to white massive ls. with some beds of cgl., ss., and sh. in lower half. Thickness 527 ft. Type loc. along the Yukon just above mouth of Nation River (the old Indian name for which is Tahkandit), where a belt of the rocks crosses the Yukon, trending NE. Conformably overlies Nation River fm. and underlies Upper Triassic rocks with, it is believed, uncon. but without apparent angular discordance.

Is upper part of Spurr's Tahkandit series.

Tahoe glacial stage.

Pleistocene: Sierra Nevada, California.

E. Blackwelder, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 865–922). *Tahoe stage.*—Next to youngest glacial stage, represented by till on E. slope of Sierra Nevada. Named for Lake Tahoe, along W. shore of which several large glaciers of this stage descended from Sierra Nevada and built strong moraines, but Lake Tahoe itself is not of glacial origin. Correlated with Iowan stage.

Takotna formation.

Middle Devonian: Southern Alaska (Kuskokwim region).

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 157–159, 179). *Tachatna series.*—Gray lss., generally thin-bedded and fissile, limy carbonaceous and chloritic slates, and occasional generally fine-grained arkoses; considerably folded; frequent quartz veins. Extends from some distance below junction of Kuskokwim with East Fork down to junction of Tachatna [Takotna] River, and from the Tachatna to below Vinasale. Fossils pronounced by Schuchert to indicate probable Middle Dev. age. Uncon. underlies Holiknuk series.

Taku group.

Devonian (?): British Columbia.

D. D. Cairnes, 1911 (Canada Geol. Surv. Summ. Rept. 1910, p. 32).

Talbot formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

G. B. Shattuck, 1901 (Johns Hopkins Univ. Circ. vol. 20, No. 152, pp. 73–75). *Talbot fm.*—Is developed as a bench of variable width around edges of Wicomico terrace, and frequently separated from it in many places by a low scarp line. Occasionally this scarp, which is the ancient sea cliff of Talbot sea, attains height of 30 to 40 ft., notably in Kent Co., Md., but there are places where the scarp seems to be entirely lacking, and it is probable that in these places it has been destroyed. Carries same sort of detritus as underlying Wicomico and Sunderland fms., but possesses a greater proportion of loam and a smaller proportion of decayed materials, and contains numerous lenses of greenish-blue clay, which frequently carry plant remains and are regarded as swamp deposits, formed in mouths of ponded streams and buried by advancing beach of Talbot sea. Base of Talbot terrace is irregular, sometimes lying above tide and sometimes below, but the top, where it borders its sea cliff, is usually limited by the 45- or 50-foot contour. Is top fm. of Columbia group. Overlies Wicomico fm. uncon. Named for Talbot Co., E. shore of Md.

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, Dec. 21). *Talbot fm.* is here restricted to the deposits on 42-foot level, which are same as typical "Chowan" fm., here abandoned. Pamlico fm. is here extended northward and applied to the deposits on the 25-foot level, which have heretofore been included in Talbot fm. [This is present accepted definition of U. S. Geol. Survey.]

The terrace fms. of Columbia group (including the Talbot) now recognized by Cooke from Del. to southern Ga. and probably into Fla., are enumerated herein under *Columbia group.*

Talcott diabase. (In Newark group.)

Upper Triassic: Central Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50, and U. S. G. S. Mon. 29, p. 476). *Talcott diabase*, the "anterior sheet" of Percival. Extends across Conn.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 91–92, 264). After a considerable accumulation of coarse sediments, forming the base of Sugarloaf arkose across bottom of the valley, a bed of lava was poured out on them which "barely enters Mass. [?] from the south" and is called *Talcott diabase*, from its occurrence at Talcott, Conn. It is important in its extension across Conn., "but it barely crosses the State and ends in Suffield, Conn."

Talcott shale. (In Bluefield formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 300, 418). *Talcott sh.*—Gray and sandy, 10 to 25 ft. thick, with marine fossils. Underlies Droop ss. and overlies Ada sh.; all members of Bluefield group [fm.]. Type loc. on S. side of Greenbrier River 0.6 mi. SE. of Talcott, Summers Co. Also observed in Monroe Co. and should be present in Mercer Co.

Talford schist.

Lower Devonian (?): Northwestern New Hampshire (Franconia quadrangle).

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., pp. 8, 13, etc.). *Talford schist* (from a brook by that name in S. part of quad.) is proposed for the schists exposed in a long, discontinuous belt, extending from Mount Hale to Russell Crag. Only few exposures on Talford Brook itself. The schists are gray quartz-mica schists and mica schists, with garnet or sillimanite in some instances. The fm. is precisely like Littleton fm. in Mount Moosilauke area, which suggests the two may be same, but lacking conclusive proof it seems better for present to establish a separate fm. for the schists in Franconia quad. and to assign them doubtfully to lower Dev. They are older than Moat volcanics, from which they are separated by a pronounced uncon.

†Talihina chert.

Ordovician, Silurian, and Devonian: Southeastern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Talihina chert.*—Upper memb. consists of blue, greenish, and white stratified flint and chert 300 ft. thick; middle memb. consists of cherty and clay shales 300 ft. thick; lower memb. consists of 300 ft. of black, bluish, and white stratified flint, chert, and cherty sh., with thin lentils of blue ls. Thickness of fm. 1,200± ft. Underlies Standley sh. and overlies Stringtown sh.

B. F. Wallis, 1915 (Okla. Geol. Surv. Bull. 23, p. 32), restricted Talihina chert to beds of pre-Richmond age, and designated the overlying beds "Unnamed chert of Upper Silurian age."

Named for exposures in Potato Hills, SW. of Talihina, Le Flore Co., where the rocks named "Talihina chert" were in 1929 (Okla. Geol. Surv. Bull. 50, p. 19) divided by H. D. Miser into following mapped fms. (descending): Arkansas novaculite, Missouri Mtn sh., Polk Creek sh., and Bigfork chert.

Talisman quartzite.

Pennsylvanian (?): Southwestern Utah (southeast and northeast of Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Talisman qtzite.*—Fine-grained pink qtzite, 400 ft. thick, underlying Elephant ls. (conformably to N., but uncon. suggested to S.) and overlying (apparently conformably) Topache ls. Type loc. Talisman mine, SE. of Frisco dist.

Talkeetna formation.

Lower Jurassic: Central southern Alaska (Cook Inlet region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 218, 219). The Lower Jurassic rocks of Matanuska Valley and Talkeetna Mtns are here named *Talkeetna fm.* They consist of 3,000± ft. of lava, aggl., breccia, and tuff, interbedded with lesser volumes of ss. and sh. containing fossil plants and marine invertebrates. Chiefly waterlaid volcanics, deposited mostly or wholly in marine waters. Overlain (conformably?) by Tuxedni ss. (Middle Jurassic). Basal contact and underlying rocks not exposed. Are a very prominent strat. and structural element in geol. of E. part of Talkeetna Mtns and of Matanuska Valley. It is possible the fm. may contain more than one strat. unit and that plants and marine shells are not of same age. The plants are oldest Jurassic known in N. Am., according to F. H. Knowlton; the invertebrates suggest Lower Jurassic, according to T. W. Stanton.

Talladega slate.

Pre-Cambrian (?) to Carboniferous: Eastern Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.; no description). [*Talladega (Ocoee) group* is used in table for rocks btw. Ladiga (Potsdam) ss. above and Archean crystalline schists below.]

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala., with explanatory chart). *Talladega (Ocoee, Algonkian)*: Classification uncertain. Probably in part Camb. Unknown thickness of qtzites and congls; argill. or clayey shales, usually partly crystalline; hard greenish sandy shales. Imperfectly crystalline. Overlain by Chilhowee (Weisner) ss., and underlain by Archean crystalline schists.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 49–61). *Talladega sl.*—Occupies belt 6 to 10 mi. or more wide, extending NE. from Chilton and Shelby Counties to State line in Cleburne Co. On SE. is bounded for most of distance by schistose or locally massive greenstone—the Hillabee chlorite schist. On NW. is bounded by several Paleozoic fms. up to Floyd sh. (Miss.). Thickness possibly 30,000 ft. Much the greater part consists either of sl. or sericite phyllite interbedded with minor beds of cgl., ss., ls., marble, dol., chert, graphitic phyllite, and quartz schist. Includes Sawyer ls. memb. (about 4,500 ft. above base), Sylacauga marble memb. (about 4,500 ft. above base, and probably same as Sawyer ls. memb.), Brewer phyllite memb. (lies a few ft. above Sawyer ls. memb.), ferruginous ss. memb. (lies 1,000± ft. above the Brewer), Jumbo dol. memb. (lies several thousand ft. above ferruginous ss. memb.), Cheaha ss. memb. (lies higher than Brewer memb.), Butting Ram ss. memb. (probably same as Cheaha ss.). Assigned to Algonkian (?) and Paleozoic. It seems safe to say it is composed of the shoreward clastic deposits accumulated at intervals during whole time that the predominantly calc. Paleozoic rocks were being deposited in the open sea to westward.

See C. F. Park, Jr., 1935 entry under *Erin sh.*

G. W. Crickmay, 1936 (Geol. Soc. Am. Proc. 1935, p. 72). It is concluded weight of evidence favors a pre-Camb. age for *Talladega series*.

Named for exposures on Talladega Creek, Talladega Co.

Tallahatta formation. (Of Claiborne group.)

Eocene (middle): Southern Alabama, Mississippi, and western Georgia.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 344 and chart opp. p. 334). Name suggested by E. A. Smith. *Tallahatta or Orangeburg fm.*—Hitherto known as the Buhrstone, a local term used for the rough siliceous rocks belonging to Lower Eocene of the Carolinas, Ga., Ala., etc., adopted by Lyell in 1845 (Quart. Jour. Geol. Soc. London, vol. 1, p. 435) for a fm. which he regarded as newer than the white ls. [Vicksburg group]. Buhrstone had been used by Finch and others as early as 1823 (Am. Jour. Sci., 1st ser., vol. 7, p. 38), but the term is of a colloquial rather than a distinctive character. Owing to very great objections to these qualitative mineralogical terms as names for fms., and loose way in which present one has been used in the literature, it has been thought best to propose a geographical name for the original group. The name selected is that of Orangeburg dist. of S. C., the typical loc. of the Buhrstone, as defined by Tuomey (Geol. S. C., 1848, p. 149), in correcting Lyell's stratigraphy. It was in Orangeburg dist. that Tuomey found the fossils which fixed the horizon, and also the thickest and finest exposures. For the exposures of nearly same age, but of different fauna and lithologic character, in Ala., Prof. E. A. Smith suggests *Tallahatta*, from the local name of the hills containing them.

Basal fm. of Claiborne group. Underlies Lisbon fm. and overlies Hatchetigbee fm., of Wilcox group.

Named for development in Tallahatta Hills, Choctaw Co., Ala.

Tallery limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 341). *Tallery ls.*—Yellow shaly and impure calc. bed, 0 to 2 ft. thick, with marine fossils. Underlies Tallery ss. and overlies Upper Tallery sh. All members of Hinton group [fm.]. Type loc. on Tallery Mtn road SE. of True, Summers Co., W. Va. Also observed in Tazewell Co., Va.

Tallery sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 296, 340). *Tallery ss.*—Usually green and shaly, but sometimes massive; 10 to 25 ft. thick. Underlies Lower Fivemile sh. and overlies Tallery ls. All members of Hinton group [fm.]. Type loc. on Tallery Mtn, Summers County, W. Va. Quarried near Athens, Mercer Co., W. Va., and also observed in Tazewell Co., Va.

Tallery shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe and Summers Counties, pp. 296, 342–343). *Upper Tallery sh.*—Usually greenish yellow and slightly calc. deposit, with marine and occasional plant fossils; 10 to 23 ft. thick; underlies Tallery ls. and overlies Tallery coal. *Lower Tallery sh.*—A red and variegated or green and sandy deposit, 25 to 38 ft. thick, underlying Tallery coal and overlying Low Gap ss. All members of Hinton group [fm.]. Type loc. same as Tallery ls. Also observed in Tazewell Co., Va.

Tallulah Falls quartzite.

Basal Cambrian or pre-Cambrian: Northeastern Georgia.

S. L. Galpin, 1915 (Ga. Geol. Surv. Bull. 30, p. 119). *Tallulah Falls qtzite.*—Qtzite, found in Rabun and Habersham Counties in vicinity of cataracts from which the name is taken. In Habersham Co. the rock is mainly a medium-grained qtzite containing some muscovite (sericitic), less biotite, and at times garnet and feldspar. Occasionally the percentage of feldspar rises until the rock bears more resemblance to granite than to qtzite. The qtzite appears to pass conformably into micaceous schists, although there has been considerable intrusion of igneous material near the transition zone. Probably thins rapidly to W. and SW. Probably later than Roan gneiss.

Named for development in vicinity of Tallulah Falls, Rabun Co.

Taloga formation. (In Cimarron group.)

Permian: Western Oklahoma and southern Kansas.

F. W. Cragin, 1897 (Am. Geol., vol. 19, pp. 362–363). *Taloga fm.*—Name proposed to include all of Kiger div. above Day Creek dol., the persistence of Hackberry shales and Big Basin ss. in central Okla. being doubtful, and younger rocks of Kiger div. being present farther W.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, pp. 703–737), used this name as defined by Cragin, as did E. Haworth and J. Bennett, 1908 (Univ. Geol. Surv. Kans., vol. 9). R. C. Moore and W. P. Haynes, however, discarded the name (Kans. Geol. Surv. Bull. 3, 1917), and used *Greer fm.* to include Big Basin ss. and Hackberry sh. of Cragin, as did R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2). There is no other record of *Taloga fm.*, and †Greer fm. was discarded in 1924 by its author.

Named for Taloga, Dewey Co., Okla.

Talon formation.

Devonian(?): Quebec.

J. A. Dresser, 1912 (Canada Geol. Surv. Mem. 35, p. 29).

Talpa limestone. (In Clyde formation.)

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 428). *Talpa bed.*—Nearly all ls., mostly hard and massive, of gray, bluish, and yellowish colors and rather uneven texture. Fossiliferous. Thickness 200 to 300 ft. Memb. of Albany div. Underlies Paint Rock bed and overlies Grape Creek bed.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, p. 36), redefined Paintrock by removing from its base 70 ft. of beds, which they transferred to *Talpa fm.* They gave thickness of Talpa as 400 ft. (See 1918 entry under *Paint Rock bed.*)

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 197–198). *Talpa ls.* is top memb. of Clyde fm. (of Wichita group). Overlies Grape Creek sh. and ls. bed.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 169). Talpa ls. of Drake is top bed of Clyde fm.

Named for Talpa, Coleman Co.

Tamabra.

Cretaceous: Mexico.

J. A. Villatoro, 1932 (Bol. petróleo, vol. 34, Nos. 4–6).

Tamaha sandstone member (of Savanna sandstone).

Pennsylvanian: Eastern Oklahoma (Muskogee, Haskell, and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Tamaha ss. memb.*—Basal memb. of Savanna ss. Thin-bedded, slabby ss.; rarely massive; bedding regular; fine to medium texture; brown; sometimes greenish, brown, and gray; weathers dark brown; much mica and many dark argill. streaks; ripple marks. Thickness in Muskogee-Porum area 10 to 20 ft. Separated from younger Keota ss. memb. by 60 to 70 ft. of sh. Named for exposures at Tamaha, Haskell Co.

Tamán beds.

Jurassic: Mexico.

A. Heim, 1926 (Eclogae geol. Helvetiae, vol. 20, p. 84).

Tamana series.

Tertiary: Trinidad.

G. P. Wall and J. G. Sawkins, 1860 (Geol. of Trinidad, pp. 39–41).

Tamarack formation.

Term applied by O. H. Hershey (Am. Geol., vol. 27, p. 226, 1901) to the gabbro in Klamath Mtn region of northern Calif., which he assigned to pre-Cret.

Tamasopo series.

Lower Cretaceous: Northeastern Mexico.

E. A. Trager, 1926 (A. A. P. G. Bull., vol. 10, No. 7, pp. 671–675, 688). Author proposes that name *Tamasopo series* be applied to that part of Lower Cret. section which includes the two important producing horizons. This series may be divided into two parts: (1) The upper part, which is the Lower Cret. producing horizon in Northern dist., is named the *Tamaulipas* [ls.]. Tamaulipas has been proposed because of its typical exposures in the State of Tamaulipas. (2) The lower part, which is the producing horizon in the South fields and which is typically exposed at El Abra, for which the term "El Abra" is proposed. The exact relationship btw. the producing horizon of the South fields and that of Panuco field, both of which have been termed Tamasopo, is not known. The top of the Tamasopo of the South fields is very badly eroded, and it is thought the Tamaulipas of Panuco dist. uncon. overlies the Tamasopo of the South fields. In outcrop the Tamaulipas is a thin-bedded to massive white to gray, finely crystalline ls. which has been accorded thicknesses of more than 3,000 ft. This ls. underlies a large part of Mexico and is easily distinguished by its physical properties combined with its abundant fauna. It is in part, if not entirely, Lower Cret. If the determination of the presence of Jurassic is correct, then the Tamaulipas ls. is considerably less than 3,000 to 5,000 ft. thick within Panuco dist., as has been previously inferred from outcrop data. The Tamaulipas ls. has heretofore been called "Tamasopo ls.," but that name is a "misnomer." The Tamaulipas ls. is overlain by Upper Cret. San Felipe (San Juan) fm.

†Tamasopo limestone.

Lower Cretaceous: Northeastern Mexico.

Replaced by Tamaulipas ls., as explained under *Tamasopo series*.

Tamaulipas limestone.

Lower Cretaceous (Comanche series): Northeastern Mexico.

See *San Tamaulipas fm.*, also definition under *Tamasopo series*.

Tamesi formation.

Cretaceous: Mexico.

E. T. Dumble and E. R. Applin, 1924 (Pan-Am. Geol., vol. 41, p. 340).

Tamihy series.

Cretaceous (?): Southwestern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines, Mem. 38, map 16, 121°30′ to 122°). *Tamihy series.*—Cgl., green and black sss., and gray shales. Mapped along Tamihy Creek, B. C. and Wash.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 518). *Tamihy series.*—Heterogeneous mass of gray cgl., black qtzitic ss., dark-gray paper shales, gray grit, and green sss. in rapid alternation. Thickness 2,500± ft. Occurs 2 mi. down Tamihy Creek. Assigned to Cret. (?). Seems to lie uncon. on Carbf.

Tampa limestone.

Miocene (lower): Central and northern Florida and southern Georgia.

L. C. Johnson, 1888 (Am. Jour. Sci., 3d, vol. 36, p. 235). The southern lakes, like Thonotosassa and Topoptaliga, have for their bed another phase or stage of the Mio., which for convenience may be called *Tampa fm.*, constituting so thick a layer that the influence of the underlying Eocene is not felt. The same is true of Tampa and Hillsborough Bays. [According to Dall (p. 335 of book cited below) the beds referred to are=part of Tampa ls. of Dall.]

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 112, 113, 117–119, 157, 158, 335). *Tampa ls.*, [also *Tampa beds*], which appears obscurely at Ballast Point and with clearness at other localities, overlying the *Orthaulax* bed, was first clearly described [but not named] by Allen in 1846. He observes: "The first layer of solid rock beneath the soil is a stratum of ls.; it is hard and white, has an earthy texture, and appears to have resulted from comminuted and decomposed shells. The surface of this rock is exposed in several places in vicinity of Fort Brooke; about 2 mi. N., near Hillsboro River; 4 mi. W., on shore of the bay; and 6 or 7 mi. E., in banks of a small stream." This rock I have named *Tampa ls.* It overlies *Orthaulax* bed and underlies Alum Bluff beds. Included in *Tampa group*. Thickness 25 to 30 ft. The chert of Hillsboro River is only a cherty phase of Tampa ls.

G. C. Matson and F. G. Clapp, 1909 (Fla. Geol. Surv. 2d Ann. Rept.). *Tampa fm.* as here defined consists of 0 to 130 ft. of yellow to gray lss., locally cherty, and greenish clay, and it includes (descending): Greenish-gray clay, 15 ft. [now assigned to Alum Bluff group]; "Cerithium rock" (formerly called "Tampa ls."), 40 ft.; "silex bed" (formerly called "Tampa silex bed"), 4 to 10 ft.; ls. similar to "Cerithium rock," 6 ft.; greenish clay, like top bed, 41 to 64 ft. It underlies Alum Bluff group, and is regarded as contemp. with Chattahoochee fm.

C. W. Cooke and S. Mossom, 1929 (Fla. Geol. Surv. 20th Ann. Rept). Name changed to *Tampa ls.*, because fm. is chiefly ls., and redefined so as to include the contemp. "Chattahoochee fm." Early observers attempted to discriminate btw. the "silex bed" (also called "*Orthaulax pugnax* zone" by Dall), the "Tampa ls.," and the "Cerithium rock." Latterly the tendency has been to regard these supposed separate entities as merely different facies or parts of a single fm. The *Orthaulax pugnax* zone lies near top of the fm.

Named for exposures at Tampa, where it underlies the town, and at other places around Tampa Bay.

†Tampa group (broad sense).

Miocene (lower and middle): Northern and southern Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 112–113, 157, 335). The Mio. rocks of Fla. above those forming Chattahoochee group and below the upper fossiliferous bed at Alum Bluff I include in the group which, from their oldest known typical exposure, I name the *Tampa group*. This may be divided into three sets of beds: (1) The Chipola beds (including Sopchoppy ls., *Orthaulax* bed, Bailey's "infusorial earth," the White Beach sandrock, and Chipola marl (or lower bed at Alum Bluff); (2) the Tampa beds (including Tampa ls.); and (3) Alum Bluff beds, or unfossiliferous sand and clay strata intervening btw. Chipola marl and the upper fossiliferous bed at Alum Bluff.

Name abandoned for *Tampa fm.* in narrow sense, which was later changed to *Tampa ls.*

Named for exposures on Tampa Bay.

†Tampa silex bed.

Miocene (lower): Central Florida.

Term used in some early repts to designate the very fossiliferous siliceous bed, 4 to 10 ft. thick, characterized by *Orthaulax pugnax* and included in middle part of Tampa ls. Has also been called *Orthaulax bed*. Contains in abundance the mineral silica (silex), "the most abundant constituent of the earth's crust."

Named for exposures at Tampa.

Tampanogos shales.

See *Timpanogos shales*.

†Tanana schist.

Pre-Cambrian: Eastern Alaska (along Tanana River).

A. H. Brooks, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 468–469, 478, 483). *Tanana schists*, pre-Sil., widely distributed on Tanana River, much less metamorphosed than the gneisses.

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, p. 60), discarded this name for *Birch Creek schist*, the older term.

Taneha sand.

A subsurface sand, of early Penn. (Cherokee) age, in Okla., 0 to 60± ft. thick, lying lower than Bartlesville sand, higher than Burgess sand, and correlated with Tucker and Booch sands. Type region is Rogers and Tulsa Counties.

Taneum andesite.

Miocene: Central Washington (Mount Stuart quadrangle).

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Taneum andesite.*—Hypersthene andesite, including tuffs and tuff-breccias, as well as loose-textured lavas. Thickness 200 to 300 ft. Exposed over several sq. mi. on south branch of Taneum Creek. Of Mio. age.

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139), gave thickness of *Taneum andesite* as 0 to 1,000 ft.

E. J. Saunders, 1914 (Wash. Geol. Surv. Bull. 9), gave thickness of *Taneum andesite* in Kittitas Co. as 300 to 1,500 ft.

Taneytown facies.

Upper Triassic: Maryland.

G. E. Dorsey, 1919 (Geol. Soc. Am. Bull., vol. 30, pp. 155–156). *Taneytown facies.*—Easternmost facies of Newark system in Md. Consists of (1) gray, pink, and red highly arkosic sss., in places very micaceous, underlain by (2) "Potomac marble" (coarse quartz cgl. or ls. cgl.).

Probably named for occurrence at or near Taneytown, Carroll Co.

Taninul limestone.

Upper Cretaceous: Mexico.

J. E. Brantly, 1924 (A. A. P. G. Bull., vol. 8, No. 1, p. 24).

Tank volcanics.

Quaternary(?): Southern California (Kern County).

A. C. Lawson, 1906 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 431–462). *Tank volcanics.*—Andesitic lava flows and tuffs, best exposed in vicinity of railway tank 2 mi. below Tehachapi station, on Tehachapi Creek. Older than Cable fm. and younger than Atlas fm.

Tank Hill limestone.

Lower Ordovician (Chazy): Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171). *Tank Hill ls.*—Lower part is gray fine-grained thin-bedded lss. containing some conglomeratic beds; upper part is thicker-bedded lss. and makes a line of high cliffs a little below Eureka qtzite; upper 50 ft. is shaly ls. and sandy sh. Total thickness 450 ft. Fossils [listed] are of Chazy age, according to E. Kirk. Is in fault relation to underlying Yellow Hill ls., and conformably overlain by Eureka qtzite. Named for exposures on W. face of Tank Hill, in Ely Springs Range.

Tanlajas formation.

Eocene: Mexico.

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, pp. 129, 134). Assigned to Tert.

W. A. Ver Wiebe, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 485). Assigned to Eo.

Tanner shale.

Lower Triassic: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 338). *Tanner shales* is name assigned to basal sh. beds of Moenkopian series outcropping at Tanner's Crossing of Little Colorado River. Thickness 100 ft.

†Tanners Hill red. (In Conewango formation.)

Devonian or Carboniferous: Northwestern Pennsylvania.

Name locally applied (J. F. Carll, 2d Pa. Geol. Survey Rept. I, 1875) to bed of red sh., 15 to 20 ft. thick, lying about 100 ft. above base of Conewango fm. in Warren Co., Pa. Is exposed on Tanner's Hill, Warren Co., according to F. A. Randall (2d Pa. Geol. Surv. Rept. I₄, p. 297, 1883).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 67). In Warren, Pa., region near top of Ellicott sh. memb. of Chadakoin stage is a bright-red paint-rock layer, the so-called "*Tanner's Hill red*" *band* much mentioned in Pa. repts. A red layer 2 or 3 ft. thick occurs beneath Panama cgl. in Wrightsville and Lottsville region, just W. of Warren, Pa. This is presumably Tanners Hill red band. [On pp. 78–79:] At Warren, Pa., Panama cgl. is believed to be represented by the micaceous sparsely pebbled flags immediately above "Tanner's Hill red" band.

Tanner's Hill quarry rock. (In Conewango formation.)

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

F. A. Randall, 1883 (2d Pa. Geol. Surv. Rept. I_4, pp. 297, 304–308, and well sections by J. F. Carll in same rept). *Tanner's Hill quarry rock.*—Yellowish ss., partly massive, partly false-bedded, 14 ft. thick. Is quarried in Tanners Hill section, Warren Co. Lies 151 ft. above Tanners Hill red [sh.].

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 86). In Warren area the Bimber Run cgl. memb. has been variously known, but chiefly as the *"Tanner's Hill quarry rock."*

Tantalus conglomerate.

Jurassic or Cretaceous: Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Mem. 5, p. 35).

Tantalus basalt.

Latest Pleistocene or Recent: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Tantalus volcanics.*—Basalt, clinker, balls, etc., overlying black ash ("black sand") and erupted from Tantalus cone. Included in uppermost part of Honolulu volcanic series [q. v.]. Occurs at Honolulu.

Tantoyuca formation.

Eocene: Mexico.

W. A. Ver Wiebe, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 487).

Taosan series.

A term introduced by C. [R.] Keyes to cover the oldest pre-Camb. rocks of N. Mex. Named for Taos Co. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 11.)

Tapeats sandstone. (Of Tonto group.)

Middle Cambrian: Northern Arizona (Grand Canyon).

L. F. Noble, 1914 (U. S. G. S. Bull. 549). *Tapeats ss.*—Brown slabby, cross-bedded ss.; basal part contains lenses of cgl. having rounded pebbles. Thickness 0 to 285 ft. Is basal fm. of Tonto group. Rests, with great visible angular uncon., on Dox ss., top fm. of Unkar group (Algonkian), and, in places, upon the still older Vishnu schist (Archean). Conformably overlain by Bright Angel sh. Named for Tapeats Creek, below mouth of which, just N. of Shinumo quad., the bed of Colorado River lies within this ss.

Tappan moraine.

Pleistocene (Wisconsin stage): Southeastern New York (Rockland County).

J. B. Woodworth, 1905 (N. Y. State Mus. Bull. 84, pp. 93–94, pl. 2). Named for development at Tappan, Rockland Co.

Tar sands.

Upper Cretaceous: Canada.

R. G. McConnell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 32D to 36D, 53D, 58D to 59D). Exact syn. Dakota.

Tarkio limestone member (of Wabaunsee formation).

Pennsylvanian: Southwestern Iowa, northwestern Missouri, eastern Kansas, and southeastern Nebraska.

S. Calvin, 1901 (Iowa Geol. Surv. vol. 11, pp. 420, 422, 430–437). *Tarkio ls.*—Ls., 27 ft. thick, interbedded with thin sh. beds, and lying about 125 ft. above Nodaway coal. Constitutes second and last assemblage of lss. in Page Co., Iowa.

G. L. Smith, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 77–90, 273–282). *Tarkio ls.*—Yellow, blue, gray, and brown ls. and gray calc. sh., 6 to 12 ft. thick. Underlies McKissick's Grove shales and overlies City Bluffs sh.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 9–18), divided the rocks btw. McKissick Grove shales above and City Bluffs shales below into (descending): Tarkio ls., 12± ft.; sh., 30 to 40 ft.; Preston ls., 2½ to 3 ft.; sh., 17 to 21 ft.; Fargo ls., 11 ft.; sh., 30 to 32 ft.; Burlingame ls., 5 ft. 2 in.; sh., 8 to 12 ft.; Rulo ls., 1 ft. 4 in. They described *Tarkio ls.* as consisting of (descending): ls., 4 ft.; sh., 3 ft. 11 in.; ls., 6 in.; sh., 6 in.; ls., 6 in; sh., 16 in.; ls., 6 to 11 in.

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13, 2d ser.). *Tarkio ls.* is basal memb. of Wabaunsee fm. and same as "Barclay" ls. and "Wyckoff" ls., and Greene has little doubt it is same as Burlingame ls.

J. L. Tilton, 1924 (Iowa Geol. Surv. vol. 29, pp. 230–264), divided the Wabaunsee of SW. Iowa into (descending): McKissick Grove sh., 91 to 93 ft.; *Tarkio ls.* (restricted), 4 ft.; sh. and soft ls., 12 ft.; Preston ls., 1 to 2 ft.; and included the Rulo, Burlingame, and Fargo lss. of Nebr. in Scranton sh.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 57, 90). *Tarkio ls.* is not same as Burlingame ls. but lies 80 to 100 ft. above Burlingame ls. It belongs to Wabaunsee fm. Lies 25 ft. higher than Emporia ls. It overlies Willard sh. memb. and underlies Pierson Point sh., the basal bed of McKissick Grove sh. [This is definition of Tarkio ls. adopted by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr., by Condra in his 1935 rept, and by Moore in his 1936 rept. See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 229, 230). S. Calvin (Iowa Geol. Surv. vol. 11) applied *Tarkio* to rocks on Tarkio Creek, N. of Coin, Page Co., Iowa. Condra, who has carefully studied type Tarkio, concludes the beds named Tarkio by Calvin are unquestionably = beds that have been called Emporia in Kans. Hinds and Greene (1915) misidentified Burlingame ls. as Tarkio ls. Since usage of past 20 years has led to application of *Tarkio* to a ls. that is not recognized at the locality on Tarkio Creek, N. of Coin, Iowa, and since it is desirable to use *Tarkio* in its currently understood sense, the exposures of the Tarkio on Mill Creek, SW. of Maplehill, Kans., may appropriately be chosen as a new "type loc." This procedure may at first seem anomalous, but it is theoretically and practically in accord with principles of good stratigraphy. We follow the principle of usage in accepting *Tarkio* for the ls. thus designated by Condra and Bengston (1915). Thickness in vicinity of Maplehill 1–10± ft. Can be traced from Nebr. southward to northern Lyon Co., Kans., but no outcrops identifiable as Tarkio have been found farther S.

Tarouba shale.

Eocene: Trinidad.

G. A. Waring, 1926 (Johns Hopkins Univ. Studies in geol., No. 7, p. 43).

Tarrant formation.

Upper Cretaceous (Gulf series): Eastern Texas (Trinity and Brazos River regions).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 239, 270, 425). *Tarrant fm.* (from W. L. Moreman's unpublished description).—Type loc., 1 mi. E. of Tarrant station, Tarrant Co., at crossing of St. Louis, San Francisco & Texas Railway over a tributary of Bear Creek. Typical thickness 15 ft. Consists of gray and brownish-gray sandy clay and intermittent thin brownish ls. strata and calc. concretions. The basal stratum, which uncon. overlies Woodbine sand, is a phosphatic pebble cgl. 1 to 6 in. thick. The top is a parting of limonitic material less than 1 in. thick. Underlies Britton fm. Is = basal part of Eagle Ford.

Tarryall formation.

Carboniferous and Triassic (?): Central Colorado (South Park region).

G. A. Muilenburg, 1925 (Colo. Geol. Surv. Bull. 31, pp. 12–25). [*Tarryall fm.* on map, *Tarryall series* in heading on p. 23, which includes *Upper Tarryall fm.* and *Lower Tarryall fm.*]. *Upper Tarryall fm.* consists of 6,000± ft. of bright-red ss. and variegated shales at top, becoming darker and more chocolate-colored at base, also gray sss. with pebbly streaks. *Lower Tarryall fm.* consists of 3,000 to 5,000± ft. of gray to reddish gritty ss. and interbedded sh., with pebbly and conglomeratic streaks. Difficult to separate from Upper Tarryall fm. The Upper Tarryall fm. is = Wyoming fm., and Lower Tarryall fm. is same as Maroon fm. Assigned to Penn. If Morrison fm. is present it has not been separated from Upper Tarryall fm. Exposed in and around Tarryall Creek, Park Co.

Tar Springs sandstone. (Of Chester group.)

Mississippian: Western Kentucky, southern Illinois, and southwestern Indiana.

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, p. 174 and pl. showing geol. section of Hancock, Breckinridge, and Mead[e] Counties, Ky.) and 1857 (Ky. Geol. Surv. vol. 2, pp. 85–88). *Tar Spring and Shot Pouch ss.*—Sub-Carbf. ss., 50 to 70 ft. thick, forming cliff at the Tar Spring, Breckinridge Co., Ky. Overlies Upper Pentremital and Archimedes ls. and is separated from overlying Millstone grit by more than 258 ft. of shales, with interbedded thin lss. and at base a soft ss. Occupies same geologic horizon as *Rock House ss.* on head of Shotpouch Creek.

A. D. Brokaw, 1916 (Ill. Geol. Surv. Extr. from Bull. 35), defined *Tar Springs ss.* of SE. Ill. (parts of Saline, Williamson, Pope, and Johnson Counties) as consisting of 150± ft. of yellowish-brown ss., reddish in places, with locally a sh. above the middle; underlying Menard fm. and overlying Sloans Valley fm. In Breckinridge Co., Ky., it contains tar springs. [†*Sloans Valley* was later discarded for *Glen Dean ls.*]

C. Butts, 1917 (Ky. Geol. Surv., Miss. fms of western Ky, p. 112). *Tar Springs ss.* of Breckinridge Co., Ky., underlies Buffalo Wallow fm. and overlies Glen Dean ls. [The Buffalo Wallow is=Clore, Palestine, Menard, Waltersburg, and Vienna fms. of western Ky. and SW. Ill.]

S. Weller, 1920 (Ill. Geol. Surv. Bull. 41). In Pope and Johnson Counties, Ill., *Tar Springs ss.* underlies Vienna ls. and overlies Glen Dean ls., and Waltersburg ss. separates Vienna ls. from overlying Menard ls.

At one time Tar Springs ss. was believed to be same as †Big Clifty ss., but latter is now known to be same as the older Cypress ss.

Named for Tar Springs, 3 mi. S. of Cloverport, Breckinridge Co., Ky.

Taseko formation.

Oligocene (?): British Columbia.

J. D. MacKenzie, 1921 (Canada Geol. Surv. Summ. Rept. 1920, pt. A, pp. 52, 77).

†Tassajara lake (?) bed. [U. S. Geographic Board has adopted spelling Tassajero.]

Pliocene probably: Western California (Alameda County).

J. G. Cooper, 1894 (Calif. Acad. Sci. Proc., 2d ser., vol. 4, p. 170). *Tassajara lake (?) bed.*—Along a small branch of Walnut Creek, in Alameda Co., N. of Livermore, is a deposit which contains chiefly living species, and was formerly called *Quat.*, but one extinct species has been described from there, and its high elevation, nearly corresponding with Contra Costa lake bed, makes it probable it may better be called *Plio.* [Fossils listed.]

Probably named for exposures on Tassajero Creek, Alameda Co.

Tassajero formation.

Pliocene or Pleistocene: Berkeley Hills, California.

B. L. Clark, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 151). Moraga fault shows conclusively that Moraga series and Orinda and Siesta fms. are cut off at the fault, and that the continental deposits to E. of fault are younger than any on W. side of the fault. All of these rocks, which are so well exposed on W. side of Moraga fault, are buried beneath these later sediments on E. side. The continental beds on E. side of the fault have thickness of over 4,000 ft. They contain no lavas, and tuff beds are lacking except in lowest portion of section exposed in an anticline W. of town of Lafayette. A sliver block along Las Trampas fault, which is on SW. side of Lafayette, exposed vesicular lavas which undoubtedly underlie this section of later Plio. deposits E. of Moraga fault. Vertebrate fossils of Orinda and Siestan fms. of Berkeley Hills area place the fms. in Lower Plio. A limb bone of *Equus* was obtained in the series E. of Moraga fault. This places these beds either as Upper Plio. or Lower Pleist. The name *Tassajero fm.* is proposed for this series of deposits. Type section is on SW. side of Mount Diablo where it is crossed by Tassajero Creek. It is probable Tassajero fm. includes beds of Middle and Upper Plio. and Lower Pleist. age.

†Tatalina group.

Lower Ordovician, possibly Cambrian, and (chiefly) pre-Cambrian: Northeastern Alaska (Yukon-Tanana region).

L. M. Prindle, 1913 (U. S. G. S. Bull. 525, pp. 37-38). *Tatalina group*.—An aggregate of feldspathic fragmental rocks, including cgls., sss., and graywackes, interbedded with argillites which are in places altered to phyllites; considerable chert. As mapped [in Fairbanks quad.] includes some ls. which may or may not be an integral part of the group. In White Mtns region [in Fairbanks quad.] includes considerable greenstone in form of ancient tuffs and lavas lithologically similar to the rocks described as undiff. greenstones but older than most of them. The group is typically exposed in valley of Tatalina River. Thickness probably several thousand ft. Rests uncon. on Birch Creek schist, and in White Mtns is overlain by ls. ranging in age from Ord. to Dev. Fossils indicate upper part of group is Ord. Lower part may be Camb., but provisionally the group is referred to Ord.

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). Upper part of Tatalina group of Prindle is Middle Ord. and is here named *Fossil Creek volcanics*. Major part of group is pre-Camb., but it includes some Lower Ord. and possibly some Camb. It is here included in assemblage mapped as "undiff. pre-Middle Ord. rocks," which appear to be contemp. with part of Tindir group of pre-Camb. and Lower Camb. (?) age. Tatalina group is therefore abandoned.

Tatay limestone.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 334, 338).

Tate member. (In McMillan formation.)

Upper Ordovician: Central Kentucky to southwestern Ohio.

A. F. Foerste, 1906 (Ky. Geol. Surv. Bull. 7, pp. 19, 212). *Tate layer* belongs in upper half of Fairmount bed.

A. F. Foerste, 1912 (Denison Univ. Sci. Lab. Bull. 17, pp. 18, 23, 49). *Tate memb.*—Important, practically unfossiliferous argill. section, 0 to 30 ft. thick, occurring btw. Fairview and McMillan divisions of the Maysville. [In table on p. 23 and on p. 18 *Tate memb.* is included in McMillan fm.] Traceable from Casey and Boyle Counties in central Ky. to Adams Co., Ohio.

A. F. Foerste, 1924 (Canada Dept. Mines, Geol. Surv., Mem. 138, No. 121 geol. ser., p. 30, chart opp. p. 58). *Bellevue (Tate)* underlies Corryville and overlies Fairmount. Writer has assumed that Tate memb. corresponds to Bellevue.

Derivation of name not stated.

Tatei formation.

Cambrian: British Columbia.

L. D. Burling, 1922 (Geol. Soc. Am. Bull., vol. 33, p. 109).

Tatina group.

Ordovician and Silurian (?): Central southern Alaska (Mount McKinley region).

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, pp. 55, 69-73, map). *Tatina group*.—Sediments, dominantly calc. but including considerable argill. and some aren. material, which form oldest known Paleozoic terrane of Mount McKinley region. Consist of blue lss. interbedded with black carbonaceous argillites and thin-bedded siliceous lss. and calc. slates, along N. front of Alaska Range. Ord. fossils in argillites in lower part. Upper part may be post-Ord. Thickness 4,000 to 5,000+ ft. Type exposures in upper basin of Tatina River, formerly called Rohn River. Exposed on the river and traced to East Fork of the Toklat. Without doubt older than Tonzona group.

†Tatman formation.

Eocene (middle?): Northern Wyoming (Bighorn Basin).

W. J. Sinclair and W. Granger, 1912 (Am. Mus. Nat. Hist. Bull., vol. 31, pp. 60-62). *Tatman fm.*—Yellowish shales, yellow-brown and gray sss., and much lignite. Thickness 0 to 600 ft. Except a few scraps of bone no vertebrate fossils found. Invertebrate fossils suggest probably Eo., possibly Bridger. Named for Tatman Mtn. Not found N. of Gray Bull River. Lies conformably on Lost Cabin fm. (of Wind River group), and is overlain by *post-Tatman andesitic gravels* [apparently *Tatman Mtn gravels* of their 1911 rept].

Tatman Mountain gravels.

Oligocene (?): Northern Wyoming (Bighorn Basin).

W. J. Sinclair and W. Granger, 1911 (Am. Mus. Nat. Hist. Bull., vol. 30, pp. 88, 105–111). *Tatman Mtn gravels*, 30 to 60 ft. thick, of Olig. (?) age (no fossils). On Tatman Mtn overlie beds that may correspond to Uinta and Bridger fms. (Eo.). These gravels are fragments of a fm. now almost entirely destroyed by erosion.

Tatonduk shales.

Ordovician: Canada (Yukon).

L. D. Burling, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 128).

Tatums sand.

A subsurface sand, of Penn. age, in Tatums pool, Carter Co., Okla., lying at depths of 1,200 to 2,800 ft. in the producing area. Thickness 125 ft. (See A. A. P. G. Bull., vol. 19, No. 3, 1935, pp. 401–411.)

Taunton clays.

Name applied by J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, p. 986), in heading, to Pleist. clays occurring near Taunton, Mass., which were worked for brick.

Tawas moraine.

Pleistocene (Wisconsin stage): Northeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Included in Port Huron morainic system. Named for Tawas, Iosco Co.

Taylor marl.

Upper Cretaceous (Gulf series): Central and eastern Texas.

R. T. Hill, 1892 (Artesian Invest. Final Rept., pt. 3, p. 73, 52d Cong., 1st sess., S. Ex. Doc. 41, pt. 3). *Taylor or Exogyra ponderosa marls.*—Chalky clays, 1,200 ft. thick, characterized by *Exogyra ponderosa*. Overlie Austin-Dallas chalk and underlie Uppermost or Glauconitic div. (Navarro fm.) of Cret.

Named for Taylor Prairie, central Tex.

Taylor meta-andesite.

Mississippian: Northern California (Taylorsville region).

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Taylor meta-andesite.*—Green, in places slaty meta-andesite, more than 1,000 ft. thick. Occurs as lava flows, tuffs, and volcanic cgl. Conformably overlies Arlington fm. and conformably underlies Shoofly fm.

Named for exposures around Taylor Rock, Taylorsville region.

Taylor sandstone. (In Greene formation.)

Permian: Northern West Virginia and southwestern Pennsylvania.

R. V. Hennen, 1909 (W. Va. Geol. Surv. Rept. Marshall, Wetzel, and Tyler Counties, p. 173). *Taylor ss.*, 20 to 165 ft. thick, lies 100 to 150 ft. below Gilmore ls. and higher in section than Nineveh ss. Named for Taylor Twp, Greene Co., Pa.

In some subsequent repts of W. Va. Geol. Surv. the name *Taylor ss.* has been applied to a ss. lying btw. *Upper* and *Middle Rockport lss.* and in other repts to a ss. lying btw. *Middle* and *Lower Rockport lss.*

Taylor Branch limestone.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

See under *South Fork ls.*

Taylors Ridge.

A name applied (in table and without definition) by G. Little (Hdb. of Ga., Com. of Agric., 1876, p. 40) to the representative of Medina epoch in Ga. Placed above "Cincinnati shales" and below "Fossiliferous Iron, of Clinton epoch."

Taylorsville formation.

Devonian: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Taylor[s]ville slates,* 1,800 ft. thick. Older than Arlington beds and younger than Montgomery ls.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Taylorsville fm.*—Chiefly slates and thin-bedded sss., among which there are numerous small layers of fine black chert or occasional less regular masses of red chert, but at base there is locally a fine greenish-gray cgl. with indistinct pebbles, and near middle well-defined beds of light-colored qtzite. Thickness 1,800 ft. Rests with probable uncon. on Montgomery ls. Is older than Arlington fm., from which it is separated by granite. Fossils not distinctive, but fm. is believed to be Dev.

Named for exposures on E. face of spur above the ls. about 1 mi. S. of Taylorsville, Plumas Co.

Taylortown limestone. (In Washington formation.)

Permian: Southwestern Pennsylvania (western part of Washington County).

E. V. d'Invilliers, 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, p. 2577). *Taylortown ls.*—Compact, massive ls., 10 to 20 ft. thick. Lies 2 to 10 ft. below Little Washington coal at all exposures in western Washington Co. Overlies Taylortown (Waynesburg "B" coal of Rept. K). [Probably named for *Taylorstown* or *Taylorstown Station*, Washington Co.,]

Taylorville slates.

See *Taylorsville fm.*

Tazewell substage.

Pleistocene: Mississippi Valley.

See under *Mankato substage* and *Wisconsin stage.*

Tazewell loess.

Pleistocene: Iowa and Illinois.

See 1933 entry under *Wisconsin stage.*

Tazin series.

Pre-Cambrian: Alberta and Northwest Territories.

C. Camsell, 1915 (Canada Geol. Surv. Summ. Rept. 1914, pp. 58, 59) and 1916 (Canada Geol. Surv. Mem. 84, p. 25).

Teanaway basalt.

Eocene: Central Washington (Mount Stuart and Snoqualmie quadrangles).

G. O. Smith and B. Willis, 1901 (Am. Inst. Min. Engrs. Trans., vol. 30, p. 359). *Teanaway basalt.*—Older than Roslyn ss. and younger than Swauk ss.; all of Eo. age.

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Teanaway basalt* underlies Roslyn fm. and rests with slight uncon. on Swauk fm.

G. O. Smith, 1904 (U. S. G. S. Mount Stuart folio, No. 106). *Teanaway basalt* is a series of lava flows with interbedded tuffs; the basalt is black and very compact. Conformably underlies Roslyn ss. (Eo.) and rests uncon. on Swauk fm. (Eo.).

G. O. Smith and F. C. Calkins, 1906 (U. S. G. S. Snoqualmie folio, No. 139), gave thickness as 500 to 6,000 ft.

Teapot sandstone member (of Mesaverde formation).

Upper Cretaceous: Eastern Wyoming.

V. H. Barnett, 1915 (U. S. G. S. Bull. 581, p. 113). [See 1915 entry under †*Little Pine Ridge ss.*]

Teapot Mountain porphyry.

Early Tertiary (?): Central Arizona (Ray district).

F. L. Ransome, 1919 (U. S. G. S. P. P. 115, p. 126, pl. 45). Of the two varieties of quartz monzonite porphyry in Ray dist. the Granite Mtn porphyry occurs almost wholly in S. half of dist., while *Teapot Mtn porphyry* is characteristic of N. half. Both are intrusive. Largest exposure of Teapot Mtn porphyry is on ridge S. of Teapot Mtn and W. of the metallized schist area.

Teay formation.

Pleistocene: Southwestern West Virginia.

M. R. Campbell, 1900 (U. S. G. S. Huntington folio, No. 69). *Teay fm.*—Gravel, sand, and finely laminated clay deposited by ancient Kanawha River. Thickness 0 to 60 ft. Forms floor of Teay Valley, Cabell Co.

Tecovas formation. (In Dockum group.)

Triassic (Upper?): Panhandle of Texas.

C. N. Gould, 1907 (U. S. G. S. W. S. P. 191, pp. 20–29). *Tecovas fm.*—Largely shales. Lower part more or less sandy sh., chiefly maroon, lavender, yellow, and white; upper part dark-red or magenta sh. Thickness 90 to 220 ft. Lower fm. of Dockum group. Uncon. overlies Quartermaster fm. and underlies Trujillo fm.

Named for exposures on Tecovas Creek, Potter Co.

Tecuja beds.

See *Tecuya beds.*

Tecumseh shale. (In Shawnee group, Kansas.)

Tecumseh shale member (of Shawnee formation, Missouri).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 28). *Tecumseh sh.*—Fine-textured olive-colored shales, containing many ferruginous concretions and occasional beds of soft shaly ss. Thickness 75 ft. Basal part of Upper Coal Measures in Shawnee Co., Kans. Underlies Calhoun [Deer Creek] ls.

The present generally accepted definition treats Tecumseh sh. of Mo. as a memb. of Shawnee fm., overlying Lecompton ls. memb. and underlying Deer Creek ls. memb. In Kans. the Shawnee is treated as a group and the Tecumseh sh. as a fm. G. E. Condra and R. C. Moore have divided Tecumseh sh. into 3 members (descending)—Rakes Creek sh., Ost ls., and Kenosha sh.; and Moore stated (1936) that to N. the upper bdy of their Rakes Creek sh. extends up to base of Rock Bluff ls. of Condra. (See 1936 entry under *Rakes Creek sh.*)

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Named for exposures at Tecumseh, Shawnee Co., Kans.

Tecuya beds.

Miocene (lower): Southern California (San Joaquin Valley).

C. Stock, 1920 (Calif. Univ. Pub. Dept. Geol. Bull., vol. 12, No. 4). *Tecuya beds.*—Land-laid beds in which red sss. and shales are most striking lithologic members, but lavas and tuffs are also present. Rests uncon. on Tejon fm. in immediate vicinity of Tecuja [Tecuya] Canyon, in lower part of San Joaquin Valley, and is overlain, without evidence of uncon., by Monterey marine deposits, presumably with Vaqueros fauna. The beds may be contemp. with part of Sespe fm. or may belong to Monterey series.

B. L. Clark, 1921 (Jour. Geol., vol. 29, pp. 586–614, and Proc. First Pan-Pacific Sci. Conf., pt. 3, pp. 801–818). The *Tecuja beds* are continental deposits intercalated in marine Vaqueros group, and it seems to writer they are lower Mio., rather than upper Olig.

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169), included *Tecuya* in Mio. but showed it as older than Vaqueros ss.

Tegucigalpa.

Upper Triassic: Honduras.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 356).

Tehachapi marble.

Southern California (Kern County).

H. G. Hanks, 1886 (Calif. State Min. Bur. 6th Ann. Rept. State Min. pt. 1, p. 23). *Tehachapi marble.*—A large deposit of yellow brecciated marble situated ½ mi. from town of Tehachapi, Kern Co., on road to Caliente, also 9 mi. W. of Tehachapi, in Bright's Valley.

Tehachapi formation.

Quaternary (?): Southern California (Kern County).

A. C. Lawson, 1906 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, pp. 431–462). *Tehachapi fm.*—A great body of post-lacustrine coarse alluvium in fresh, undecomposed condition, only slightly cemented. Thickness 250 ft. Younger than Cable fm.

Probably named for occurrence near town of Tehachapi and in Tehachapi Creek Valley, Kern Co.

Tehama formation.

Pliocene: Northern California (Tehama County).

R. D. Russell and V. L. Vander Hoof, 1931 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 20, No. 2, pp. 11–21). *Tehama fm.*—Name proposed by Mr. Russell. Consists of 2,000± ft. of massive pale greenish-gray to pale-buff sandy clays, which are usually tuffaceous. Intercalations of sand and gravel, often strongly cross-bedded, are present throughout. A massive coarse-grained pumice tuff memb. (for which C. A. Anderson and R. D. Russell propose name *Nomlaki tuff memb.*) occurs near base. This same tuff memb. occurs near base of Tuscan fm., so that the two fms. must be in part contemp., and they in fact interfinger, but their conditions of deposition are in general dissimilar. The Tehama consists of flood-plain deposits laid down on a comparatively low-lying land surface, while the Tuscan is largely composed of aggls., presumably mud flows. The Tuscan fm. is almost exclusively andesitic material derived from old volcanoes in Lassen region; the Tehama, with exception of Nomlaki tuff memb., contains only a very subordinate amount of volcanic debris. The Tuscan fm. extends along E. border of Sacramento Valley from Pentz northward almost to Pit River and E. into Lassen Peak region. The Tehama fm. occurs on W. side of Sacramento Valley. The Tehama fm. lies, with uncon. and overlap, on Cretaceous Chico-Shasta series, and is overlain discon., and locally with angular uncon., by Red Bluff fm. (Pleist.). Named for outcrops in Tehama Co. Strat. evidence indicates Tehama and Tuscan fms. are probably Plio. Vertebrate evidence (from above Nomlaki tuff memb.) indicates that both are Upper Middle to Upper Plio.

Tehuacana member (of Kincaid formation).

Eocene (lower): Eastern Texas.

G. D. Harris, 1896 (Bulls. Am. Pal., vol. 1, No. 4, pp. 129, 155). In vicinity of Tehuacana, Limestone Co., the ls. beds of the Midway aggregate at least 40 ft. They are overlain by yellowish and bluish, slightly argill. sandy layers, which so far as observed are unfossiliferous. West of the College, say ½ mi., yellowish calc. sands occur 45 ft. or more below base of the ls. (p. 129). [In correlation table on p. 155 Harris placed *Tehuacana ls.* in middle Midway, and showed it as overlain by upper Midway sands to S. of Tehuacana and as underlain by lower Midway boulder clay to N. of Tehuacana, and he called the *upper Midway* the *Wills Point clays and sand*, which is a restriction of *Wills Point* as used by others.]

F. B. and H. J. Plummer, 1928 (Pan-Am. Geol., vol. 49, p. 297), divided Midway into an upper zone of sandy clays and silts containing large concretionary masses, a middle zone of dark-gray clays, and a basal zone of yellowish or buff-gray clays and glauconitic sands, and stated "that the lowest and middle divisions are in some places separated by a ls. lentil known as the *Tehuacana ls.*, and in other places by a layer of glauconitic sand."

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 496, 532, 535, 536, 539, 541, 542, 544, 545, 553). *Tehuacana ls. lentil.*—Top part of Pisgah memb. of Kincaid fm. Proposed by Harris (1896) for the Midway ls. at Tehuacana. Consists of 4 to 50 ft. of coquina, oolite, compact indurated shell marl and ls. Extends through Limestone, Navarro, and Kaufman Counties. Type loc. is the abandoned quarry at Tehuacana, Limestone Co. Underlies Wills Point fm. [restricted].

J. Gardner, 1935 (Univ. Tex. Bull. 3301, pp. 22–26), excluded these beds from Pisgah memb. and treated them as a distinct memb., called *Tehuacana memb. of Kincaid fm.*, which she described as consisting of calc. glauconitic sands, characteristically indurated with a calc. cement, the heavy glauconitic, highly fossiliferous, loosely indurated sands with or without phosphatic nodules, and all other equiv. deposits btw. top of Pisgah memb. (restricted) and base of Wills Point fm. The name Tehuacana "ls." commonly applied to this unit is largely a misnomer, although it does contain intercalated sandy ls. lenses. Lower part of the Tehuacana is typically exposed along W. face of scarp on which town of Tehuacana stands. The higher horizons are best represented in the quarry ½ mi. E. of the town. About 72 ft. of section are included in the Tehuacana outcrops. About 20 ft. above base is oyster bed, and 10 ft. higher is another oyster bed. Max. thickness of outcrop is less than 100 ft., but indicated thickness in well logs approximates 200 ft.

†Tehuacana formation. (Broad usage.)

Eocene (lower): Eastern Texas.

Julia Gardner, 1932 (Prel. ed. geol. map of Tex.), applied *Tehuacana fm.* to lower part of Midway group and restricted *Wills Point fm.* to upper part of Midway group.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 532–533). The name *Tehuacana* was given by Harris to designate the Midway ls. at Tehuacana, and is now in good usage among geologists for this ls. lentil. Miss Gardner selected Tehuacana Bluff (the steep hill just W. of town of Tehuacana, Limestone Co.) as typical of *Tehuacana fm.* as used in prel. ed. of Tex. geol. map for all Midway deposits beneath Wills Point fm. [restricted], and this is best possible type loc. for basal Midway div. The name *Tehuacana* being in good standing among geologists for the ls. lentil, it seems best to apply a new name to the basal fm. of Midway group, in order to avoid confusion. Julia Gardner has proposed for it the name *Kincaid fm.*

Tejon formation.

Eocene (upper): Western California.

W. M. Gabb, 1869 (Calif. Geol. Surv. Pal., vol. 2, p. xiii, as reported by J. D. Whitney from unpublished paper by Gabb, and footnote by Gabb on p. 129). Div. B of Cret. of previous Calif. repts is here named *Tejon group*, from locality where it is most strongly developed. This div. of the Cret. is peculiar to Calif. Is found most extensively developed in vicinity of Fort Tejon and about Martinez. From latter locality it forms an almost continuous belt in the Coast Ranges to Marsh's, 15 mi. E. of Monte Diablo, where it sinks under San Joaquin plain. It was also discovered at various points in E. face of same range as far S. as New Idria, and in summer of 1866, by Mr. Gabb, in Mendocino Co., near Round Valley, the latter locality being most northern point at which it is as yet known. Is the only coal-producing fm. in Calif. Contains a large and highly characteristic series of fossils, the larger part peculiar to itself, while a considerable precentage is found extending below into the next [Martinez] group, and several species still farther down into Chico group. [On p. 147 Gabb mentioned "beds intermediate btw. Tejon group and Martinez group W. of town of Martinez," but no such beds are mentioned in connection with definitions of Tejon or Martinez.]

In 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 94, 281) the name *Tejon fm.* was restricted by B. L. Clark to upper part of the Tejon of previous usage, or to the beds containing a "typical Tejon fauna," the uncon. underlying beds being named *Meganos group*. The U. S. Geol. Survey uses the restricted definition of Tejon fm. The Eo. age of Tejon fm. has long been recognized.

See also under *Domengine fm.*

Named for occurrence in vicinity of Fort Tejon, Kern Co.

Tekonsha moraine.

Pleistocene (Wisconsin stage): Southern Michigan. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for Tekonsha, Calhoun Co.

Telegraph Creek formation. (Of Montana group.)

Upper Cretaceous: Central southern Montana (Stillwater to Rosebud Counties region).

W. T. Thom, Jr., July 6, 1922 (U. S. G. S. Bull. 736B, p. 38). *Telegraph Creek fm.*—Yellow sandy sh. parted in middle by a thin bed of concretionary ss., which caps an escarpment. Less prominent layers of concretionary ss. occur in upper half of fm. Thickness 320 ft. Underlies Virgelle ss. memb. of Eagle ss. and overlies Niobrara sh. Fossils predominantly Montana types. They include several sp. found in Eagle ss., mingled with forms usually found in Niobrara sh., of latest Colorado age. Typically developed at head of Telegraph Creek, T. 2 S., Rs. 28 and 29 E., Crow Indian Res.

†Telegraph Hill sandstone. (In Franciscan group.)

Jurassic(?): Western California (San Francisco).

R. Crandall, 1907 (Am. Phil. Soc. Proc., vol. 46, pp. 3-58). *Telegraph Hill ss.*—Sss. and shales very similar to the older San Bruno ss. of the Franciscan. Thickness 800 to 1,000 ft. Is topmost fm. of Franciscan or Golden Gate series. At the Potrero the fm. rests on the jaspers of the Franciscan, which overlie San Bruno ss. Named for exposures at Telegraph Hill, San Francisco.

A. C. Lawson (U. S. G. S. San Francisco folio, No. 193, 1914) mapped this ss. as *Marin ss.*

Telescope group.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930 (Econ. Geol., vol. 25, p. 311 and map). *Telescope group.*—Consists of 7 mapped units (descending): *Redlands dolomitic ls., Radcliff fm., Sentinel dol., Wildrose fm., Mountain Girl cgl.-qtzite, Middle Park fm.,* and *Sour Dough dolomitic ls.* The Mountain Girl cgl.-qtzite overlies Middle Park fm. with discon.(?), and the Sour Dough ls. noncon. overlies Surprise fm. The names of these fms. are derived from geographic terms used in this [southern] part of Panamint Range. The rocks have nearly all been metamorphosed to some degree. In absence of diagnostic paleontologic evidence the age of all fms. is open to question. Tentative assignment to Lower Paleozoic has been made largely on lithologic grounds. The rocks are undeformed.

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July-Oct. 1932, pp. 329-356), redefined *Telescope group*, by including at top a newly named fm. (Hanaupah fm.) 1,500± ft. thick. The fm. overlying Telescope group is in this publication named *Death Valley fm.* It also is assigned to lower Paleozoic (?). Appears to be named for Telescope Peak, S. part of Panamint Range, on and around which the fms. of the group are mapped.

Tellera (also Tellara) limestone.

Pennsylvanian (?): Central northern New Mexico (Sandia Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257-259; Conspectus of geol. fms. of N. Mex., pp. 3, 11). [*Tellera* on p. 3; *Tellara lss.* on p. 11.] Uppermost gray ls. memb. of Maderan series, exposed on E. flank of Sandia Range. Thickness 300 ft. [Derivation of name not given.]

Tellico sandstone. (In Blount group.)

Lower Ordovician (Chazyan): Southeastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 4). *Tellico ss.*—Bluish-gray and gray calc. sss. and sandy shales closely interbedded. Weathers to porous sandy rock with strong red color. Southeast of Bays Mtn is 800 to 900 ft. thick and overlies Athens sh. and underlies Sevier sh.; NW. of Bays Mtn is 250 to 500 ft. thick and overlies Chickamauga ls. and underlies Sevier sh.

According to C. Butts and E. O. Ulrich is of Chazy age. Is considered by A. Keith to be strat. equiv. of Moccasin ls. of E. Tenn., but according to C. Butts and E. O. Ulrich the Moccasin of E. Tenn. is all of Black River age, and typical Moccasin of SW. Va. is a facies of lower or Lowville part of the Black River.

Named for exposures in cut on Tellico River, Monroe Co., Tenn.

Tellowa formation. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44). *Tellowa fm.*—Interbedded ss. and sh. with one large and several small coal seams, composing all Carbf. rocks of Tazewell area that overlie Sequoyah fm. Thickness 500 ft. Is similar in composition to Sequoyah fm., but carries some larger coal seams. [Type loc. not stated and unknown.]

Telluride conglomerate.

Oligocene(?): Southwestern Colorado.

W. Cross, 1901 (U. S. G. S. Bull. 182, pp. 29-39). *Telluride cgl.*—Cgl. free from volcanic material but containing pebbles of very hard sed. rocks of Mesozoic and

Paleozoic age and of schists, granites, and Algonkian qtzites. Thickness in Silverton quad. 1,000 ft. Overlies Dolores fm. uncon. and uncon. underlies San Juan series of igneous rocks. In previous rept called San Miguel cgl., but that name is preoccupied. Named for exposures about town of Telluride and throughout Telluride quad.

Temapache limestone.

Oligocene: Mexico.

E. T. Dumble, 1918 (Calif. Acad. Sci. Proc., 4th ser., vol. 8, p. 146). Assigned to Tert.

W. A. Ver Wiebe, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 494). *Temapache beds* assigned to Olig.

Temblor formation.

Miocene (middle): Southern California (Kern County).

F. M. Anderson 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, pp. 168–187). *Temblor beds.*—The entire series of Mio. sands and shales below Monterey shales in Mount Diablo Range. Thickness 1,500 ft. Include (descending):

"Button beds," 100 ft. (sandy beds characterized by great numbers of small discoidal sea urchins, *Astrodapsis*).

Siliceous and clay shales with interstratified ss., 600 ft.

Sss. with numerous fossil species, 800 ft.

Rest uncon. on Domijean sands. In some places there is distinct overlapping of Monterey shales beyond borders of Temblor beds. [Fossils listed.]

F. M. Anderson, 1908 (Calif. Acad. Sci. Proc., 4th ser., vol. 3, pp. 1–40). *Temblor beds.*—Calc. beds, clay sh., sands, and gravels, with a pebbly cgl. at base and containing typical lower Mio. fossils. Thickness 450 to 550 ft. The "Reef bed" of former rept [which was included in †Coalinga beds] is properly a part of Temblor beds. Rest uncon. on Olig.(?) organic shales, which in former rept were thought to be Mio. and were called *Monterey shales*, and which overlie Domijean sands. Strat. and faunally "Vaqueros ss." agrees with Temblor beds and is without doubt to be correlated with the Temblor of Mount Diablo Range.

J. P. Smith, 1910 (Jour. Geol., vol. 18, No. 3). *Temblor ss.*—Type Temblor is younger than type Vaqueros, and carries fauna like that of *Ocoya Creek beds*. The Temblor fauna carries *Turritella ocoyana* and other fossils, while the older or type Vaqueros is characterized by *Turritella inezana* fauna. True Vaqueros is absent in Coalinga region, the type section of the Temblor, and true Temblor is absent in Salinas Valley, the type region of the Vaqueros. True Temblor underlies the diatomaceous Monterey sh.

F. M. Anderson, 1911 (Calif. Acad. Sci. Proc., 4th ser., vol. 3, pp. 17+). *Temblor group.*—[Describes these deposits in Kern River region and the part of Mount Diablo Range that is locally known as "Temblor Mtns."] Chiefly marine, but locally contains a fresh-water or brackish-water facies. Thickness ranges up to 1,760 ft. Correlates with *Ocoya Creek beds*. If Monterey is present it cannot be separated from Temblor group. The more shaly part is nearest the base, and the beds become coarser toward top, though clays are distributed throughout the column. Called "Vaqueros" by Arnold and others. Uncon. underlies Kern River group and rests uncon. on granite.

F. M. Anderson and Bruce Martin, 1914 (Calif. Acad. Sci. Proc., 4th ser., vol. 4, pp. 31–51). *Temblor (Vaqueros) beds.*—[Gives details of the beds.] Thickness 500 to 2,500 ft. in Temblor Basin and San Juan dist. Uncon. underlies Monterey sh. and uncon. overlies granite. It has yet to be shown that the so-called Vaqueros beds of Salinas Valley are older in time than the Temblor deposits at base of Mio. in the Great Valley.

B. L. Clark, 1921 (Jour. Geol., vol. 29, pp. 586–614). The Monterey series contains two fairly distinct but closely related faunas, the upper the *Temblor group* or *Turritella ocoyana* zone, the lower the *Vaqueros group* or *Turritella inezana* zone. A very large percentage of Vaqueros species is common to the Temblor. The marine Temblor includes the middle Mio. land fm. locally known as the *Big Blue*. The Temblor group corresponds to "Salinas sh." and "Monterey sh." of other repts, but is older than Maricopa sh. and Briones ss. In most places it uncon. overlies Vaqueros group and uncon. underlies Santa Margarita fm.

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770). Faunas of Vaqueros and Temblor horizons have always been found in same sequence, and though they are very different they occur in similar facies of deposition (arkosic sss.). To N. the Temblor is conformable on underlying Vaqueros; in southern Calif. there is well-marked uncon. btw. them.

The present generally accepted definition of Temblor fm. applies the name to the deposits that include the *Turritella ocoyana* zone, of middle Mio. age and younger than Vaqueros fm. (*Turritella inezana* zone), of late lower Mio. age. H. G. Schenck, however (A. A. P. G. Bull., vol. 19, No. 4, pp. 521–534, 1935), considers lower part of type Temblor is = upper part of Vaqueros at its type loc.

Named for exposures on Temblor ranch, in McKittrick dist., Kern Co.

Temecula Canyon granite.

Age(?): California.

W. A. Goodyear, 1889 (Calif. State Min. Bur. 9th Ann. Rept., p. 149).

Temescal formation.

Recent: Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Temescal fm.*—Secondary alluvium derived from main alluvial embankment of San Antonio fm. in course of its degradation, and consisting of same kind of material, namely, fragments of Mesozoic and Tert. rocks. Thickness varies up to 13 ft. Rests uncon. on marine Merritt sand, of Pleist. age. Named for development along Temescal Creek, Alameda Co.

Temescal porphyry.

Late Jurassic(?): Southern California (Riverside County).

P. H. Dudley, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 223). *Temescal porphyry.*—Extensive dacite porphyry in part of Riverside Co. btw. towns of Riverside and San Jacinto and Corona and Elsinore. Younger than Elsinore series and older than Alberhill clays (Eocene). [Dudley gave full description in Calif. Jour. Mines and Geol., vol. 31, No. 4, 1935, pp. 491, 496–500 (and map), and assigned it to late Jurassic(?).]

†Temiscamian series.

†Temiscaming series.

Variants of †Timiskamian series.

Temiscouata group.

Silurian (Niagaran): Quebec.

H. W. McGerrigle, 1934 (Quebec Bur. Mines Ann. Rept. 1933, pt. D, p. 116).

Temperance River group.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 14, pp. 143–146). *Temperance River group.*—Succession of very distinctly and thinly bedded fine-grained diabases and melaphyrs, with strongly developed amygdaloids, and several seams of detrital matter, in shape of red shaly ss. and cgl., one ss. exceeding 200 ft. thick; toward base some layers of dense ashbed diabase and diabase porphyrite. Thickness 2,500 to 3,000 ft. Overlies Beaver Bay group. Included in Keweenawan series. Mapped along Temperance River.

Temperance River member.

Pre-Cambrian (Keweenawan): Northeastern Minnesota.

A. H. Elftman, 1898 (Am. Geol., vol. 21, pp. 90–109, 175–188). *Temperance River memb.* of Keweenawan series includes greater part of Agate Bay group, the eastern end of Duluth group, and all of Temperance River group of Irving. It consists of (1) diabase and diabase porphyrite with interbedded sss.; (2) basic and intermediate surface flows with interbedded sss.; and (3) 100+ ft. of cgl. and qtzite at base. Rests uncon. on *Red Rock memb.*, which was named for its persistent red color and which consists of intrusives and equivalent effusives, associated with St. Louis River gabbro and parts of Lester River and Beaver Bay groups of Irving.

Temple Bar conglomerate.

Pleistocene (early): Northwestern Arizona.

W. T. Lee, 1908 (U. S. G. S. Bull. 352, p. 17). *Temple Bar cgl.*—Sand and gravel having wide distribution in western Ariz., in the Colorado and other valleys of that region, filling low places generally to an altitude of 3,000 ft. or more. Typically exposed near mouth of Virgin River at Temple Bar [NW. corner of Mohave Co.], where it consists of slightly consolidated sand and gravel exposed in nearly perpendicular cliffs, in which are included sheets of basalt. Where exposed along Colorado River it is evidently a river deposit, but it merges laterally into deposits of angular mtn wash in some places and possibly into lacustrine deposits in others. Rests uncon. on Greggs breccia and older fms. and is apparently = in age to the widespread detrital accumulation filling the low places of the Southwest generally and forming the desert plains of Ariz. and parts of southern Calif. No fossils, and at present no means of definitely correlating with other fms. In composition, geologic and physiographic relations, and general appearance is similar to Gila cgl., but greater part of Temple Bar cgl. is usually not so well consolidated as Gila cgl., although in places, especially where the older portions are exposed, it is as firmly cemented. Assigned to early Pleist.

Some geologists think this deposit may include some Plio., as does the Gila cgl.

Temple Butte limestone.

Devonian (Upper ?): Northern Arizona (Grand Canyon).

C. D. Walcott, 1889 (Geol. Soc. Am. Bull., vol. 1, p. 50). *Temple Butte ls.*, 0 to 94 ft. thick, of Dev. age. Underlies Redwall ls. (Carbf.) and overlies Tonto in Grand Canyon of the Colorado but is in places entirely absent, either through erosion or nondeposition, and where absent Redwall ls. rests on Tonto group.

N. H. Darton, 1910 (U. S. G. S. Bull. 435). *Temple Butte ls.*—Purple and cream-colored ls. and ss., 0 to 100 ft. thick.

Named for Temple Butte, 3 mi. S. of junction of Little Colorado River with Colorado River.

Tempoal shale.

Eocene: Mexico.

E. T. Dumble and E. R. Applin, 1924 (Pan-Am. Geol., vol. 41, June, pp. 336, 338).

Tenejapa formation.

Tertiary: Mexico.

W. A. Ver Wiebe, 1925 (Pan-Am. Geol., vol. 44, p. 134).

Tenistipa limestone.

Cretaceous (?): Mexico.

A. Heim, 1926 (Eclogae geol. Helvetiae, vol. 20, p. 86).

Tenley formation.

Pliocene (?): District of Columbia.

C. K. Wentworth, 1930 (Va. Geol. Surv. Bull. 32, p. 37). Term *Brandywine fm.* as defined by W. B. Clark in 1915 includes a considerable part of the terrace surface deposits formerly called *Lafayette* in Wash. region. It has become apparent, however, that other parts of former Lafayette fm. could not be included in Brandywine of Clark. As result of field studies in 1921 and 1922 writer divided [unpublished?] former Lafayette fm. of Wash. region into (1) an older and higher terrace and gravel fm., the *Tenley fm.*, from Tenleytown, D. C., and (2) a younger and lower terrace and gravel fm., the Brandywine of Clark. As the Tenley terrace is not preserved on the Coastal Plain in Wash. area it will not be described in this rept.

Foregoing is only known use of *Tenley fm.* Whether the deposit corresponds to Bryn Mawr gravel is a debated point.

Tenmile granite.

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Tenmile granite.*—Pink and gray biotite granite. Intrudes Archean schists, but does not intrude the Algonkian rocks. Named for Tenmile Creek, which enters Animas River SE. of Snowdon Peak.

Was assigned to Algonkian by E. S. Larsen in U. S. G. S. Bull. 843, 1933. The terms "Algonkian system" and "Archean system" were discarded by

U. S. Geol. Survey in 1934. For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

†Tenmile sands.

Pleistocene: Southern South Carolina (Charleston County).

E. Sloan 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 20). While these white clays [Hampton] accumulated in good bodies in elevated spots, along a favored zone, the argill. silts which were deposited more southerly appear in places interbedded in thin seams with fine varicolored sands, aggregating from 20 to 40 ft. in thickness. This appears to have been associated with the formation of an outer reef, barrier, or ridge, designated *Ten Mile sands*, on seaward slope of which the marine Pleist. deposited. The Ten Mile sands include a capping of reddish loam, which probably represented the terminal expression of the Hampton red clays. Very fine grained pure-white eolian sands accumulated over the Ten Mile sands. Is a fresh-water deposit.

C. W. Cooke (personal communication, 1935). The beds described are a facies of Talbot fm.

Named for exposures at Ten Mile Hill, on Charleston-Lanes Railway (A. C. L. R. R.) and at Ten Mile Hill, on Charleston-Branchville Railway (S. C. R. R.), Charleston Co.

Tenmile limestone. (In Greene formation.)

Permian: Southwestern Pennsylvania (Washington and Greene Counties).

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 97, 105). *Ten-mile ls.*—Lies in interval btw. Pursley coal and Boyd coal, and near base of Greene fm. Is No. VII of vol. K. Lies 14 to 40 ft. above Upper Washington ls. and 19 to 35 ft. below Rogersville ls. Is thick in Washington Co. but rarely more than 3 ft. thick in Greene Co. Is usually earthy.

Tenmile River beds.

Pennsylvanian: Southeastern Massachusetts and eastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 164–173). The Rhode Island Coal Measures E. of Providence and Seekonk Rivers as far as E. bank of Tenmile River afford characteristic exposures of slightly altered ss., pebbly beds, and shales. Coal has been found in bed of Tenmile River [Mass.]. These strata may for reference be denoted *Tenmile River beds.* Belong relatively high in the Coal Measures, but may = upper part of Cranston beds of R. I. Lie 1,000 ft. lower stratigraphically than Seekonk beds.

†Tennessee sandstone.

Pennsylvanian: Western Arkansas coal field.

A. J. Collier, 1907 (U. S. G. S. Bull. 326, p. 19). Lower ss. memb. of Fort Smith fm. is typically exposed in Tennessee Ridge, Sebastian Co., and from this occurrence has been locally called "Tennessee ss." It is 20 to 50 ft. thick, hard, flaggy, and ripple-marked.

Tennessee marble.

Commercial term for Holston ls. of Tenn., which is largely of red color.

†Tennesseean system.

E. O. Ulrich, 1905 (U. S. G. S. P. P. 36, table on p. 24), divided the Miss. rocks of Ky.-Ill. fluorite dist. into 2 major divisions (the rank of which was not indicated). The upper, designated *Tennesseean*, included the Chester and Meramec groups (the latter including Warsaw), and the lower, designated *Waverlyan*, included Osage and Kinderhook groups. He stated that he would explain his classification in a paper in preparation.

S. Weller, 1907 (Ill. Geol. Surv. Bull. 6, p. 23), quoted Ulrich's 1905 table and stated: The 2 major divisions of the Miss. made by Ulrich, the Waverlyan and the Tennesseean, are of doubtful utility, in Ill. at least; if they are to be retained at all the dividing line btw. them, as also the line btw. the Osage group and the Meramec group, should be shifted so as to include Warsaw fm. in the Osage.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 581–582), used *Tennesseean system* and *Waverlyan system*, to include the rocks designated by those names in his 1905 publication, and explained why he regarded the assemblages as "systems." His quoted explanation is also published in U. S. G. S. Bull. 769, 1925.

S. Weller, 1920 (Jour. Geol., vol. 28, pp. 415–416). There is no basis for recognition of so-called *Waverlyan* and *Tennesseean* as systems.

†Tennessee River group.

See †*Harpeth and Tennessee River group.*

Tennessee River gravels.

Pleistocene: Western Kentucky.

R. H. Loughridge, 1888 (Ky. Geol. Surv. Rept. Jackson's Purchase region). *Tennessee River gravel*, basal Quaternary fm. Overlies Lagrange group.

F. J. Fohs, 1907 (Ky. Geol. Surv. Bull. 9, p. 67). *Tennessee River gravels.*—White gravels and clay, 20 to 110 ft. thick, composing lower part of Lafayette fm. Underlies Paducah fm. (upper part of Lafayette) and overlies Penn.

Probably named for exposures along Tennessee River.

†Tennesseic.

A variant of †Tennesseean system.

Tennison Creek shale.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 90, 97). [See under *Swope fm.*]

J. M. Jewett, 1932 (pp. 90, 100, 103 of book cited above). *Tennison Creek sh.* is proposed for the strata overlying Schubert Creek ls. and underlying Critzer ls., all members of Swope fm. Tennison Creek sh. is generally less than 5 ft. thick, yellow, locally fossiliferous, and contains local thin ls. beds; is quite dark in a few places. Named for Tennison Creek, in W. part of Bourbon Co.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 80), discarded *Tennison Creek sh.* It appears to be included in his Bourbon fm., as he stated Critzer ls. occurs near top of that unit.

Tensleep sandstone.

Pennsylvanian: Wyoming (rather widespread).

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, pp. 394–401). *Tensleep ss.*—White ss., 50 to 200 ft. thick. Underlies Chugwater fm. and overlies Amsden fm. Named for exposures in walls of lower canyon of Tensleep Creek.

†Tentaculite limestone.

Silurian (Cayugan): New York.

W. W. Mather, 1840 (N. Y. Geol. Surv. 4th Rept., pp. 237–238). Underlies Pentamerus ls. [Coeymans ls.] and overlies Water lss. [Rondout ls.].

Paleontologic name (from *Tentaculites*) for ls. later named *Manlius ls.*

tepee zone.

A zone, 500± ft. thick, in Pierre sh. of eastern Colo. that is characterized by hard calc. concretions which form "tepee buttes." These "tepee buttes" occur at horizons in the Pierre varying from 750 to 1,300 ft. above its base.

Tepetate formation.

Tertiary: Mexico (Lower California).

A. Heim, 1922 (Geol. Mag., vol. 59, p. 534).

Tequepis sandstone.

Miocene: Southern California (Santa Barbara County).

R. N. Nelson, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 166–167). *Tequepis ss.*—Top fm. of Monterey series in upper Santa Ynez River region. Is younger than Salinas sh., and uncon. below Fernando Plio.

R. N. Nelson, 1925 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 15, No. 10). *Tequepis ss.*—Fine-grained light-gray feldspathic and tuffaceous sss., in places interbedded with thin layers of brown bituminous sh., and with 100 ft. of diatomaceous sh. at top. Characterized by abundance of brown fish scales. Max. thickness 1,000 ft.

The massive cream-gray tuff that overlies Salinas sh. of N. side of Santa Ynez River ½ mi. E. of Redrock Canyon is considered to be part of Tequepis ss. The Tequepis is a unit of rather limited extent, overlying Salinas sh. in W. part of the dist. along Santa Ynez River. Is top fm. of Monterey group, which is uncon. overlain by Fernando Plio. Named for development on Tequepis rancho.

Terlingua clay.

Upper Cretaceous (Gulf series): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 33–41). *Terlingua beds.*—Yellowish-white indurated stratified chalk, gradually changing upward to impure gray marl, which becomes less and less calc. until it is a true clay; the uppermost clays contain some thin layers of concretionary ls. and calc. sss. Thickness 1,250 ft. Grade upward into Rattlesnake beds [Aguja fm. of present nomenclature] and grade downward into Boquillas flags. Correspond to Austin chalk and Taylor marls of Austin region.

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 271, 472), restricted Terlingua to the equiv. of Austin chalk, and called the overlying beds *Taylor marl* and the underlying beds *Boquillas.*

The U. S. Geol. Survey at present uses the name as defined by Udden, but calls the fm. *Terlingua clay.*

Named for exposures along Terlingua Creek, Brewster Co., in Terlingua quad.

Terra Blanca formation.

Quaternary: Panhandle of Texas (northern part).

R. T. Hill, 1890 (Am. Geol., vol. 5, p. 69). The bottom of great valley of Canadian River through the Staked Plains, which for convenience I here term the Older valley of the Canadian, is but slightly concave, almost a plain itself, and covered with an extensive detrital fm. of calc. pan, accompanied by siliceous pebbles, much worn and rounded. For this fm. I have proposed the name *Terra-Blanca,* used by Mexican inhabitants of the valley. Overlies Red Beds.

Terra Cotta series.

Devonian(?), Silurian, and Ordovician: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 156–157, 180). *Terra Cotta series.*—Heavy-bedded impure lss., slates, and arkoses, with probably some volcanic rocks; heavily folded and cut by intrusives. Conformably underlie Tordrillo series. May be of same age as Skwentna series (Jurassic?), but differs lithologically. [Named for Terra Cotta Mtns.]

The rocks of area described include Ord., Sil., and Dev.(?) beds.

Terra Nova.

A time term for middle part of Lower Camb. Introduced by C. D. Walcott in 1888 (Nature, vol. 38, p. 551) and assigned to basal part of Lower Camb. Later (Am. Jour. Sci., 3d, vol. 37, p. 383, 1889) assigned by him to middle part of Lower Camb., and still later (Walcott, U. S. G. S. 10th Ann. Rept., p. 548, 1890) replaced by *Placentia.*

Terranovan.

Pre-Cambrian and later: Newfoundland and New Hampshire.

T. S. Hunt, 1870 (Am. Jour. Sci., 2d, vol. 50, p. 87). From these investigations of Mr. Alex. Murray we learn that btw. the Laurentian and the Quebec group there exists several thousand ft. of strata, including soft bluish-gray mica slates and micaceous lss. belonging to Potsdam group, besides a great mass of whitish granitoid mica slates, whose relation to the Potsdam is still uncertain. To the whole of these we may perhaps give the provisional name of *Terranovan series,* in allusion to the name Newfoundland.

T. S. Hunt, 1871 (Am. Jour. Sci., 3d, vol. 1, p. 182). The series of micaceous schists with interstratified gneisses which I have elsewhere (this Jour., July 1870, p. 87) designated *Terranovan series* (the White Mtn series) are, in present state of knowledge, supposed to be newer than Huronian, to which I refer the crystalline schists with associated serpentines and diorites of Green Mtns.

T. S. Hunt, 1872 (Am. Ass. Adv. Sci. Proc. 20th meeting, p. 32). The peculiar gneisses and mica schists of White Mtn series appear to be developed to great extent in Newfoundland, which has led me to propose for them the name *Terranovan system*.

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 218). T. S. Hunt (Am. Jour. Sci., 3d, vol. 1, 1870, p. 87) gave name *Terranovan* to the strata btw. Laurentian gneisses and the fossiliferous Camb. strata. Later (Chem. and geol. essays, 1875, p. 194) he restricted the name to the gneissic series and did not consider the upper series. *Avalon* is now proposed for the fms. btw. basal beds of Camb. and the Archean gneisses of Newfoundland. Type loc. is Avalon Peninsula.

Terra nova is Latin for *Newfoundland*.

Terry limestone. (In Hinton formation.)

Mississippian: Southern West Virginia.

C. E. Krebs and D. D. Teets, Jr., 1916 (W. Va. Geol. Surv. Rept. Raleigh and western Mercer and Summers Counties, p. 69). *Terry ls.*—Gray ls., with marine fossils, 1 ft. thick at Terry, Raleigh Co., where it lies 346 ft. below top of Mauch Chunk sh. and is underlain by an undet. thickness of Mauch Chunk strata.

R. V. Hennen and D. D. Teets, Jr., 1919 (W. Va. Geol. Surv. Rept. Fayette Co., pp. 113, 335). *Terry ls.* lies 10 to 14 ft. below Princeton cgl., the intervening beds being gray sh. [later named Terry sh.]. Author believes *Terry ls.* is same as Upper Hinton ls. of Krebs.

Terry sandstone member (of Pierre shale).

Upper Cretaceous: Central northern Colorado (Larimer County).

M. W. Ball, 1924 (A. A. P. G. Bull., vol. 8, No. 1, pp. 81–87). *Terry ss.* was named and mapped [unpublished repts] by A. T. Schwennensen, E. W. Krampert, and C. H. Henley. It is 16 ft. thick, lies 604 ft. below Rocky Ridge ss. and 383 ft. above Hygiene ss. Forms part of the island in Terry Lake and also helps to form two of the promontories jutting into the lake. [See 1924 entry under *Hygiene ss.*]

K. F. Mather, J. Gilluly, and R. G. Lusk, 1928 (U. S. G. S. Bull. 796B). *Terry ss. memb. of Pierre sh.* is 0 to 20 ft. thick, lies 200 to 400 ft. above Hygiene ss. and 300 to 600 ft. below Rocky Ridge ss. Closely resembles Hygiene ss. but is much thinner and not nearly so persistent along the strike of the beds.

Terry shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Tazewell County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 295, 330). *Terry sh.*—Greenish-brown sandy sh. with occasional lentils of coal and streaks of red sh. Contains plants. Thickness 10 to 50 ft. Top memb. of Hinton group [fm.]. Overlies Terry ls. and underlies Princeton cgl. or ss. Named for association with Terry ls. Observed in Mercer and Summers Counties, W. Va., and in Tazewell Co., Va.

Tertiary period (or system).

The time (and the rocks) of the older period of Cenozoic era, following the Cretaceous system and preceding the Quaternary system. For definition see U. S. G. S. Bull. 769, pp. 49–56. Also see under †*Primitive*.

Tertic.

A variant of Tertiary employed by some geologists.

Tesnus formation.

Pennsylvanian: Western Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 45). *Tesnus fm.*—Consists of ss., sh., chert, and a few lenticular layers of cgl., with, at base, Rough Creek sh. memb. Thickness of fm. 3,370 ft. Underlies Dimple fm. and uncon. overlies Santiago chert (Miss. ?). Named by Baker.

C. Schuchert, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 383–400). It is generally held that the local *Tesnus* and *Dimple* fms. are older than and uncon. underlie *Gaptank fm.*, but there is no convincing evidence this is so, and it may well be that the first-named fms. are only a nearer-shore phase, to SE., of the Gaptank. The Tesnus has almost no fossils, while those of the Dimple do not indicate more than Penn. time. Fossils collected by Baker and Bowman in lss. supposed to be of Dimple age I believe belong to Gaptank fm. The Gaptank fossils indicate the time to be at least = Canyon and lower Cisco. The Tesnus may = Strawn, or even Strawn and Bend.

but fossils must be found before definite correlations can be made. The *Dimple* may be of Strawn age. The Haymond is at best but part of the Tesnus.

P. B. and R. E. King, 1928 (Univ. Tex. Bull. 2801). Gaptank fm. grades into underlying Haymond fm., which clearly overlies and grades into Dimple fm., which in turn overlies and grades into Tesnus fm.

Named for exposures at and around Tesnus, Brewster Co.

Tessey limestone.

Permian: Western Texas (Brewster County).

J. A. Udden, 1917 (Univ. Tex. Bull. 1753, p. 53). *Tessey fm.*—Mostly unstratified dolomitic rock, quite like Vidrio in general appearance. In places has well-marked bedding planes and in places is brecciated. Considerable part of rock is only slightly dolomitic; some of fm. is finely oolitic and in thin sections showed shreds of Bryozoa and a few minute Foraminifera. In its upper part near mouth of canyon one layer is entirely calc. and contains abundant *Fusulina*. Thickness 1,400 ft. Uncon. overlain by Comanchean Cret. Grades into underlying Gilliam fm. Named for post office once located about 2 mi. N. of mouth of Gilliam Canyon but now defunct.

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 73–84). The strata overlying Word fm. and underlying Bissett fm. in Glass Mtns are herein referred to *Capitan fm.* They were originally divided by Udden into 3 units (descending)—*Tessey, Gilliam*, and *Vidrio fms.* They were subdivided along Gilliland Canyon, where they are separable into massive dol. below (Vidrio), thin-bedded dol. in middle (Gilliam), and massive dol. above (Tessey). The work of R. E. King and writer has shown that the 3 subdivisions established by Udden are local phases of the interfingering of different facies. The natural units in W. part of Glass Mtns do not correspond in age to those in the E., and neither those in E. or W. have any more than a local significance. For this reason it is here proposed to use the general term *Capitan fm.* for these rocks, and to reduce the Vidrio, Gilliam, and Tessey to the rank of members of this fm. Tessey memb. is 100 to 1,050 ft. thick; Gilliam memb. is 500 to 873 ft. thick; and Vidrio memb. is 600 to 1,200 ft. thick. In W. part of Glass Mtns the equivalents of Tessey memb. and upper part of Gilliam memb. appear to have been removed by erosion, and the upper massive memb. of Capitan fm., 215 to 800 ft. thick, is believed to correspond to lower part of Gilliam and upper part of Vidrio. Beneath this upper memb is *Altuda memb.*, consisting of 450 ft. of thin-bedded brown dolomitic ls., sandy ls., and siliceous sh., which merges into massive dol. a short distance E. of Old Blue Mtn, and is not represented as such in Gilliland Canyon. Beneath the Altuda lies the lower massive memb. of Capitan fm., 85 to 300 ft. thick.

P. B. King, 1933 (Historical geol. of R. C. Moore, p. 325), substituted *Glass Mtns fm.* for the rocks to which he in 1931 applied the name *Capitan* fm., and called the subdivisions *Tessey massive ls. memb., Gilliam thin-bedded ls. memb., Vidrio massive ls. memb.*, and *Altuda siliceous sh. memb.*

The name *Glass Mtns* being preoccupied, and the deposits designated by that name being the southern extension of Capitan ls., they are designated by latter name by U. S. Geol. Survey. (See P. B. King, 1934, Geol. Soc. Am. Bull., vol. 45, pp. 697–798.)

The Survey's present approved definition of *Tessey ls.* treats the beds as a distinct fm., instead of including them in Capitan ls. (See U. S. G. S. P. P. 187, by P. B. King, in press.)

Tetagouche series.

Ordovician: New Brunswick.

G. A. Young, 1911 (Canada Geol. Surv. Mem. 18, p. 28).

Tetelna volcanics.

Carboniferous: Southeastern Alaska (central Copper River region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 36, map). *Tetelna volcanics.*—Intrusive diorites, andesitic lavas, diabase dikes, some altered sediments, and porous greenish qtzite. [Derivation of name not stated, and map shows no geographic feature of that name, but the fm. is mapped along Indian Creek, the Indian name of which is Tetelna.]

Teton formation.

Triassic and Permian: Yellowstone National Park, Wyoming.

W. H. Weed, 1896 (U. S. G. S. Yellowstone Park folio, No. 30). *Teton fm.*—Top memb. a ss., generally bright yellow, with red weathered surface; next below is a red aren. sh., which rests on gray and greenish calc. shales, often micaceous; basal memb. is ss., usually of dull-brown color and more or less calc., characterized by rods and rolls of white chert and carrying interbedded gray lss. containing linguloid shells. Overlain by Ellis fm. and underlain by Quadrant qtzite. Named for Teton Range [to SW. of Yel. Park]. Is thinner at N. end of Teton Range and in Gallatin Range (in NW. corner of park, where it is 200 ft. thick) than in Snake River region (in southern part of park), where it is 400 ft. thick.

Tetrazoic.

A time (life) term applied by E. Hitchcock (Geol. Vt., 1861, vol. 1, p. 19) to Cret. system.

Tetro limestone.

Mississippian: Central northern Utah (Tintic district).

G. W. Crane, 1915 (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151). *Tetro ls.*—Hard fine-grained blue cherty ls., 355 ft. thick, underlying Humbug ls. and overlying 160 ft. of carbonaceous sh. or shaly ls., in Tintic dist.

This ls. forms a part of Pine Canyon ls. It was evidently named for Tetro mine.

Teutonic limestone.

Middle Cambrian: Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Teutonic ls.*—Descending: (1) Dark-gray finely banded argill. ls., cross-bedded in upper part, weathering light gray, 114 ft.; (2) dark-blue ls. with countless veinlets, 77 ft.; (3) fault breccia, 30 ft.; (4) dark bluish-gray ls. with countless veinlets, 170 ft.; (5) dark bluish-gray ls., thinly bedded, ribboned, or mottled with bands or small blotches of yellowish-brown argill. material, 175 ft. Total 566 ft. Underlies Dagmar ls. and overlies Ophir fm. Named for Teutonic Ridge.

Texado group.

Age (?): British Columbia.

O. E. Le Roy, 1908 (Canada Dept. Mines Geol. Surv. Branch Pub. 996, p. 12). Devono-Carbf.

J. G. McConnell, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 70), Triassic (?), and 1914 (Mem. 58, p. 21), Jurassic (?); E. M. J. Burwash, 1918 (Geol. of Vancouver and vicinity), Carbf.; C. O. Swanson, 1925 (Canada Geol. Surv. Summ. Rept. 1924, pt. A, p. 109), Jurassic (?).

†Texan system.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lvii, 276–282). *Texan system.*—At base sandy shales and mica schists (Mason series); in middle qtzites and sss. (Llano series, restricted sense); at top shaly beds and marble (Packsaddle series). Uncon. underlies Camb. and overlies Archean group. Assigned to Eparchean group. Covers period marked by great eruptions of igneous matter, intrusive and extrusive.

Conflicts with Llano series, older name.

Named for State of Texas.

†Texana limestone.

Paleontologic name applied in some early repts to Walnut clay (Lower Cret.) of Tex.

Texas Creek granodiorite.

Jurassic or Cretaceous: Southeastern Alaska (Hyder district).

A. F. Buddington, 1929 (U. S. G. S. Bull. 807, pp. 22–27, 58–60, maps, etc.). The porphyritic granodiorite composing the Texas Creek batholith and forming basal part of the Coast Range intrusives. Named for occurrence along Texas Creek.

Texhoma-Gose sand.

See *Gose sand*.

Texhoman series.

Name introduced by C. R. Keyes to include the late Tert. deposits of Kans. (See Iowa Acad. Sci. Proc., vol. 22, 1915, p. 255.)

†Texian system.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 562-563, 658-659). *Texian or Algonkian system*. Includes Mason, Llano [narrow usage], and Packsaddle series.

Same as Texan system of Comstock and Dumble 1890, and same as Llano series of present usage.

Texon sand.

A subsurface oil-producing zone in Clear Fork fm. of Big Lake dist., N. of town of Texon, Reagan Co., Tex. Lies 50 to 100 ft. below Big Lake lime, and 2,845 to 3,137 ft. below surface.

Thane volcanic group.

Lower or Middle Jurassic (?): Southeastern Alaska (Juneau region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 247, 251-252, chart opp. p. 270). *Thane volcanic group*.—In descending order, melaphyre tuff, ls., and interbedded tuff and sl., probably 5,000± ft. thick. Underlain, apparently conformably, by Gastineau volcanic group (Upper Triassic). Believed to be directly overlain by Treadwell sl. (Upper Jurassic?), but Gastineau Channel separates the 2 fms. No fossils. Tentatively referred to Lower or Middle Jurassic.

The settlement of Thane, on Gastineau Channel, lies in midst of these rocks.

Thanet gabbro.

Pre-Cambrian: Ontario.

F. D. Adams and A. E. Barlow, 1910 (Canada Geol. Surv. Mem. 6, p. 150).

†Thayer shale. (In Kansas City formation.)

Pennsylvanian: Eastern Kansas and northwestern Missouri.

E. Haworth, 1895 (Kans. Univ. Quart., vol. 3, p. 276 and pl. opp. p. 290; Am. Jour. Sci., 3d, vol. 50, p. 459 and pl. opp. p. 466). *Thayer shales*.—Shales and sss., with two or more coals, 20 to 200 ft. thick, underlying Iola ls. and overlying Erie or Triple ls. system.

Same as Chanute sh., broad usage, according to H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13); same as Chanute sh. restricted, according to N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 49). But R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 75), states it is=Fontana-Chanute shales.

Named for exposures at Thayer, Neosho Co., Kans.

Thaynes limestone (also **Thaynes group**).

Lower Triassic: Northeastern Utah, southwestern Wyoming, and southeastern Idaho.

J. M. Boutwell, 1907 (Jour. Geol., vol. 15, pp. 439-458). *Thaynes ls.* (also *Thaynes fm.*).—Essentially a calc fm. Comprises two parts separated by a red-sh. memb., each made up of ls., calc. ss., normal ss., and sh. Most of true lss. are in upper part, and sss. predominate in lower part, though each type is found throughout. A very characteristic rock occurring at many horizons is a dense, homogeneous blue-gray calc. ss., which appears superficially to be a ls. but on exposure loses its low calc. content and becomes a medium fine-grained brown ss. [Detailed section in Park City dist., Utah, given; fossils listed.] Thickness 1,190 ft. Underlies Ankareh sh. (red) and overlies Woodside sh. (red). Named after Thaynes Canyon, whose deep and extended incision affords best exposures of the fm. in Park City dist., Utah.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56, pp. 50+, chart opp. p. 50, map, pl. 3, etc.). *Thaynes fm.*—In SW. Wyo. consists of very fossiliferous gray lss. and thin-bedded yellow sss., containing abundant fauna. Thickness in SW. Wyo. 2,400 to 2,600+ ft. Conformably underlies Nugget fm. and conformably overlies Woodside fm.

J. M. Boutwell, 1912 (U. S. G. S. P. P. 77, p. 55, pls. 2, 5). *Thaynes fm.*—Essentially calc. Comprises two parts separated by a red sh. memb., each made up of ls., calc. ss., normal ss., and sh. Most of true lss. are in upper part and sss. predominate in lower part. A characteristic rock at many horizons is a very fossiliferous dense, homogeneous blue-gray calc. ss. which appears superficially to be a ls. Thickness of fm. in Park City dist., Utah, 1,290± ft.; the upper part 630± ft.; the middle red sh. memb. 115± ft.; and lower part 445± ft. Conformably underlies Ankareh sh. (red) and overlies Woodside sh. (dark red). [Fossils listed.] Extends into Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492). *Thaynes* deposits in Fort Hall Ind. Res., SE. Idaho, become a *group*, divisible into 3 fms., here named (descending) Portneuf ls., 1,500± ft. thick; Fort Hall fm., 800± ft. thick; and Ross [*Ross Fork* now] ls., 1,350± ft. thick.

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 32, 35). *Thaynes group* (including Portneuf ls., Fort Hall fm., and Ross ls.) underlies Ankareh ss. and overlies Woodside sh. in Fort Hall Ind. Res., SE. Idaho.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713), replaced *Ankareh ss.*, as used by him in previous repts, with *Timothy ss.*, and explained that the lithologic unit called by him *Thaynes group* in SE. Idaho corresponds to *Thaynes fm.* as used by Veatch in SW. Wyo., and also corresponds to *Thaynes ls.* of Boutwell in Park City dist., Utah, but includes at top lss. that are equiv. in time to basal part of Boutwell's Ankareh sh. of Park City dist., Utah.

Thebes sandstone. (Of Richmond group.)

Upper Ordovician: Southwestern Illinois and southeastern Missouri.

A. H. Worthen, 1866 (Ill. Geol. Surv. vol. 1, p. 139). *Thebes ss.*—Regularly bedded brown ss., sometimes massive; well exposed in bluffs at town of Thebes. Included in Cincinnati group. Separated from overlying Cape Girardeau ls. by brown sandy shales and underlain by 5 ft. of yellowish-brown sh. resting on Trenton ls.

In many subsequent early Ill. and Mo. repts the brown sandy sh. referred to above was included with the ss. under name *Thebes ss. and sh.* and, later, *Thebes fm.* Worthen himself in 1868 (Ill. Geol. Surv. vol. 3, pp. 20-29) used *Thebes ss. and sh.* In 1909, however (Am. Jour. Sci., 4th, vol. 28, p. 515), Savage named the sh. *Orchard Creek sh.*, restricted *Thebes* to the ss., and reported an uncon. btw. the sh. and the ss. The name of the ls. referred to above was many years ago shortened to *Girardeau ls.* The Orchard Creek sh. is now classified as early Sil. and Thebes ss. as Upper Ord. (Richmond). The ls. underlying Thebes ss. has long been known as *Fernvale ls.* The Thebes is contemp. with lower part of Maquoketa sh.

Named for Thebes, Alexander Co., Ill.

The Dalles beds.

The Dalles group.

The Dalles formation.

See *Dalles fm.*

Theresa dolomite.

Upper Cambrian: Central to eastern New York.

H. P. Cushing, 1908 (Geol. Soc. Am. Bull., vol. 19, pp. 159-160). *Theresa fm.*—Somewhat calc. sandy dolomites with interbedded weak sss., especially near base. Thickness 20 to 70 ft. Very closely related to underlying Potsdam ss. and formerly included in Potsdam but here separated as distinct fm. Base drawn at base of first dol. layer. Uncon. overlain by Pamelia ls. (of late Chazy age) in Theresa and Alexandria Bay quads., Jefferson Co. Named for Theresa Twp, in which it is exposed in its entirety.

J. M. Clarke, 1908 (N. Y. State Mus. Bull. 121, pp. 11-13). *Theresa fm.* (*so-called "passage beds"*).—A dol. fm. quite like the rocks which elsewhere immediately overlie

Potsdam ss. around the Adirondacks and which have been regarded and mapped as passage beds into Beekmantown fm. Seems to hold a fauna not before recognized in State. Beekmantown is absent in Theresa and Alexandria quads., and Theresa fm. is uncon. overlain by Pamelia ls. [of Chazy age].

In 1910 (N. Y. State Mus. Bull. 140, pp. 11–12) J. M. Clarke applied *Galway fm.* to passage beds btw. Potsdam ss. [restricted] and Little Falls dol. in Broadalbin quad., Fulton and Saratoga Counties, while on pp. 99 and 127 of same Bull. (140) E. O. Ulrich and H. P. Cushing applied *Theresa fm.* to passage beds btw. Potsdam ss. and Little Falls dol. of Mohawk Valley, which they described as consisting of alternating vitreous ss., calc. ss., and gray, usually somewhat sandy dolomites. In N. Y. State Mus. Bull. 145, 1910, H. P. Cushing applied *Theresa dol.* to beds above Potsdam ss. in Thousand Islands region, which he stated are overlain, everywhere uncon., by Little Falls dol. In 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27) E. O. Ulrich showed *Upper Theresa*, as he called it, as=Tribes Hill ls. and separated from *typical Theresa* by an enormous hiatus representing 5,000 ft. of strata deposited elsewhere. The same year (N. Y. State Mus. Bull. 153, pp. 8–38 and map) W. J. Miller applied *Theresa fm.* to 200 ft. of beds btw. Potsdam ss. and Little Falls dol. in Broadalbin quad., which J. M. Clarke in 1910 called *Galway fm.* In 1914 (N. Y. State Mus. Bull. 169) H. P. Cushing and R. Ruedemann transferred to Theresa fm., under name *Hoyt ls. memb.*, the basal 100 ft. of Little Falls dol., consisting of thick-bedded dol. and ls. with black oolite, which are "now considered a phase of upper part of Theresa fm." In 1916 (N. Y. State Mus. Bull. 191) Cushing included in Theresa fm., toward its top, a ss. to which G. H. Chadwick had in 1915 applied name *Heuvelton (20-foot) ss.* and treated as a fm. distinct from underlying "*Theresa mixed beds or fm. as restricted by Ulrich.*" But Cushing stated: There is some evidence this Heuvelton ss. and some overlying beds, as well as 0 to 40 ft. of beds underlying this ss., will have to be separated from upper part of Theresa fm., but evidence is not yet decisive, and lithologically these beds are much like underlying typical Theresa, although they occupy time interval of Little Falls dol. He also applied *Theresa* to the beds beneath these doubtful strata, and stated they seem to be exact equiv. of typical Theresa of Theresa quad. In 1920 (N. Y. State Mus. Bull. 217, 218) G. H. Chadwick mapped *Heuvelton white ss.* as a distinct fm., but stated that it seems linked stratigraphically with Theresa below, though its few fossils suggest a later age, and that in Canton quad. it is apparent summit of Theresa fm., and not a lentil in Theresa, as Cushing found to W. He assigned Theresa to "Upper Cambrian (Saratogan, Ozarkian of Ulrich)," and gave its thickness as probably btw. 50 and 100 ft. R. Ruedemann, 1929 (Geol. Soc. Am. Bull., vol. 40, No. 2, pp. 412, 414), 1930 (N. Y. State Mus. Bull. 285, p. 27), and 1933 (16th Int. Geol. Cong. Guidebook 1, p. 17) did not exclude *Hoyt ls.* from *Theresa fm.* But W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 191, 239), excluded *Hoyt ls.* from *Theresa fm.* and included it in Little Falls dol.

The U. S. Geol. Survey treats Hoyt ls. as a memb. of Theresa dol. and classifies Theresa and overlying Little Falls dol. as Upper Camb.

Theresa syenite.

Pre-Cambrian: Northeastern New York (Theresa quadrangle).

H. P. Cushing et al., 1910 (N. Y. State Mus. Bull. 145, p. 38, map). *Theresa syenite*, of early pre-Cambric age but younger than Laurentian granite gneiss. A small intrusive mass, less than 2 mi. in length and less than ½ mi. broad, lying S. of Theresa.

Thermopolis shale. (Of Colorado group.)

Upper Cretaceous: Central northern Wyoming and central southern Montana (Stillwater-Rosebud Counties region).

C. T. Lupton, Jan. 21, 1916 (U. S. G. S. Bull. 621, p. 168). *Thermopolis sh.*—A mass of generally shaly rocks, limited below by top of upper ss. bed (Greybull sand of drillers) of Cloverly fm. and above by base of Mowry sh., with both of which fms. it is conformable. Thickness 700± ft. Consists of dark-colored sh. containing one or more lenticular beds of ss., the most persistent of which is the Muddy sand, well known to oil operators, which is 15 to 55 ft. thick and lies 210 to 330 ft. above top of Greybull sand. Named for exposures near town of Thermopolis, Hot Springs Co., Wyo.

D. F. Hewett and C. T. Lupton, 1917 (U. S. G. S. Bull. 656, p. 19). *Thermopolis sh.*—Mainly dark sh., 400 to 800 ft. thick, sandy near its top and base, and containing a persistent bed of ss. near its middle. The sandy beds, 100 ft. or more thick, near base have been termed "rusty beds" by Washburne (U. S. G. S. Bull. 340, p. 350, 1908), [who treated them as basal memb. of Colorado fm. in Bighorn Basin, Wyo.]. Overlies Cloverly fm., of which Greybull ss. is top memb.

In U. S. G. S. P. P. 149, p. 64, 1927, W. T. Lee included in his Greybull ss. the rusty beds described above as basal part of Thermopolis sh. R. S. Knappen and G. F. Moulton, 1931 (U. S. G. S. Bull. 822, pp. 23–28) included the rusty beds in Thermopolis sh. and treated Greybull ss. as top memb. of Cloverly fm. This is present approved definition of Thermopolis sh., except that in Black Hills region the 10 to 50 ft. of dark-gray sh. and sandy sh. to which Collier applied name *Nefsy sh. memb. of Graneros sh.*, and which represents upper part of Thermopolis sh., is now included in Mowry sh., and *Nefsy* has been abandoned. This constitutes a local redefinition of Mowry sh. and Thermopolis sh.

Thessalon group.

Pre-Cambrian (Keewatin): Western Ontario (north shore of Lake Huron).

A. Winchell, 1888 (4th Int. Geol. Cong., London, Am. Comm. Repts, p. A14). *Thessalon red qtzite*, Huronian, Canada.

A. E. Barlow, 1893 (Geol. Soc. Am. Bull., vol. 4, p. 328). *Thessalon schists*, Huronian, Ont.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52). *Thessalon group.*—Greenstones and green schists mapped by Logan and Murray as "Huronian sl." are of Keewatin age.

†Theta subdivision.

A Greek name applied by F. W. Cragin (U. S. G. S. Bull. 266, 1905) to basal 250 ft. of Malone fm. of Malone Mtn, El Paso Co., Tex.

Thetford series.

Age (?): Quebec.

J. A. Dresser, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 188). [Age not assigned.]

R. Harvie, Jr., 1913 (12th Int. Geol. Cong. Guidebook 2, p. 104), assigned to pre-Camb. (?).

J. K. Knox, 1918 (thesis, Univ. Chicago, p. 33), assigned to post-Ord.

Thetis group.

A name applied by A. J. Collier (U. S. G. S. Bull. 259, 1905, p. 179) to a group of coal beds mined at Thetis mine, E. of Cape Lisburne, Alaska, which are now classified by U. S. Geol. Survey as of Upper Cret. age.

Thibert series.

Triassic: British Columbia.

F. A. Kerr, 1926 (Canada Geol. Surv. Summ. Rept. 1925, pt. A, p. 84).

Thiensville formation.

Devonian: Southeastern Wisconsin (Ozaukee and Milwaukee Counties).

E. R. Pohl, 1929 (Pub. Mus. City Milwaukee Bull., vol. 11, pp. 7–8). Milwaukee fm. rests discon. on *Thiensville fm.* (provisional) of Raasch [ms.]. The position of the provisional *Ozaukee* and Thiensville fms. of Raasch[ms.] is to N., about 30 mi. from Milwaukee, occupied by *Lake Church fm.* (provisional of Raasch), but since the types of animal life in either are entirely distinct they must not be considered as equiv. nor are they contemp. Although in no place is the complete section of latter seen, these beds are about 12 ft. thick, and from them have come some of most interesting pelecypods of region. [These fms. are not defined.]

E. R. Pohl, 1930 (Tenn. Acad. Sci. Jour., vol. 5, p. 56), showed Dev. of Wis. as divided into Milwaukee fm., uncon. on *Lake Church fm.*, in turn uncon. on *Ozaukee fm.*, and dropped *Thiensville* from classification. "The Ozaukee and Lake Church fms. are probably previous invasions from same directions." "*Ozaukee* is ms. name of Raasch, who is at present considering the strat. interrelationships of Dev. fms. of Wis."

G. O. Raasch, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 260, 262–264). *Thiensville fm.* (*novum*).—Mainly dol. of dark-chocolate, light-chocolate, or brownish-gray color, which may be massive and vesicular or finely laminated. In general moderately thick-bedded. Ranges from extremely firm and compact to highly porous. Many layers have bituminous odor. Thickness 50–65 ft. Fossils remain largely undescribed. In Ozaukee Co. rests on Lake Church fm. (Dev.), but S. of Ozaukee-Milwaukee Co. line it lies on Sil. Differs distinctly, lithologically and faunally, from Lake Church fm. and from overlying Milwaukee fm. [Middle Dev.]. Has been removed by post-Dev. erosion N. of type loc., which is cut on highway 57, 2 mi. N. of Thiensville, Ozaukee Co. Surface outcrops were formerly generally confused with Niagaran, and in subsurface borings it was formerly confused with the Waubakee.

Thomas clay. (In Conemaugh formation.)

Pennsylvanian: Western Maryland (Georges Creek Basin).

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 7). *Thomas clay* lies short distance below Lower Bakerstown (Thomas) coal in Georges Creek Basin.

Thomas limestone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 60, 119, pl. 6). *Thomas ls.*—A thin fresh-water ls. Underlies fire clay beneath Lower Bakerstown (Thomas) coal and overlies Pine Creek ls. in Upper Potomac Basin, Md. Named for its position beneath Thomas coal. [On p. 119 it is stated that *Thomas ls.* is thin ls. in fire clay, that it is 10 ft. thick, and that it rests on Buffalo ss.]

Thomas sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland and northeastern West Virginia.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 60, 119, pl. 6). *Thomas ss.*—Rests on Lower Bakerstown (Thomas) coal and lies a short distance below Cambridge red bed in Upper Potomac Basin, Md. Is of variable thickness; 25 ft. thick in Upper Potomac Basin. Is named for its position above Thomas coal.

D. B. Reger, 1924 (W. Va. Geol. Surv. Rept. Mineral and Grant Counties). The name "Thomas" ss. is a misnomer. The ss. that outcrops at Thomas, Tucker Co., W. Va., is Saltsburg ss., which overlies Upper Bakerstown coal. It would have been much better to apply name *Lower Saltsburg ss.* to the ss. that occurs in interval btw. Upper and Lower Bakerstown coals.

Thomas sand.

A subsurface sand, of Penn.(?) age, in central southern Okla., lying lower than Smith sand and correlated with Brown sand. The name has also been applied to a sand in Thomas pool, Kay Co., central northern Okla., lying at 2,055 ft. depth and immediately above Pawhuska lime.

Thomas Hill shale.

Pennsylvanian: Northeastern Missouri.

H. A. Wheeler, 1893 (Mo. Geol. Surv. Sheet Rept. 2 (vol. 9), p. 63). *Thomas Hill shales.*—Three sh. beds, aggregating 50 to 55 ft., btw. Bevier coal below and Summit coal above at Thomas Hill. [As thus described it would include Macon City sh. of C. H. Gordon.]

A part of Cherokee sh.

Named for exposures at Thomas Hill, Randolph Co.

Thomas Hill fire clay.

Under clay of Summit coal, in Cherokee sh. of NE. Mo. Named for Thomas Hill, Randolph Co.

Thomaston granite gneiss.

Ordovician (?): Western and western central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 109-110 and map). *Thomaston granite gneiss.*—A number of masses of gneissoid granite, some of considerable size, one of the larger of which occurs in Thomaston. Foliation unevenly developed, and rock varies from almost massive granite to distinctly schistose phases. Where least metamorphosed, as at Plymouth quarry at Thomaston and at places on Candlewood Mtn, the rock is remarkably white, has medium grain, and is flecked by numerous small scales of mica (biotite). Locally, as in Wilton area, it is distinctly porphyritic, with phenocrysts of microcline. Is of igneous origin. Often occurs as dikes.

H. S. Palmer, 1921 (U. S. G. S. W. S. P. 466, pp. 144, 179). *Thomaston granite gneiss* is later than Hoosac schist.

W. M. Agar, 1934 (Am. Jour. Sci., 5th, vol. 27, pp. 354-373). Age of *Thomaston granite gneiss*, as derived from radioactive minerals in its accompanying pegmatites, is late Ord.

Thomonde beds.

Miocene: Haiti.

W. F. Jones, 1918 (Jour. Geol., vol. 26, p. 736).

Thompson limestone.

Middle Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370-394). *Thompson ls.*—10 to 30 ft. of ls., gray above and red below. Its position everywhere appears to clearly indicate that it lies btw. Mormon and Hardgrave sss.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Thompson ls.*—Gray and red ls. lentils in calc. sh. Thickness 10 to 30 ft. Appears to conformably overlie Mormon ss. Rests on Fant meta-andesite, which in turn is younger than Hardgrave ss.

Named for exposures on Thompson's ranch, on W. slope of Mount Jura, E. of Taylorsville, Plumas Co.

†Thompson slate.

Pre-Cambrian: Minnesota.

See *Thomson sl.* (the correct spelling). N. H. Winchell, in Minn. Geol. and Nat. Hist. Surv. Final Rept., vol. 4, 1899, heading on p. 551, used, evidently inadvertently, *Thompson sl.* for the fm. which on pp. 7, 551, and other pages he spelled *Thomson sl.*, the name of the town for which it was named. Winchell's typographic error on p. 551 was, unfortunately, perpetuated on p. 389 of U. S. G. S. Bull. 191.

Thompson dolomite.

Cambrian: Alberta.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 42, p. 288). *Thompson dol.*—Dolomites, 600 ft. thick, underlying Paget oolites and overlying Bosworthian series. [Apparently the upper dolomitic part of Upper Camb. Bosworth fm.]

Derivation of name not stated.

Thompson red shale.

Middle Jurassic: Northern California (Mount Jura).

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81). [See under *Combe ss.*]

Thompson Canyon sandstone bed. (In Price River formation.)

Upper Cretaceous: Central eastern Utah (Book Cliffs).

D. J. Fisher, 1935 (U. S. G. S. Bull. 852). *Thompson Canyon ss. bed.*—Massive, faintly cross-bedded straw-colored ss. that weathers into rounded surfaces. Thickness 10 to 15 ft. Included in Neslen coal-bearing memb. of Price River fm. Is older than Bluecastle ss. bed to W. and lies about 15 ft. lower than Sulphur Canyon ss. bed to E. Directly overlies Ballard coal zone and lies 0 to 50 ft. below Chesterfield coal zone. Named for Thompson Canyon.

†Thompson Creek beds.

Oligocene (lower): Western central Montana (Broadwater County, Helena-Boulder region).

E. Douglass, 1902 (Am. Phil. Soc. Trans., vol. 20, n. s., pt. 3, pp. 237–245). *Thompson Creek beds*, the White River (Olig.) deposits on Thompson Creek [3 mi.] NW. of Three Forks. Apparently belong to lower White River or *Titanotherium* horizon, but may belong in part to *Oreodon* horizon. Local name given until correlation is established.

H. F. Osborn, 1909 (U. S. G. S. Bull. 361, p. 103). Beds on Thompson Creek, Mont., are lower Olig. *Titanotherium* zone.

Thompson River silts.

Pleistocene: British Columbia.

R. A. Daly, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 166).

†Thomson slate.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Carlton County) and northwestern Wisconsin.

J. E. Spurr, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 159–166). *Thomson slates (St. Louis slates, Cloquet slates)*.—Schistose or slaty rocks continuously exposed along St. Louis River not far from Duluth, near Thomson, Carlton, and Cloquet, Minn. Have already been called St. Louis, but that name is preoccupied. So *Thomson* (already used [in ms.?] by Prof. N. H. Winchell) is adopted.

N. H. Winchell, 1899 (Minn. Geol. and Nat. Hist. Surv. Final Rept. vol. 4), described this fm. under heading (p. 551) *Thompson sl.*, but on pp. 7, 551, and throughout his rept. he used *Thomson sl.*, the name subsequently used by other geologists and the name of the town in Minn. for which it apparently was named.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, pl. 14), mapped the sl., graywacke, schist, qtzite, and ls. of Carlton, Thomson, and St. Louis River, in St. Louis and Carlton Counties, Minn., as Virginia sl.

Thomson moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Thomson, Carlton Co.

Thorn Creek gas sand.

Drillers' term for a sand in Pocono fm. of Butler Co., Pa., which lies about 100 ft. above Butler 2d sand.

Thorn Hill formation.

Ordovician (Lower): Northeastern Tennessee (Morristown quadrangle).

G. M. Hall and H. C. Amick, 1934 (Tenn. Acad. Sci. Jour., vol. 9, No. 2, pp. 158–161). *Thorn Hill fm.*—Approx. 524 ft. 4 in. of dol. with very subordinate amounts of sh. of different colors. The dol. is in fairly massive beds, some of which contain openings more or less completely filled with dol. crystals. Some beds are cherty. Predominantly light-colored, but some beds are rather dark-hued. Base is marked by a sandy dol. which is very inconspicuous when fresh but which weathers to rusty porous ss. Thorn Hill post office is on the highway about ½ mi. from type exposure. Underlies Mosheim ls. and overlies Forked Deer ls. Is approx.=Cotter fm. of Ozark region. Section studied is along U. S. Highway 25E. btw. Indian Creek and Bean Gap.

Thornton fire clay. (In Conemaugh formation.)

Pennsylvanian: Northern West Virginia, western Maryland, and eastern Ohio.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 322). *Thornton fire clay*.—Lies just under Mahoning coal and occasionally replaces it; overlies Mahoning ls. Thickness 0 to 6 ft. Named for Thornton, Taylor Co., W. Va. [In places he shows 19 ft. of fire clay overlying Lower Mahoning ss. and calls it *Mahoning fire clay*.]

Is a bed in Mahoning ss. memb. of Conemaugh fm.

Thorofare andesite.

Silurian (post-Niagaran): Central southern Maine (Penobscot Bay region).

G. O. Smith, 1896 (Geology of the Fox Islands, Maine, pp. 12, 30–45). *Thoroughfare volcanics.*—Red, gray, and purple volcanic rocks, occupying greater part of two southern peninsulas of North Haven and continuing across the Thoroughfare to NE. shore of Vinal Haven and NW. part of Calderwood's Neck. Consist of lavas and pyroclastics, in approx. following (ascending) succession: (1) Dark-gray pyroxene andesite and andesite porphyry; (2) volcanic cgl., which to S. and W. grades into breccias showing both tuffaceous and flow characters; (3) red basaltic andesites; (4) more acid hornblende andesite; (5) interbedded acid and basic tuffs and amygdaloidal flows; (6) quartz porphyry tuffs and small amounts of quartz porphyry. Conformably underlie Vinalhaven rhyolite.

G. O. Smith, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 7). *Thorofare andesite.*—Name applied to rocks earlier described and mapped as *Thoroughfare volcanics.* Assigned to Sil. Are of post-Niagara age—probably late Sil.

Named for development on shores of Fox Island Thorofare, btw. North Haven and Vinalhaven Islands, Penobscot Bay region.

Thorold sandstone member (of Albion sandstone).

Silurian (early): Western New York and western Ontario.

A. W. Grabau, 1913 (Geol. Soc. Am. Bull., vol. 24, pp. 431, 460–463). [*Thorold ss.* on p. 431; *Thorold qtzite* on p. 460.] The *upper gray* or *Thorold ss.* [the "Grey band" of the Medina] separates the red Medina beds from overlying Clinton. Will be called *Thorold qtzite*, from exposure at Thorold, Ont., on Welland Canal. Is traceable eastward to Rochester and Oswego, occurring everywhere at top of the Medina. Beyond Oswego it is represented by Oneida cgl. Is 10 to 12 ft. thick in western N. Y. but in Nottawassaga Twp, Ont., it is said to be 35 ft. thick. Along Niagara Gorge consists of 7½ ft. of hard, massively bedded, compact quartzose ss. resembling Whirlpool ss. and commonly showing irregular cross-bedding; sometimes a thin basal bed is separated by a few in. of reddish sh. from the main mass. Rests on Medina red sss. and is overlain by Sodus sh. (6 ft. of olive-green to grayish, sometimes purplish-gray sh.) [which he included in the Medina, although it had previously been included in Clinton, and is still included in that fm.].

In Niagara folio (No. 190, 1913) of U. S. Geol. Survey the *Thorold ss.* was treated as topmost memb. of *Albion ss.* (a name suggested by J. M. Clarke to replace "Upper Medina" of the literature), and was described as consisting of 5 ft. of hard gray ss. In 1914 (Sci., n. s., vol. 39, pp. 915–918) E. M. Kindle (author of Paleozoic geology of Niagara folio) objected to *Albion ss.* and advocated Grabau's restricted definition of *Medina* (which applied the name to "Upper Medina" of the literature), and he treated *Thorold ss.* as top memb. of *Medina fm.* and assigned to the Clinton of Niagara Gorge the overlying sh., which he called *Sodus sh.*

In Geol. Soc. Am. Bull., vol. 25, p. 310, 1914, C. Schuchert stated that at Thorold, Ont., the *Thorold memb.* (consisting of 10 ft. of white fine-grained ss.) is overlain by 4 ft. of bluish-green argill. sh., which he included in Medina fm. but excluded from Thorold ss. In his Niagara Gorge section, however, he treated Thorold as top memb. of his Medina fm., and referred to the Clinton the 2½ to 6 ft. of sh. discon. overlying the Thorold and underlying the Wolcott ls., which is "often correlated with Sodus memb. at Rochester" but without anything "of value to support this reference." The same year (Canada Geol. Surv. Summ. Rept. 1913, pp. 179–188) M. Y. Williams treated *Thorold ss.* as top div. of Medina and assigned Sodus sh. to the Clinton.

In 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 4) R. S. Bassler treated Thorold ss. as top memb. of Albion and assigned Sodus to Clinton.

In 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 332, 341, 359, 364, etc.) G. H. Chadwick excluded Thorold ss. from Medina and named the sh. overlying it *Maplewood sh.*, which he showed to be considerably older than Sodus sh., and, although included in Clinton group of Hall, its "strat. relations are with the beds below rather than above it." In 1919 (Canada Geol. Surv. Mem. 111) M. Y. Williams treated Thorold ss. as top memb. of *Medina-Cataract*. In 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, pp. 443, 456) E. R. Cumings proposed that Albion ss. be restricted to beds btw. Whirlpool ss. and Thorold ss., and he included Thorold in *Medinan series*, as did A. F. Foerste in 1923 (Denison Univ. Bull., Jour. Sci. Lab., vol. 20, pp. 50–51).

In 1923 (Md. Geol. Surv. Sil. vol., pp. 244, 267, 347) E. O. Ulrich transferred Thorold ss. to Clinton fm. and applied *Albion* to underlying rocks down to base of Whirlpool ss.

In 1924 (Canada Dept. Mines, Geol. Surv. Mem. 138) A. F. Foerste stated that *Thorold ss.* is top *memb.* of Cataract fm. of southern Ontario. But according to C. Schuchert, 1913 (Geol. Soc. Am. Bull., vol. 24), the Cataract fm. corresponds to only lower 50 ft. of the 135 ft. of Albion ss. at Niagara Falls.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 323), treated *Thorold ss.* as basal memb. of Clinton and restricted *Albion* to underlying beds. She listed Thorold as present at Rochester and in west-central N. Y.

G. H. Chadwick, 1935 (A. A. P. G. Bull., vol. 19, No. 5, p. 702), stated the ss. at Rochester that was formerly called Thorold ss. is not true Thorold, but younger and of Clinton age. He has named it *Kodak white ss.*

The U. S. Geol. Survey still classifies Thorold ss. as top memb. of Albion ss.

Thoroughfare andesite.

Silurian: Maine. See *Thorofare andesite*.

Thorp Springs limestone.

Lower Cretaceous (Comanche series): Central northern Texas.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, p. 509). *Thorp Springs ls. subdivision.*—Lies near base of Glen Rose beds. Is one of Caprotina lss. of Shumard. Massive stratum, composed almost exclusively of shells of *Requienia texana* Roemer. Thickness about 20 ft. Outcrops for several miles along bed of river at Granbury and Thorp Springs [Hood Co.] and also in bed of Paluxy at Glen Rose.

Thousand Creek beds.

Pliocene: Northwestern Nevada.

J. C. Merriam, 1910 (Univ. Calif. Pub., Dept. Geol. Bull., vol. 6, No. 2, p. 43). *Thousand Creek beds.*—Sedimentary series whose age and relations to Virgin Valley beds have not been determined. The beds are not a strat. unit and may be partly of age of Virgin Valley beds and partly later.

J. C. Merriam, 1911 (Univ. Calif. Pub., Dept. Geol. Bull., vol. 6, No. 11, p. 210). Thousand Creek fauna assigned to upper part of lower Plio., and Virgin Valley beds assigned to middle Mio.

J. C. Merriam, 1917 (Univ. Calif. Pub., Dept. Geol. Bull., vol. 10, No. 22, p. 428). *Thousand Creek fm.*—Strat. relations of these beds, which occur in valley of Thousand Creek, not yet fully known, but there is every reason to consider them much later than Virgin Valley (middle Mio.). [Fauna listed.] Assigned to Plio.

H. F. Osborn, 1921 (Geol. Soc. Am. Bull., vol. 32, p. 332). *Thousand Creek fm.* of Nev. is middle Plio.

W. D. Matthew, 1924 (Geol. Soc. Am. Bull., vol. 35, opp. p. 746). Mammals of Thousand Creek fm. are late Mio and [or?] early Plio.

Thousand Springs basalt.

Pleistocene: Southern Idaho (Gooding County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, pp. 434–439). *Thousand*

Springs basalt.—A feldspar pahoehoe basalt filling a canyon of Snake River N. of and shallower than present canyon. It is filled with tubes and open contacts. Thickness 100± ft. Older than McKinney basalt and younger than Malad basalt. Thousand Springs, SW. of Wendell, in Gooding Co., issue from this basalt.

Thrall limestone member (of Foraker limestone).

Pennsylvanian: Southeastern Kansas (Butler and Greenwood Counties).

N. W. Bass (Kans. Geol. Surv. Bull. 23, in press). *Thrall ls. memb. of Foraker ls.*—Light-gray ls. that weathers cream-colored and contains specimens of a large fusulinid in abundance. Lowermost 6 in. and uppermost ft. is thin-bedded and inclined to be shaly. Middle 2 to 2½ ft. occurs in 2 or 3 beds that commonly form a prominent ledge and contain a conspicuous layer of chert nodules. Persistent from Elmdale, Kans., into Okla., but in southern Kans. it thickens greatly and appears to coalesce with adjacent beds and thus lose its identity. Thickness, 1 ft. 4 in. near Elmdale, on Cottonwood River; 1½ ft. in Browning oil pool; 3 ft. in W. part of Greenwood Co.; 9± ft. in Sallyards oil field; 13 ft. E. of Beaumont, Kans. Lies 11½ ft. above Americus ls. memb. of Foraker. Named for Thrall post office, Greenwood Co.

Thrall sand.

Drillers' name for a porous soft green altered basic igneous rock called serpentine, which lies in Taylor marl and produces oil at Thrall and Lytton Springs, Tex. Probably younger than Lytton Springs sand.

Threeforks shale (also **Threeforks limestone**).

Upper Devonian: Montana (rather widespread), western Wyoming, southeastern Idaho, northern Utah.

A. C. Peale, 1893 (U. S. G. S. Bull. 110). *Three Forks shales.*—In Three Forks region consists of (descending): (1) Yellow laminated ss., 25 ft.; (2) dark bluish-drab or black argill. lss., 45 ft.; (3) highly fossiliferous green, purple, and black argill. and calc. sh., 70 ft.; (4) grayish-brown compact, close-grained ls., 15 to 20 ft.; (5) reddish and brownish-yellow calc. and argill. shales, 65 ft. Rests on Jefferson ls. and underlies Madison ls.

Named for fine development of fm. at junction of three forks of Missouri River, near Three Forks, Mont. In some areas the fm. becomes so calc. that it is called *Threeforks ls.*

Threemile limestone. (In Chase group.)

Permian: Northeastern Kansas.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12). *Threemile ls.*—Basal memb. of Wreford ls. Underlies Havensville sh. and overlies Speiser sh. of Council Grove group. [Graphic section on p. 12 shows it as consisting of flinty ls. 10 ft. thick. Derivation of name not stated. Replaces Fourmile ls. of Condra and Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 32).]

Three Sisters formation.

Pre-Cambrian: British Columbia.

J. F. Walker, 1934 (Canada Dept. Mines Geol. Surv. Mem. 172, No. 2345, p. 7).

Three Twins member (of Chalk Bluff formation).

Permian: Southeastern New Mexico (Pecos Valley).

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7). North from Little McKittrick to Spencer Draw the top of Carlsbad ls. grades into sss., which in turn are in part displaced by anhydritic sands, sandy redbeds, anhydrites, fine greenish sss., thin greenish-gray sandy shales and dolomitic lss. This sequence of beds is here named *Three Twins memb. of Chalk Bluff fm.*, from Three Twins Hills, where, in Spencer Draw, a partial section is exposed. This member is top part of the fm. It is underlain by Azotea tongue of Carlsbad ls., or, where that is absent, by lithologically similar Seven Rivers memb. The Three Twins and Seven Rivers members represent greater part of Chalk Bluff fm. and are=Carlsbad and Capitan lss. of reef zone.

Thrifty formation. (In Cisco group.)

Pennsylvanian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31, 38). *Thrifty fm.*—Thick shales (less fossiliferous and brighter in color than those of Graham fm.), lss. (thicker and somewhat more massive than those of other divisions of Cisco), some ss., and coal. Breckenridge ls. memb. at top and Avis ss. memb. at base in Brazos River region. Thickness 100 to 125 ft. to S., 150 to 200 ft. to N. Underlies Harpersville fm. and discon. overlies Graham fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), followed above definition.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+). Avis ss. of Brazos River region is same as Parks Mtn ss. of Drake of Colorado River region; and in McCulloch Co. (Colorado River region) this ss. is called *Avis ss.* and treated as basal memb. of Thrifty fm., the underlying Speck Mtn ls. being treated as top of Graham fm.

Wallace Lee and C. O. Nickell (ms. soon to be published as a Univ. Tex. Bull.) followed Plummer and Moore's 1922 definition of Thrifty fm. in Brazos River region, and in Colorado River region included in the Thrifty the Speck Mtn ls. and underlying beds down to base of *Bellerophon* ls. of Drake.

Named for Thrifty, Brown Co., Colorado River region.

Thule formation.

Pre-Cambrian: Greenland.

L. Koch, 1929 (Meddelelser om Grönland, Bd. 73, Afd. 1, No. 1, p. 7).

Thunder Bay limestone.

Middle Devonian: Northeastern Michigan (Thunder Bay).

C. C. Douglass, 1839? (Mich. Leg. H. Doc. 27, btw. pp. 97 and 111). *Thunder Bay ls.*—Beds of ls. and gray clay or sh. containing abundant fossils. Occurs on S. cape of Thunder Bay. Overlain by black bituminous sh. and underlain by black bituminous ls.

Thunder Bay slates.

Pre-Cambrian (upper Huronian): Canada (Thunder Bay, Lake Superior).

R. D. Irving, 1883 (U. S. G. S. 3d Ann. Rept., pl. 3, map). *Animikie or Thunder Bay slates* of north shore, Vermillion Lake iron-bearing series, and iron-bearing rocks of the south shore all included in Huronian.

Thunder Bay series.

Middle Devonian: Northeastern Michigan.

A. W. Grabau, 1902 (Mich. Geol. Surv. Rept. 1901, p. 192). *Thunder Bay series.*—Clay, sh., and lss., 130 ft. thick, overlying Alpena ls. and forming upper shales of Traverse group. Named for exposures on Thunder Bay, at and around Alpena.

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526), restricted *Thunder Bay stage* by removing at top their Squaw Bay ls. (See 1935 entry under *Traverse fm.*)

Thunder Bay shales.

E. R. Pohl, 1930 (Tenn. Acad. Sci. Jour., vol. 5, No. 2, p. 61). I suggest that "Olentangy" be entirely dropped from nomenclature of SW. Ont., and that all beds demonstrably below "Encrinal ls." be known as *Thunder Bay shales.*

Thunderhead conglomerate. (In Chilhowee group.)

Cambrian (Lower): Eastern Tennessee and western North Carolina.

A. Keith, 1895 (U. S. G. S. Knoxville folio, No. 16, p. 2). *Thunderhead cgl.*—Heavy series of cgl., graywacke, and ss., with many small partings of sl. General color gray. Sl. beds black or dark gray when fresh. Thickness believed to be 3,000 ft. Little variety in fm. and no division into beds of distinct character. The coarse beds vary only in proportion of quartz and feldspar. All sl. beds are same in composition. Overlies Cades cgl. and underlies Hazel sl. [This is type area of fm.]

C. W. Hayes, 1895 (U. S. G. S. Cleveland folio, No. 20), applied *Thunderhead* to 3 fms. (descending)—*Thunderhead cgl.*, 300± ft.; *Thunderhead sl.*, 1,500± ft.; *Thunderhead cgl.*, 800–1,000 ft.; the latter fm. resting conformably on Pigeon sl.

Named for development on Thunder Head, Blount Co., Tenn., and Swain Co., N. C.

Thunderhead slate.

See under *Thunderhead cgl.*, C. W. Hayes, 1895.

Thurber sand.

Drillers' name for a gas sand in Strawn fm. of central northern Tex., lying 140 ft. below Thurber coal.

Thurman sandstone.

Pennsylvanian (Allegheny): Eastern and central Oklahoma.

J. A. Taff, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 439). *Thurman ss.*—Brown ss. and shaly beds with, at base, 50 ft. or more of cgl. composed of angular or little-rounded chert fragments in a brown ss. matrix. Thickness 200 ft. Top fm. of Coal Measures. Overlies Boggy sh. [Mapped (pl. 64) as *Shawnee ss.*, but, Shawnee being preoccupied, Thurman ss. is adopted in text.]

Named for former village of Thurman, northern part of Pittsburg Co., (about 6 mi. W. of Indianola), which is near if not on outcrops of the fm.

Thurmond formation. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

M. R. Campbell, 1902 (U. S. G. S. Raleigh folio, No. 77). *Thurmond fm.*—Prevailingly sandy beds underlying Quinnimont coal (basal bed of Quinnimont fm.) and overlying Bluestone fm. in region E. of Guyandot Basin. Thickness 450 to 725 ft. Is = Pocahontas and Clark fms. combined of southern part of Raleigh quad. The new name Thurmond is introduced, because in area E. of Guyandot Basin the Pocahontas [No. 3] coal (the dividing line btw. Pocahontas and Clark fms.) is not recognized and the fms. cannot be separated. Well exposed at town of Thurmond, Fayette Co.

Tiawah lime.

Pennsylvanian: Northeastern Oklahoma (Rogers County).

S. W. Lohman, 1932 (Summaries and abstracts of technical papers presented before the Tulsa Geol. Soc. 1932, unpaged, paper dated Dec. 19, 1932). *Tiawah lime.*—Above the Red Fork sand, in lower part of Boggy fm., is the Pink lime. Separated from latter by a sandy sh. is an intermittent ls. horizon (upper Pink lime) that is very persistent on outcrop and particularly well developed in hills about town of Tiawah, from which it may take its name.

Tibbit Hill schist.

Pre-Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 10).

Tice shale. (Of Monterey group.)

Miocene (middle): Western California (San Francisco region).

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193). *Tice sh.*—Bituminous sh., prevailingly chalky, in some places whitish, in others pinkish or yellowish. A fm. of Monterey group. Overlies Oursan ss. and underlies Hambre ss. Thickness 460 ft. Named for exposures along Tice Creek, in Concord quad.

Tichenor limestone member (of Ludlowville shale).

Middle Devonian: Western to central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 22 and table). In Ontario Co. the succession of Hamilton beds from base up is Shaffer sh. (= Skaneateles sh.), Centerfield ls., Canandaigua sh. (= Ludlowville sh.), Encrinal (Tichenor) ls., and Moscow sh.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63). *Tichenor ls.* in Canandaigua and Naples quads. consists of 1 ft. of compact, hard bluish-gray, often crinoidal ls., commonly known as *Encrinal ls.* Underlies Moscow sh. and overlies Canandaigua [Ludlowville] sh. Well exposed at Tichenor Point, on Canandaigua Lake, in Ontario Co.

Subsequent repts up to 1930 continued to apply *Tichenor ls.* to the thin ls. described, which according to D. D. Luther (N. Y. State Mus. Bull. 99, 1906) is persistent for more than 100 mi. E. of Buffalo quad.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, p. 226). *Tichenor memb.* [Redefinition.].—The 1-ft. bed. of ls. at Tichenor type section when traced westward becomes one of a group of several layers of same lithic character and containing a definite fauna, which is a recurrence of that of Centerfield ls. These crinoidal lss. and the associated shales contain same fauna as type Tichenor and the 10 ft. of sh. below it. *It is here proposed to unite the 10 ft. of sh. with the 1-ft. crinoidal bed at Tichenor Point,* under the name *Tichenor,* and to apply this name to these lss. and associated shales as far W. as Lake Erie. West of Bullis Bridge the Tichenor becomes thinner and most of the thin bands disappear. It is only 2½ ft. thick on Cazenovia Creek at Spring Brook and is a single layer of hard crinoidal and pyritiferous ls. 1½ ft. thick on shores of Lake Erie. Grabau proposed *Morse Creek ls.* for this single layer, but there is little advantage in continuing this name in any other than a subsidiary sense, since its relation to the Tichenor is clearly established. The Tichenor does not correlate with the "Encrinal" which forms summit of Ludlowville fm. in Cayuga Lake region [which Cooper calls *Menteth ls.*], as it apparently disappears by becoming shaly E. of Seneca Lake. Localities for examination of the Tichenor are Lake Erie shore btw. Lakewood and Pike Creek; Jacox Run, in Genesee Valley; Murder Creek at Darien; Hills Gulch, 5 mi. S. of Le Roy; Bullis Bridge, 4½ mi. NE. of Spring Brook; Cazenovia Creek at Spring Brook; and Smoke Creek at Windom.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 369, 393), included *Tichenor ls.* in Ludlowville sh. It lies 50 to 75 ft. below Menteth ls. in Ontario Co., but in Erie Co. the Menteth ls. rests on Tichenor ls., through overlap.

The U. S. Geol. Survey treats *Tichenor ls.* as a *memb.* in upper part of Ludlowville sh., and follows the definition of N. Y. State Survey, which does not include in it the underlying 10-ft. bed of sh. which Cooper (1930) included.

Ticholeptus beds.

A paleontologic name applied by E. D. Cope to lower Mio. beds of the Western States containing fossil remains of *Ticholeptus.*

Tickville rhyolite.

Tertiary (Eocene?): Central northern Utah.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, pp. 60–61). *Tickville rhyolite.*—Five small bodies of intrusive rhyolite occurring near Tickville.

Tidioute shale member.

Devonian or Carboniferous: Northwestern Pennsylvania (Crawford County).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, pp. 116–119, table opp. p. 61). *Tidioute sh. memb.*—Olivaceous mica-flecked sh., containing in basal 1 or 2 ft. the famous Echini fossils. Thickness 5 to 23 ft. Is present, but only about 5 ft. thick, at type section of Hayfield sh., which was named for Hayfield Twp. Crawford Co. It rests on Cobham cgl. (Cussewago ss.) and is overlain by Hayfield sh. sensu stricto, which is approx. 20 ft. thick at Tidioute. [The Hayfield sh. of Chadwick was defined as resting on Cussewago ss., so that introduction of *Tidioute sh. memb.* constituted a restriction of Chadwick's Hayfield sh.] Named for excellent exposure along Allegany River at Tidioute and especially for the exposures along State highway through Dennis Run, 1 mi. SW. of Tidioute, which seems to be max. development of the memb. (23 ft.).

Tieton andesite.

Pleistocene: Central Washington (Ellensburg region).

G. O. Smith, 1903 (U. S. G. S. Ellensburg folio, No. 86). *Tieton andesite.*—Flows of lava with associated aggl., occupying old valleys. Flowed down Tieton Cañyon. Near mouth of Tieton River is 200 ft. thick. Of Pleist. age.

†Tiffany beds. (In Wasatch formation.)

Eocene: Southwestern Colorado and northwestern New Mexico.

W. Granger, 1917 (Am. Mus. Nat. Hist. Bull. 37, pp. 826–830). *Tiffany beds.*—These beds—300 ft. or more thick—contain the fauna discovered by Gidley and cannot properly be correlated, on a faunal basis, with any part of Gallina Wasatch.

Gidley says fauna appears to be intermediate btw. Fort Union and Wasatch. To those familiar with our Eocene mammalian faunas the position of this one as intermediate btw. the Torrejon and Wasatch is manifest. This horizon should be specially designated, and writer suggests *Tiffany beds*, after Tiffany station, on Denver & Rio Grande Railway 4 mi. S. of Mason schoolhouse. Possibly the vertical range of fauna characterizing these beds is greater than 300 ft., but fm. is not cut through to its base at Mason schoolhouse or at any other points where fossils were found. Fauna resembles Torrejon more than Wasatch. According to Gardner the beds overlap on Torrejon and Puerco and rest on Animas fm.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, pp. 43–48). "Tiffany beds" are a faunal zone at and near base of Wasatch fm., as they are not different in lithology from the beds above and in fact are separable only by their fauna. This zone has been traced northward from type loc. in sec. 20, T. 33 N., R. 6 W., to S. part of T. 35 N., R. 6 W., and eastward as far as Pagosa Junction. It undoubtedly extends beyond that locality, but how far has not been determined. In all this region it can be identified by its fossils as well as by tracing the beds. Westward from type loc. it has been traced to divide btw. Animas and La Plata Rivers and southward for some miles into New Mexico. It has not yielded fossils W. or S. of its type loc., and identification depended on tracing outcrops and on lithologic comparisons. In S. part of San Juan Basin this faunal zone is apparently absent, and beds with only the typical Wasatch fauna have been observed. Just where btw. northern and southern San Juan Co. this zone wedges out has not been determined. [Fossils listed.] Granger placed "Tiffany beds" in Eocene, but Matthew would put them and underlying Torrejon fm. in Cret.

Tigaraha schist.

Early Paleozoic or older: Northwestern Alaska (Seward Peninsula).

F. H. Moffit, 1913 (U. S. G. S. Bull. 533, pp. 20–23, maps). *Tigaraha schist.*—All that part of Kigluaik group btw. top of ls. of Mount Osborn and base of Nome group. Is brown-weathering biotite schist several thousand ft. thick. Upper part is siliceous graphitic schist, irregular in distribution and thickness. Type loc. includes a sharp peak, near head of Buffalo Creek, which is here named Tigaraha Mtn, *ti-ga-rah-a* being Eskimo word for *pointed*. Assigned to Paleozoic, possibly in part pre-Paleozoic.

Tiger Creek sandstone member (of Bristow formation).

Pennsylvanian: Central Oklahoma (Creek County).

A. E. Fath, 1917 (U. S. G. S. Bull. 661B, pp. 73–74, pl. 5). *Tiger Creek ss.*—Well exposed in S. part of sec. 6, T. 17 N., R. 10 E., on S. side of a small tributary to Tiger Creek, for which it is named. Thickness 20 to 30 ft. Is lowest outcropping bed that overlies the sh., 100 to 130 ft. thick, whose outcrop extends from sec. 4, T. 17 N., R. 10 E., to and beyond sec. 7, T. 16 N., R. 10 E. Its lower 2 or 3 ft. is highly fossiliferous, containing innumerable impressions of *Fusulina*. The ss. as a whole varies greatly in lithologic character. In some places it is light-gray to yellowish-brown friable ss. that cannot be distinguished from other sss. in region. In other places as much as half of it is so calc. that it can be called a ls. In still other places the *Fusulina*-bearing portion is separated from upper portion by as much as 15 ft. of sh. All gradations btw. these various facies are known—from ls. through sandy ls. and limy ss. to common siliceous ss.—and any or all of these facies may be present as layers or lenses in a single exposure. In Hominy quad., to N., this bed lies above Avant ls., according to personal communication of R. H. Wood. At Arkansas River the distance btw. the 2 beds is 60 ft. To S. of Arkansas River both Avant ls. and the sh. that separates the Avant from Tiger Creek ss. decrease in thickness, and near S. bdy of Hominy quad. the Avant ls. is only 1 or 2 ft. thick and Tiger Creek ss. is separated from it by only 3 to 5 ft. of sh. The Avant probably thins out and disappears before reaching Bristow quad.

A. E. Fath, 1925 (U. S. G. S. Bull. 759, pp. 13–15). *Tiger Creek ss.* is basal *memb.* of Bristow fm. and rests on the thick sh. bed that forms upper part of Copan fm. as herein delimited. The Tiger Creek ss. persists from Nowata quad. through Bristow quad.

Tightner formation.

Mississippian: Northern California (Colfax region).

H. G. Ferguson, 1929 (Am. Inst. Min. and Met. Engrs. Tech. Pub. 211, p. 4). *Tightner fm.*—Almost entirely fine-grained greenish hornblende schist with varying amounts of quartz, probably for most part secondary. Near the veins the schist is altered to talc schist. A small amount of quartzose mica schist and rare beds of glistening black sl. are interbedded. Small lenses of coarsely crystalline white ls. occur here and there. Dominantly of volcanic origin. Thickness probably 7,000 ft. Underlies, probably uncon., Kanaka fm., and is believed to overlie Blue Canyon fm., but the two are in fault contact. Named for fact it forms principal wall rock of Tightner mine. Extends from North Yuba to South Yuba.

Tigre limestone.

Oligocene: Panama and Costa Rica.

D. F. McDonald et al., 1919 (A. A. P. G. Bull., vol. 3, p. 364).

Tijeras quartzite.

Pre-Cambrian: New Mexico.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257-259; Conspectus of geol. fms. of N. Mex., pp. 4, 11). *Tijeras qtzites.*—Qtzite beds 250 ft. thick, best exposed in great Tijeras arch of pre-Cambric rocks at S. end of Sandia Range.

Tilden limestone lentil (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 44, map, and sections). *Tilden ls. lentil of Bingham qtzite.*—White or light-colored siliceous marble. Max. thickness 100± ft. [In sections is shown to lie a considerable distance below Phoenix ls. and above Yampa ls., both lentils in Bingham qtzite. Named for Tilden mining claim.]

Tilden formation.

Cambrian: Southwestern Montana (Argenta, Beaverhead County).

P. J. Shenon, 1931 (Mont. Bur. Mines and Geol. Bull. 6). *Tilden fm.*—Chiefly gray to pinkish-gray sandy ls., the more sandy beds near base. Contains ore deposits. Directly overlies Flathead qtzite, without angular contact, and is separated from overlying Ermont fm. (Dev.) by color contrast. Best exposed NW. of Ermont mine, where following section of 421 ft. (descending) was measured: (1) Muddy-colored sandy ls. in beds 1 to 4 ft. thick with 8-in. bed of oolitic ls. 10 ft. above base, 102 ft.; (2) light-gray thin-bedded sandy ls. that weathers buff, 12 ft.; (3) massive crystalline bluish-gray sandy ls., 190 ft.; (4) fine-grained pinkish-gray ls. that weathers tan, 10 ft.; (5) gray sandy ls., 20 ft.; (6) thin-bedded white siliceous ls., 12 ft.; (7) gray sandy ls., with 6 outstanding beds, mostly massive, pebbly ls. at base containing angular quartz fragments, 75 ft. No fossils found. Tentatively assigned to Camb. because occupies about same strat. position as Gallatin fm. of Threeforks region and Silver Hill, Hasmark, and Red Lion fms. of Philipsburg quad., but absence of sh. at top of Flathead qtzite and throughout the Tilden is in marked contrast with those regions. [Derivation of name not stated, and no geographic feature called Tilden is shown on map accompanying rept.]

Tillite Canyon formation.

Age (?): Eastern Greenland.

C. Teichert, 1933 (Meddelelser om Grönland, Bd. 95, No. 1, pp. 74, 79).

Tillman sand lens.

A subsurface sand, of Lower Cret. age and a few ft. to 20 ft. thick, forming top bed of Davis oil and gas horizon in Webster Co., NW. La. Named for lease on which first producing well was drilled. (See under *Davis oil and gas horizon.*) Is said to lie in lower part of Glen Rose fm.

†Timber Belt beds.

Eocene: Eastern Texas.

E. T. Dumble and R. A. F. Penrose, Jr., 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. xxxvi, 17, 22). *Timber Belt or Sabine River beds.*—Siliceous sand and greensand marls, with smaller quantities of white, brown, and black clays and with frequent beds of lignite. Thickness 800 to 1,000 ft. Underlie Fayette beds and overlie Basal clays.

Included Wilcox group, part of Claiborne group, and Jackson of present classification.

Named for great timber region of eastern Tex.

Timber Canyon fanglomerate.

Pleistocene (upper): Southern California (Ventura and Los Angeles Basins).

U. S. Grant, IV, and H. R. Gale, 1931 (San Diego Soc. Nat. Hist. Mem., vol. 1, pp. 37, 38, 63). *Timber Canyon fangl.*—Reddish fangl., of upper Pleist. age, occurring on top of the ridges and beveling the edges of the upturned marine beds W. of Timber Canyon, on N. side of Santa Clara Valley. This deposit was formed at base of Santa Paula Peak. Is present in Ventura and Los Angeles Basins.

†Timber Creek beds.

Eocene: New Jersey.

W. M. Gabb and G. H. Horn, 1862 (Acad. Nat. Sci. Phila. Jour., 2d ser., vol. 5, pp. 111, 135), referred to a part of *middle marl bed*—Rancocas fm. of current nomenclature—exposed on Timber Creek, N. J., as *Timber Creek beds*, but did not define the term.

†Timber Creek group.

Upper Cretaceous (Gulf series): Eastern Texas.

R. T. Hill and C. A. White, 1887 (Phila. Acad. Nat. Sci. Proc. 1887, pp. 40, 44; Am. Jour. Sci., 3d, vol. 33, pp. 296, 298). *Timber Creek group* or *Lower Cross Timbers.*—Fossiliferous coarse-grained friable ferruginous sands alternating with thin seams of yellow clay; contains lignite. Outcrop coextensive with region known as *Lower Cross Timbers*. Uncon. overlies Washita div. of Comanche series and underlies Eagle Ford shales. Same as Dakota ss.

Name replaced by *Woodbine sand*, by R. T. Hill, because, as stated by him, of previous use of Timber Creek beds in N. J. "Timber Creek bed" has also been used for the part of Woodbine sand that was later named *Lewisville*.

†Timber Creek beds.

Upper Cretaceous: Eastern Texas (north of Colorado River).

J. A. Taff, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, p. 285). Dakota sands (Lower Cross Timbers) divided into (descending) *Timber Creek beds*, 50–100 ft.; Dexter sand; and Basal clay, 200+ft.

Timbered Hills group.

Cambrian (Upper): Southern Oklahoma (Arbuckle and Wichita Mountains).

C. E. Decker, 1933 (Tulsa Geol. Soc. Digest, pp. 55–57). *Timbered Hills group* underlies Fort Sill ls. (basal fm. of Arbuckle group) and overlies pre-Camb. Includes (descending) Honey Creek fm., Cap Mtn ss. (=Honey Creek of W. part of mtns), and Reagan ss. [Derivation of name not stated.]

Timber Ridge sand.

A subsurface sand, 10 or more ft. thick, in Muskogee Co., central eastern Okla., which in Timber Ridge pool lies at 1,540 to 1,560 ft. depth, the Muskogee sand lying at 1,480 to 1,510 ft. C. W. Wilson, Jr., says (A. A. P. G. Bull., vol. 19, No. 4, 1935, pp. 505, 515) this sand corresponds to Coata ss. memb. of Atoka fm., and that it is one of the Dutcher sands.

Times porphyry.

Tertiary (middle or late): Northwestern Arizona (Oatman district).

F. L. Ransome, 1923 (U. S. G. S. Bull. 743). Irregular mass of micrographic granite porphyry. Intrudes Alcyone trachyte and Moss porphyry. Exposed in Times Gulch.

†Timiskamian series.

Lower part of Huronian series of U. S. Geol. Survey. See U. S. G. S. Bull. 769, pp. 124–125. Also called "Timiskaming series."

Timiskaming.

Name applied to a glacial lake, of Pleist. age, in Canada, north of Great Lakes region.

Timms Point formation.

Pleistocene: Southern California.

U. S. Grant, IV, and H. R. Gale, Nov. 3, 1931 (San Diego Soc. Nat. Hist. Mem., vol. 1, 1931, pp. 37, 42–43). *Timms Point zone* introduced to replace *Deadman Island "Plio.,"* since Deadman Island no longer exists, having been entirely removed by steam shovels. The beds, predominantly clayey, contain a cold-water fauna, which is correlated with a glacial age and assigned to Pleist. They underlie, apparently conformably, typical San Pedro zone and uncon. overlie Las Posas zone.

A. Clark, Dec. 19, 1931 (San Diego Soc. Nat. Hist. Trans., vol. 7, No. 4, pp. 37, 40). *Timms Point fm.*—Uncemented clayey fine sands and silts, predominantly yellowish, with local finer gray streaks and patches. Exposed thickness 30 ft. Has been called *Santa Barbara, San Diego,* and *Deadman Island Plio.* Lower part at least of Santa Barbara fm. is believed to be older than Timms Point fm., and San Diego fm. is older than Timms Point. Therefore *Timms Point* is proposed for the silts and sands uncon. overlying Mio. sh. and underlying Lower San Pedro sands [shown as absent at Timms Point but present on Deadman Island], with Timms Point the type section. Was considered Plio. by Arnold, but small percentage of extinct species, the presence of a cool-water fauna attributable to a glacial stage, and the very modern aspect of the underlying faunas in vicinity of San Pedro indicate these beds are best considered Pleist. instead of Plio.

D. Cassell and A. J. Tieje, 1933 (Pan-Am. Geol., vol. 59, No. 5, p. 376). Writers regard it significant that Las Posas fm. of Grant and Gale does not appear [in deep well near Ventura] btw. the Timms Point (upper Pico of some authors) and middle Pico beds, and therefore restore it to position first assigned it by Pressler above Timms Point horizon.

U. S. Grant, IV, 1935 (Pan-Am. Geol., vol. 64, No. 1, pp. 73–74). At San Pedro *Timm Point fm.* underlies San Pedro fm. and overlies Lomita fm., all marine Pleist. [Fossils listed.]

Timothy sandstone.

Lower Triassic: Southeastern Idaho.

G. R. Mansfield, 1920 (Am. Jour. Sci. 4th, vol. 50, p. 62; U. S. G. S. Bull. 713, pp. 29, 50). *Timothy ss.*—Somewhat sugary yellowish to grayish ss. in beds 1 to 3 in. thick, weathering pinkish. Thickness 800 ft. Uncon. underlies Higham grit and overlies (uncon. ?) Thaynes group. Previously described as *Ankareh ss.* Named for Timothy Creek, in Lanes Creek and Freedom quads, which cuts the fm.

Timpahutean series.

Timpahuten series.

Terms applied by C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53), 1924 (vol. 41, p. 78), and 1926 (vol. 46), to *Lone Mtn ls.* (Upper Ord. and Sil.) of Nev. and to supposedly contemp. deposits in other States, including Laketown dol. (Sil.) of Utah. "Title is derived from Timpahute Peak, N. of Las Vegas."

Timpanogos shales.

C. [R.] Keyes, 1924 (Pan-Am. Geol. vol. 41, p. 38). *Timpanogos shales,* 2,000 ft. thick, composing Monon series in Utah. Of Early Cambric age. [Derivation of name not stated. On p. 48 it is spelled *Tampanogos.*]

Timpas limestone. (Of Colorado group.)

Upper Cretaceous: Eastern Colorado and northeastern New Mexico.

G. K. Gilbert, 1896 (U. S. G. S. 17th Ann. Rept., pt. 2, p. 566). *Timpas fm.*—Series of lss. and calc. shales of prevailing blue colors. Thickness 175 ft. Lower fm. of Niobrara group. Underlies Apishapa fm. and overlies Carlile sh. (top fm of Benton group). Named for Timpas Creek, which enters Arkansas River below Rocky Ford, Colo.

The Niobrara and Benton are not now treated as groups, the broader term *Colorado group,* which includes them both, being considered the more

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

useful group name. Where the Niobrara deposits and Benton deposits are not subdivided they are called *Niobrara ls.* and *Benton sh.*, respectively.

Tinaja granite porphyry.

Age (?) : Mexico.

S. F. Emmons, 1910 (Econ. Geol., vol. 5, p. 327).

Tindir group.

Pre-Cambrian and Lower Cambrian(?): Northeastern Alaska (Yukon-Tanana region).

D. D. Cairnes, 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 185–187). *Tindir group*, Camb. or pre-Camb., Alaska and Yukon. [See also Cairnes, Canada Geol. Surv. Summ. Rept. 1912, p. 11, 1914, and Canada Geol. Surv. Mem. 67, p. 44, 1914.]

J. B. Mertie, Jr., 1930 (U. S. G. S. Bull. 816, p. 21), 1932 (U. S. G. S. Bull. 836, p. 369), and 1933 (Wash. Acad. Sci. Jour., vol. 23, No. 8, p. 399). Assigned to pre-Camb. and Lower Camb.(?).

J. B. Mertie, Jr., 1937 (U. S. G. S. Bull. 872). *Tindir group (pre-Camb. and Lower Camb.?)*.—A thick sequence of sed. rocks interbedded with basic lava flows and intruded by igneous rocks. The intrusives, however, are not properly a part of the group. The sediments consist of dol., ls., sh., sl., and qtzite. The igneous rocks are mainly diabase and basalt of greenstone habit, together with an undet. proportion of lavas and tuffaceous beds of hematitic habit. Thickness 19,000+ ft. in Yukon-Tanana region. [Long description.]

Named for exposures along Int. Bdy btw. Tindir, Cathedral, and Harrington Creeks.

Tinkers Falls member.

Upper Devonian: Central New York (Onondaga County).

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 790–806). *Tinkers Falls memb.*—Basal memb. of Tully fm. At type section (in face of Tinkers Falls just under the main overhanging ledge) it consists of 6½ ft. of alternating thin layers of dark calc. sh. and shaly ls. abounding in *Chonetes aurora*. At June's quarry and ravine, not far W. of Tinkers Falls, it is 1½ ft. thick, but E. of type section it thickens to 14± ft. at N. end of Deruyter Reservoir, Cazenovia quad. Can not be traced far W. of type section. Underlies Apulia memb. of Tully and overlies Hamilton.

Tinley Park moraine.

Pleistocene: Northeastern Illinois (Chicago region).

M. M. Leighton and G. E. Ekblaw, 1932 (16th Int. Geol. Cong. Guidebook 26, p. 15). The inner memb. of Valparaiso morainic system W. of Chicago is the well-defined Arlington Heights moraine, which S. of Chicago is known as *Tinley Park moraine*.

†Tintic andesite.

Tertiary: Central northern Utah (Tintic district).

G. W. Tower Jr., and G. O. Smith, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3), mapped the only andesite in Tintic dist. as *Tintic andesite*. A geographic name for the rock is considered unnecessary and *Tintic* conflicts with Tintic qtzite, of same area.

Tintic quartzite.

Lower Cambrian and pre-Cambian (?): Central northern Utah (Tintic district).

G. O. Smith, 1900 (U. S. G. S. Tintic folio, No. 65). *Tintic qtzite.*—Clay slates and qtzites, the qtzites white, weathering brownish red, very pure, compact, and fine-grained, with occasional beds of fine quartz pebbles. Several beds of green, yellow, and red clay slates occur near top. Underlies Mammoth ls. In mapping, the base of lowest bed of ls. was taken as contact btw. the two fms., so that some slates are included in Mammoth ls. Exposed thickness about 7,000 ft., but base not found.

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107), restricted Tintic qtzite to the massive qtzites, and transferred to his overlying Ophir fm. 100 to 190± ft. of sh. or sl.

KIMIKA ... GEOLOGICA

which were included in Tintic qtzite as originally defined. This is present approved definition. (See U. S. G. S. P. P. 107, p. 25.)

Exposed in Tintic Canyon and at other places in Tintic dist.

†Tintic slate.

Middle and Lower Cambrian: Central northern Utah (Tintic district).

G. W. Crane, 1915 (Am. Inst. Min. Engrs. Bull. 106, pp. 2149–2151). *Tintic sl.*—Thinly laminated green sl. with intercalated bands of impure gray banded ls. near top and thin bands of brown qtzitic sl. near bottom. Thickness 358 ft. Underlies Golden Ray ls. and overlies Tintic qtzite.

Replaced by *Ophir fm.*, the name *Tintic* being adopted for the qtzite.

Tinton sand member (of Redbank sand).

Upper Cretaceous: Eastern New Jersey (Monmouth County).

S. Weller, 1905 (N. J. Geol. Surv. Ann. Rept. 1904, pp. 147, 154–159, and Jour. Geol., vol. 13, pp. 76, 81). *Tinton beds.*—Hard glauconitic, indurated sand bed, 22 ft. thick. For faunal and strat. reasons it is separated from underlying Red Bank sand and recognized as a distinct fm. Fauna is more closely allied to beds below than to beds above. Underlies Sewell [Hornerstown] marl. Exposed at Tinton Falls. Was included in Red Sand of Cook.

The U. S. Geol. Survey has since 1909 (U. S. G. S. Trenton folio, No. 167) treated Tinton sand as top memb. of Redbank sand, but most repts of N. J. Geol. Surv. still treat it as a distinct fm.

Tioga glacial stage.

Pleistocene: Sierra Nevada, California.

E. Blackwelder, 1931 (Geol. Soc. Am. Bull., vol. 42, pp. 865–922). *Tioga stage.*—Youngest glacial stage on E. slope of Sierra Nevada. Named for fact the glacier depositing the till occupied Tioga Pass, and its lobes descended both SW. and NE. therefrom. Correlated with Wisconsin stage.

Tioga magnafacies.

Devonian or Carboniferous: Central northern Pennsylvania (Tioga-Elkland region).

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 23). Westward the Pocono-like magnafacies (herein termed "*Pocono" magnafacies*) assumes a finer-grained, less well sorted facies of brown (limonitic) weathering qtzitic micaceous ss. usually replete with mud balls and triturated cellulose. This facies occasionally contains brackish-water faunas. In Tioga and Elkland area of Pa. a parvafacies of this magnafacies, which is now known to be of Chautauquan age, was mistaken by M. L. Fuller (U. S. G. S. Elkland-Tioga folio, No. 93, 1903) for Oswayo fm., at top of Conewango series. From this mistaken correlation the eastern development of this magnafacies has ever since been termed the *Oswayo*. For this magnafacies the name *Tioga* is proposed. The Oswayo fm. in Olean, N. Y., area represents the Oswayo *sensu stricto* parvafacies expression of the Tioga magnafacies.

Tiona sand.

Drillers' term. Western Pa. Of Chemung age. Older than Speechley sand and younger than Bradford oil sand group. In W. Va. the name has been applied to a sand higher than Speechley sand.

†Tionesta sandstone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477, 489, 490). *Tionesta ss.*—Massive coarse gray or yellowish rock, sometimes much blotched and streaked with iron peroxide. Thickness 50 to 60 ft. Separated from overlying Brookville coal by 0 to 15 ft. of sl. and sh. and overlies Tionesta group [Mercer sh. memb. of Pottsville fm.]. [As thus defined the name applies to Homewood ss. memb. of Pottsville fm.]

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2, p. 53). *Piedmont (Tionesta) ss.* is=Homewood ss. The name "Tionesta" has in late publications of the survey been replaced by "Piedmont," as the former was considered only a synonym for the Congl., but I think it evident that at *Tionesta* [Forest Co., Pa.], where this stratum got its name, the rock occupies same relation to other members of the series as the one at the top of our section, and that there is no valid reason why it should not retain the original name at least through this region.

Replaced by Homewood ss. memb., the better-established name.

†Tionesta group. (In Pottsville formation.)

Pennsylvanian: Northwestern Pennsylvania.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477). *Tionesta group* underlies Tionesta ss. and overlies Seral cgl. and ss. [evidently Connoquenessing ss.]. Thickness 10 to 100 ft. Includes Mahoning ls. [upper Mercer ls.], Tionesta or Mercer coal, Upper, Middle, and Lower Porter coals, Mercer ls., and other strata.

Corresponds approx. to Mercer sh. memb. of Pottsville fm.

Tionesta series.

Pennsylvanian: Western Pennsylvania.

F. Platt, 1875 (2d Pa. Geol. Surv. Rept. H, pp. 8–9). Hodge [J. T.] in 1839 named and described the *Sharon series* as underneath Cgl. No. XII, from his explorations W. of Allegheny River. Lesley in 1841 [where?] named and described the *Tionesta series* as overlying Cgl. No. XII as he approached the Allegheny River from Potter Co. The Tionesta ss. is Cgl. No. XII, and therefore the *Tionesta series of coal beds* is same as *Sharon series*. It is therefore necessary to expunge the whole Tionesta group, sandrock, and coal beds from Mr. Rogers' column.

The term "Cgl. XII" as used in some early Pa. Geol. Surv. repts. was applied to the upper or Homewood ss. memb. of Pottsville fm. of present nomenclature, and in other repts to all of Pottsville fm. of present usage.

Tionesta iron shales. (In Pottsville formation.)

Pennsylvanian: Northwestern Pennsylvania.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Tionesta iron shales.*—Shales containing iron ore, sometimes in shape of concretions and again as a stratum of calc. ore on top of Upper Mercer ls. Thickness 20 ft. Underlie Tionesta coal, and sometimes separated from underlying Upper Mercer ls. by a thin bed of coal.

Is a part of Mercer sh. memb.

Tionesta clay. (In Pottsville formation.)

Pennsylvanian: Southeastern Ohio (Hocking Valley).

E. Orton, 1884 (Ohio Geol. Surv. vol. 5). *Tionesta clay*, 0 to 5 ft. thick, underlies Tionesta coal and lies 10 ft. above Upper Mercer horizon.

Is a part of Mercer sh. memb.

Tippah sandstone member (of Porters Creek clay).

Eocene (lower): Northeastern Mississippi and southwestern Tennessee.

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, p. 64). *Tippah ss.*—Unconsolidated white and yellow sands, gray in places, with glauconite grains; upper 4 or 5 ft. consists of hard fossiliferous, coarsely grained glauconitic ss. Thickness of fm. 75–100 ft. Overlies Porter's Creek fm. and underlies Ackerman clays. Top fm. of Midway group.

The Tippah ss. has since 1925 been treated as top memb. of Porters Creek clay. (See C. W. Cooke, U. S. G. S. P. P. 140E, 1925, and E. N. Lowe, L. W. Stephenson, and G. A. Waring, U. S. G. S. W. S. P. 576, 1928.) It is not known to extend S. of Tippah Co., Miss.

Named for Tippah Co., Miss., "where it is prominently exposed in broken hills and ridges."

Tipperary erosion surface.

Pleistocene: Northeastern Utah and southwestern Wyoming (Uinta Mountains).

W. H. Bradley, 1936 (U. S. G. S. P. P. 185). Older than Blacks Fork glacial stage. Lies 150 ft. above post-Bear Mtn surface. Named for its largest remnant, Tipperary bench, which lies btw. Smith Fork and Little Dry Creek, Wyo.

Tipton sandstone.

Pre-Cambrian (?): Northwestern Iowa.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 187; Sci., n. s., vol. 40, p. 144). *Tipton terrane.*—Sss., 425 ft. thick, composing basal fm. of Keweenawan series.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, p. 317). The so-called Tipton sss. and shales may eventually prove to be Mid Cambric in age rather [than] pre-Camb.

Derivation of name not stated.

Tipton shale member (also **Tipton tongue**) of Green River formation.

Eocene: Southwestern Wyoming (Sweetwater County) and northwestern Colorado (Moffat County).

A. R. Schultz, 1920 (U. S. G. S. Bull. 702). *Tipton sh. memb. of Green River fm.*—Thin fissile sh. and ss.; pronounced oolitic ls. (in places 20 to 50 ft. thick) near base; also other oolitic and concretionary beds locally resembling huge oyster shells scattered on surface. Thickness 100 to 325 ft. Underlies Cathedral Bluffs red beds memb. of Green River fm. and overlies Wasatch fm. Named for exposures in vicinity of Tipton, a station on Union Pacific R. R. in Sweetwater Co., Wyo. To N. of Tipton station the Tipton sh. has been removed by erosion over greater part of Great Divide Basin.

J. D. Sears, 1924 (U. S. G. S. Bull. 751G). In basin of Vermilion Creek, in NW. Moffat Co., Colo., and southern Sweetwater Co., Wyo., the upper and lower parts of Wasatch fm. are separated by Tipton tongue of Green River fm. This tongue, which is characterized by gray fissile sh. and oil sh., wedges out southward, and the main part of the Wasatch and the upper part (here called Cathedral Bluffs tongue) merge into a continuous fm. comparable to that E. of Godiva Ridge. According to Schultz the Cathedral Bluffs tongue (which he called a memb. of Green River fm.) passes northwestward by lateral variation into typical Green River shales.

Tip Top sand.

Tertiary or older: Western Kentucky (Hardin and Meade Counties).

A. H. Sutton, 1931 (Ky. Geol. Surv., ser. 6, vol. 37, pp. 275, 285). *Tip Top sand* is proposed to designate the small deposit of soft and poorly cemented sand along Dixie Highway about ¼ to ½ mi. NW. of Illinois Central station of Tip Top. The deposit lies partly in Hardin Co. and partly in Meade Co. and covers an area of approx. 40 acres. Color is white, yellowish white, and yellow. Upper part is stained by iron oxides leached from overburden of soil, but lower beds are white except where they have come in contact with surface waters. Consists predominantly of quartz grains with minor amounts of other sediments, chiefly lenses, 2 to 6 in. thick, of yellowish and white clay interbedded with the sand. It is quarried for glass, pottery, and molding sand by Ky. Silica Co. Exact age unknown. Whether it is Tert. or a filling of an earlier sink hole is not settled. It lies on a floor of St. Louis ls. and is about 50 ft. thick.

†Tisbury beds.

†Tisbury gravel.

Pleistocene: Southeastern Massachusetts (Marthas Vineyard, Gay Head, and other localities).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 975–988 and chart). *Tisbury beds.*—A glacial deposit, consisting of rather ferruginous stratified clays and clayey sands occurring at Marthas Vineyard, Gay Head, and other localities. Separated from deposits of last glacial epoch by Vineyard erosion interval, and from underlying interglacial Sankaty beds by Gay Head interval of erosion and folding. Well exposed in Chilmark and West Tisbury [Marthas Vineyard]. *The Mohegan Bluff beds* on Block Island are an extension of this series.

J. B. Woodworth, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 197–212). Thickness of *Tisbury beds* on Marthas Vineyard 150 ft.

A. C. Veatch, 1903 (Jour. Geol., vol. 11, pp. 766–776). The greater part of Manhasset beds of Long Island are regarded as=Tisbury of Woodworth.

M. L. Fuller, 1903 (Am. Geol., vol. 32, pp. 308–311). Manhasset gravel is probably to be correlated with *Tisbury beds* of Marthas Vineyard and Mohegan Bluff beds of Block Island.

A. C. Veatch, 1906 (U. S. G. S. P. P. 44). *Tisbury (Manhasset) gravel* on Long Island varies in thickness from 0 to 250 ft.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). The deposits formerly called "Tisbury beds" by Woodworth are here divided into Manhasset fm. (glacial), Jacob sand (transitional), and Gardiners clay (interglacial), all of which are present on Marthas Vineyard.

Named for exposures at West Tisbury, Marthas Vineyard.

Tishomingo granite.

Pre-Cambrian: Central southern Oklahoma (Arbuckle Mountains).

R. T. Hill, 1891 (Am. Jour. Sci., 3d, vol. 42, p. 118). *Tishomingo granite* lies in heart of Chickasaw Nation, S. of and underlying Wapanucka ls. dist. At its eastern outcrop it is composed of red feldspar, white and black mica, quartz, and hornblende, with numerous pegmatitic veins. In W. part of Chickasaw Nation the feldspar is albite. The granite is intersected by numerous dikes of diabase.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79, p. 2), and 1903 (Tishomingo folio, No. 98, p. 2). *Tishomingo granite.*—Coarse pink or red pegmatitic granite with numerous dikes of basic rocks. Quartz monzonite occurs in intimate relations to the granite and appears as phases of it. In some instances the monzonite occurs with some definition of bdy. Again it blends with the granite gradually.

C. W. Tomlinson, 1928. [See under *Colbert porphyry.*]

Named for Tishomingo, Johnston Co., which is located on the granite.

†Titanotherium beds.

A paleontologic term applied in early repts to Chadron fm. The sss. in upper part of the Chadron have been called "Titanotherium sss."

Titkana limestones.

Cambrian: British Columbia and Alberta.

C. D. Walcott, 1913 (Smithsonian Misc. Coll., vol. 57, No. 12, pp. 334, 337).

Titus Canyon formation.

Oligocene (lower): Southeastern California (Grapevine and Funeral Mountains).

C. Stock and F. D. Bode, 1935 (Nat. Acad. Sci. Proc., vol. 21, No. 1, pp. 571–579, map). *Titus Canyon fm.*—Red and green qtzite cgls., calc. sss., calc. mudstones, algal lss., and tuffaceous sss., with ls. breccia at base. Near middle occurs algal ls. zone, consisting of yellow and blue-gray algal lss. and red or maroon calc. mudstones. All fossils occur below this algal ls. zone. They are lower Olig. Thickness 3,000± ft. Type occurrence in Titus Canyon, near Leadfield, Calif. Thickness near Leadfield 2,200± ft. The fm. dips E.-NE. off E. flank of Grapevine and Funeral Mtns. Rests uncon. on Paleozoic and pre-Paleozoic. Is uncon. overlain by 400 to 500 ft. of lower Mio. (?) cgl. which is interbedded with and lenses upward into rhyolite flows and associated sed. tuffs which attain thickness of 7,000 ft. near Titus Canyon.

Tiverton arkose.

Carboniferous: Southeastern Rhode Island.

A. F. Foerste, 1899 (U. S. G. S. Mon. 33, pp. 378–379). *Tiverton arkose.*—Arkose extending along escarpment from Steep Brook to Tiverton Four Corners [eastern part of Newport Co.]. Exposed at several places in Tiverton. Thickness 100 to 200 ft. Probably same as Natick arkose.

A part of Wamsutta fm. as mapped by B. K. Emerson, U. S. G. S. Bull. 597, 1917.

Tivola tongue (of Ocala limestone).

Eocene (upper): Central Georgia (Houston, Twiggs, and adjacent counties).

C. W. Cooke and H. K. Shearer, 1918 (U. S. G. S. P. P. 120C, pp. 51–56). *Tivola tongue of Ocala ls.*—A bed of bryozoan-bearing ls. typically exposed at quarry of Planters Limestone Co., 2 mi. S. of Tivola, Houston Co., which projects as far N. as Rich Hill, Crawford Co., and intrudes far into the main area of the contemp. Barnwell fm., in which it forms an important horizon marker near the base in Houston, Twiggs, and adjacent counties. It extends laterally into lower part of

Twiggs clay memb. of Barnwell fm. In most places it is underlain by thin sandy beds that are classed with the Barnwell. Its thickness in a few places exceeds 40 ft., but is commonly much thinner. Is of Jackson age.

Tizapan basalt.

Tertiary: Mexico.

R. H. Palmer, 1926 (Pan-Am. Geol., vol. 45, p. 127).

Tlaxcala formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 335).

Toborg sand.

A shallow oil sand of Cret.(?) age, lying at 400 to 425 ft. depth in Yates oil field of Tex.

Toboso conglomerate facies.

Mississippian: Central Ohio.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 657, 667–669). *Toboso cgl. facies of Cuyahoga fm.* in E. part of Licking Co. Largely nonfossiliferous cgls. and sss. with shales in lower part. Thickness 558 ft. Includes (descending): (1) Berne memb., 1 to 2 ft.; (2) Black Hand memb., 100 ft.; (3) sss. and shales, 488 ft.

Includes Cuyahoga fm. and lower part of Black Hand fm.

Probably named for occurrence at Toboso, Licking Co.

†Tobucksy sandstone.

Pennsylvanian: Central eastern Oklahoma.

H. M. Chance, 1890 (Am. Inst. Min. Engrs. Trans., vol. 18, pp. 658, 659). *Tobucksy ss.*—Massive ss., 200 ft. thick, forming basal part of Coal Measures in Choctaw coal field. Underlies Grady [Hartshorne] coal, and overlies shales and sss. probably of Subcarboniferous age.

Same as Hartshorne ss., later but better-established name.

Derivation of name not known.

Toby conglomerate.

Pre-Cambrian: British Columbia.

J. F. Walker, 1926 (Canada Geol. Surv. Mem. 148, p. 13).

Toccoa quartzite.

Basal Cambrian or pre-Cambrian: Northeastern Georgia.

S. L. Galpin, 1915 (Ga. Geol. Surv. Bull. 30, p. 120). *Toccoa qtzite.*—From 2 mi. E. of Ayersville to within about 1½ mi. of Toccoa there are several striking outcrops of qtzite, which usually dip to NW., although in some cases sheeting planes dipping to SE. are so strongly developed that they obscure what appears to be the true bedding of the rock. The fm. seems to pass upward into siliceous and micaceous schists with occasional narrow bands or layers of biotite, or even hornblendic schist. Below the qtzite comes into sharp contact with hornblende schists (Roan). No conclusive evidence obtained to show whether this contact is intrusive. The qtzite shows considerable variation in composition, especially toward a feldspathic phase which bears strong resemblance to an igneous gneiss but which seems to pass gradually into the typical rock.

Named for exposures in a ballast quarry N. of Southern Ry and about 2 mi. W. of Toccoa, Stephens Co.

Tochatwi group.

Pre-Cambrian: Northwest Territories.

C. Lausen, 1929 (Canadian Min. and Met. Bull. 202, p. 386).

Tocito sandstone lentil (of Mancos shale).

Upper Cretaceous: Northwestern New Mexico (San Juan Basin).

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134). On Chaco and San Juan Rivers near the Hogback, NW. N. Mex., a notable bed of coarse brown cross-bedded ss., about 35 ft. thick, occurs 735± ft. above base of Mancos sh. It contains lenses of pebbles of chert and quartz as much as ½ in. diam. and resistant enough to make a cliff. It is known to petroleum geologists as Tocito ss., though sometimes also called by them Frontier ss. In this rept it is called *Tocito ss. lentil of Mancos sh.* Named for outcrops of the ss. near Tocito trading post, San Juan Co., N. Mex. Also outcrops near Beautiful Mtn, about 25 mi. SW. of type loc.

†Tocquan gneiss.

See †*Tucquan gneiss.*

†Todd Valley formation.

Pleistocene: Eastern Nebraska (Saunders County).

A. L. Lugn, 1934 (Nebr. State Mus., vol. 1, Bull. 41, pp. 324, 349–350). *Todd Valley fm.*—A valley fill of, chiefly, fine sand, becoming coarser near bottom. Consists of fluvioglacial deposits. Occurs in "an old Platte channel" across Saunders Co. from near North Bend to Ashland. Thickness 120 to 190+ ft. Younger than Loveland fm. (of Sangamon age) and older than Peorian loess. Probably formed in late Iowan time. Named for its occurrence in Todd Valley, an old filled Platte River valley.

Todilto limestone member (of Morrison formation).

Upper Jurassic: Northwestern New Mexico and extreme northeastern Arizona.

H. E. Gregory, 1916 (U. S. G. S. W. S. P. 380) and 1917 (U. S. G. S. P. P. 93). *Todilto fm.*—Where developed as ls. the fm. is very thin; where developed as calc. sh. it is much thicker. The ls. is dense and gray. Thickness of fm. 3 to 200 ft. Conformably underlies Navajo ss. and conformably overlies Wingate ss. Named for Todilto Park, McKinley Co., N. Mex.

A. A. Baker, C. H. Dane, E. T. McKnight, et al., June 1, 1931 (U. S. G. S. prel. maps showing geol. structure of Valley-Navajo Mtn region, San Juan Co., Utah, and of parts of Grand and San Juan Counties, Utah). *Kayenta fm.* introduced for deposits btw. Navajo ss. (above) and Wingate ss. (below) because field studies of A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., show that Todilto fm. at its type loc. is younger than the beds btw. Navajo ss. and Wingate ss.

According to subsequent studies by Messrs. Reeside, Baker, and Dane the typical Todilto ls. of Todilto Park is basal memb. of Morrison fm. and rests uncon. on Wingate ss.; but in SE. Utah and parts of SW. Colo. the Morrison is separated from the Wingate by several intervening fms., in descending order Summerville, Curtis, Entrada, Carmel, Navajo, and Kayenta. (See U. S. G. S. P. P. 183, 1936, p. 9.)

In some areas the Todilto rocks are chiefly gyp. and are called *Todilto gyp. memb.* In other areas they are of mixed lithology and are called *Todilto memb.*

Todos Santos formation.

Mesozoic: Mexico.

S. F. Emmons and G. P. Merrill, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 514). Cret.; included in Chico [Upper Cret.].

W. A. VerWiebe, 1925 (Pan-Am. Geol., vol. 44, p. 131), assigned this fm. to Triassic and Jurassic.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 329), assigned it to Lower Cret. or older.

Togiak gravels.

Pleistocene: Southwestern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, p. 177). *Togiak gravels*, Pleist., occur along banks of Togiak River and Togiak Lake.

Tohachi shale.

Tertiary (Eocene ?): Northwestern New Mexico and northeastern Arizona.

H. E. Gregory, 1916 (U. S. G. S. W. S. P. 380). *Tohachi sh.*—Dark-brown and white shales and subordinate sss., 200 to 1,100 ft. thick. Overlain, uncon. (?), by Chuska ss. Rests uncon. on Mesaverde and later Cret. fms. Named for Tohachi Indian School, McKinley Co., NW. New Mex., where it is exposed.

Tok sandstone.

Tertiary(?): Eastern Alaska.

A. H. Brooks, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 473, 483). *Tok ss.*—Soft, friable yellowish ss., thinly bedded, containing thin beds of fine feldspathic cgl. Thickness 50+ ft. Few plants. Tentatively Tert.(?). Several exposures occur a few mi. below mouth of Tok River.

Tokio formation.

Upper Cretaceous: Southwestern Arkansas and southeastern Oklahoma.

H. D. Miser and A. H. Purdue, 1918 (U. S. G. S. Bull. 690, pp. 19, 24). *Tokio sand memb. of Bingen fm.*—Contains sand and clay, in addition to a basal gravel and 3 higher gravels. The sand is incoherent, firmly packed gray quartz sand in beds some of which are over 30 ft. thick. Conspicuously cross-bedded. Contains disseminated particles of kaolin and a few scattered pebbles. Weathers red and produces a gray sandy soil. Light-colored and dark-colored clays are interbedded with the sand. Some of them contain fossil plants and small quantities of iron pyrites and lignitiferous matter. The light-colored clays are in beds 5 to 6 ft. thick and consist of plastic ball clays and nonplastic kaolins. The memb. is widely distributed W. of Tokio [Hempstead Co., Ark.] and Highland. It comprises upper 100 to 150 ft. of Bingen fm. The underlying part of the Bingen consists of gravels, greenish arkosic sand, red clay, and dark plant-bearing clay. The Tokio memb. is conformably overlain by Brownstown marl.

C. H. Dane (U. S. G. S. Press Bull. 8823, Sept. 10, 1926) and L. W. Stephenson (A. A. P. G. Bull., vol. 11, No. 1, Jan. 1927) divided †Bingen fm. into *Tokio fm.* (above) and Woodbine fm. (below), and discarded Bingen. They also *redefined Tokio* by including in it, at base, a gravel bed 30 to 40 ft. thick, beneath which an uncon. had been discovered. The beds beneath the uncon. and above the Kiamichi clay they identified as Woodbine fm. (See also Dane, Ark. Geol. Surv. Bull. 1, 1929.)

†Tokio sand member.

See explanation under *Tokio fm.*

Tokun formation.

Tertiary (probably Miocene): Southeastern Alaska (Controller Bay region).

G. C. Martin, 1908 (U. S. G. S. Bull. 335, pp. 24, 35). *Tokun fm.*—Lower 2,000± ft. chiefly sandy shales; upper 500 ft. a bed of ss. Conformably overlies Kushtaka fm., the transition apparently representing a change from fresh-water to marine conditions. The Tokun outcrops on both shores of Lake Tokun. [Gives area of occurrence, detailed section, fossils, etc.]

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, p. 771). *Tokun fm.*, which occurs to N. of Bering Lake, closely resembles lower part of Katalla fm. to S. of Bering Lake. Martin thought Katalla fm. was older than Stillwater and Tokun fms., but writer suggests Tokun fm. is = lower part of Katalla fm., which he has named *Split Creek memb.*, and that this is underlain by Kushtaka fm. Katalla fm. is here assigned to upper Olig., on basis of lithologic similarity to fossiliferous beds in Yakataga dist. that are assigned to upper Olig. by B. L. Clark.

Tolay volcanics.

Pliocene (lower): Central western California (Petaluma district).

R. R. Morse and T. L. Bailey, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 10, pp. 1437–1455). *Tolay volcanics.*—A hitherto unrecognized fm. disclosed in core drilling at Petaluma. Includes great thickness of flows, breccias, tuffs, and aggls. Rough review of well samples shows, in general, that the fm. is acidic below, basaltic in middle, andesitic above, and that it terminates with extensive deposits of pyroclastic material, which, at top, are interbedded with lowermost Petaluma shales. [On p. 1443 and elsewhere they seem to include the transition beds in Petaluma fm.] Thickness 4,162+ ft. Upper few hundred ft. appear at surface in small area W. of Tolay Creek, near Lakeville School, Petaluma quad., where they conformably underlie Petaluma fm., believed to be Lower Plio. On this evidence and by inference from relations of rocks in adjoining areas, the Tolay volcanics are assigned to Lower Plio. The Upper Mio. San Pablo strata are unknown at Petaluma. If present they must occur in the unknown interval below Tolay volcanics, where it is possible Monterey also may be represented.

Tolchico shale.

Lower Triassic: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 338). *Tolchico shales* is name given to 2d sh. memb. of Ward's Moenkopian series, finely displayed around mouth of Canyon Diablo. Thickness 100 ft.

Name probably derived from Tolchico Settlement, The Crossing, Little Colorado River, Coconino Co.

Toledo moraine.

Pleistocene (Wisconsin stage): Northern Ohio. Equivalent to Goodland and Imlay moraines of southern Michigan. Named for Toledo, Ohio. Same as Cleveland moraine.

Toledo formation.

Oligocene: Northwestern Oregon (Lincoln County).

Harrison & Eaton (firm), 1920 (Min. Res. Oreg., Oreg. Bur. Min. and Geol., vol. 3, No. 1). *Toledo div.*—Tuffaceous ss. and shales, green gray on unweathered surfaces, but weathers white, yellow, and red. The ss. is rather thinly bedded, and sandy sh. makes up greater part of series. Thickness 2,800 ft. Underlies Yaquina ss. and overlies Coaledo fm. Type loc. 3 mi. S. of Toledo, Lincoln Co.

W. D. Smith, 1924 (Econ. Geol., vol. 19, p. 458), gave thickness as 3,000 ft.

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12). It is possible to divide *Toledo fm.* into at least 2 members, the upper consisting of 1,000± ft. of sss. and the lower 1,200± ft. of concretionary sh. of lower Olig. age, here named *Moody sh.* It is believed there is no angular uncon. btw. Toledo fm. and overlying Yaquina fm.

H. G. Schenck, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, pp. 22–31). *Toledo fm.* uncon. overlies Burpee fm.

Tolenas marble.

Probably late Tertiary or Quaternary: Western California.

W. L. Watts, 1890 (Calif. State Min. Bur. 10th Ann. Rept., pp. 668–669). *Tolenas marble.*—Pure waxlike aragonite, the work of springs; quarried at Tolenas Springs, Solano Co.

Toll Pit beds.

Silurian: Southeastern Michigan.

W. H. Sherzer and A. W. Grabau, 1910 (Mich. Geol. Surv. Pub. 2, geol. ser. 1, pp. 47+). *Toll Pit beds.*—At Toll Pit quarry, near Scofield, the upper part of the Sylvania is interstratified with some dolomitic layers carrying Anderdon fauna. Pre-Dundee erosion has carried away all of Monroe beds except this thin layer of Anderdon in the upper Sylvania. Traces of Dundee still remain at this loc.

Tolovana limestone.

Silurian (Niagaran): Northeastern Alaska (Preacher, Tolovana, and Hot Springs districts).

J. B. Mertie, Jr., 1936 (U. S. G. S. Bull. 872). *Tolovana ls.*—Composed entirely of carbonate rocks without any important admixture of argill. or aren. members. Both ls. and dol. are present. In White Mtns these rocks are dark to light gray, crystalline, and weather white, yellowish, or buff. Generally massive. Niagaran (middle Sil.) fossils from lower 500 ft. It is possible uppermost part may be late Sil. Thickness possibly as much as 3,000 ft. Rests with possible discon. on undiff. pre-Middle Ord. rocks and is overlain, probably with great uncon., by Dev. rocks.

Toltec trap.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and p. 21). Then succeed [next above National ss.] various trap belts of which little is known, 1,710 ft. wide. In southern of these belts was worked the Toltec mine, on a large quartzose vein. [Called *Toltec traps* on map, and shown as next below Oneida cgl.]

Tomahawk amygdaloid.

Same as Torch Lake amygdaloid. Derivation of name not known.

Tomales formation.

Upper Pleistocene: Western California (Marin and Sonoma Counties).

R. E. Dickerson, 1922 (Calif. Acad. Sci. Proc., 4th ser., vol. 11, No. 19, with maps). *Tomales fm.*—Largely land or stream-laid deposits, including terrace deposits containing a small but distinctive Pleist. fauna, and also probably material composing alluvial fans. In part of area the fm. consists of lignitic beds overlain by loosely consolidated tan-colored sss. and cgls. (or perhaps fangls. would be a better designation) of lighter color than the tan-colored sss. of Millerton fm. A small estuarine fauna found in upper beds indicates that during part of time the region was occupied by a shallow bay. Rests uncon. (important break) on Millerton fm.

Named for occurrence on NE. side of Tomales Bay, where most of headlands are thinly coated with the loosely consolidated sss. and cgls. of Tomales fm.

Tomales Bay deposits.

Pleistocene: Western California (Marin County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 4, p. 76). *Tomales Bay deposits.*—According to Anderson they consist of coarse arkose detritus with indistinct horizontal stratification. Generally found in the larger depressions of the peninsula. Range in elev. from 500 ft. downward. Form a series of low, broad hills, extending along middle of valley near Olema, and occur at intervals on both shores of Tomales Bay, forming there a system of low bench-like terraces below 200 ft. height. West of main ridge they are found in occasional patches around flanks of hills at head of Drake's Estero and N. of Abbott's Lagoon.

Tombigbee sand member (of Eutaw formation).

Upper Cretaceous: Northeastern Mississippi, western Tennessee, southern Alabama, and western Georgia.

E. W. Hilgard, 1860 (Rept. geol. and agric. Miss., pp. 3, 61, 68–75). *Tombigbee sand group.*—Sharp fine-grained, strongly micaceous fossiliferous sands, laminated when indurate, and cemented by carbonate of lime; usually of greenish tint, but not infrequently gray, bluish, black, yellowish, and sometimes orange red. Clays and noncalc., also nonmicaceous, sands are also found. Thickness 150 to 160± ft. Underlies Rotten ls. group [Selma chalk] and overlies Eutaw group.

J. M. Safford, 1864 (Am. Jour. Sci., 2d, vol. 37, pp. 361–363), suggested that Tombigbee sand of Hilgard "most likely ought to be included in his Eutaw group." But the Tombigbee continued to be treated as a distinct fm. until about 1905, when U. S. Geol. Survey and Miss. Geol. Survey began to include it in Eutaw fm. but continued to define the Tombigbee as including all sands up to base of Selma chalk. In 1911 L. W. Stephenson (Ga. Geol. Surv. Bull. 26, pl. 5) divided the sands that had previously been called *Coffee sand* in Tenn. and *Tombigbee sand* in Miss. into 2 members, the upper being called *Coffee sand memb.* of Eutaw fm. and the lower being called *Tombigbee sand memb.* of the Eutaw. Later (Wash. Acad. Sci. Jour., vol. 7, No. 9, 1917) Stephenson showed that Coffee sand of Miss. grades laterally into lower part of Selma chalk, so that in parts of NE. Miss. the Tombigbee sand is overlain by Selma chalk and in other parts of that area it is overlain by Coffee sand, which is now treated as a distinct fm.

Named for exposures on Tombigbee River near Aberdeen, Monroe Co., and at Plymouth Bluff, Lowndes Co., Miss.

†Tombigbee.

Eocene: Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.). The name *Tombigbee (Lignitic)* is applied to the deposits underlying the Buhrstone and including the Hatchetigbee at the top and the Black Bluff [Sucarnoochee clay] at base. [As thus defined it corresponds to Wilcox group and upper fm. of Midway group.]

Preoccupied by Tombigbee sand memb.

†Tombigbee chalk.

Upper Cretaceous: Southwestern Alabama and northeastern Mississippi.

W J McGee, 1890 and 1891 (Am. Jour. Sci., 3d, vol. 40, pp. 25, 30, 31, 1890; U. S. G. S. 12th Ann. Rept., pt. 1, pp. 419, 475), referred to: The peculiar middle Cret. fm. which [E. A.] Smith and [L. C.] Johnson now designate [unpublished] the Tombigbee chalk (the "Rotten ls." of the books).

The only known use of *Tombigbee chalk* by either E. A. Smith or L. C. Johnson is in the table of contents of Ala. Geol. Surv. Bull. 2, 1892, but in the text heading *Tombigbee* does not appear. The name in the table of contents appears to be an oversight. W. H. Dall and G. D. Harris, however, used *Tombigbee chalk* in U. S. G. S. Bull. 84, 1891, p. 166. The name was also used by C. W. Hayes and M. R. Campbell in 1895 (Nat. Geog. Mag., vol. 6, p. 125), but throughout the text they used *Rotten ls.* The name *Tombigbee chalk* conflicts with Tombigbee sand memb., the older name, and was years ago replaced by *Selma chalk*, which also replaces †*Rotten ls.*

Apparently named for development on both sides of Tombigbee River in Greene, Hale, Sumter, and Marengo Counties, Ala., and near Tombigbee River in NE. Miss.

Tombstone sandstone.

Upper Cretaceous: Central southern Montana (Livingston quadrangle).

W. H. Weed, 1893 (U. S. G. S. Bull. 105, pp. 16, 18). *Tombstone sss.*, 150 ft. thick, lie at top of Montana group at Cokedale, 10 mi. W. of Livingston, Mont., and are overlain by massive white bluff sss., 75 ft. thick, which form basal memb. of Laramie fm. They sometimes form bluff exposures but more often weather out in "tombstone ledges."

Tomichi limestone.

Upper, Middle, and Lower Ordovician: Central Colorado (Monarch-Tomichi region).

R. D. Crawford, 1913 (Colo. Geol. Surv. Bull. 4, p. 56). *Tomichi ls.*—In descending order: (1) Argill. ls. and calc. sh., few ft.; (2) ls. which grades into dolomitic ls., with little chert (*Receptaculites oweni* up to 50 ft. and cup corals to top), 100 ft.; (3) very persistent qtzite, 28 to 30 ft., locally called "parting qtzite;" (4) probable uncon.; (5) sandy bed, 15 ft.; (6) cherty bluish-gray mag. ls., 200 to 290 ft. Rests uncon. on Sawatch qtzite. Overlain by Ouray ls. (Miss. and Dev.). Named for Tomichi, Gunnison Co.

Tomifobia slates and limestones.

Ordovician: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, p. 11).

†Tomlinson stage.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

H. M. Chance, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 52). *Tomlinson stage.*—In Indian Territory consists of (descending): 50 ft. of ss.; 320 ft. of shales; 100 ft. of sss.; and 200 ft. of shales with 3 ft. of coal near bottom. Overlies Norristown stage [Hartshorne ss.] and underlies Poteau stage along Choctaw, Oklahoma & Gulf Ry in Indian Territory.

Includes McAlester group and Savanna ss.

Probably named for Tomlinson, Scott Co., Ark.

Tomlinson shale.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Tomlinson sh.*—Sh., 500 to 600 ft. thick, underlying Greenwood ss. and overlying Hartwell ss. All included in Sebastian stage. [The Hartwell ss. is absent in Okla.]

Named for Tomlinson, Scott Co., Ark.

Tomstown dolomite.

Lower Cambrian: Central southern Pennsylvania, western Maryland, and northern Virginia as far south as Massanutten Mountain.

G. W. Stose, 1906 (Jour. Geol., vol. 14, p. 208). *Tomstown ls.*—Drab to white mag. lss. with purer lss. (of mottled dark- and light-gray colors) near base. About

800 ft. thick. Underlies Waynesboro fm. and overlies Antietam ss. Exposed at Tomstown, Franklin Co., Pa.

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170), gave thickness as 1,000± ft.

Tonganoxie sandstone.

Pennsylvanian: Northeastern Kansas.

J. M. Jewett and C. C. Williams, May 1, 1935 (Kans. Acad. Sci. Trans., vol. 38, pp. 191–198). *Tonganoxie ss.*—Massive ss. to sandy sh., mostly micaceous, fine-grained, and uniform, usually cross-bedded, brown or gray; 30 ft. thick. Occurs on uplands in extreme W. part of Johnson Co. Included in Stranger fm.

N. D. Newell, May 15, 1935 (Kans. Geol. Surv. Bull. 21, p. 82). The dominantly sandy and nonmarine beds from top of Sibley coal (which lies 8 to 10 ft. below top of Stranger fm.) to base of Stranger fm. were termed *Tonganoxie* by J. M. Patterson, in unpublished thesis, from a town in Leavenworth Co., Kans.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 147, etc.). *Tonganoxie ss.* was erroneously attributed by Newell (Bull. 21) to J. M. Patterson. The name was originated by Moore. Is basal memb. of Stranger fm. Includes heavy cross-bedded channel sss., sandy shales, and several coal beds and extends up to top of Sibley coal. Nearly all of Tonganoxie ss. in Kans. is nonmarine. In much of Douglas, Leavenworth, and Wyandotte Counties it rests uncon. on various parts of Stanton, Weston, and Iatan fm.s. Thickness varies from 3 or 4 ft. near Elk City, Kans., to nearly 100 ft. in E. part of Leavenworth Co. Type loc., area E. of Tonganoxie, Leavenworth Co. Good exposures along U. S. Highway 40 in secs. 26 and 35, T. 11 S., R. 21 E., about 7 mi. E. of Tonganoxie and on Stranger Creek and its tributaries N. of Linwood.

Tongue River member (of Fort Union formation).

Eocene: Northeastern Wyoming; northeastern, southeastern, and central southern Montana; and southwestern North Dakota.

J. A. Taff, 1909 (U. S. G. S. Bull. 341, pp. 129–130). The coal-bearing rocks of Sheridan coal field, Wyo., are divided into 3 coal groups (descending)—Ulm coal group, intermediate coal group [=part at least of Sentinel Butte sh. memb. exclusive of Roland coal], and *Tongue River coal group*. The top bed of Tongue River coal group is Roland coal. It includes also several other coals (Smith, Dietz, Monarch, Carney, and Masters). Is exposed along Tongue River.

W. T. Thom, Jr., and C. E. Dobbin, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 484–499). *Tongue River memb. of Fort Union fm.*—Yellow or light-colored strata containing massive sss. and numerous thick coal beds. Top of memb. is placed beneath bed K of Sidney field, bed F of Sentinel Butte field, and Roland coal of Sheridan field. Base is placed beneath the light-colored coal-bearing rocks which characteristically form a marked clinker-capped escarpment rising above lowlands or badlands developed from the somber Lebo sh., with which it intertongues at the contact. According to interpretation of writers the term *Fort Union fm.* should be restricted to Lebo andesitic (or sh.) memb. and Tongue River memb., although overlying Sentinel Butte sh. is classed as Fort Union (?) by U. S. Geol. Surv. The Tongue River memb. is well exposed along Tongue River btw. Carneyville, Wyo., and Brandenburg, Mont., and along the Yellowstone btw. Burns, Mont., and Buford, (Fort Union), N. Dak., also in Missouri Valley above Fort Clark, N. Dak.

Tonkawa sand.

A subsurface sand of Penn. age and 0 to 700 (?) ft. thick, in central and northern Okla. Correlated with lower part of Nelagoney fm. Lies lower than Endicott sand series and higher than Layton sand and Layton lime.

Tonkawa limes.

Drillers' term for Penn. lss. in Oklahoma City field, central Okla., lying somewhat lower than Tonkawa sand.

Tonkawatla formation.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 123).

Tonoloway limestone. (In Cayuga group.)

Silurian: Central Pennsylvania to western Virginia.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28). *Tonoloway ls.*—Underlies Bossardville ls. and overlies Wills Creek fm. in Pa.-Md.-Va. region.

G. W. Stose, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Tonoloway ls.*—Top fm. of Cayuga group. Consists of 400 ft. of ls. with some sh. Overlies Wills Creek sh. and underlies Helderberg ls.

Named for exposures on lower slopes of Tonoloway Ridge, Washington Co., Md.

Tonopah formation.

Tertiary: Central Nevada (Tonopah district).

J. E. Spurr, 1905 (U. S. G. S. P. P. 42, pp. 41+, map). *Tonopah rhyolite-dacite* occupies large part of Tonopah dist. In N. part of area mapped it intrudes the earlier andesite and in many places the later andesite. In S. half of area it contains many inclusions of later andesites, as well as probable earlier andesites, vein quartz, and granitic fragments. It often intrudes or overlies Fraction dacite breccia. Above Fraction dacite breccia proper is a series of coarse pumiceous tuffs which are rudely layered and rarely well stratified and in which Tonopah rhyolite-dacite sheets are often interbedded, with no sign of intrusion. Occasionally also thin sheets of the rhyolite-dacite are found in lower part of overlying Siebert tuffs (lake beds).

T. B. Nolan, 1930 (The underground geology of western part of Tonopah dist.: Univ. Nev. Bull., vol. 24, No. 4, pp. 10–13). The name *Tonopah fm.* is proposed for what has been called "Lower rhyolite" by J. A. Burgess (Econ. Geol., vol. 4, p. 687, 1909). The fm. has also been called "Tonopah rhyolite" or "Tonopah rhyolite-dacite" (J. E. Spurr, U. S. G. S. P. P. 42, p. 41, 1905, and Econ. Geol., vol. 10, p. 745, 1915), and correlated with rhyolite exposed on the surface N. of the mining dist. These exposures have not yet been studied by writer, but from descriptions of their lithology and relations they do not appear to be in any way related to the beds herein discussed. The fm. as here defined includes rocks previously mapped as "Glassy trachyte" and "Montana breccia" but does not include all exposures that have been so assigned by Spurr, Burgess, and others. Best exposures of fm. are in westerly workings of Tonopah Extension mine, notably on 1,200-ft., 1,540-ft., and 1,880-ft. levels. Less extensive but equally significant exposures are present in 1,050-ft. level from Extension No. 1 shaft, 1,000-ft. level and 1,140-ft. levels of the Sand Grass, the 700-ft. level of the Mizpah, and the 800-ft. and 960-ft. levels of the West End. Outstanding feature of fm. is that it is composed of an interbedded sequence of volcanic breccias, massive tuffs of varying grain size, porphyritic flows, banded flows, and water-laid deposits of several kinds, the most striking of which is probably the well-laminated material that closely resembles much of Esmeralda fm. The rocks described by Burgess as bedded pyroclastic material belong to this fm., and the exposures in Tonopah Extension workings add abundant proof of nonintrusive character of great bulk of these rocks. Some intrusive rocks are, however, included within the fm., as may be expected in such an accumulation of dominantly volcanic debris. Base of fm. not yet exposed. In all but a few places its top is marked by the intrusive West End rhyolite, which separates it from Mizpah trachyte. On 1,300-ft. level of Midway mine the West End rhyolite is absent and Tonopah fm. is seen in contact with Mizpah trachyte. Base of fm. is not exposed, so total thickness of fm. is unknown, but approx. 1,000 ft. is present in W. part of Tonopah Extension mine, exclusive of the interbedded Sandgrass andesite. Is uncon. overlain by Esmeralda ["Siebert"] fm. (upper Mio.) and contains fragments of black sl. that presumably belong to Camb. or Ord. The Sandgrass andesite and Mizpah trachyte are of essentially same geol. age as Tonopah fm. Age of Tonopah fm. is most probably Tert., and older than upper Mio.

†Tonopah rhyolite.

†Tonopah rhyolite dacite.

See 1930 entry under *Tonopah fm.*

Tonto group.

Middle Cambrian: Arizona.

G. K. Gilbert, 1874 (Phil. Soc. Wash. Bull., vol. 1, p. 109). *On the age of the Tonto sss.*—A group of rocks exposed in the Grand Cañon of the Colorado, and locally designated as the *Tonto group.* Full description will appear in Wheeler Rept.

G. K. Gilbert, 1875 (U. S. Geog. and Geol. Surv. W. 100th Mer., vol. 3, pp. 60, 171–186, fig. 82). *Tonto group.*—Consists of (descending): Marbled ls. (mottled ls.), 75 to 200 ft.; *Tonto sh.* (aren. and argill. shales), 600 ft.; *Tonto ss.* (vitreous ss.), 80 ft. Uncon. overlies Archean crystalline schists and granites and underlies Redwall ls. group in Grand Canyon. Tonto group floors the valleys that contain the headwaters of Big Williams Fork of the Colorado and of the Verde and Tonto Creek, tributaries of Salt River, Ariz.

The "Marbled ls." is now known as *Muav ls.*, the "Tonto sh." as *Bright Angel sh.*, and the "Tonto ss." as *Tapeats ss.*

†Tonto shale.

Middle Cambrian: Arizona.

G. K. Gilbert, 1875. (See under *Tonto group.*)

Replaced by *Bright Angel sh.*

†Tonto sandstone.

Middle Cambrian: Arizona.

G. K. Gilbert, 1875. (See under *Tonto group.*)

Replaced by *Tapeats ss.*

†Tonto limestone.

A name applied in some early repts to the †Marbled or mottled ls. forming top fm. of Tonto group (Middle Camb.) in Grand Canyon, Ariz. Replaced by *Muav ls.*

Tontoan series.

A name employed by C. [R.] Keyes instead of Tonto group of other geologists.

Tonzona group.

Silurian, Devonian, and Carboniferous: Central southern Alaska (Tonzona district, Kuskokwim region).

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, pp. 55, 66, 73, map). *Tonzona group.*—Black, red, and green argillites and cherts, with some graywackes, along inland front of Alaska Range and in Yukon-Tanana region; no ls., in which respect it differs from Tatina group. Thickness 4,000 to 5,000± ft. In upper Nenana Basin some gneisses (altered rhyolites) are associated with these rocks. Younger than Tatina group. Overlain, probably uncon., by Dev. ls. (Middle? Dev.). No fossils. Assigned to Sil. or Dev. Named for Tonzona River, in whose basin these rocks typically occur.

Later work (by P. S. Smith and J. B. Mertie, Jr.) proved that Tonzona group includes Carbf., Dev., and Sil. rocks, but they have not yet been differentiated.

Tookcarak diabase.

Pre-Cambrian: Canada (Belcher Islands).

E. S. Moore, 1918 (Jour. Geol., vol. 26, p. 417).

Topache limestone.

Mississippian and Devonian (?): Southwestern Utah (southeast and northeast of Frisco district).

B. S. Butler, 1913 (U. S. G. S. P. P. 80). *Topache ls.*—Heavy-bedded blue ls. with beds of sh. and chert. Thickness 1,500 ft. Underlies (apparently conformably) Talisman qtzite and overlies (conformably) Mowitza sh. (Upper Dev.). Type loc. Topache Peak, SE. of Frisco dist. G. H. Girty says fauna is without much doubt Miss., and that one lot is suggestive of upper Miss.

J. Gilluly, 1932 (U. S. G. S. P. P. 173, p. 21), stated that possibly several hundred ft. of Topache ls. is Dev., but that upper part is known to be Miss.

Topanga formation.

Miocene (middle): Southern California (Santa Monica and Santa Ana Mountains).

W. S. W. Kew, 1923 (A. A. P. G. Bull., vol. 7, pp. 411–420). *Topanga fm.*—Name proposed to include the rocks lying below Modelo fm. and above Vaqueros fm., and containing *Turritella ocoyana* fauna. The strata are essentially ss. Formerly included in Vaqueros fm. (now restricted to *Turritella inezana* fauna). Uncon. overlies true Vaqueros fm., and in Topanga Canyon, Los Angeles Co., is overlain with marked uncon. by Modelo fm. [In U. S. G. S. Bull. 753, 1924, Kew gave thickness of Topanga fm. as 6,000± ft.]

†Topatopa formation.

Eocene: Southern California (Ventura County).

G. H. Eldridge, 1907 (U. S. G. S. Bull. 309). *Topatopa fm.*—Lowest fm. outcropping in mtns N. of Santa Clara Valley. Total thickness unknown, but about 5,500 ft. are exposed. This consists of very hard submassive sss. (light gray to white) and qtzites (greenish gray, clear or mottled with white); shales (of slightly bluish hue) that differ from the qtzites in carrying additional content of mica and in fineness of their material. The qtzites and sss. greatly predominate in lower 2,000 ft. and the shales predominate in upper 2,500 ft. Qtzites also occur near middle of fm. The conspicuous features of the fm. are a tendency to broad concretionary structure in some of its members; the presence of smaller brown ferruginous sand concretions; the sparse distribution of fossil oysters and other imperfect molluscan remains through great part of its thickness, more particularly in the shales; some evidences of woody tissue; and frequent recurrence of what appears to be fucoids. Underlies Sespe fm. and probably rests on granite.

According to W. S. W. Kew (U. S. G. S. Bull. 753, pl. 3) †*Topatopa fm.* as above defined corresponds to Martinez and Meganos fms. of Bull. 753, the deposits corresponding to Tejon fm. having been included in overlying Sespe fm. of Eldridge. Topatopa fm. of Arnold as described in U. S. G. S. Bull. 321, 1907, corresponds to Tejon, Meganos, and Martinez fms. of present terminology, all of which Kew has differentiated and mapped in neighboring areas.

Topeka limestone. (In Shawnee group, Kansas.)

Topeka limestone member (of Shawnee formation, Missouri).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

E. Haworth, 1895 (Kans. Univ. Quart. vol. 3, pl. opp. p. 290; Am. Jour. Sci., 3d, vol. 50, pl. opp. p. 466). *Topeka ls.*—Three lss., separated by shales and separated from overlying Topeka coal by a thick bed of sh.

Haworth's 1908 classification (Univ. Geol. Surv. Kans., vol. 9) defined Topeka ls. as belonging to Shawnee fm., as underlying Severy sh., and as overlying Calhoun sh. This has been for many years the commonly accepted definition. In Kans. the Shawnee is now treated as a group and Topeka ls. as a fm.

R. C. Moore, Aug. 31, 1936 (Kans. Geol. Surv. Bull. 22, pp. 48, 194–195). Type loc. of *Topeka ls.* is Topeka, Kans. All its members are well exposed in SE¼ sec. 5, T. 11 S., R. 16 E., and vicinity, NE. of Topeka. Thickness ranges from less than 10 ft. in Nebr. to more than 50 ft. in parts of southern Kans. Divided into (descending) Coal Creek ls., Holt sh., DuBois ls., Turner Creek sh., and Hartford ls.

R. C. Moore, Sept. 4 to 7, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 41). *Topeka ls.* divided into (descending) Coal Creek ls., Holt sh., DuBois ls., Turner Creek sh., Hartford ls., Jones Point sh., and Dashner ls.

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser.), after further detailed surveys, made the following changes in the nomenclature of this part of the geol. column: (1) Reclassified the subdivisions of *Topeka ls.* as follows (descending): Coal Cr. ls., Holt sh., DuBois ls., Turner Cr. sh., Sheldon ls., Jones Point sh., Curzen ls., Iowa Point sh. and Wolf River ls. (new name); (2) restricted *Calhoun sh.* to the 1 to 44 ft. of beds btw. Wolf River ls. and Ervine Cr. ls. (top memb. of Deer Cr. ls.), but did not name any of its subdivisions; and (3) classified the subdivisions of Deer Cr. ls. as follows (descending): Ervine Cr. ls., Burroak sh. (new name), Haynies ls., Larsh sh., Rock Bluff ls., Oskaloosa sh., and Ozawkie ls. The outcrops at Topeka include only the Sheldon-Wolf River interval, and is same as Hartford ls. as originally used and as used by Moore in 1936. The Sheldon ls. at Curzen is upper bed of interval previously classified as Curzen. It is here proposed to restrict *Curzen* to lower 6 to 7 ft. of interval previously classified as Curzen and to continue to use the name Sheldon. The Iowa Point sh. has heretofore been included in Calhoun sh., but it can be traced into lower part of Topeka fm. at Topeka, and is therefore not of Calhoun age.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Tophet limestone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 356). *Tophet ls.*—Shaly calc. bed, 0 to 5 ft. thick, with marine fossils. Underlies Hackett sh. and overlies Upper Tophet sh.; all members of Hinton group [fm.]. Type loc. on hill road toward Lick Creek 0.2 mi. N. of Tophet, Summers Co. Also observed in Mercer Co.

Tophet sandstone. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 357). *Tophet ss.*—Reddish or greenish brown, shaly, 10 to 25 ft. thick. Underlies Upper Tophet sh. and overlies Tophet coal, where present, or Lower Tophet sh. All members of Hinton group [fm.]. Type loc. same as Tophet ls. Also observed in Mercer Co.

Tophet shale. (In Hinton formation.)

Mississippian: Southeastern West Virginia.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 297, 356–358). *Upper Tophet sh.*—Red and variegated sh., in part sandy; 10 to 15 ft. thick; underlies Tophet ls. and overlies Tophet ss. *Lower Tophet sh.*—Mostly red and variegated, with ss. streaks; plants at top; 20 to 35 ft. thick; underlies Tophet coal, where present, or Tophet ss.; overlies Goodwyn ss. All members of Hinton group [fm.]. Type loc. in vicinity of Tophet, Summers Co. Also observed in Mercer Co. Probably present in Monroe Co.

Top Hill sandstone.

Pennsylvanian: Western central Kentucky.

D. D. Owen, 1856 (Ky. Geol. Surv. vol. 1, pl. showing geol. section of Hancock, Breckinridge, and Mead[e] Counties, Ky.). *Top Hill ss.*, 51 ft. thick, forms top of Coal Measures.

Toquima formation.

Ordovician (Lower, Middle, and Upper ?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Toquima fm.*—Major part of fm. is gray-green chloritic schists merging into similar knotted schists in S. part of dist. Interspersed are numerous beds of dark blocky siliceous sl. or chert, much like the black jaspilite, and occasional beds (nowhere more than 100 ft. thick) of brown to gray crystalline ls. in massive beds. Basal part of fm. consists (descending) of (1) 200 ft. of gray ls. with black jaspilite; (2) a few ft. of qtzite; (3) a few ft. of dark sl. carrying Normanskill graptolites; (4) 0 to 50 ft. of qtzite. Thickness of fm. at least 4,000 ft. and may be much more. Overlies Zanzibar ls. and underlies Perm. (?) ss. Present over considerable part of Toquima Range.

Torbay slate.

Pre-Cambrian: Newfoundland.

C. D. Walcott, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 219). *Torbay slates.*—Green, purple, pinkish, or red, very fine-grained slates, in frequent alternations; in some cases they approach in hardness jasper or chert. Thickness 3,300 ft. Included in Avalon terrane. Finely exposed at Torbay and covers great area from Cape St. Francis to Cape Race, St. Marys Bay and across to Concepcion Bay.

Torbrook sandstone.

Silurian: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 203).

Torcer formation.

Lower Cretaceous: Western Texas (Malone Mountain region).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 254–257, 286). Name *Torcer fm.* is here applied to the portion of the section at and near Torcer (formerly Malone) station, on Southern Pacific Ry. W. of Sierra Blanca, which is of Neocomian age, overlies the Jurassic, and underlies the *Dufrenoya* (Gargasian) level. Type loc. is taken in Malone Mtn, though exposures occur also in Malone Hills in the flat about 1 mi. E. of the station. This name covers the Cret. portion of Cragin's "Malone fm.," that name having been restricted to rocks of Jurassic age. Thickness of Cret. part more than 831 ft. Included in Trinity group of Comanche series. The fm. is chiefly ls., some ls. cgl., calc. grit, calc. sh., cgl.; at base 30 ft. of calc. ss. and siliceous ls. that yielded *Astieria* and another ribbed Cret. ammonite.

Torch Lake amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name applied to an amygdaloid of Central Mine group that lies at a horizon below Old Colony ss. It occurs on property of Torch Lake Mining Company, in Houghton Co. The mineralized part is the Torch Lake lode.

Torch Lake flow.

Includes Torch Lake amygdaloid and underlying trap.

Torchlight sandstone member (of Frontier formation).

Upper Cretaceous: Northern Wyoming (Basin and Greybull oil and gas fields) and southern Montana (Carbon, Bighorn, Yellowstone, and Stillwater Counties).

F. F. Hintze, Jr., 1915 (Wyo. State Geol. Bull. 10, p. 23). *Torchlight ss.* (commonly known as *ss. B*) consists of 20 to 30 ft. of light-gray, often white saccharoidal ss., often strongly cross-bedded. Always capped by layer of black and gray pebbles, poorly cemented together. Top memb. of Benton. Lies discon. below Basin sh. (of Niobrara age) and is separated from underlying Peay ss. by 350 to 400 ft. of black adobe sh. and sandy sh. and bentonite.

C. T. Lupton, Jan. 21, 1916 (U. S. G. S. Bull. 621, pp. 167, 169–171), treated *Torchlight ss.* as a *memb.* of Frontier fm., stated that it lies 292 ft. above Peay ss. memb. in Basin oil field, where it is 83 ft. thick and is overlain by 7 ft. of cgl. forming top bed of Frontier fm.; also that it is exposed in Torchlight dome and that it is *ss. B* of Washburne (U. S. G. S. Bull. 340, 1908, p. 350).

Torchlight sand.

A subsurface sand lying at or near horizon of Torchlight ss. memb. of Frontier fm.

Tordrillo formation.

Middle Jurassic: Southern Alaska (Cook Inlet region).

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 153–155). *Tordrillo series.*—Considerable thickness of black shales, often carbonaceous, intercalated with many beds of ss., arkose, and impure lss.; ss. seems to become predominant in upper part. Plant remains throughout. Highly folded or cut through by intrusives. On E. side of Tordrillo Mtns it conformably overlies Skwentna series; on W. side it overlies Terra Cotta series. Evidence obtained favors Cret. age.

A. H. Brooks, 1906 (U. S. G. S. P. P. 45, table opp. p. 206), assigned this fm. to Middle Jurassic, on basis of fossils obtained.

Torio limestone.

Age(?): Panama.

O. H. Hershey, 1901 (Univ. Calif. Dept. Geol. Bull., vol. 2, p. 239).

Tornado limestone.

Pennsylvanian (early) and Mississippian (early): Central Arizona (Ray quadrangle).

F. L. Ransome, 1915 (Wash. Acad. Sci. Jour., vol. 5, pp. 380–385). *Tornado ls.*—Thick-bedded light-gray ls., consisting of (descending): (1) Upper part thinner-bedded and contains thin layers of calc. sh., but shows no marked lithologic distinction from lower part; (2) very massive memb., 100 ft. thick; (3) few transitional beds; (4) alternating dark- and light-gray members, 75 ft. Total thickness 1,000+ ft. Upper part contains early Penn. fossils, and lower part contains Miss. [early], according to Girty. Could not separate the two. Rests conformably on Martin ls. (Dev.). Top of fm. is an erosion surface in Ray quad. Named for Tornado Peak, Dripping Spring Range.

A. A. Stoyanow, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 508, 517–521). The name *Tornado ls.* is discarded in this paper, and *Escabrosa ls.* is here used for entire Lower Miss. in depositional area SE. of Mazatzal land. The Penn. part of the "Tornado" is here named *Galiuro ls.*, because in certain ways it is different from Naco ls., or the Penn. of extreme SE Ariz.

Tornillo clay.

Upper Cretaceous (Gulf series): Western Texas.

J. A. Udden, 1907 (Univ. Tex. Bull. 93, pp. 17, 54–60). *Tornillo clays.*—Fine-textured, almost unfossiliferous clays, 600 to 700 or more ft. thick; of gray, olive-green, dull-blue, red, yellow, purple, dirty-brown, black, and white colors. Weather into lumpy surface. Grade into Rattlesnake beds [Aguja fm. of present nomenclature] below and into Chisos beds above.

Named for exposures along Tornillo Creek, Brewster Co., in Chisos Mtns quad.

†Toro formation.

Lower Cretaceous: Western California (San Luis Obispo region).

H. W. Fairbanks, 1904 (U. S. G. S. San Luis folio, No. 101). *Toro fm.*—Dark thin-bedded clay sh., with thin irregular layers of cgl. at bottom and near middle. Thickness about 3,000 ft. Uncon. underlies Chico deposits and uncon. overlies Franciscan deposits. Is local representative of the Knoxville. Named for exposures along Toro Creek, San Luis Obispo Co.

Replaced by Knoxville fm., the local name "Toro" being considered unnecessary.

Toro limestone.

Pliocene or Miocene: Panama and Costa Rica.

D. F. MacDonald, 1915 (U. S. Bur. Mines Bull. 86, p. 26).

D. F. MacDonald, 1919 (U. S. Nat. Mus. Bull. 103, p. 532, assigned to Plio.; A. A. P. G. Bull., vol. 3, p. 365, assigned to Mio.).

Toronto limestone.

Pennsylvanian: Southeastern Kansas.

E. Haworth and W. H. H. Piatt, 1894 (Kans. Univ. Quart., vol. 2, p. 117). *Toronto ls.*—Ls. toward top of Penn., in section along Verdigris River from Kans. State line to Madison, Greenwood Co., Kans. Believed to be same as Garnett-Burlington ls., but correlation not established. Separated from underlying Carlyle ls. by 125 ft. of sh. and ss. Overlain by series of Penn. shales and sss. with two thin lss.

This name fell into disuse for many years. According to G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 12), this ls. is same as Weeping Water ls. of Nebr., and is basal bed of Oread ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 32, 48, 162–163), revived *Toronto ls.* for basal bed of Oread ls. in Kans., and stated that there is doubt as to its equiv. to Weeping Water ls. of Nebr. and that its type loc. is Toronto, Woodson Co., Kans.

Toronto stage.

Toronto formation.

Pleistocene: **Ontario.**

W. Upham, 1895 (Am. Geol., vol. 16, p. 105). *Toronto stage*, Pleist., is included in Champlain epoch.

T. C. Chamberlin, 1895 (Jour. Geol., vol. 3, pp. 270–277). Position of *Toronto fm.* [of Ontario] is rather uncertain. May be later than Wisconsin fm.

Toronto fm. has been used in many Canada repts, the latest recorded being Coleman, 1933 (Ont. Dept. Mines 41st Ann. Rept., pt. 7, p. 3), who stated that it includes Don and Scarborough beds.

Torpedo sandstone member (of Ochelata formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

O. B. Hopkins, 1918 (U. S. G. S. Bull. 686H, pp. 76–77, pl. 12). *Torpedo ss.*—Lowest bench of massive cliff-making ss., 75± ft. above valley floor at Torpedo. It rims the valley of Sand Creek and is typically exposed 1 mi. NW. of Torpedo, on N. side of creek, where it consists of 30± ft. of massive medium-grained ss. which breaks into large ripple-marked blocks. Rests on sh. Near Torpedo is overlain by a thin ls. which writer believes may be Stanton ls. of Kans., but this ls. disappears to N. Separated from overlying Okesa ss. by 25± ft. of sh. Forms top memb. of Wilson fm. of Shannon and Trout 1915 rept.

F. R. Clark, 1918 (U. S. G. S. Bull. 686–I, p. 95). *Torpedo ss.* is separated from overlying Okesa ss. by 25 to 75 ft. of sh. The Torpedo is 20 to 30 ft. thick, massive, and generally forms a ledge. In many places its upper surface is filled with tubelike openings. An impure siliceous ls., probably the Stanton, lies 2 to 9 ft. above the Torpedo, the interval being filled with limy sh.; in places the ls. rests on the ss.

See also under *Okesa ss. memb.*

Torrance shale.

Permian (?): Central-northern New Mexico (Manzano Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 3, 11). *Torrance shales.*—Upper or vermilion section of Bernalillan series of Carbonic red-beds in Manzano Mtns. Thickness 500 ft. Overlie Yeso fm. [Derivation of name not given.]

Torregon formation.

Eocene: New Mexico.

See *Torrejon fm.*, the approved spelling.

Torrejon formation. (Of Nacimiento group.)

Eocene: Northwestern New Mexico.

J. L. Wortman, 1897 (as reported by G. N. Calkins, secy of Biology section, A. A. A. S., in Sci., n. s., vol. 6, p. 852). Dr. Matthew reported on status of Puerco fauna. A review of Puerco fauna, based on Dr. Wortman's geological observations in field and records kept by Am. Mus. collecting parties, shows that Upper Puerco and Lower Puerco beds do not contain a sp. in common, and only 3 or 4 genera pass through. The two faunas are entirely distinct. Dr. Wortman proposes to call the upper beds *Torregon fm.*, retaining the name Puerco for the lower beds.

W. D. Matthew, 1900 (Am. Mus. Nat. Hist. Bull., vol. 12, p. 20). *Torrejon fm.* is 300 ft. thick.

J. H. Gardner, 1910 (Jour. Geol., vol. 18, No. 8, p. 713; U. S. G. S. Bull. 381, p. 464). *Torrejon fm.*—Variegated clay sh. and soft coarse-grained ss. of white, gray, and tan colors. Thickness 275 ft. Cannot everywhere be readily separated from underlying Puerco fm. without fossil evidence. Is upper fm. of Nacimiento group (Cope's original Puerco).

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, pp. 39+). The Torrejon fm., as defined by its fauna, is known to extend from Arroyo Torrejon in Sandoval Co., N. Mex., across southern and western parts of San Juan Basin almost to Colo.-N. Mex. bdy. Is probably uncon. on Puerco fm. Where Puerco is presumably absent the Torrejon rests with erosional uncon. on older beds. Is uncon. overlain by Wasatch fm. [Fossils listed.] [See also 1924 entry under *Puerco fm.*]

Torrey sand.

Eocene: Southern California (San Diego County).

M. A. Hanna, 1926 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 7, pp. 187–246). *Torrey sand.*—Sand, usually coarse, porous, and unconsolidated; color usually white to light brown; highly cross-bedded. Consists of clean, moderately well rounded grains of quartz with varying amounts of feldspar, some muscovite and biotite, and minor amounts of ferromagnesians. Thickness more than 200 ft. Pinches out to S., where it probably was not deposited. Probably increases in thickness to N. Is middle div. of La Jolla fm. in La Jolla quad. Grades into overlying Rose Canyon sh. and into underlying Delmar sand. Typically exposed on Torrey Pines grade, where the highway climbs from Soledad Valley to 400-ft. terrace to S.

Torrington member (of Lance formation).

Upper Cretaceous: Southeastern Wyoming (Goshen County).

E. M. Schlaikjer, 1935 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 76, No. 2, pp. 31–54, 65). *Torrington memb. of Lance fm.*—Continental deposits, 60 to 100+ ft. thick, comprising top memb. of Lance fm. in Goshen Hole area, Goshen Co. Contains in upper part a new and very advanced form of *Triceratops*. That this memb. is=at least part of Arapahoe-Denver beds in Denver Basin is indicated by close affinity of ceratopsians found in both. It rests on brackish-water deposits (80 to 125 ft. thick) that are correlated with some part of Cannonball marine memb. of Lance fm. to E. Is overlain by lower Olig. Chadron fm. Named for proximity to town of Torrington, Wyo., on North Platte River N. of typical exposures on Horse Creek. In commenting on fauna (listed) Reeside says (letter): "All of the lots represent a brackish-water fauna. There are no strictly fresh-water shells and no typically marine shells. All of the species occur in Laramie fm. of Denver Basin, and most of them have been recorded from lower Lance fm. By themselves they do not indicate an extension of Cannonball sea into SE. Wyo., though they do indicate the presence somewhere nearby of truly marine waters." Perhaps the brackish-water deposit in Goshen Hole represents a different phase of the Cannonball, or a tongue of that sea which is somewhat earlier than the one represented in North and South Dak. It is believed that the 2 are nearly equiv. in time.

†Toston beds.

Oligocene (middle): Western central Montana (Broadwater County, in Helena-Big Belt region).

E. Douglass, 1902 (Am. Phil. Soc. Trans., vol. 20, n. s., pt. 3, pp. 237–245). *Toston beds*, the White River deposits NE. of Toston, near Cottonwood Creek. Local name given for convenience until correlation is established.

Totatlanika schist.

Pre-Devonian: Central Alaska (Bonnifield region).

S. R. Capps, 1912 (U. S. G. S. Bull. 501, p. 22, map). *Totatlanika schist.*—Series of quartz-feldspar schists and gneisses which form much of foothill ranges of Bonnifield region and parts of higher mtns to S., btw. Nenana and Delta Rivers, and probably occur W. of Nenana River. One belt of fm. occurs across basin of Totatlanika Creek. Thickness probably exceeds 3,000 ft. No fossils. Overlies schists thought to be pre-Ord. and underlies beds provisionally assigned to Carbf. Tentatively assigned to Sil. or Lower Dev.

This fm. is now considered to be pre-Dev.

†Totsen series.

†Totsen group.

Early Paleozoic(?): Northern Alaska.

F. C. Schrader, 1902 (Geol. Soc. Am. Bull., vol. 13, p. 239). *Totsen series.*—Mainly mica schist; some quartz schist; locally becomes graphitic and in places carries much quartz in small veins and lenticular bodies. Essentially of sed. origin, but is accompanied by igneous effusives or basaltic flows. Thickness 6,000 to 7,000 ft. Seems to uncon. overlie Skajit fm., and is uncon. overlain by Bergman series. Tentatively referred to Upper Sil.

Named for Totsenbetna, a name formerly applied by the natives to Wild Creek; *betna* signifies *river*.

For a time these rocks were by some authors included in Birch Creek schist (pre-Camb.), but they are now considered, in part at least, younger and probably of Paleozoic age.

†Toughkenamon rock.

Pre-Cambrian: Southeastern Pennsylvania (Chester County).

P. Frazer, 1883 (2d Pa. Geol. Surv. Rept. C4, pp. 307-308, 319, 321). *Toughkenamon rock,* lower memb. of Potsdam ss., is composed of weathered particles of a gneiss or syenite loosely compacted and laminated. Named for development near Toughkenamon station. The upper memb. of Potsdam ss. is the Kennett rock.

Replaced by Setters fm. (pre-Camb.). (See U. S. G. S. Coatesville-West Chester folio, No. 223, in which the rocks at and near Toughkenamon Station are mapped as Setters fm.)

Toughnut series.

Mesozoic (Lower Cretaceous ?): Southeastern Arizona (Tombstone district).

W. P. Blake, 1902 (Tombstone and its mines). [See under *Contention series.*]

J. A. Church, 1903 (Am. Inst. Min. Engrs. Trans., vol. 33, pp. 3-37). *Toughnut series* includes (descending): Contention sh. series, 700 ft.; Blue lime, 90 ft.; *Toughnut qtzite,* 120 to 140 ft.; White lime, 60 ft., Overlies Herschel qtzite.

F. L. Ransome, 1920 (U. S. G. S. Bull. 710D). Herschell qtzite, white lime, blue lime, Contention sh. series, and Randolph ls. of Church are Mesozoic, probably Comanche (Lower Cret.).

Toughnut quartzite.

See under *Toughnut series.*

†Towanda sandstone. (In Chemung formation.)

Upper Devonian: Northeastern Pennsylvania (Bradford County).

A. Sherwood, 1878 (2d Pa. Geol. Surv. Rept. G, pp. 38-39). *Towanda ss.*—In Wysox Twp. opposite and a little above Towanda, there is an extensive outcrop, perhaps 300 ft. in thickness, having a considerable dip to N., and containing carbonized stems or reedlike plants. Color is gray, except toward top of section, where there are one or two beds of red sh., one of which is 10 ft. thick. Included in Chemung.

Only recorded use of name. Definition considered inadequate by U. S. Geol. Survey workers.

Towanda limestone member (of Doyle shale).

Permian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1920 (Kans. Geol. Surv. Bull. 6, pt. 2, p. 61). One bed of ls., well exposed in W. part of El Dorado field near Towanda, which was of great assistance in mapping the structure of the field, has been designated as *Towanda bed.*

A. E. Fath, 1921 (Kans. Geol. Surv. Bull. 7, p. 54). *Towanda ls. bed of Doyle sh.*—Bluish-gray slabby ls., 5 to 9½ ft. thick in Eldorado oil and gas field, Butler Co., Kans. Lies 50 to 60 ft. below top of Doyle sh. and 35 ft. above base.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 44). *Towanda ls. memb. of Doyle fm.* persists widely as a very irregular unit. We have observed its outcrop at many places [mentioned] from type loc. northward in Kans. and at several places in Nebr. [mentioned]. In places (as NE. of Barnes, Kans.) it consists of 3 rather massive lss. and interbedded sh., but at most places btw. type loc. and Nebr. it is represented by 5 to 10 ft. or more of drab-colored slabby lss. that weather very irregularly and yellowish brown. Overlies Holmesville sh. (basal memb. of Doyle) and underlies Gage sh. (top memb. of Doyle).

Tow Creek sandstone. (In Mesaverde formation.)

Upper Cretaceous: Northwestern Colorado (Routt County).

K. M. Willson, 1920 (Colo. Geol. Surv. Bull. 23, pp. 30-39). *Tow Creek ss.*—Though massive throughout it has 2 or 3 more or less prominent divisions due to erosion of streaks of softer material. Is of brown color. Thickness 100 to 112 ft. Lies 890 ft. above base of Mesaverde fm. in Tow Creek anticline. Forms top of ridges on both sides of Tow Creek.

V. C. Perini, 1920 (Colo. Geol. Surv. Bull. 23, p. 51). *Tow Creek ss.* is most outstanding rock of lower part of Mesaverde fm. near Steamboat Springs, Routt Co. Is very massive; at some places 100 ft. thick; of cream color on fresh surfaces; weathers yellow; texture differs at various outcrops, but in general is a medium-grained ss.

Tower sandstone lentil (of Green River formation).

Eocene: Southwestern Wyoming (Sweetwater County).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 40, 45). *Tower ss.*—Massive or irregularly bedded ferruginous ss. Is lower part of Upper Green River group, and well shown in cliffs at Green River Station and in that vicinity, especially up and down the river for several miles; is also well exposed on E. side of Green River below mouth of Currant Creek. Rests uncon. on Lower Green River group and is overlain by the plant beds that form upper part of Upper Green River group.

W. H. Bradley, 1926 (U. S. G. S. P. P. 140D, p. 123, pl. 59). The Tower ss. of Powell is lenticular and therefore here designated *Tower ss. lentil of Green River fm.* It forms the tops of the weathered rock masses in vicinity of town of Green River, Sweetwater Co., known as The Towers. In N. part of Sweetwater Co. it appears to be replaced by lower part of the plant-bearing beds, which are herein named *Morrow Creek memb. of Green River fm.* The Tower ss. consists of cross-bedded and massive beds of medium- to coarse-grained brown ss. firmly indurated by limonitic cement. Thickness 0 to 250± ft. It rests uncon. on Laney sh. memb. of Green River fm. and is conformably overlain by Morrow Creek memb.

†Tower group.

Pre-Cambrian: Northeastern Minnesota (Vermilion district).

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept., btw. pp. 330 and 367). *Tower group.*—Earthy schists (sericitic and argillitic) with beds of hematite, 5,000 ft. thick, which change to chloritic schists. Thickness of group 15,000 ft. Includes Stuntz cgl. Underlies Ogishke cgl. and overlies graywacke group, all of which have previously been included in Keewatin.

J. M. Clements, 1903 (U. S. G. S. Mon. 45, pl. 2), mapped the rocks at Tower as (descending) Ogishke cgl., Soudan fm., Ely greenstone, and an undet. fm.

Tower Creek conglomerate.

Pliocene: Yellowstone National Park.

A. Hague et al., 1904 (geol. maps in U. S. G. S. Yellowstone Nat. Park Atlas, to accompany U. S. G. S. Mon. 32). *Tower Creek cgl.* (*Plio.*), gneissic and andesitic pebbles in friable ss. [This name was adopted by U. S. Geol. Survey to replace the descriptive term *Canyon cgl.*, used in Yellowstone Nat. Park folio, 1896.]

Named for exposure on Yellowstone River opp. mouth of Tower Creek, Canyon quad., Yellowstone Park. Largest development of rock is in NW. corner of Gallatin quad.

Towle shale.

Pennsylvanian: Kansas and Nebraska.

R. C. Moore and G. E. Condra (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.). [*Towle sh.* shown as underlying Aspinwall ls., overlying Brownville ls., and forming basal bed of Admire sh. Derivation of name not stated.]

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8, p. 9). *Towle sh. fm.*—About 2 to 2½ ft. of gray sh. at top, 10 to 11 ft. of red sh. in middle, and 1± ft. of gray sh. at base. Total thickness 14± ft. Underlies Aspinwall ls. fm. and overlies Brownville ls. fm. Basal fm. of Admire group (*Perm.*).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred all beds above Brownville ls. to Perm. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.)

E. C. Reed (Asst. State Geol. Nebr.), 1936 (letter dated Oct. 16). Type loc. of Towle sh. is Towle farm, 2 mi. S. and 3 mi W. of Falls City, SW¼ sec. 20, T. 1 N., R. 16 E., Richardson Co., Nebr.

Towner greenstone.

Pre-Cambrian: Southeastern Wyoming (Medicine Bow Mountains).

E. Blackwelder, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 615, 622, etc.). *Towner greenstone.*—Schistose basic greenstones, probably derived from pyroclastics and flows. Underlies (probably conformably) French sl. and overlies (probably conformably) Ranger marble. Best exposed along new road btw. Brooklyn Lodge and Towner Lake.

Town Mountain granite.

Pre-Cambrian: Central Texas (Llano uplift).

H. B. Stenzel, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 144). [See under *Sixmile granite*.]

Towow formation.

Carboniferous (Pennsylvanian?): Southwestern Maine.

F. J. Katz, 1917 (Wash. Acad. Sci. Jour., vol. 7, p. 199). *Towow fm.*—Graphitic and pyritiferous quartz slates and carbonaceous sericite phyllite occurring in twp. of Lebanon, and surrounded by Rindgemere fm.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, pp. 174–175). *Towow fm.*—Uniformly very fine-grained and thin-bedded dark gray to black carbonaceous or graphitic siliceous slates and sericite sl. or phyllite. In general richly carbonaceous and in places graphitic and impregnated with pyrite and in small individual crystals and lenticular masses. Lithologically identical with Diamond Island sl. and the black pyritiferous part of Scarboro phyllite. Top presumably not present. Rests on Rindgemere fm. Thickness seems to be a few hundred ft. Approx.=a portion of lower part of Casco Bay group. Occurs only in Lebanon Twp, York Co. Assigned to Penn.(?). Name derived from original name of first settlement in town of Lebanon.

Trabuco formation.

Cretaceous: Southern California (Santa Ana Mountains).

E. L. Packard, 1916 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 9, pp. 140–141). *Trabuco fm.*—Massive red cgls., composed of angular and water-worn boulders loosely cemented, with subordinate bands of red ss. Thickness 200 ft. No fossils found, but from strat. relations the fm. is probably but slightly older than Chico group and presumably represents some phase of the pre-Chico Cret. Grades into overlying Chico group and rests uncon. on basement complex. Extends from North Star Canyon nearly to Trabuco Canyon. Best exposed at Harding Canyon.

R. Eckis, 1934 (Calif. Dept. Public Works, Water Res. Div. Bull. 45, p. 42). *Trabuco fm.* is probably of Chico age. [In table on p. 38 *Trabuco fm.*, 300 to 750 ft. thick, is placed beneath Chico fm. and uncon. above Jurassic intrusives.]

Tracey sand.

A subsurface sand in Chester group (Miss.) of Lawrence Co., Ill. (See Ill. Geol. Surv. Bull. 54, table 5, 1927.)

Tracy sand.

A subsurface sand, of early Chester (Miss.) age, in Ind. that has been correlated with Paoli ls. of Cumings.

†Tracy City Measures.

Pennsylvanian: Southeastern Tennessee.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 148–153, 167, 169). *Tracy City Measures.*—Sss., shales, and coals, surmounted by a heavy ss., here named Emory ss. Comprises middle div. of Coal Measures. Most important coal bed is "Main Sewanee." Thickness of fm. 250 to 500 ft. Overlies Bon Air Measures and underlies Brushy Mtn Measures.

Included upper part of Lee group (lower Pottsville), and is now divided into several fms., including Rockcastle (†Emory) ss., Vandever sh., Bonair ss., and Whitwell sh. Has also been called "Tracy City group" (see G. H. Ashley, Tenn. Geol. Surv. Bull. 2A, p. 21).

Named for Tracy City, Grundy Co.

Tracy Creek andesite.

Miocene (?): Southwestern Colorado (southern part of Saguache quadrangle and part of Del Norte quadrangle).

E. S. Larsen, 1935 (U. S. G. S. Bull. 843). *Tracy Creek andesite.*—Flows and subordinate tuff-breccia, in part andesite but chiefly tridymite dacite. In upper drainage of Tracy Creek and to N. lowest memb. is dense dark-gray platy andesite.

To N. this memb. consists of a number of flows with some breccia of tridymite dacite. Occurs in extreme S. part of Saguache quad. but extends a short distance into Del Norte quad. and makes up much of drainage of Tracy Creek, for which it is named. Underlies Conejos andesite. Overlies Beidell latite-andesite irregularly. Is of pre-Potosi age. Assigned to Miocene (?).

Traders iron-formation member (of Vulcan iron-formation).

Pre-Cambrian (middle Huronian): Northwestern Michigan (Menominee district).

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62). *Traders ore-bearing memb.*—Ferruginous cgls. and qtzite, ferruginous quartzose slates, and iron-ore deposits; the cgls. and qtzite usually at base. Thickness 85 to 170 ft. Basal memb. of Vulcan fm. Underlies Brier sl. memb. Uncon. overlies Negaunee fm., which is so thin in Menominee dist. that it is mapped with Vulcan fm. Named for Traders mine [N. of Lake Antoine].

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), adopted *iron-fm.* and *iron-fm. memb.* as lithologic terms, and changed age of *Vulcan iron-fm.* from upper Huronian to middle Huronian.

Tradewater formation. (Of Pottsville group.)

Pennsylvanian: Western Kentucky and southeastern Illinois.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 27). *Tradewater fm.*—Chiefly sh., with occasional inconstant ss. beds, 175 to 700 ft. thick in Webster Co., Ky. Includes coal No. 5 near top and Bell coal near base. Uncon. underlies Pennsylvanian De Koven fm. and overlies Caseyville cgl.

Top fm. of Pottsville group in western Ky. and SE. Ill. Underlies Carbondale fm. and overlies Caseyville ss.

Named for exposures along Tradewater River E. of Battery Rock, Ky.

Trail formation.

Lower Jurassic: Northern California (Taylorsville region).

J. S. Diller, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 370–394). *Trail beds*, Triassic (?); 2,900 ft. thick. On structural grounds regarded as Triassic and probably newer than Hosselkus ls.

J. S. Diller, 1908 (U. S. G. S. Bull. 353). *Trail fm.*—Largely slaty shales with some interbedded sss. and cgls. Shales often purplish or red but perhaps more frequently gray, with pencil structure locally developed; in places contain numerous cherty nodules of carbonate of lime. The sss. generally fine, often somewhat slaty, thin-bedded, and gray to almost black. Fresh-water fossils. Thickness 2,900 ft. Overlaps, uncon., Swearinger sl., Hosselkus ls., and Robinson fm. Is next older than marine Hardgrave ss., with which it is assumed to be uncon.

C. H. Crickmay, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 81, and No. 5, pp. 895–903), renamed the basal Lower Jurassic Trail fm. of Diller *Lilac ss.*, and stated that *Trail tuff and cgl.*, 2,000± ft. thick, is Upper Jurassic, and next to youngest Jurassic fm. in Taylorsville region.

Named for exposures along Hosselkus Creek on the trail, Plumas Co.

Trail Creek formation.

Silurian (Niagaran): Central Idaho (Hailey-Bayhorse region).

L. G. Westgate and C. P. Ross, 1930 (U. S. G. S. Bull. 814, pp. 10, 23). *Trail Creek fm.*—Siliceous argillites and qtzitic sss.; in basal 60 ft. the qtzitic ss. layers are separated by thin seams of carbonaceous argillites containing abundant graptolite fauna of Niagaran age. Thickness 500± ft. Older than Milligen fm. (Miss. and Dev.?) and younger than Phi Kappa fm. (Ord.). Exposures confined to W. side of Trail Creek, in its upper part, Hailey quad.

C. P. Ross, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 5, p. 956 and table opp. p. 940). In quads. to W. of Hailey quad. the *Trail Creek fm.* underlies Laketown dol. and overlies Saturday Mtn fm. [See also C. P. Ross, U. S. G. S. Bull. 877, in press, pp. 11, 22–23.]

Trail Crossing basalt.

Eocene (?): Central northern Oregon (Deschutes Basin).

H. T. Stearns, 1931 (U. S. G. S. W. S. P. 637, p. 134). *Trail Crossing basalt (Eocene?)*.—Oldest rocks that outcrop in Middle Deschutes River Basin. Exposed on both banks of Crooked River at Trail Crossing and extend NE. across Haystack Butte country in a belt about 1 mi. wide. Whether the basalt is a sill or an extrusive mass undet. Overlain in places by several ft. of tuffs probably belonging to Eocene Clarno fm. At Trail Crossing is separated by angular uncon. from fresh black basalt flows that overlie the tuffs.

Training School volcanics.

Pleistocene (late): Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Training School volcanics.*—Basalt and bedded cinders. Included in middle part of Honolulu volcanic series [q. v.]. The Maunawili Training School for Girls is located near the source of the flow.

†Trampan formation.

Miocene (upper): Western California (San Francisco region).

A. C. Lawson and C. Palache, 1902 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 2, pp. 447–448). *Trampan fm.*—Marine beds, aggregating about 2,000 ft., succeeding the fresh-water Orindan deposits. Fauna is, in opinion of Prof. J. C. Merriam, closely allied to that of San Pablo fm. Named for exposures along Las Trampas Creek, Contra Costa Co.

A. C. Lawson, 1914 (U. S. G. S. San Francisco folio, No. 193), mapped the marine beds formerly called "Trampan fm." as *San Pablo fm.*

Trangville beds.

Name used in chart opp. p. 206 of U. S. G. S. P. P. 45, 1906. Is misprint for *Tranquille beds*, the name used by Dawson in publication cited.

Tranquille beds.

Tertiary: British Columbia.

G. M. Dawson, 1896 (Canada Geol. Surv., n. s., vol. 7, pp. 26B, 72B–73B, 165B–182B).

Trappean series.

A lithologic term (meaning "pertaining to or of the nature of trap or trap rock") applied in a titular sense in some early repts to the Keweenawan rocks of Lake Superior region.

Traveller rhyolite.

Age (?): Western Maine (Piscataquis County).

F. W. Toppan, 1932 (Geol. of Maine, Dept. Geol. Union Coll., Schenectady, N. Y., pp. 69–70). *Traveller rhyolite* forms mass of Traveller Mtns, a group of peaks N. of Katahdin. Occupies about 100 sq. mi. Is in igneous contact with Katahdin granite.

Traverse formation.

Middle Devonian: Michigan (Lower Peninsula).

A. Winchell, 1871 (Mich. Geol. Surv. Rept. Prog., pp. 26–33). *Little Traverse group.*—Series of thick-bedded mag. buffish granular lss. underlying Huron group and overlying Corniferous group in Lower Peninsula of Mich. In general conforms to Hamilton group of N. Y.

A. C. Lane, as reported by M. E. Wadsworth, 1893 (Mich. Geol. Surv. Rept. for 1891 and 1892, p. 66). *Traverse group*, 100 to 600 ft. thick, underlies St. Clair shales [Antrim sh. of present nomenclature] and overlies Dundee ls.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2, btw. pp. 1 and 31). *Traverse group.*—Bluish calc. shales and lss. or dolomites, 100 to 600 ft. thick. Underlies St. Clair [Antrim] black shales and overlies Dundee ls. Outcrops at both Little Traverse [Bay] and Grand Traverse, and "Little" may as well be dropped.

A. W. Grabau, 1902 (Mich. State Bd. Geol. Surv. Rept. 1901, pp. 163+). *Traverse group* divided into (descending) Thunder Bay series, Alpena ls., Long Lake series, and Bell shales.

E. R. Pohl, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 14). *Traverse group* of northern counties of Lower Peninsula divided into (descending) Petoskey fm., Charlevoix stage, and Gravel Point stage ("basal div. of Traverse group in Mich."). In Lake Huron section Grabau has recently (unpublished ms., 1915, pp. 290–308) assigned Bell shales to their proper place as basal memb. of Presque Isle series, which also includes the respectively higher Grand Lake and Long Lake members. [p. 4.] [On p. 25 Pohl states:] The fourfold subdivision previously adopted for Traverse group in Presque Isle and Alpena Counties has more recently been restricted by Grabau, the Bell shales now forming lowest memb. of Presque Isle series. The downward sequence as now understood is as follows (Grabau, unpublished ms. 1915, pp. 298, 308, 318, 441):

Thunder Bay series (stage), 137–190 ft.
Alpena series (stage), 118–134 ft.
Presque Isle series (stage):
  Long Lake beds (memb.), 157–169 ft.
  Grand Lake ls. (memb.), 39 ft.
  Bell shales (memb.), 60–80 ft.
Total thickness Traverse group 511–612 ft.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38, pp. 19–64), correlated the subdivisions of *Traverse group* as listed in this (1933) entry under *Charlevoix stage.*

A. S. Warthin, Jr., and G. A. Cooper, 1935 (Wash. Acad. Sci. Jour., vol. 25, No. 12, pp. 524–526). *Traverse group* of Thunder Bay region divided into:

Squaw Bay ls., 12± ft. ("Probably should be excluded from Traverse group.")
Covered interval, 3 ft.
Thunder Bay stage:
  Partridge Point fm., 14+ ft.
  Covered interval, 70 ft.
  Potter Farm fm., 36 ft.
  Norway Point fm., 46 ft.
Alpena ls. stage [restricted].
Long Lake stage [redefined]:
  Killians ls., 23 ft. (The "black Alpena" zone of previous repts.)
  Genshaw fm., 51 ft.
  Ferron Point fm., 35± ft.
Rockport ls.
Bell sh. (Base of Traverse group in Alpena region.)

Travester shale.

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; and Conspectus of geol. fms. of N. Mex., pp. 3, 12). *Travester shales.*—Variegated beds 100 ft. thick, lying immediately above Exter sss. and well displayed in Travester Canyon, NE. N. Mex. Underlie Chaquaqua shales. Included in Morrisonian series.

Travis Peak formation. (In Trinity group.)

Lower Cretaceous (Comanche series): Texas.

R. T. Hill, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 118–119, 133). *Travis Peak sands or water-bearing beds.*—Sandy beds, 200 to 300 ft. thick, underlying Fredericksburg div., and divided into upper or Packsand beds and Basal or Contact beds, the latter consisting of cgls. Exposed 1 mi. below Travis Peak P. O., where basal aren. beds of overlying Fredericksburg div. are also exposed. Latter include 1st *Caprotina* horizon.

R. T. Hill and J. A. Taff, 1892 (Final geol. rept. artesian invest.; 52d Cong., 1st sess., S. Ex. Doc. 41, pt. 3, pl. opp. p. 90). *Travis cgl. and sands (Trinity).*—Base of Cret. along Colorado River in Burnet and Bastrop Counties. Underlies Alternating beds [Glen Rose ls.].

R. T. Hill and T. W. Vaughan, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 216, 219–222). *Travis Peak fm.*—Coarse angular cross-bedded sand, becoming more finely triturated until it reaches condition known in Tex. as "pack sand," i. e., a very fine-grained, loosely consolidated sand cemented by carbonate of lime, and containing patches of red and greenish-white clays, with usually a cgl. at base. Thickness 263 ft. Basal fm. of Trinity div. and of Comanche series. Underlies Glen Rose fm. or "Alternating beds," the basal bed of which is Caprotina horizon No. 1.

Named for Travis Peak post office, Burnet Co.

Travis Peak limestone. (In Travis Peak formation.)

Lower Cretaceous (Comanche series): Northeastern Texas.

W. M. Winton, 1925 (Univ. Tex. Bull. 2544), divided the beds beneath Glen Rose ls. in Denton Co. into (descending) Trinity sand, *Travis Peak ls.*, and Trinity sand.

Treadwell slate.

Upper Jurassic (?): Southeastern Alaska (Juneau region).

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 255–256, 270, chart opp. p. 247). *Treadwell sl.*—Black clay sl. with some cgl. and much graywacke. Thickness probably 7,000± ft. Apparently comprises oldest rocks on Treadwell Island, and is supposed to overlie Thane volcanic group, but Gastineau Channel separates the fms. Underlies Douglas Island volcanic group with apparent conformity. No fossils. Tentatively assigned to Upper Jurassic but may be post-Jurassic.

Treasure Mountain quartz latite. (Of Potosi volcanic series.)

Miocene: Southern Colorado (Summitville region).

H. B. Patton, 1917 (Colo. Geol. Surv. Bull. 13, pp. 20, 33–35). *Treasure Mtn latite.*—Biotite latite, differing in several material respects from the other latites of Platoro-Summitville dist. Color varies from light to dark gray, but locally may be light to dark brown. Name *Treasure Mtn* not altogether satisfactory, and study of this fm. to E. may make change necessary. The name was used by Dr. E. S. Larsen in his field notes. Included in Potosi volcanic series.

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718, table opp. p. 12). *Treasure Mtn latite* of Platoro-Summitville dist. is 1,000+ ft. thick. Named for exposures on Treasure Mtn, in NW. part of Summitville quad.

E. S. Larsen, 1935 (U. S. G. S. Bull 843), changed name to *Treasure Mtn quartz latite.*

Treat limestone.

Upper Ordovician (Richmond): Northeastern Illinois.

See under *Aux Sable ls.*

†Trego zone. (In Niobrara formation.)

Upper Cretaceous: Northwestern Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 51). *Trego zone.*—Lower bluish and marly zone of Smoky Hill chalk, underlying upper, more chalky, Norton zone. Lenses of hard so-called "Bell rock" in base or transition to underlying Osborne ls. Named for Trego Co.

Is basal part of Smoky Hill chalk memb. (See W. W. Rubey and N. W. Bass, Kans. Geol. Surv. Bull. 10, 1925, p. 28.)

Tremaines Bridge beds.

Upper Ordovician: Northern New York (Black River Valley).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 137, 141, 149, 154). *Tremaines Bridge beds* (zone of *Dekayella ulrichi* and *Arthropora cincinnatiensis*).—Basal zone of Pulaski fm. Observed only at head of "gulf" just above bridge leading to Tremaines and below Pulaski. Overlie Moose Creek beds and underlie Worthville beds.

Trembling Lake limestone.

Pre-Cambrian: Ontario.

Name applied by W. E. Logan, 1865 (Canada Geol. Surv. 16th Rept. Prog., p. 20, map), to one of the lss. in Grenville series of Ontario.

†Trempealeau formation.

Upper Cambrian: Southern Wisconsin, northern Illinois and Iowa, and southern Minnesota.

F. T. Thwaites, 1923 (Jour. Geol., vol. 31, No. 7, p. 547). *Trempealeau fm.* has been called *St. Lawrence fm.*, and in older literature was correlated with the Mendota of Madison region, Wis. The name is proposed [unpublished at this time] by E. O. Ulrich, who divides the fm. into following members, descending order:

- Norwalk fine-grained dolomitic ss. [This is lower and fossiliferous part of Jordan ss. of current nomenclature.]
- Lodi yellow and purple sandy thin-bedded dol. locally called "sh."
- St. Lawrence or Black Earth dol. [This is a restriction of St. Lawrence as heretofore defined and used.]
- Sandy dolomitic shales of local distribution.

Is overlain by Jordan ss. [restricted] and rests on Mazomanie fm.

E. O. Ulrich, 1924 (Wis. Acad. Sci., Arts, and Lett. Trans., vol. 21, pp. 72–90). In its fullest development *Trempealeau fm.* is divisible into 4 lithologically and faunally distinct members [listed below]. Locally one or two of these subdivisions might be mapped separately, but as a rule topographic conditions are such that only the lower mag. ls. memb. lends itself readily to such separate treatment.

Norwalk ss. memb., 50 ft. [See above.]

Lodi sh. memb., 50 ft.

St. Lawrence ls. or dol. restricted, 25 ft.

Basal sh. or shaly ss. with considerable greensand and occasionally thin layers of dolomitized ss., with usually at bottom a thin layer of ss. cgl., 0 to 20 ft. thick. This basal sh. may be of same age as St. Lawrence dol., and until this is determined no special name for the sh. is proposed.

There is considerable variation in character and sequence of component beds of the fm. from place to place. Thus in E. Wis. the upper (Norwalk) memb. is commonly and perhaps always absent. But the yellow calc. shaly Lodi memb. is generally present and may also be called most characteristic part of the fm. The same might be said of next underlying St. Lawrence ls. or dol. memb., but in middle and N. parts of State this memb. is entirely wanting in many places, or is so altered by addition of relatively coarse quartz sand that recognition of its zone is rendered difficult and uncertain. The fm. rests on Mazomanie ss. or, where that is absent, on Franconia ss. Is overlain by Jordan ss. restricted. Is well displayed and in fairly typical composition in Trempealeau Bluff on Mississippi River [at Trempealeau, Trempealeau Co., Wis.].

A. C. Trowbridge and G. I. Atwater, 1934 (Geol. Soc. Am. Bull., vol. 45, p. 60). St. Lawrence fm. should continue to be used for the beds btw. Franconia ss. and Jordan ss. More than half of Trempealeau fm. as defined is Jordan and should remain Jordan.

J. M. Wanenmacher, W. H. Twenhofel, and G. O. Raasch, 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 21–25). *Trempealeau fm.* divided into (descending) Jordan ss. memb., Lodi sh. memb., St. Lawrence (Mendota or Black Earth) memb., and basal greensand and greensand cgl. memb. Rests uncon. on Franconia fm. and is overlain by Madison fm. [Foregoing use of St. Lawrence is Ulrich's restricted St. Lawrence.]

A. C. Trowbridge, W. H. Twenhofel, and F. T. Thwaites, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., pp. 93, 116, 123, 131, etc.), expanded *Trempealeau fm.* by including in it, at top, *all* of Jordan ss. and the overlying Madison ss., but G. O. Raasch objected to inclusion of Madison. (See also under *Madison ss.*).

The U. S. Geol. Survey has not adopted Trempealeau fm., but treats its subdivisions (Madison ss., Jordan ss., and St. Lawrence fm.—the latter including Lodi sh. memb. and underlying beds down to top of Franconia ss.) as distinct fms.

Trent marl.

Miocene (lower): Coastal Plain of southern North Carolina.

B. L. Miller, 1910 (Geol. Soc. Am. Bull., vol. 20, pp. 674–675; also chart opp. p. 646). *Trent fm.*—A distinctly calc. fm. (fine-grained calc. marls or lss.) with little or no glauconite present. Along Neuse and Trent Rivers rests on Cret. strata belonging to Peedee fm., but farther W. it lies on pre-Camb. crystalline rocks. Assigned to Eocene. Is uncon. overlain by Castle Hayne fm.

Later work by L. B. Kellum proved that the marl (marine) at Trent type loc. is lower Mio., and that the marl (also marine) at Castle Hayne type loc. is upper Eocene (Jackson), and he restricted the names to accord, reporting a thickness of 0 to 100 ft. for Trent marl. (See U. S. G. S. P. P. 143, 1926, also Jour. Geol., vol. 33, pp. 183–187, 1925.)

Named for exposures along Trent River from vicinity of Trenton, Jones Co., to near junction of Trent and Neuse Rivers.

Trenton limestone. (**Trenton group** in parts of N. Y.)

Middle Ordovician: New York, Michigan, Pennsylvania, northern Ohio, and western Virginia.

L. Vanuxem, 1838 (N. Y. Geol. Surv. 2d Rept., pp. 257, 276, 283). *Trenton ls.*—Forms Trenton Falls (Oneida Co., N. Y.), whence its name. Thickness 10 to 125 ft.; at Trenton Falls is over 100 ft. thick. Consists of light-gray or sparry ls., which forms upper mass of Trenton Falls, underlain by dark or black, almost compact ls. Is overlain by black sh. [Utica sh.] and underlain by birdseye ls. [Lowville?]. [As thus defined includes Amsterdam ls., which forms upper part of Black River group.]

T. A. Conrad, 1839 (Phila. Acad. Nat. Sci. Jour., vol. 8, pt. 1, pp. 228–235), applied *Trenton ls.* to beds overlain by black sh. [Utica] and underlain by Mohawk ls. [Amsterdam ls.?].

In 1842 (Geol. N. Y., pt. 3) Vanuxem defined *Trenton ls.* as 0 to 300 ft. thick, practically repeated his 1838 description of its lithology, and called underlying fm. *Black River ls.*, in which he included the Lowville of present nomenclature. This is present commonly accepted definition of Trenton, although for many years most writers used *Trenton ls.* to include not only the Trenton proper, but all of underlying Black River group, while some writers used *Trenton group*, also *Trenton fm.* and *Trenton ls.*, to include the Trenton proper, all of Black River group, and in some cases Chazy ls. also. In central N. Y. *Trenton ls.* has been applied to the ls. underlying Dolgeville sh. (considered a shaly representative of upper part of the Trenton at its type section, and overlain by Utica sh.). Repts give thickness of *Trenton proper* as 200 ft. in Utica quad.; 300+ ft. in Clinton Co., N. Y.; 400+ ft. in Thousand Islands region; and 20 ft. in Broadalbin quad., Fulton and Saratoga Counties, N. Y. In parts of N. Y. the Trenton is a *group*, separated into several named fms. of ls. and sh.

In 1926 (N. Y. State Mus. Bull. 270, p. 65) F. Holzwasser stated that the 450 ft. of Trenton ls. at Trenton Falls is middle Trenton, "the base and upper beds of that fm. not being exposed."

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 283). *Trenton beds* comprise lss., shales, and sss. Glens Falls ls. has been determined to be of very early (basal) Trenton age. It is well developed in Mohawk and Upper Hudson valleys, where it has a thickness of 17 to 40 ft. It is missing below the typical Trenton ls. at Trenton Falls.

†Trenton gravel.

Pleistocene: Southeastern Pennsylvania and western New Jersey.

H. C. Lewis, 1881 (Phila. Acad. Nat. Sci. Proc. 1880, vol. 32, pp. 296–309). *Trenton gravel.*—The last and newest of all the gravels. Is an alluvial gravel, 0 to 100 ft. thick. At Phila. lies close along the river and rises a few ft. above it. Covers flat ground of Camden and lower part of Phila. and forms islands in the river. From its great development farther up the river is now called *Trenton gravel.*

Is a local development of *Cape May fm.*, which name replaces it. Part of city of Trenton, N. J., is built on terrace covered with this gravel.

Trenton clays.

Upper Cretaceous: Western New Jersey.

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 197). *Trenton clays.*—Commonly red or red-spotted grading into blue at bottom of pits. In some places upper layer is white clay, and locally a black lignitic clay occurs beneath the blue clay; elsewhere a sand bed underlies the clay. Belong in Raritan fm. [broad use of Raritan, which included Magothy fm.]. Two mi. E. of Trenton the clays are dug in a number of pits along Pond Run. They are locally known as *Dogtown clays*, from occurrence at Dogtown, near Trenton.

†Trenton conglomerate.

Name used in some early repts for an intraformational ls. cgl. of lower Trenton age in Rensselaer Co., N. Y., that was later named *Rysedorph cgl.* Has also been called "Lower Trenton cgl."

†Trenton period.

A term applied in some early repts to the time during which Trenton ls., Black River group, and Chazy ls. were deposited; also to the time during which only Trenton ls. and Black River group were deposited. In latter sense the name is now replaced by *Mohawkian epoch*. In former sense it covers Middle Ordovician or Mohawkian epoch and upper part of Lower Ordovician epoch. The U. S. Geol. Survey employs *Trenton epoch* to include the time covered by deposition of Trenton ls.

Trenton Falls series.

Ordovician: New York.

T. A. Conrad, 1837 (N. Y. Geol. Surv. 1st Ann. Rept., p. 165), in a description of gray sss. and shales of Salmon River, stated that their fossils were "very different from those of *Trenton Falls series of rocks* on which they repose."

†Trentonian.

A time term proposed by A. W. Grabau in 1909 (Sci., n. s., vol. 29, pp. 351–356) to include Upper Ordovician series and upper part of Middle Ordovician (Mohawkian) series, because "Trenton deposition covers at least one-half this division" and because "Trenton period was used by Dana for Trenton ls. and later divisions." He suggested, however, that *Nashvillean* might be a better name "if the Nashville group of Safford covers both Trenton and later Ordovicic formations."

Trent River shales.

Age (?): British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 105). [No age assigned.]

J. D. MacKenzie, 1922 (Canadian Inst. Min. and Met. Mon. Bull. 122, p. 679). Trent River fm. is Cret.

Tres Hermanos sandstone member (of Mancos shale).

Upper Cretaceous: Central northern New Mexico.

C. L. Herrick, 1900 (Am. Geol., vol. 25, pp. 331–346; N. Mex. Univ. Bull., vol. 2, pt. 1, pp. 3–63, pt. 2, pp. 1–17). *Tres Hermanos ss.*—Massive yellow ss., 75 ft. thick. Lies 225+ ft. lower than Punta de la Mesa ss. and 100+ ft. below the cephalopod zone. Is separated from underlying gastropod zone (containing Benton fossils) by 100 ft. of yellow sh. Lies 150 to 250 ft. above Dakota ss. [Derivation of name not stated.]

W. T. Lee, 1912 (Geol. Soc. Am. Bull., vol. 23, pp. 592–598). *Tres Hermanos ss. memb. of Mancos sh.* lies lower than and in close association with the concretion (Septaria) zone and higher than the gastropod zone of previous repts. It is typically developed in Rio Puerco field, but is readily recognized in Tijeras, Hagan, and Cerrillos fields, and is probably represented throughout San Juan Basin. It consists of a series of yellow sss. 150± ft. thick on Rio Puerco and thinner in some other fields. It thickens westward and thins to E. The name may be used to designate the zone of yellow ss. that occurs near base of Mancos sh. in all the fields described in central N. Mex. W. of the mtns.

W. T. Lee, 1915 (U. S. G. S. P. P. 95, July 12, 1915, p. 45). Near base of Mancos sh. is *Tres Hermanos ss. memb.*, which is recognizable from Datil Mtns to Casa Salazar but not found farther N., near Gallina. This ss. is coal-bearing in Datil Mtns, but in Rio Puerco field only a single layer of carbonaceous sh. was found in it.

W. T. Lee, 1917 (U. S. G. S. P. P. 101, pp. 172, 174, 179, 199, 203, 213–214). *Tres Hermanos ss. memb. of Mancos sh.* lies 1,147± ft. below Punta de la Mesa ss. at Casa Salazar. At its type loc. it is 20 ft. thick and consists of thin irregular layers of ss. an in. or less thick, on whose faces are ripple marks, worm tracks, and markings of many kinds; the sandy layers are separated in some places by films of sh.; a few imperfect casts of gastropods were found in it, and impressions supposed to be *Halymenites major* are abundant in some places. The ss. is unlike any other rocks near it and has a peculiar appearance that makes its recognition easy. About 100 ft. above it is a small ridge of ls. 3± ft. thick, which presumably represents Greenhorn ls. In Hagan field the Tres Hermanos is only 5 ft. thick, but increases to 15 or 20 ft. nearby. Near Rogers, 2 mi. SW. of Cerrillos, it is 20 ft. thick and consists of hard quartzose ss., in thin irregular layers and weathers yellowish brown. In Tijeras coal field it is 145 ft. thick and consists of hard quartzose ss. containing worm borings and indefinite markings of various kinds.

D. E. Winchester, 1920 (U. S. G. S. Bull. 716A, pp. 3, 6). The two lower resistant and persistent ss. members of Miguel fm. may represent Tres Hermanos ss. of Lee, but they are the least conspicuous of the sss. in this area and were not mapped. They are exposed 1 mi. E. of Tres Hermanos Buttes [shown on map a short distance E. of Gallego Creek].

C. B. Hunt, 1936 (U. S. G. S. Bull. 860-B, pp. 40, 41, 42). East of Mount Taylor are the 3 prominent sss. [separated by shales] in lower 350 ft. of Mancos sh. to each and all of which the name "Tres Hermanos ss." has been applied in previous repts. These sss. are medium and fine-grained buff sss., prominent in vicinity of Seboyeta but thin out to E. and NE. Fossils collected from them suggest Graneros age. The upper ss. (No. 3) is 30 ft. thick, and is separated from ss. No. 2 (75 ft. thick) by 30 ft. of sh. The lower ss. (No. 1) is 50 ft. thick and lies 65 ft. below ss. No. 2 and 72 ft. above Dakota (?) ss.

Tres Pinos sandstone.

Eocene: Southern California (San Benito County).

P. F. Kerr and H. G. Schenck, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 470 and 475). *Tres Pinos ss.*—Massive coarse-grained quartzose buff-colored marine ss., with cgl. phases; jointed; more indurated on exposed surfaces; large erosional cavities common. Thickness about 900 ft. No diagnostic fossils. Of possible Eo. age. Quite similar lithologically to Pinecate ss. and may prove to be same. But at present is considered to be Tejon (?), because it overlies well-established Meganos deposits with no marked uncon.

Probably named for exposures at or near Tres Pinos or Tres Pinos Creek.

Trias.

Same as Triassic. Used chiefly by Europeans.

Triassic period (or **system**).

The time (and the rocks) of the oldest period of Mesozoic era, following the Carboniferous period and preceding the Jurassic period. For definition see U. S. G. S. Bull. 769, p. 64.

Tribes Hill limestone. (In Beekmantown group.)

Lower Ordovician: Central, eastern, and northern New York.

E. O. Ulrich and H. P. Cushing, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 780-781; and N. Y. State Mus. Bull. 140). [See explanation in item 11 (1910) under *Beekmantown group*.] In 1911 (Am. Jour. Sci., 4th, vol. 31, pp. 135-144) Cushing described *Tribes Hill ls.* as much more calc. and more fossiliferous than underlying Little Falls dol. [restricted]. Repts give thickness in Thousand Islands region as 0 to 40 ft. Named for exposures at Tribes Hill, Montgomery Co. [about 30 mi. E. of type loc. of Little Falls dol.].

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 33). Evidence so far obtained indicates *Tribes Hill ls.* is at least as old as lower Beekmantown as now restricted. Overlies Little Falls dol., and is present in Thousand Islands region.

H. P. Cushing, 1916 (N. Y. State Mus. Bull. 191, p. 35). *Tribes Hill fm.* believed to be of oldest Beekmantown age. Rests uncon. on Theresa fm. in Brier Hill, Ogdensburg, and Red Mills quads.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 263, 270). Beekmantown submergence in N. Y. in general begins with *Tribes Hill ls.*, which overlies Little Falls dol. nearly everywhere in Mohawk Valley, the type region. [But in tables on pp. 191, 194, and 268 she excluded Tribes Hill from Beekmantown. She also listed Tribes Hill as present in central, east-central, and eastern N. Y.]

See also under *Beekmantown group* and *Little Falls dol.* The U. S. Geol. Survey classifies Tribes Hill ls. as of Beekmantown age (upper part of div. B).

†Tribune limestone. (In Chester group.)

Mississippian: Western Kentucky and southeastern Illinois.

E. O. Ulrich, 1904 (Mo. Bur. Geol. and Mines vol. 2, 2d ser., p. 109). *Tribune ls.*—Main ls. of Chester group; underlies Birdsville fm. and overlies [so-called] Cypress ss. [Not true Cypress, which is much higher, but the Aux Vases ss., according to Ulrich and others.]

Now divided into several named fms. Abandoned by Ulrich in 1917 (Ky. Geol. Surv. Mississippian series of western Ky., p. 7).

Named for Tribune, Crittenden Co., Ky., but the ls. on which town of Tribune is built is now known to be Menard ls., in middle of †Birdsville fm.

†Triceratops beds.

A name applied to deposits of Western States that contain the remains of the dinosaur *Triceratops*, a genus belonging to the Ceratopsidae family. The U. S. Geol. Survey now classifies the *Triceratops*-bearing beds as Upper Cret.

†Trickham bed. (In Graham formation.)

Pennsylvanian: Central Texas (Coleman County).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 402). *Trickham bed*.—Sandy clay, chiefly bluish, with some ss., ls., and cgl. Thickness 100 to 160 ft. Basal memb. of Cisco div. Underlies *Bellerophon* bed and overlies *Campophyllum* bed, of Canyon div.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, pp. 136, 154, table 2). state (p. 136) that their Graham fm. (of Cisco group) includes *basal shales of Trickham bed* of Drake. Their table 2 shows *upper part* of Trickham beds is = Avis ss., which is made basal memb. of their Thrifty fm. Named for Trickham, Coleman Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103). *Trickham sh. of Drake* lies near bottom of Thrifty fm. in Colorado River Valley [but he included it in Graham fm.].

Wallace Lee and C. O. Nickell state (rept completed and soon to be published by Tex. Geol. Surv.) *Trickham bed* of Drake is same as Wayland sh. memb. of Graham fm. and is abandoned. This is accepted by U. S. Geol. Survey for its repts.

Trident.

Name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to 575 ft. of lss. of early Miss. age in Mont. Derivation of name unknown.

Trimble granite.

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Trimble granite*.—Fine-grained gray biotite granite. Intrudes Eolus granite in neighborhood of Trimble Pass, La Plata Co., but does not intrude Ignacio qtzite [Upper Camb.]. [Mapped over large area surrounding Trimble Pass.]

For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

Trimmers Rock sandstone.

Upper Devonian: Southern central Pennsylvania.

B. Willard, 1935 (Geol. Soc. Am. Proc. 1934, p. 123). *Trimmers Rock ss.* is introduced to supplant *Ithaca* in Susquehanna Valley, Lehigh Valley, and Upper Delaware Valley, because of more inclusive nature of the Pa. beds than typical Ithaca. [In Susquehanna Valley shown as underlying Parkhead ss. (?) and overlying Losh Run sh.; in Lehigh Valley shown as underlying Catskill red beds and overlying Burket ("Genesee") sh.; in Upper Delaware Valley shown as underlying Delaware River flags.]

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 8, pp. 1195-1218). *Trimmers Rock memb. of Fort Littleton fm*.—Is usually a ridge-forming ss., gray to greenish gray, massive to flaggy. Occurs in central and eastern Pa. Underlies Parkhead memb. and overlies Losh Run memb. In Lycoming Co. 3,000 ft. thick and is time equiv. of lower Chemung and all of Portage group. Thins to W. and finally disappears. Is distinguished from Chemung chiefly by lacking *Spirifer disjunctus*. Well developed in region of Susquehanna and Juniata Valleys. Named for Trimmers Rock, a prominent hill which it supports 1½ mi. E. of Newport, Perry Co. Corresponds to Ithaca, Enfield, and much if not all of the Sherburne. [Long description.] The strata that I. C. White called *Starrucca* in Monroe Co., are simply upper part of Trimmers Rock ss.

B. Willard, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 4, pp. 571, 588). In part of Pike and Monroe Counties Delaware River flags rest on marine Portage (the Trimmers Rock ss.), the intervening local Analomink red sh. being absent. Beyond the Lehigh the Delaware River and Trimmers Rock fms. have not been clearly separated, both being fossiliferous marine Portage. [Table on p. 571 shows following downward succession: Delaware River flags, Analomink red sh., and Trimmers Rock ss. Table on p. 606 shows Trimmers Rock ss.=Delaware River and Analomink.]

Trincheras division.

A term used by E. T. Dumble (Am. Inst. Min. Engrs. Trans., vol. 29, 1900, and vol. 31, 1902) for 2,000± ft. of "late Tertiary" [Cret. or Tert.] andesitic lavas and sss. in Sonora, Mexico, and Cochise Co., SE. Ariz. Derivation of name not stated.

Trinidad lignitic group.

F. V. Hayden, 1875 (U. S. Geol. and Geog. Surv. Terr., Bull. 1, p. 402). At Trinidad the Lignite or coal-bearing group reaches a thickness of about 2,000 ft., containing a large number of coal beds and seams. As the development of the fm. is very typical at that loc., I have designated it as the *Trinidad Lignitic group*.

According to J. B. Reeside, Jr., these beds correspond to Raton and Vermejo fms. of present nomenclature.

Trinidad sandstone.

Upper Cretaceous (Montana): Southeastern Colorado and northeastern New Mexico.

R. C. Hills, 1899 (U. S. G. S. Elmoro folio, No. 58). *Trinidad fm.*—Upper 70 to 80 ft. light-gray ss. with sometimes a pale-greenish tint, usually massive, *Halymenites* abundant; lower 75 ft. thin layers of fine-grained dark-gray ss. with sh. partings. Underlies Laramie fm. and overlies Pierre sh. Uncertain what part of Fox Hills group it represents.

N. H. Darton, 1905 (U. S. G. S. P. P. 32), treated *Trinidad ss.* as upper memb. of Fox Hills fm. in eastern Colo., the rest of the Fox Hills being described as consisting of aren. yellowish shales with occasional bands of yellowish clay.

G. B. Richardson, 1910 (U. S. G. S. Bull. 381). *Trinidad ss.* of Trinidad coal field consists of 150 to 225 ft. of massive fine-grained feldspathic ss. lying between thinner-bedded ss. and sh. by which it merges into overlying Laramie fm. and underlying Pierre sh. Contains fossils which T. W. Stanton says are known only from Fox Hills and upper Pierre.

W. T. Lee, 1913 (Am. Jour. Sci., 4th, vol. 35, pp. 531-534). *Trinidad ss.* underlies Vermejo fm. and overlies Pierre sh. in Trinidad-Raton coal field.

W. T. Lee, 1917 (U. S. G. S. P. P. 101). *Trinidad ss.* [*restricted*].—Massive feldspathic light-gray ss., 70 to 100± ft. thick in Raton Mesa region. Conformably underlies Vermejo fm. and conformably overlies Pierre sh. The name as here used applies to only the "Upper Trinidad" of Hills, his "Lower Trinidad" (consisting of a few ft. to 200± ft. of alternating beds of thin-bedded fine-grained ss. and sh.) being here included, as the transitional zone, in top of Pierre sh., from which it is not clearly separable, while it is usually sharply separated from the massive ss. here called *Trinidad ss.* It is doubtful whether these transitional beds should be included in a fm. with the overlying ss. or regarded as a part of underlying sh., but for purposes of this paper they are included in Pierre sh. The Trinidad persists with slight variation throughout Trinidad coal field and over much of Raton field. It should probably be placed as far down in time scale as lower part of the Fox Hills if not somewhat lower.

J. B. Reeside, Jr., 1924 (U. S. G. S. P. P. 134, pl. 4), correlated Vermejo fm. with Fox Hills ss. of Denver region and Trinidad ss. with upper part of Pierre sh. of that region.

Named for exposures at Trinidad, Las Animas Co.

Trinity group (also **Trinity sand**).

Lower Cretaceous (Comanche series): Texas, central southern and southeastern Oklahoma, southwestern Arkansas, and northwestern Louisiana.

R. T. Hill, 1888 (Sci., vol. 11, p. 21). *Trinity fm.*—Alternations of fine, closely packed white sands and red and blue gypsiferous marl, with occasional thin but extensive beds of fissile, aren., and crystalline lss., highly fossiliferous, often wave-marked, and seldom more than 10 in. thick; in places extensive strata of poor saccharoidal gyp. are present. Underlies Comanche series and overlies Carbf. [This definition applied to basal part of Trinity group of current nomenclature.]

In a rept published later in 1888 (Ark. Geol. Surv., vol. 2) Hill (p. 188) divided his *Trinity div.* in SW. Ark. (400± ft. thick, p. 123) into upper crawfish sands (=Upper Dinosaur sands of Tex.), *Ostrea franklini* beds and ls. (=Lower Dinosaur sands of Tex.), and basal lignitic sands; and stated that it underlies Fredericksburg div. and rests uncon. on Carbf. rocks. On p. 125 he stated that his Trinity underlies lowest Comanche (very early Cret., Neocomian), and that it is either uppermost Jurassic, lowest Cret. (Wealden), or transitional Jura-Cret. In 1889 (Tex. Geol. Surv. Bull. 4, pp. xiii-xiv) Hill definitely included *Trinity div.* in Lower Cret. or Comanche series, and divided it into upper or Packsand beds and Basal or Contact beds. In 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 503–528) Hill included Walnut clay and Paluxy sand in the Fredericksburg and divided the Trinity ("possibly pre-Cret., Jurassic?") into Glen Rose or Alternating beds and Trinity or Basal sands. In 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 269–279) J. A. Taff included Paluxy sand in Trinity group. In 1894 (Geol. Soc. Am. Bull., vol. 5, pl. 13, pp. 317–319) Hill divided Fredericksburg into (descending) Caprina ls., Comanche Peak chalk, and Walnut clay, and divided the Trinity into (descending) Paluxy sands, Glen Rose beds, and Trinity sands. In 1901 (U. S. G. S. 21st Ann. Rept., pt. 7) Hill divided the Trinity into (descending) Paluxy, Glen Rose, and Travis Peak, the latter name replacing the narrow use of Trinity for the basal sands of the group. This is the present generally approved definition of *Trinity group*.

In Tex. the Trinity is now called a group, divided, in eastern Tex., into (descending) Paluxy sand, Glen Rose ls., and Travis Peak sand. In southern Okla. and Ark. the Trinity deposits are not divisible, and *Trinity sand* is adopted name of U. S. Geol. Survey for the deposits of Trinity age, which there are chiefly sand. But *Trinity sand* in restricted sense in which the name was used in some early repts (for basal sand of Trinity group) was long ago replaced by *Travis Peak sand*.

Named for exposures on the Trinity Rivers of Tex.

†Trinity formation.

Term applied by O. H. Hershey (Am. Geol., vol. 27, p. 226, 1901) to the serpentine in Klamath Mtn region of northern Calif.

Trinityan series.

A name proposed by C. [R.] Keyes for basal part of Lower Cret. (Comanche) series of Ariz., correlated with Aptian of Europe and divided into (descending) Morita shales (1,800 ft.) and Etholen cgl. (100 ft.). (See Pan-Am. Geol., vol. 64, No. 2, 1935, pp. 128, 129, 139.)

Trinity Bay sandstone.

Age (?): Newfoundland.

J. B. Jukes, 1839 (Rept. geol. of Newfoundland, p. 2), and 1840 (Edinburgh New Phil. Jour., vol. 29, p. 106).

Triphammer shale member.

Upper Devonian: Central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). *Triphammer sh. memb.*—Top div. of Ithaca facies subgroup in vicinity of Ithaca. Thickness 140 ft. Includes *Beebe ls.*, 1 to 3 ft. thick, which may be coeval with Parrish ls. at base of Rhinestreet sh. to W. Overlies Marathon ss. memb. and underlies Hatch ss. memb. The Triphammer and Marathon probably constitute Oneonta of the East.

†Triple limestone system.

Pennsylvanian: Eastern Kansas.

See under †*Erie ls.*

Trippe limestone.

Middle Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Trippe ls.*—Largely thin-bedded sh., with mottled lss. similar to those so abundant in the older Abercrombie fm. Also contains a few dark dol. layers, beds of more massive ls., and several horizons of finely laminated white dol. and ls. Most beds appear lenticular. Thickness 725 ft. No fossils, but assigned to Middle Camb. because it is lithologically similar to Abercrombie fm. Underlies Lamb dol. and rests on Young Peak dol. Named for exposures in Trippe Gulch, on S. side of North Pass Canyon, Gold Hill dist.

See also U. S. G. S. P. P. 177, 1934, by T. B. Nolan.

Triste formation.

Cretaceous: Mexico.

W. F. Foshag, 1934 (Econ. Geol., vol. 29, No. 4, p. 335).

Triumph conglomerate.

Term applied by J. F. Carll (2d Pa. Geol. Surv. Rept. I, pp. 38–40, 1875) to the coarse cgl. that appears in hilltops at Triumph, Warren Co., NW. Pa. Probably same as Olean cgl. memb. of Pottsville fm.

Triunfo formation.

Tertiary: Mexico.

W. A. Ver Wiebe, 1925 (Pan-Am. Geol., vol. 44, p. 133).

Trivoli cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179–193) to upper part of McLeansboro fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Includes coal No. 8. Derivation of name not stated.

Trizoic.

A time (life) term applied by E. Hitchcock (Geol. Vt., 1861, vol. 1, p. 19) to "Oolitic" (probably=Upper and Middle Jurassic of present nomenclature).

Troedsson Cliff formation.

Ordovician (Trenton ?): Northwest Greenland (Washington Land).

L. Koch, 1929 (Meddelelser om Grönland, Bd. 73, Afd. 1, No. 1, p. 27).

Tropic shale.

Upper Cretaceous (Colorado): Central southern Utah (Kaiparowits Plateau region).

H. E. Gregory and R. C. Moore, 1931 (U. S. G. S. P. P. 164). *Tropic sh.*—Chiefly uniform dark-drab clayey sh. and fine-textured sandy sh., thinly laminated and soft, which breaks down readily to form slopes and broad, gently undulating flats. Upper third is more or less sandy and in places contains thin beds of ss. Gyp. is uncommon. Thickness 600 to 1,400 ft. Conformably underlies Straight Cliffs ss. and conformably overlies Dakota (?) ss. Exposed at and around village of Tropic, Garfield Co., for which it is named. The village is built on this sh.

Trough Creek limestone member (of Mauch Chunk formation).

Mississippian: Central Pennsylvania (Huntingdon County).

I. C. White, 1885 (2d Pa. Geol. Surv. Rept. T_3, pp. 73–76, 85). *Trough Creek ls. group.*—On S. bank of Trough Creek [Huntingdon Co.], ¾ mi. below Todd (Brick) mills, on Mr. Taylor's land, it consists of (descending): Red limy sh., 10 ft.;

red ls., 4 ft.; red limy sh., 16 ft.; gray ls., 2½ ft.; red sl., 3 ft.; gray-green ls., 4 ft. Here it rests on Pocono ss., but elsewhere it is separated from Pocono ss. by 141 ft. of red and variegated shales, thick sss., and shales with gray flagstones. Whole thickness 50 ft. [He in places includes these beds in Mauch Chunk sh. and in other places excludes them from it and treats them as a distinct div.]

C. Butts, 1924 (Am. Jour. Sci., 5th, vol. 8, pp. 249–257). *Trough Creek ls.* of I. C. White is in base of Mauch Chunk red sh. and probably is a tongue of marine Greenbrier ls. Is younger than Loyalhanna ls.

C. Butts (U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227, in press). *Trough Creek ls. memb. (of Mauch Chunk fm.)*.—Red and gray ls., 0 to 32 ft. thick. Occurs at base or in lower part of Mauch Chunk fm., being in places underlain by red and green sh., with thin layers of soft yellow ss., forming basal part of Mauch Chunk fm.

Trousdale shale.

Upper Devonian: Central Tennessee.

E. R. Pohl, April 1930 (Tenn. Acad. Sci. Jour., vol. 5, No. 2, pp. 56–63). Because of unestablished relations of the Genesee equiv. in Tenn. the name *Trousdale sh.* is here tentatively proposed for it. The study of presence of Genesee deposits in Tenn. is in progress by author, and a detailed rept should be forthcoming shortly.

E. R. Pohl, August 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 151–152). The black shales of central Tenn. that were formerly called "Chattanooga" comprise 2 fms. of Lower Miss. (Kinderhookian) age, separated by widespread erosional uncon., and locally one fm. of Upper Dev. age. The upper of the Miss. shales correlates by physical and faunal evidence with Sunbury sh. of Ohio and Ky., and the lower Miss. sh. correlates with Cleveland sh. of Ohio and Ky. The Upper Dev. black sh. (which contains Genesee-Portage fossils) is present in N. part of State only, and is physically associated with fossiliferous Dev. lss. For it the name *Trousdale sh.* is suggested. [Derivation of name not stated. There are 2 Trousdales in central Tenn., one in Sumner Co. and one in Warren Co. The former appears to be the type.]

Trout Creek sandstone (distinct formation). Also
Trout Creek sandstone member (of Iles formation).

Upper Cretaceous: Northwestern Colorado (Yampa region).

N. M. Fenneman and H. S. Gale, 1906 (U. S. G. S. Bull. 297, p. 26). *Trout Creek ss. memb. of Mesaverde fm.*—Ledge-making ss., massive, white, containing great concretions; iron-oxide stains common. Thickness 75 ft. Underlies middle coal group (400 ft. thick) of Mesaverde fm. Lies 1,900 ft. above base of Mesaverde. Named for Trout Creek, NE. side of Twentymile Park, about 10 mi. NW. of Yampa.

E. T. Hancock, 1925 (U. S. G. S. Bull. 757). *Trout Creek ss.* is here treated as top memb. of Iles fm. (of Mesaverde group) in Axial and Monument Butte quads.

M. R. Campbell, 1931 (Tentative correlation of named geol. units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Trout Creek ss.* is elevated to rank of a fm. of Mesaverde group in Yampa coal field, where it underlies Mount Harris fm. and overlies Milner fm.

Trout Creek formation.

Miocene (middle): Southeastern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Trout Creek fm.*—Fine white and cream-colored ash beds, containing fossil plants referred by Knowlton to upper Eo. but pronounced by Dr. Chester Stock to be lower Mio. Thickness undet. Type loc., Trout Creek, on E. side of Alvord Valley, SE. part of Harney Co.

R. E. Fuller, 1931 (Univ. Wash. Pub. Geol., vol. 3, No. 1, p. 52). Vertebrate remains recently collected by Stock indicate quite clearly that Trout Creek fm. is not earlier than middle Mio. (Chester Stock, personal communication.)

Troutdale granite.

Pre-Cambrian (?): Central northern Colorado (Georgetown-Central City-Montezuma region).

J. Underhill, 1906 (Univ. Colo. Studies, vol. 3, No. 4, p. 272; also Colo. Sci. Soc. Proc., vol. 8, pp. 103–122). *Troutdale granite*.—Hypidiomorphic mixture of quartz, red or pink feldspar, and biotite. Is probably same as granite at Georgetown, but so far as known not directly connected. Named for town in Evergreen [Denver Mtn Parks] quad. [Jefferson Co.]. Differs from Central City granite in less amount of femic or ferromagnesian minerals and in presence of muscovite.

Troutdale formation.

Pleistocene: Northwestern Oregon (Willamette Valley).

E. T. Hodge, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 157). [See under *Rhododendron fm.*]

Probably named for Troutdale, Multnomah Co.

Trout Lake conglomerate.

Pre-Cambrian: Ontario.

A. P. Coleman, 1905 (Ont. Bur. Mines Rept., vol. 14, pt. 3).

Trout Pond limestone.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199, pp. 112, 114 and fig. 25). *Trout Pond ls.*—Crystalline ls., commonly siliceous and containing various green silicates that have changed to serpentine. Thickness about 50 ft. Lies btw. two qtzite fms. that are believed to correspond to Swede Pond qtzite. Occurs on Geo. W. Smith property, S. of Clintonville, Clinton Co. [Trout Pond is in Ausable quad.]

Troy shales.

Lower Cambrian: Eastern New York (Rensselaer County) and western Vermont (?).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 67–70). *Troy shales.*—Div. H of [T. N.] Dale's Rensselaer series. Consist of colored shales with small beds of calc. qtzite. Thickness 25 to 100 ft. Exposed at Troy [N. Y.], at dam in Poesten Kill, and other localities. Overlies Diamond Rock qtzite and is older than Schodack sh. and lss.—all Lower Camb.

R. Ruedemann, 1930 (N. Y. State Mus. Bull. 285, p. 27), used *Troy shales and lss.* for the beds overlying Diamond Rock qtzite and underlying Schodack shales and lss.

Troy quartzite.

Upper and Middle Cambrian: Central Arizona.

F. L. Ransome, 1915 (Wash. Acad. Sci. Jour., vol. 5, pp. 380–385). *Troy qtzite.*—Upper part consists of thin, generally yellowish to rusty worm-marked shaly qtzite indicative of a change in sedimentation preparatory to deposition of succeeding Dev. ls. Most characteristic material of these upper beds is a fine-grained unevenly colored pink and green qtzite in layers 1 or 2 in. thick separated by films of olive-gray sh. The middle and lower parts of fm. are cross-bedded pebbly strata in beds 25 to 50 ft. thick. Thickness 400 ft. Separated from underlying Mescal ls. by 75 to 100 ft. of vesicular basalt. Is top fm. of Apache group.

N. H. Darton, 1932 (Wash. Acad. Sci. Jour., vol. 22, No. 11, p. 319), removed this fossiliferous fm. from underlying nonfossiliferous fms. of Apache group, which he assigned to "Algonkian," because of uncon. at their top, their strong lithologic resemblance to the pre-Camb. Chuar and Unkar groups of the Grand Canyon, and fact that the qtzite has yielded Upper and Middle Camb. fossils.

Named for exposures on Troy Mtn, Ray quad.

Troy granite.

Pre-Cambrian: Central southern Oklahoma (Johnston County).

C. H. Taylor, 1915 (Okla. Geol. Surv. Bull. 20). Medium- to fine-grained gray granite specked with black. Occurs along Rock Creek near town of Troy, Johnston Co. Probably part of same intrusive mass as Tishomingo granite.

Truchas slate.

Pre-Cambrian: Central northern New Mexico (Santa Fe region).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 12). *Truchas slates.*—The upper sl. section of the Archeozoic succession at Picuris, N. of Santa Fe. Thickness 900 ft. [Derivation of name not given.]

Truckee formation.

Miocene: Northern and central western Nevada, eastern California (Lake Tahoe region), and southeastern Oregon.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, map V) and 1878 (U. S. Geol. Expl. 40th Par. Rept., vol. 1, p. 412). *Truckee group*.—Fresh-water deposits of Mio. age, consisting of coarse sands and gravels, white stratified trachytic tuff, pelagonite tuff, marly grits, some sss., and one 60-foot bed of saccharoidal ls. Large part of material is made of trachytic muds, which carry, especially in Oreg., numerous numbers of Mio. fossil mammals. The deposits are partly older and partly contemp. with the trachytes that are interbedded with the sediments. Thickness about 4,000 ft. Deposited in lake to which name "Pah-Ute lake" is applied. [As mapped in above-mentioned atlas the fm. occurs in disconnected areas across Nev., indicating probable deposition in several disconnected lakes. It is mapped over considerable areas in valleys E. and W. of S. end of Truckee Range and in Truckee Canyon btw. Reno and Verdi, Nev.]

Truckee fm. is used by U. S. Geol. Survey to include the deposits to which the name "Siebert fm." has been applied in some parts of Nev.

Trujillo formation. (In Dockum group.)

Triassic (Upper?): Panhandle of Texas.

C. N. Gould, 1907 (U. S. G. S. W. S. P. 191, pp. 20-29). *Trujillo fm.*—Several ledges of massive, more or less cross-bedded ss. and cgl. with interbedded red and gray shales. Thickness 25 to 250 ft. Upper fm. of Dockum group. Overlies Tecovas sh. and uncon. underlies Tert.

Named for exposures on Trujillo Creek, Oldham Co.

Trujillo formation.

Cretaceous: Puerto Rico.

C. P. Berkey, 1915 (N. Y. Acad. Sci. Annals, vol. 26, pp. 21, 61).

Trumbull gneiss.

Pre-Cambrian: Northern New York (Adirondacks).

H. L. Alling, 1918 (N. Y. State Mus. Bull. 199, pp. 45, 127, etc.). Careful studies indicate that lower beds of Hague gneiss have been "soaked" and saturated by igneous solutions of Laurentian granite. In this syntectic rock the characteristic garnets of the former are absent, but the sillimanite is still persistent. This syntectic rock is termed *Trumbull gneiss*, from Trumbull Mtn [Essex Co.]. The lower portions of the Trumbull are comparatively free from sed. admixture and approach the true Laurentian granite in character. Included in Grenville series. Rests on Dresden amphibolite.

H. L. Alling, 1924 (Am. Jour. Sci., 5th, vol. 8, pp. 30-31). At town of Graphite, Warren Co., the Hague gneiss (Grenville) is saturated by Laurentian granite, forming a composite rock. This syntectic the writer proposed to call the "Trumbull gneiss" (Alling, H. L., N. Y. State Mus. Bull. 199, 1917 [1918]), a term later abandoned. The reason for this is that such expressions as "The footwall is the Hague gneiss in its typical development, which in turn lies upon the Trumbull gneiss," give impression that both are normal strat. fms. of Grenville series.

Truro limestone.

Pennsylvanian: Central southern Iowa.

J. L. Tilton, 1897 (Iowa Acad. Sci. Proc., vol. 4, pp. 52, 54). *Truro ls.*, 0 to 2½ ft. thick, lies about 80 ft. below top of Des Moines stage in Madison Co. Underlain and overlain by sh. of Des Moines stage.

Named for Truro, Madison Co.

†Truro series.

Pleistocene: Southeastern Massachusetts (Barnstable County).

N. S. Shaler, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 541-593). *Truro series.*—Fine gray micaceous sands and sandy clays, 100+ ft. thick. Apparently overlie Nashaquitsa series but may possibly be regarded as belonging to same group as Nashaquitsa series.

J. B. Woodworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). "Truro series" of Shaler includes Gardiners clay and other deposits.

Named for occurrence in Truro, Barnstable Co.

Truxton limestone.

Mississippian: Northwestern Arizona (Grand Wash Cliffs region).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 243, 251, 338). *Truxton lss.*, applied to middle Miss. section, carrying Burlington fauna. Fine sections shown in Grand Wash Cliffs and in Yampai Cliffs, overlooking Truxton Plateau [Mohave Co.]. Thickness 450 ft. Older than Elden lss.

Tseax River lava flow.

Recent: British Columbia.

G. Hanson, 1924 (Canada Geol. Surv. Summ. Rept. 1923, pt. A, p. 39).

Tshinakin formation.

Pre-Cambrian: British Columbia.

R. A. Daly, 1913 (12th Int. Geol. Cong. Guidebook 8, p. 124).

Tuckahoe group. (In Newark group.)

Upper Triassic: Eastern Virginia (Richmond Basin).

N. S. Shaler and J. B. Woodworth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, pp. 423–435). *Tuckahoe group.*—Lower div. of Newark system in Richmond Basin. Divided into (descending) productive coal measures, 500± ft.; lower barren beds, 0–300 ft.; and Boscabel boulder beds, 0–50± ft. Underlies Chesterfield group and rests on granite and gneiss. Exposed in shafts and mines bordering Tuckahoe Creek, Goochland Co., in vicinity of Gayton.

Tuckahoe marble.

Pre-Cambrian: Southeastern New York (Westchester County).

C. P. Berkey and J. R. Healy, 1912 (Columbia Univ. Contr., vol. 20, pp. 1907–1912). "Other names for Inwood ls. are *Tuckahoe marble, Sing Sing marble,* and *Stockbridge dol.*" [Tuckahoe and Sing Sing are in Westchester Co.]

Tucker sand.

A subsurface sand, of early Penn. (Cherokee) age, in Okla., 0 to 60± ft. thick, lying lower than Bartlesville sand and higher than Burgess sand. Correlated with Booch sand, also with Taneha sand.

†Tucquan gneiss.

Pre-Cambrian: Southeastern Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, pp. 128–129, 136, 203, 204). *Tocquan (Philadelphia) gneisses and mica schists.*—Overlain by chloritic phyllites. [Seems to be named for exposures in broad, flat anticlinal arch whose axis crosses Susquehanna River at mouth of Tocquan [Tucquan] Creek (McCalls Ferry).]

Replaced by Wissahickon fm.

Tucson sandstone.

Upper Cretaceous (Benton): Southern central New Mexico (Sierra Blanca region).

G. H. Hansen, 1931 (Geo. Wash. Univ. Bull., Summaries of doctoral theses, 1925–28, p. 84). *Tucson ss.*—Chiefly hard ss., in places almost qtzitic, but contains a few thin beds of highly fossiliferous sandy limes and clay partings. Forms escarpment. Well exposed on Tucson Mtn. Thickness 200 to 400 ft. Fossils (listed) of middle Benton age. Overlies Fort Stanton sh. and underlies Sierra Blanca coal measures.

†Tucumcari beds.

Cretaceous, Jurassic, and older (?): New Mexico to southern Kansas.

W. F. Cummins, 1892 (Tex. Geol. Surv. 3d Ann. Rept., pp. 201–209). *Tucumcari beds.*—In descending order: Massive ss., 60 ft.; sh., 50 ft.; massive yellowish ss., 235 ft. Characterized by *Gryphaea* and other fossils. Assigned to Cret. Underlie Tert. and overlie Triassic on Tucumcari Mtn, N. Mex.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 381). *Tucumcari shales.*—Zone of *Gryphaea tucumcari*, consisting chiefly of clay shales and lighter-colored as a whole than underlying Blue Cut shales, which graduate insensibly into them. Included in top of Kiowa shales in southern Kans.

The fms. of Tucumcari Mtn as mapped by N. H. Darton on his geol. map of N. Mex. include (descending) Dakota ss., Purgatoire fm., Morrison fm., Navajo ss., Kayenta fm. (called Todilto on map), and Wingate ss.

Named for Mount Tucumcari, Quay Co., N. Mex., where zone of *Gryphaea tucumcari* was originally discovered by Jules Marcou.

Tufts quartzite member (of Cambridge slate).

Carboniferous or Devonian: Eastern Massachusetts (Boston region).

M. Billings, 1929 (Am. Jour. Sci., 5th, vol. 18, pp. 101, 102, 106, 107, 111, 112). *Tufts qtzite.*—In the athletic field of Tufts College, Medford, about 40 ft. of greenish, reddish, and yellowish qtzite are exposed above the Cambridge argillite. A similar rock on Evelyn St., Everett, is correlated with Tufts qtzite. [In this paper Billings assigned *Tufts qtzite* and underlying rocks to Perm. Although Tufts qtzite had been in common use for many years among geologists working in Boston Basin, and was adopted by U. S. Geol. Survey in June 1910, as *Tufts qtzite memb. of Cambridge sl.*, for rept of L. LaForge cited below, Billings appears to have been the first to publish the name.]

L. LaForge, 1932 (U. S. G. S. Bull. 839). *Tufts qtzite memb. of Cambridge sl.*—Greenish and white qtzite exposed in 3 places. Thickness probably less than 40 ft. Uncertain whether it is top memb. of Cambridge or whether there is more sl. above it. Occurs on athletic grounds of Tufts College.

Tulameen group.

Triassic (?): British Columbia.

C. Camsell, 1913 (Canada Geol. Surv. Mem. 26, p. 37).

Tulare formation.

Pliocene and Pleistocene (?): Southern California (San Joaquin Valley region).

F. M. Anderson, 1905 (Calif. Acad. Sci. Proc., 3d ser., vol. 2, p. 181). *Tulare fm.*—Fresh-water deposits of gypsiferous sands and clays exposed at intervals along W. border of Great Valley. In Kettleman Hills, 10 to 15 mi. SE. of Coalinga, and near W. shore of Tulare Lake these beds aggregate fully 1,000 ft. in thickness. They lie conformably on San Joaquin clays (upper div. of Etchegoin fm.), which they in some respects resemble. [Fossils listed.] Doubtfully assigned to Plio.

Contemp. with part of Paso Robles fm., but deposited in separate basin, according to B. L. Clark (personal communication Dec. 1932).

Tularosa formation.

Tertiary or Quaternary (?): Southeastern New Mexico.

C. L. Herrick, 1904 (Am. Geol., vol. 34, pp. 179, 187). *Tularosa fm.*—Sandy marls, largely gypsiferous and moderately saline. In many places contain fresh-water lacustrine shells. Probably derived from Cret. ss. and sh. and soft gypsiferous sh. and sss. of the Permian. Sharply separated from underlying Otero fm., of Tert. (?) age. [Derivation of name not stated.]

Tule formation.

Pleistocene: Panhandle of Texas.

W. F. Cummins, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 199–200, 203). *Tule div.*—Alternating sand and clay, 150 ft. thick, overlying Triassic in Swisher, Crosby, and Armstrong Counties. Younger than Blanco beds. Prof. Cope assigns fossils to Equus beds.

Named for Tule Canyon, Swisher Co.

Tule Spring limestone.

Pennsylvanian and Mississippian: Southeastern Arizona (Clifton region).

W. Lindgren, 1905 (U. S. G. S. P. P. 43). *Tule Spring ls.*—Heavy-bedded bluish gray lss. fairly extensively developed in N. part of Clifton quad.

W. Lindgren, 1905 (U. S. G. S. Clifton folio, No. 129). *Tule Spring ls.*—Heavy-bedded bluish-gray lss., at least 500 ft. thick, which rest conformably on Dev. Morenci sh., where present, or on Ord. Longfellow ls. where the sh. is absent. Of Penn. and Miss. age. Fossils listed. Named for exposures around Tule Springs, at head of Tule Creek, Clifton quad.

According to G. H. Girty the fossils are of Penn. and lower Miss. age. No upper Miss. fossils were found.

Tuleta sand.

A subsurface sand in Duval Co., Tex. According to A. Deussen and E. W. K. Andrau (A. A. P. G. Bull., vol. 20, No. 5, 1936, p. 540) it lies in upper part of Yegua fm., 170 ft. below Pettus sand, in Pettus dist.

Tulillo beds.

Cretaceous: Mexico.

E. Böse and O. A. Cavins, 1927 (Univ. Tex. Bull. 2748, p. 37).

Tulip Creek formation.

Middle and Lower(?) Ordovician: Central southern Oklahoma (Arbuckle Mountains).

E. O. Ulrich, 1928. See under *West Spring Creek fm.*

F. C. Edson, July 1930 (A. A. P. G. Bull., vol. 14, No. 7, p. 947). *Tulip Creek fm.* is overlain with angular uncon. by Bromide fm.

C. E. Decker, Dec., 1930 (A. A. P. G. Bull., vol. 14, No. 12, pp. 1493-1505). *Tulip Creek fm.*—Chiefly shales and sss., with some lss. Usually a thick ss. at base. Thickness of fm. 0 to 600± ft. Underlies Bromide fm. and overlies McLish fm. Whether of early Black River or late Chazy age to be determined after further study of fossils. Occurs only in W., SW., and central parts of Arbuckle Mtns.

C. E. Decker and C. A. Merritt, 1931 (Okla. Geol. Surv. Bull. 55, pp. 11+). The *Simpson* is here raised to a *group*, divided into 5 fms. (ascending): Joins, Oil Creek, McLish, *Tulip Creek*, and Bromide. A few fossils near base of the Tulip Creek seem to be upper Chazy, but those in middle and near top are typical Black River forms.

See also 1933 entries under *Simpson fm.*

Named for exposures at headwaters of Tulip Creek, in Carter Co., N. of Springer.

†Tullahoma formation.

Mississippian: Tennessee and western Kentucky.

J. M. Safford and J. B. Killebrew, 1900 (Elements of geol. of Tenn., pp. 104, 143, 144). *Tullahoma ls.* (*Siliceous group in part; Fort Payne chert; Barren group*).—Excepting Maury Green sh., the Tullahoma fm. embraces the lowest Subcarbf. rocks. Varied in character and outcrops in all divisions of State, but most extensively in East and Middle Tenn. Its most common rock is cherty or flinty ls., the chert often in thick layers. In East Tenn. the chert of dyestone ridges and the sss. and shales (Grainger sh.) of Poor Valley ridge E. of Clinch Mtn and of other allied ridges belong to it. West of Nashville it includes Erin Burry ls. of Houston Co. and the siliceous Harpeth sh. [Ridgetop sh.] of bluffs of Harpeth River and Turnbull Creek in vicinity of Kingston Springs. Thickness 200 to 600 ft., and at one locality in East Tenn. 1,200 ft. Tullahoma is located on the fm. Overlies Maury green sh. and underlies St. Louis ls.

Includes Ridgetop sh. (exclusive of Maury glauconitic memb.), New Providence fm., Fort Payne chert, and Warsaw fm. The name was also used in SE. Ill. to cover Warsaw ls. and Osage group, exclusive of Fern Glen ls.

Named for Tullahoma, Coffee Co., Tenn.

Tullock formation.

Upper Cretaceous or Eocene: Central southern, southeastern, and northeastern Montana.

G. S. Rogers and Wallace Lee, 1923 (U. S. G. S. Bull. 749, p. 29). The upper memb. of Lance fm. in Tullock Creek coal field, Mont., is herein named *Tullock* *memb.*, from exposures in valley of Tullock Creek [Treasure Co.]. It consists of yellowish ss. and sh. and contains 10 more or less lenticular coal beds. The rocks resemble lower portion of the Lance in a general way, but certain differences are apparent on close examination. Although the ss. is lithologically similar to that in lower part of fm., it commonly occurs in beds less than 20 ft. thick, which seem to be more persistent than the thicker ones that are common in lower part of the Lance. Much of the ss. and sh. is more or less calc., but true ls. was seen at only one point. The sh. is chiefly yellowish gray to brownish, and the faint greenish tint so characteristic of the sh. in lower part of Lance is very uncommon. Many bands of carbonaceous sh. are present, which help to give it a brownish-yellow cast. Thickness 300 ft. Overlain by Lebo sh. memb. of Fort Union fm.

The part of Lance fm. that underlies the Tullock deposits was later named *Hell Creek memb. of Lance fm.*, but in Dec. 1935 the Tullock and Hell Creek deposits were raised to rank of fms. by U. S. Geol. Survey, the age of *Hell Creek fm.* was changed to *Upper Cret.*, and the age of *Tullock fm.* was changed to *Upper Cret. or Eocene*. These changes were based upon a large amount of additional field work over extensive areas.

Tullock member (of Lance formation).

See *Tullock fm.*

†Tullock Creek member (of Lance formation).

Name applied by E. S. Perry to beds formerly called *Tullock memb. of Lance fm.* but now called *Tullock fm.* (See Mont. Bur. Mines and Geol. Mem. 2, 1931, p. 27, and Mem. 14, 1935, p. 10.)

Tully limestone.

Upper Devonian: New York and Pennsylvania.

L. Vanuxem, 1839 (N. Y. Geol. Surv. 3d Rept., p. 278). *Tully ls.*—A mass of bluish and brownish ls. 12 to 16 ft. thick, not remarkable for purity. Exposed at Tully Corners, at Borodino, on both sides of Skaneateles Lake, on road from Owasco to Kellogsville, at Martville and falls of Dry Creek, below Moravia, and in ravines along Cayuga Lake from 4 to 5 mi. S. of Aurora to Blooms lime-kiln.

J. Hall, 1839 (N. Y. Geol. Surv. 3d Rept., pp. 300–301, 313). *Tully ls.*—Overlies Moscow shales and underlies Upper Black sh. [Genesee sh.]. Greatest thickness (16 ft.) in Seneca Co., but maintains very uniform character over great area. Consists of three or four layers, for most part of uniform thickness. Is of light bluish-gray color; in some localities blue, fine-grained, and very compact. Few fossils.

Is well exposed in town of Tully, Onondaga Co.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19). *Hypothyridina venustula* zone at base of Tully ls. and at base of Sherburne ss. is base of Upper Dev.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included *Tully ls.* in Upper Dev.

D. W. Trainer, 1932 (N. Y. State Mus. Bull. 291, pp. 2–26). To east the *Tully ls.* grades into underlying Hamilton; to W. there is a physical and lithological hiatus that author considers a discon.

B. Willard reported (Pa. Acad. Sci. Proc., vol. 8, pp. 57–62, 1934) occurrence of a diagnostic Tully fossil (*Hypothyridina venustula*) in central Pa., and applied name *Rush memb. of Tully ls.* to the 10 ft. of ls. containing the fossil, "the first specimen of the species found in Pa." In early Pa. repts many beds were identified as Tully ls. that are now considered not to belong to that fm. Willard stated that Tully ls. is reported in wells across most of northern Pa., and that as South Danville locality is most southeasterly known occurrence of a representative of Tully fauna, "we deduce Rush memb. here approaches SE. limit of Tully deposition." In 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 1209–1213) Willard modified his 1934 nomenclature by calling his *Rush memb. of Tully ls.* the *Tully memb. of Rush fm.*, and included in his *Rush fm.* the beds called *Genesee* in his 1934 paper cited above.

B. Willard, 1935 (Pa. Acad. Sci. Proc., vol. 9, p. 44). The Tully, although dominated by Hamilton species, does mark appearance of 4 or 5 new kinds of organisms which are unrecognized in Middle Dev. of Pa. Some of the new arrivals survived into post-Tully time. The strat. and paleontology of Pa. show Tully to be base of Upper Dev. [On pp. 40 and 42 he includes Tully ls. in Portage group of Pa.]

This fm. has for many years been classified as Upper Dev. by N. Y. State Survey, U. S. Geol. Survey, and others.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, p. 309), listed 6 sp. which are "all that there are to distinguish the Tully from the Hamilton," and in footnote added that G. A. Cooper has reduced this number to 4. "As no one of these 6 sp. ranges upward into undoubted Upper Dev. strata, they are, while diagnostic, wholly noncommittal as to Middle or Upper Dev. appurtenance of the Tully. Not a single sp. originates in the Tully to persist beyond. Such forms as do continue are all Hamilton, 34 in number; nor is this fact of consequence as compared with the much larger number of Hamilton sp. unknown in the Tully that, nevertheless, reappear above it. The paleontologic claim for Upper Dev. age of the Tully ls. rests, therefore, upon the single sp. *Hypothyridina venustula*." "The strat. evidence, as now understood, is equally unconvincing. With 63 sp. of Hamilton fossils in Tully ls. that are not among the long-range Hamilton forms of the Senecan strata above, and with all its physical characteristics like those of the Hamilton lss. below, rather than those of the Senecan lss. above, the Tully seems to belong lithically and faunally in the Hamilton, although there are places, as at Taghanic Falls, where the sharp break seems to come below and a transition to occur above into the Genesee. Yet there are other places where the reverse is true. Followed westward, the Tully ls. disappears into an uncon.; but whether it goes out from top down, and is thus Middle Dev., or from bottom up, making it Upper Dev., seems never to have been investigated, although this is the decisive criterion. Footnote: I am informed that this may be treated in a forthcoming paper on the Tully by G. A. Cooper and J. S. Williams."

G. A. Cooper and J. Stewart Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 823–824). There are no known American antecedents of *Hypothyridina* and *Scutellum* in Mid. Dev. of eastern U. S. These species therefore probably reached N. Y. by migration, but whether or not they reached N. Y. during Mid. or Upper Dev. time is regarded as an open question by writers. Although Tully fauna is now regarded Upper Dev., the predominant Hamilton elements would suggest an earlier age. This question can only be convincingly settled after comparison of Tully species with actual European specimens. Because of lack of European strat. material in Nat. Mus. this comparison cannot be undertaken. The whole problem of age of Tully must await further exploration, faunal description, and strat. discrimination in western U. S., Canada, Europe, and Asia. [Divided into several members in different areas.]

B. Willard, 1936 (Geol. Soc. Am. Proc. 1935, p. 376). Since 1933 the presence of the Tully has been definitely established in Pa., where it extends from south-central part into central region of State, as a narrow band concentric to base of Allegheny Front. Isolated occurrences of fauna have been found E. of the Susquehanna. Thickness 0 to 200+ ft. Lithology ranges from dense to shaly ls. Is characterized by a fairly numerous fauna, including *Hypothyridina venustula*, *Chonetes aurora*, and *Lopholasma carinatum*, and the newly described *Echinocoelia ambocoeloides*.

For many years the true Tully ls. was believed to be absent in Pa., and the thin ls. in that State that Willard now includes in his Tully was treated as a bed in the Hamilton, and it is mapped with the Hamilton by C. Butts in U. S. G. S. Hollidaysburg-Huntingdon folio, No. 227, in press.

†Tulsa group.

Pennsylvanian: Northeastern and central northern Oklahoma.

C. N. Gould, D. W. Ohern, and L. L. Hutchison, 1910 (Okla. State Univ. Research Bull. 3, pp. 6, 10). *Tulsa group*.—Includes all rocks btw. base of Lenapah ls. (in Kans. called Upper Parsons or Coffeyville ls.) above and base of Claremore fm. or Calvin ss. below. Includes Calvin, Wetumka, and Wewoka fms. and probably 200 ft. or more of Holdenville fm. of Coalgate quad. In N. part of State includes rocks which in Kans. have been called [ascending order] Fort Scott ls., Labette shales, Pawnee ls., Bandera shales, Altamont ls., and Walnut [Nowata] shales.

Named for Tulsa Co.

Tumey formation.

Oligocene: Southern California (Fresno County).

E. R. Atwill, 1935 (A. A. P. G. Bull., vol. 19, No. 8, pp. 1192-1204). *Tumey fm.* is proposed for the ss. (800 ft. thick) mapped by Anderson and Pack (U. S. G. S. Bull. 603, 1915, pl. 1) as faulted "Vaqueros" (just N. of Arroyo Ciervo) and to the immediately overlying shales (885 ft. thick). The ss. to be called *Tumey ss.* and the sh. *Tumey sh.* This ss. and sh. sequence comprises a cartographic unit for a distance of at least 7 mi. btw. Arroyo Ciervo and Tumey Gulch. To SE. of Arroyo Ciervo the ss. appears to grade into sh. A short distance NW. of Tumey Gulch it is overlapped by ss. of Temblor age, containing following fossils [listed]. The upper 20 ft. of the sh. memb. near Arroyo Ciervo contains zone characterized by a pelecypod commonly called *"Leda" washingtonensis* Weaver. Some workers in area report uncon. about 185 ft. below this contact, separating the so-called *"Leda* sh." from main mass of underlying Tumey sh. But because of its identical lithologic characteristics and faunal content with Tumey sh., and because it is not a cartographic unit, writer classifies it as upper zone of Tumey sh. The fm. uncon. overlies Kreyenhagen sh. The strata here named *Tumey fm.* have been grouped variously with the Vaqueros and the Kreyenhagen or referred tentatively to Olig. [Fossils listed.] Assigned to Olig. Type loc. is not in Tumey Gulch, but in S½ sec. 16, T. 16 S., R. 13 E., Mount Diablo base and meridian, Fresno Co. Names are scarce in the area, and *Tumey* seemed only name that could be used.

†Tuna conglomerate.

See †*Tunangwant cgl.*

†Tunangwant conglomerate.

Devonian or Carboniferous: Northwestern Pennsylvania and southwestern New York.

J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_3, p. 79). *Tunangwant cgl.*—Probably older than Sub-Olean cgl. and younger than Salamanca cgl. [Seems to be exposed in hills bordering Tunangwant Creek, btw. Carrollton and Bradford.]

J. F. Carll, 1883 (2d Pa. Geol. Surv. Rept. I_4, pp. 180, 206-208, 230). *Tuna cgl.* is now popular name for original *Tunangwant cgl.* Lies at least 225 ft. above Salamanca cgl. and about 275 ft. below Olean cgl. on Ireland summit.

L. C. Glenn, 1904 (Geol. Soc. Am. Bull., vol. 14, pp. 522-531). *Tuna cgl.* is same as Salamanca, Panama, and Pope's Hollow cgls. [The Panama is now considered older than Salamanca (†Pope Hollow, †Tuna) and to correlate with Wolf Creek cgl.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 88). Salamanca cgl. has been called "Tuna."

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 425). Salamanca cgl. has been called *"Tuna."*

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 91). *Tunangwant cgl. lens* (or *Tuna cgl.*) is in upper part of Saegerstown sh. in northern McKean Co., Pa., and Olean-Salamanca region, N. Y. Is younger than Salamanca cgl. Was named for exposures in N. Y. along Tunangwant Creek, which flows N. through Bradford, Pa., into N. Y. Is same as Killbuck lens of Glenn, which is traceable into type Tuna. In fact, Glenn cites type loc. of Tuna as an outcrop of his Killbuck. Thickness few in. to 40 ft. Overlain by a sh. sequence of the upper Venango, throughout which occur cgl. lenses and some part of which is presumably the eastern correlate of Woodcock ss. to W. [On p. 93 he stated *Tuna cgl.* is younger than Salamanca cgl., and appears to be older than Woodcock ss. and=Hosmer Run cgl.]

Tunbridge granite.

Devonian: Northeastern Vermont (Orange County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of eastern Vt., but without definition. Probably named for Tunbridge Twp, Orange Co., or some of villages of that name within that twp.

Tunnel Hill zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 8, 12). *Tunnel Hill zone* (*Archean*) comprises a narrow belt bounded on NW. by Chauga zone and on SE. by line extending from Tugaloo River near mouth of Barton Creek, immediately N. of Rich Mtn, N. of Horse Shoe Bend, and thence northeasterly. It constitutes a narrow tongue btw. Chauga and Poor Mtn ls. zones. Rocks are porphyritic granite gneiss and gneissoids. Probably=Keith's "Henderson granite," assigned to Archean. Abundant strain effects prevail. This rock appears to have resulted from granulation and recrystallization of a porphyritic granite. The Tunnel Hill granite gneiss is a very hard rock, comprising thin bands curved to enfold rounded crystal individuals of pink feldspar (Kleine augen gneiss).

Named for exposures at Tunnel Hill, Oconee Co.

Tunnel Point beds.

Oligocene: Southwestern Oregon (Coos Bay).

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 336-343). *Tunnel Point beds.*—Shales and sss. at and SW. of Tunnel Point, Coos Bay, containing sparse fauna, distinct alike from Eo. shales below and Empire beds above. Thickness 1,200 ft. Conformable with Eo.; uncon. with Empire. Faunal change and aspect of species suggest this group of beds may represent Olig. Assigned to upper Olig. or Chipolan stage.

W. H. Dall, 1909 (U. S. G. S. P. P. 59), assigned the *beds at Tunnel Point* to Olig. and stated that they uncon. overlie Arago fm., which includes Coaledo and †Pulaski fms.

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12). *Tunnel Point ss.* of Coos Bay dist. is chiefly ss., 800± ft. thick, and is middle Olig. Writer considers it belongs to *Acila shumardi* horizon. [Fossils listed.] It overlies Bassendorf sh. (lower Olig.), which rests on Coaledo fm. [restricted], upper Eocene. [Judging by thicknesses given, the Tunnel Point ss. of Schenck is a restriction, part of Bassendorf sh. of Schenck having been included in Tunnel Point ss. of Dall and part of it in Coaledo fm. of Dall.]

H. G. Schenck, 1928 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 1, pp. 15-22, pl. opp. p. 4). *Tunnel Point ss.* is middle Olig. It conformably overlies Bassendorf sh., which rests on Coaledo fm.

Tununk sandstone member (of Mancos shale).

Upper Cretaceous: Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology of Henry Mtns, pp. 4+). *Tununk ss.*—Heavy-bedded yellow ss., 100 ft. thick, underlying Blue Gate sh. and overlying Tununk sh. in Tununk Plateau.

Now treated by U. S. Geol. Survey as a memb. of Mancos sh. in Henry Mtns region.

†Tununk shale. (In Mancos shale.)

Upper Cretaceous: Central southern Utah (Henry Mountains region).

G. K. Gilbert, 1877 (Geology of Henry Mtns, pp. 4+). *Tununk sh.*—Blue-black argill. sh. that weathers to a fine gray clay. Thickness 400 ft. Underlies Tununk ss. and overlies Henrys Fork group in Tununk Plateau.

Now treated by U. S. Geol. Survey as a part of Mancos sh. Name discarded because of conflict with Tununk ss., the adopted name.

Tununkian series.

A term introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 43, p. 295, 1925) for Upper Cret. rocks in Utah that appear to correspond to Tununk ss. of Gilbert.

Tuolumne intrusive series.

Probably Cretaceous: Yosemite National Park.

F. C. Calkins, 1930 (U. S. G. S. P. P. 160, p. 121, map). The great bulk of granitic rocks in Yosemite region belong to two series of intrusions, the members of each series exhibiting especially close relationship to one another. These may be termed the *biotite granite series* of Yosemite Valley and *Tuolumne intrusive series*. The latter includes [ascending order of age] Sentinel granodiorite, Half Dome quartz monzonite, Cathedral Peak granite, and Johnson granite porphyry—fms. which extend in large bodies from upper half of Yosemite Valley N. to Tuolumne River and NE. into High Sierra.

Named for exposures along Tuolumne River, Yosemite National Park.

Tuolumne group.

Jurassic (?) and Triassic (?): Sierra Nevada, California.

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, pp. 233-234). The recognized divisions of bedrock complex are wholly inadequate, and they ignore a very extensive and important rock group. This group is made up of tuffs, flows, and aggls. with interbedded sediments of very distinctive character in which radiolarian cherts predominate. The sediments, including a little interbedded tuff, have max. thickness of 1,100 ft. in Mariposa and Tuolumne Counties. They are interbedded with and included in a very thick series of tuffs, flows, and aggls., usually andesitic. For this group of rocks the name *Tuolumne* is proposed, from the county of that name in which they are well developed. It occurs in 2 or more parallel belts along lower W. slope of the Sierra btw. Merced-Yosemite highway on S. and Grass Valley on N., a distance of 135 mi. Although no organic remains other than Radiolaria have been found, it is thought *Tuolumne group* represents a part of both Triassic and Jurassic time. The Milton and Sailor Canyon fms. of easternmost part of Sierras are probably more or less contemp. with it.

N. L. Taliaferro, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 149). *Tuolumne group* is largely submarine basic volcanic rocks and radiolarian cherts, 15,000+ ft. thick. Is thought to be lower Mesozoic, as its stage of metamorphism is exactly similar to Mariposa group, which it uncon. underlies. Is here divided into (descending): Agua Fria slates, lss., cherts, and tuffs, 2,000+ ft.; Penyon Blanca aggls., 9,000 ft.; Hunter Valley cherts and tuffs, 1,500 ft.; pillow basalts, 1,400 ft.; aggls., tuffs, and flows, 1,500+ ft.

Tupelo tongue (of Coffee sand).

Upper Cretaceous: Northeastern Mississippi.

L. W. Stephenson, 1917 (Wash. Acad. Sci. Jour., vol. 7, pp. 243-250). *Tupelo tongue*.—A tongue of uppermost part of Coffee sand memb. of Eutaw fm., resting on Mooreville tongue of Selma chalk and overlain by a large body of Selma chalk. The material composing the tongue is dark-gray, chiefly massive calc., glauconitic sand. Thickness 100 ft. Geographic extent about 100 mi. in Lee Co. [The Coffee sand is now treated as a distinct fm.]

Named for Tupelo, Lee Co.

Tupper syenite.

Pre-Cambrian: Northern New York (Long Lake quadrangle, Adirondack Mountains).

H. P. Cushing, 1907 (N. Y. State Mus. 60th Ann. Rept., pt. 2, pp. 476-482, 515, and map). [Map reads: "Green to gray syenite, usually augite syenite; mostly very feldspathic. *Tupper syenite*."]

Exposed about Tupper Lake, Franklin Co.

Turgeon formation.

Silurian: New Brunswick.

G. A. Young, 1911 (Canada Geol. Surv. Mem. 18, p. 36).

Turk sand.

A subsurface sand, of Penn. age, in Thomas pool, Kay Co., central northern Okla., that is reported to correspond to Upper Endicott sand and to a part of Nelagoney fm. It lies at 2,600 ft. depth and several hundred ft. below Thomas sand.

Turkey Creek sandstone member (of Mineral Wells formation).

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 25, 31; Univ. Tex. Bull. 2132, pp. 77-78 and many charts). *Turkey Creek ss. memb. of Mineral Wells fm.*—The thick, very massive ss. which forms first prominent escarpment E. of outcrop of Palo Pinto ls. has been named *Turkey Creek ss.*, from creek of that name NW. of Mineral Wells (Palo Pinto Co.). Thickness 10 to 15 ft. At type loc. (on Turkey

Creek road 2¼ mi. NW. of Mineral Wells) it consists of 10 ft. of dark reddish-brown massive cgl. of small angular pebbles of quartz and qtzite in a matrix of coarse sand, is overlain by Keechi Creek ss. and sh. and underlain by Salesville sh., all members of Mineral Wells fm.

Above is definition still in use. See F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534).

Turkey Creek beds. (In Yegua formation.)

Eocene: Eastern Texas (central Brazos County).

L. C. Reed and O. M. Longnecker, Jr., 1929 (Univ. Tex. Bull. 2901, pp. 163–174). *Turkey Creek beds.*—Gritty clay mottled and lensed with sand; volcanic ash makes up part of beds. Thickness at least 25 ft. Is a lithologic div. of Yegua fm., but name is used for convenience only, and is not intended as a fm. or memb. name. [Is mapped.] Underlies Upper Turkey Creek beds, also underlies Yegua River cgl. Exposed on upper part of Turkey Creek and tributaries, also in North Turkey Creek. The *Upper Turkey Creek beds* are at least 20 ft. thick, and consist of strata varying from slightly carbonaceous laminated light-gray ashy clay to a finely laminated volcanic ash partially decomposed to bentonite and containing specks of carbonaceous matter and some thin lignite beds. Exposed along upper part of Turkey Creek.

Turkey Mountain sand.

A subsurface sand in Okla., 0 to 25 ft. thick, which is included in base of Simpson fm. (Middle and Lower Ord.) by some geologists and in top of Arbuckle ls. (Lower Ord. and Upper Camb.) by other geologists. In Turkey Mtn pool, Tulsa Co., this sand lies at 2,145 ft. depth and the Wilcox sand at 2,090 ft. depth.

Turkey Mountain lime.

Drillers' term for 100 ± ft. of beds in NE. Okla. correlated with upper part of Arbuckle ls.

Turkey Ridge sandstone member.

Middle Devonian (Marcellus): Central Pennsylvania (Juniata, Dauphin, and Perry Counties).

B. Willard, 1935 (Geol. Soc. Am. Bull., vol. 46, Proc. Pal. Soc. Feb. 28, pp. 202–203). *Turkey Ridge ss. memb.*—Flaggy to massive, rather coarse hard olive-gray ss., underlying Mexico ss. and overlying Shamokin black sh.; all members of Marcellus fm. in central Pa. Named for Turkey Ridge, which separates Juniata and Perry Counties. Best exposed in Delaware Creek section. Max. thickness (slightly over 200 ft.) in Juniata Valley; gradually thins to E. and to W. Distribution nearly = that of Mexico ss. Is merely reworked Oriskany.

Turkey Run limestone member (of Buck Creek formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

K. C. Heald and K. F. Mather, 1919 (U. S. G. S. Bull. 686M, pp. 150, 153). *Turkey Run ls.*—Dark-gray ls., fine-grained, thin-bedded, hard, brittle; weathers into smoothly rounded slabs a few inches long; weathered surface generally light gray, with many curving traceries and irregular patterns of darker gray or yellowish brown, due to fragments of brachiopod and gastropod shells, the margins of which are thus etched by weathering. On fresh fracture the color is much darker bluish gray, at some places almost black. Thickness 1 to 3 ft. Well-preserved fossils very rare; in fact, this ls. can most readily be distinguished from the lithologically similar ls. 60 ft. higher by absence of the brachiopod species commonly found in higher bed. Lies 40 to 90 ft. above Deer Creek ls. memb. of Pawhuska ls. Lies 45 ± ft. above Little Hominy ls. and about same distance below Bird Creek ls. Named for excellent exposures near head of Turkey Run, in secs. 9, 16, and 17, T. 24 N., R. 8 E.

Turkey Track limestone layer. (In Richmond group.)

Upper Ordovician: Southwestern Ohio.

J. J. Wolford, 1930 (Ohio Jour. Sci., vol. 30, No. 5, p. 304). *Turkey Track ls. layer.*—Hard fine-grained, essentially barren ls., top of which bears impressions resembling turkey tracks. Thickness approx. 7 in. Base of this ls. has been designated by Dr. Geo. M. Austin as plane of division btw. Whitewater and Liberty fms. in SW. Ohio.

Turner sandy member (of Carlile shale).

Upper Cretaceous: Northeastern Wyoming and southeastern Montana.

W. W. Rubey, 1930 (U. S. G. S. P. P. 165A). *Turner sandy memb.*—Upper and major part of Carlile sh. in NE. Wyo. and SE. Mont. Consists of 150 to 200 ft. of more or less sandy sh. and siltstone, with iron-stained concretions, persistent thin beds of ss., locally conglomeratic and phosphatic and containing abundant shark teeth, in lower part. Marine fossils. Forms a minor scarp. A distinct faunal break and possible uncon. at base. Overlies lower part of Carlile sh., which consists of 75 to 125 ft. of dark-gray sh. with a few calc. concretions. Named for exposures along Turner Creek in Twps 46 and 47 N., R. 64 W., Weston Co., Wyo.

Turner Creek shale. (In Topeka limestone.)

Pennsylvanian: Southeastern Nebraska, southwestern Iowa, northeastern Kansas, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 42, 52, 53). *Turner Creek sh.*—Bluish-gray calc. sh., named for the Turner Creek exposure SE. of Du Bois, Nebr. Thickness 5 ft. in SW. Iowa, 3¾ ft. in SE. Nebr., 4½ ft. in Kans., 5+ ft. in Mo. Overlies *Curzen ls.* and underlies Du Bois ls. [This is definition followed by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr. G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), discarded *Curzon ls.* for Hartford ls., the older name. For Condra's latest interpretation of strat. position of this sh. see 1937 entry under *Topeka ls.*]

Turnley hornstone.

Turnley shale.

Pre-Cambrian (Belt series): Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, p. 434). *Turnley hornstones.*—The Turnley beds comprise 200 ft. of *Turnley quartzitic hornstone*, underlain by 200 ft. of *Turnley sh.*, the latter consisting of red sandy strata indurated to very dense hornstone of light-brown biotite and quartz and containing in middle a bed of impure iron ore 20 to 30 ft. thick. The Turnley qtzitic hornstones, although well bedded, are very dense and hard and of gray-black color, finely saccharoidal, with conchoidal fracture. In color, composition, and relation to overlying Alpreston qtzite (=(?) Flathead qtzite) the Turnley beds correspond to red Spokane sh. of Belt series at Whitehall, Townsend, and Helena. They occur only on slopes above Turnley placer, in SW. part of Elkhorn min. dist.

†Turritella marl.

Paleontologic term applied in early repts to Caloosahatchee marl (lower Plio.).

†Turritella limestone.

†Turritella rock.

Paleontologic terms applied in early repts to Clayton fm. (basal Eocene).

Turtleback complex.

Upper Jurassic: Northwestern Washington (San Juan Islands).

R. D. McLellan, 1927 (Univ. Wash. Pub. Geol., vol. 2, pp. 142, 148–154). *Turtleback complex.*—Intrusive igneous rocks, both acid and basic, of so many different types and ages that it is impossible to map them individually. It is a confused network or injection breccia containing dunites of Fidalgo fm.; basalt and andesite porphyrite belonging to Eagle Cliff porphyrite; Wark gabbro-diorite; Colquitz quartz diorite; scattered offshoots of diorite-porphyrite, rhyolite porphyry, granodiorite porphyry, aplites, pegmatites, igneous quartz veins, and lamprophyric rocks ranging from the more basic porphyrites to the ultrabasic pyroxenites and hornblendites. Well exposed on Turtleback Mtn. Assigned to late Jurassic.

Turtle Mountain group.

Devonian and Carboniferous: Alberta.

J. D. MacKenzie, 1914 (Canada Geol. Surv. Mus. Bull. 4, p. 5).

Tusayan series.

A term proposed by C. [R.] Keyes to include Coconino ss., Hermit sh., and Supai fm. of Grand Canyon region. Derivation of name not stated. (See Pan-Am. Geol., vol. 66, No. 3, 1936, pp. 195–216.)

†Tuscahoma marl.

Eocene (lower): Southwestern Alabama.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, p. 50). [See *Bells Landing marl memb.*, for definition.]

Conflicts with Tuscahoma sand, better-established name, of which it is a single memb.

Named for exposures at Tuscahoma, on Tombigbee River, in Choctaw Co.

Tuscahoma sand. (In Wilcox group.)

Eocene (lower): Southern Alabama.

E. A. Smith, 1888 (Ala. Geol. Surv. Rept. Prog. 1884–88, geographic map of Ala.). *Tuscahoma (Bells Landing)*: Underlies Bashi (Wood's Bluff) and overlies Nanafalia. [All of definition.]

For more specific definition see †*Bells Landing series*, a binomial name which has one year's priority over Tuscahoma but which has been used in two senses.

Belongs in Wilcox group and contains deposits of both marine and nonmarine origin. (See also 1932 entry under *Salt Mtn ls.*)

Named for exposures at Tuscahoma, on Tombigbee River, in Choctaw Co.

Tuscaloosa formation.

Upper Cretaceous: Coastal Plain from western Tennessee, northeastern Mississippi, and northwestern Alabama, across southern Alabama, Georgia, South Carolina, and North Carolina.

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 18, 95–117, 136–138, pl. 11). *Tuscaloosa fm.*—Irregularly or obscurely bedded qtzitic and micaceous sands, of yellowish, gray, pink, and light-purple colors, often cross-stratified; interbedded with heterogeneous clays, of mottled, purple, and gray colors, sometimes carbonaceous or lignitiferous; also lenticular pebble beds (pebbles commonly of chert) and discontinuous lignitic layers. No fossils except lignite and leaf impressions. Of undet. age but probably Cret. Thickness probably 1,000 ft. Rests uncon. on eroded surface of Carbf. or other Paleozoic rocks. Underlies Eutaw fm.

In eastern S. C. and in N. C. the Tuscaloosa is overlain by Black Creek fm. (of Upper Cret. age). It is possible (according to L. W. Stephenson and C. W. Cooke, personal communication) that in these States beds older than the Tuscaloosa may in the future be differentiated from the deposits now called by that name. In S. C. the Tuscaloosa replaces †Middendorf fm. and in N. C. it replaces †Cape Fear fm.

Named for Tuscaloosa, Tuscaloosa Co., Ala., and Tuscaloosa (Black Warrior) River at Steele's Bluff and White's Bluff, Hale Co., Ala.

Tuscan tuff.

Pliocene: Northern California (Lassen Peak, Redding, and Chico regions).

J. S. Diller, 1895 (U. S. G. S. Lassen Peak folio, No. 15). *Tuscan fm.*—Composed wholly of fragmental material derived from the numerous volcanoes of Lassen Peak dist. Much of it is fine, clearly stratified, and properly called tuff, but a large part is aggl. of coarse and fine material intermingled. Most fragments are angular, but some beds are made up of pebbles well rounded by water action. Best exposed in canyons of Mill, Deer, and other creeks on their way from the mtns to Sacramento Valley. At a number of points there are sheets of lava in the tuff. Is youngest Tert. deposit in region. Rests on Ione fm. [The deposits mapped and described as *Tuscan fm.* in 1892 prel. proof-sheet ed. of Lassen Peak folio are divided into Tuscan fm. and Ione fm. in the completed Lassen Peak folio.]

The Tuscan tuff ranges in thickness up to more than 1,000 ft.

See under *Nomlaki tuff memb.* and under *Tehama fm.*

N. E. A. Hinds, 1932 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 20, No. 11, pp. 375–410), assigned Tuscan fm. to late Plio.

Named for exposures at or near Tuscan Springs, Lassen Peak quad.

Tuscarora sandstone.

Tuscarora quartzite.

Silurian (early): Central southern and eastern Pennsylvania, western Maryland, western Virginia, and eastern West Virginia.

N. H. Darton, 1896 (U. S. G. S. Piedmont folio, W. Va.-Md., No. 28, and Franklin folio, W. Va.-Va., No. 32). *Tuscarora qtzite.*—White and gray massive qtzite, 250 to 480 ft. thick. Underlies the red Cacapon ss. and overlies the red Juniata fm. Is a part of the Medina of early repts on this region. Assigned to Sil. [Derivation of name not stated.]

W. B. Clark, 1897 (Md. Geol. Surv. vol. 1, pp. 172–188). *Tuscarora fm.* (white Medina ss.) of Appalachian region of Md. is chiefly ss., hard and massive, generally white or gray. Few fossils have been found, but it is undoubted equiv. of white Medina ss. to north. Is found at widely separated points in Appalachian dist. Named for Tuscarora Mtn, Pa. [which extends along border line of Juniata and Perry Counties, Pa.]. Is 1,500 ft. thick in W. part of dist. Assigned to Sil.

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 107, pp. 34–35). *Arthrophycus* is only fossil mentioned as coming from Tuscarora ss., which is regarded as perhaps nearly identical with the White Medina of Pa. and N. Y. Surveys.

This fm. continued to be assigned to Sil. until 1907, when R. S. Bassler (Min. Res. Va. (Watson), p. 102) classified it as Ord., and repeated this assignment in 1908 (Econ. Geol., vol. 3, p. 510). Other geologists, however, continued to classify it as Sil., and it is now universally assigned to that system.

Tuscher formation.

Tertiary? (Eocene?): Central eastern Utah (Book Cliffs).

D. J. Fisher, 1936 (U. S. G. S. Bull. 852). *Tuscher fm.*—Largely quartz sss., massive, cross-bedded, friable, light gray to creamy white, with minor interbedded buff to gray shales. Thickness 131 to 600± ft. Underlies Wasatch fm. and overlies Price River fm. Erosional uncon. almost certain both at top and base. Named after canyon just E. of Green River.

Tuscumbia limestone.

Mississippian: Northern Alabama.

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala., with explanatory chart). *Tuscumbia (St. Louis).*—Tuscumbia ls., a somewhat cherty ls. 20 to 150 ft. thick, occurring in immediate valley of Tennessee River from Huntsville westward. Overlies Lauderdale cherty ls. and underlies Mountain ls. Is=upper part of Fort Payne chert.

Tuscumbia ls. as later defined by C. Butts (Ala. Geol. Surv. Spec. Rept. No. 14, 1926) applies to the lss. of Ala. that underlie Ste. Genevieve ls., overlie Fort Payne chert (restricted), and include rocks corresponding to only St. Louis, Spergen, and Warsaw limestones of Mississippi Valley section. This is present definition of U. S. Geol. Survey. (See also under *Fort Payne chert.*)

Named for exposures at Tuscumbia, Colbert Co.

†Tuskaloosa fm.

Cretaceous: Alabama.

An early spelling of *Tuscaloosa fm.*

Tusquitee quartzite.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 4). *Tusquitee qtzite.*—Almost entirely white qtzite, of remarkably uniform appearance throughout all its areas. Composed of fine grains of rolled quartz sand. To N., W., and S. of Marble there are a few seams of fine cgl. in the qtzite. On headwaters of Cheoah River some qtzites of medium grain contain sl. pebbles of same nature as underlying Nantahala sl. But as a rule the grain of the rock is very fine. The beds

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

of qtzite range in thickness from a few inches up to 2 or 3 ft. Interbedded with the qtzites are a few seams and layers of black sl. and schist similar to those of underlying Nantahala sl. These are seldom over a foot thick. Thickness of fm. 20 to 500 ft. Underlies Brasstown schist and overlies Nantahala sl.

Named for excellent exposures in Tusquitee Mtns, Clay Co., N. C.

Tutshi series.

Age (?): British Columbia.

R. G. McConnell, 1906 (Canada Geol. Surv. Summ. Rept. 1905, p. 28).

Tutshi series.

Cretaceous: Yukon.

D. D. Cairnes, 1908 (Canada Dept. Mines, Geol. Surv. Branch, Pub. 982, pp. 23, 31).

Tuxedni sandstone.

Middle Jurassic: Central southern Alaska (Cook Inlet region).

G. C. Martin and F. J. Katz, 1912 (U. S. G. S. Bull. 485, p. 59, map, chart opp. p. 30). *Tuxedni ss.*—Chiefly ss. but contains much sh. and a few thin beds of ls. and cgl. Thickness exposed at type section (on S. shore of Tuxedni Bay) 1,128 ft. Base exposed on S. shore of E. arm of Iniskin Bay, where it rests uncon. on crystalline rocks. Marine invertebrates and fossil plants, the former in great abundance and variety and referred to Middle Jurassic by T. W. Stanton. Underlies Chinitna sh.

Tuxpam formation.

Tuxpan formation.

Miocene: Mexico (Vera Cruz).

E. T. Dumble, 1911 (Sci., n. s., vol. 33, p. 234). *Tuxpam fm.*, Mio., Mexico.

T. W. Vaughan, 1924 (Geol. Soc. Am. Bull., vol. 35, p. 737). *Tuxpan fm.*, Mio., Mexico. Named for city of Tuxpan (which is also spelled Tuxpam), Vera Cruz.

Tuxtepec formation.

Miocene: Isthmus of Tehuantepec.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 375).

Tuxtla formation.

Lower Cretaceous: Mexico.

C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 328).

Tuya lavas.

Tertiary: British Columbia.

F. A. Kerr, 1926 (Canada Geol. Surv. Summ. Rept. 1925, pt. A, p. 94).

Twelvemile beds.

Tertiary: Southwestern Alaska (Yukon gold district).

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3). *Twelvemile beds.*—Slightly consolidated and coarse-bedded gravels and sands that carry seams of light-brown sandy lignite and fragments of wood, but no fossil leaves or shells. Exposed at junction of Twelvemile Creek and Mission Creek. Overlies Mission Creek series, probably uncon. Are younger than Kenai series and probably of Mio. or Plio. age and deposited in lake.

Twentymile sandstone (distinct formation). Also

Twentymile sandstone member (of Williams Fork formation).

Upper Cretaceous: Northwestern Colorado (Yampa region).

N. M. Fenneman and H. S. Gale, 1906 (U. S. G. S. Bull. 297, p. 27). *Twentymile ss. memb. of Mesaverde fm.*—Massive ss.; in a single bed in some places, but in other places it consists of a series of massive layers aggregating several hundred ft. Thickness 75 to several hundred ft. Underlies upper coal group (400 ft. thick) of Mesaverde fm. Is separated from underlying Trout Creek ss. memb. by 600 ft. of weak sss. and shales underlain by 400 ft. of coal-bearing rocks called Middle coal group. Named for Twentymile Park, about 10 mi. NW. of Yampa.

E. T. Hancock, 1925 (U. S. G. S. Bull. 757). *Twentymile ss.* is here treated as a memb. of Williams Fork fm. (of Mesaverde group) in Axial and Monument Butte quads.

M. R. Campbell, 1931 (Tentative correlation of named geologic units of Colo., compiled by M. G. Wilmarth, U. S. G. S. separate chart). *Twentymile ss.* is elevated to rank of a fm. of Mesaverde group in Yampa coal field, where it underlies Holderness fm. and overlies Mount Harris fm.

Twentymile coal group. (In Mesaverde group.)

Name locally applied to the group of coal-bearing strata overlying Twentymile ss. memb. of Williams Fork fm. to N. of Axial Basin, NW. Colo.

Twiggs clay member (of Barnwell formation).

Eocene (upper): Eastern Georgia.

C. W. Cooke and H. K. Shearer, 1917 and 1918 (Ga. Geol. Surv. Bull. 31, pp. 14, 158–173, 1917; U. S. G. S. P. P. 120C, pp. 51–56, 1918). *Twiggs clay memb.*—Extensive but not entirely continuous beds and lenses of clay, varying from porous and siliceous to calc., glauconitic, pyritiferous, carbonaceous, or lignitic. Max. thickness 100 ft. *Basal memb. of Barnwell fm.* (of Jackson age) in most of its area, but near Savannah River it tongues out and older strata of the Barnwell (*Ostrea georgiana* zone) underlie the Twiggs memb. Replaces "Congaree" clay memb., which was originally included in McBean fm., of Claiborne age, and supposed to be=Congaree shales of Sloan. The latter, however, are now known to be much older than Twiggs clay.

Named for exposures in Twiggs Co. Typically seen near Pikes Peak station, on Macon, Dublin, and Savannah R. R.

Twilight granite.

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Twilight granite.*—Light grayish-pink gneissoid granite. Intrudes the Archean schists in this quad. and in Engineer Mtn quad. Composes Twilight Peak, in Needle Mtns quad. Does not intrude the Algonkian rocks.

Was assigned to "Algonkian" by E. S. Larsen in U. S. G. S. Bull. 843, 1933. The terms "Algonkian system" and "Archean system" were discarded by U. S. Geol. Survey in 1934. On 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

Twin Buttes member (of Bridger formation).

Eocene: Southwestern Wyoming.

H. E. Wood, 2d, 1934. (See under *Blacks Fork memb. of Bridger fm.*)

Twin Creek limestone.

Upper Jurassic: Southwestern Wyoming and southeastern Idaho.

A. C. Veatch, 1907 (U. S. G. S. P. P. 56, pp. 56+, chart opp. p. 50, map, etc.). *Twin Creek fm.*—Black and gray calc. shales and thin-bedded shaly lss. with occasional beds of yellow ss. Thickness in SW. Wyo. 3,500 to 3,800 ft. Abundant marine Jurassic fauna [listed]. Conformably underlies Beckwith fm. and conformably overlies Nugget fm. Named for excellent exposures on Twin Creek, btw. Sage and Fossil, SW. Wyo.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, p 3). Typical Twin Creek ls. of SW. Wyo. is considered=Carmel fm.

Twin Lakes quartz monzonite porphyry.

Tertiary: Central Colorado (Chaffee and Lake Counties).

J. V. Howell, 1919 (Colo. Geol. Surv. Bull. 17). *Twin Lakes quartz monzonite porphyry.*—A fresh coarse-grained light-gray monzonite carrying large euhedral orthoclase crystals. Found on both sides of valley of Lake Creek below Everett and in vicinity of Twin Lakes, Lake Co. ["Probably late Paleozoic" on map and on p. 33; "tentatively assigned to Mesozoic and correlated with Mesozoic intrusions elsewhere" on p. 51.]

J. T. Stark and F. F. Barnes, 1935 (Colo. Sci. Soc. Proc., vol. 13, No. 8, map). *Twin Lakes porphyry* assigned to Tert.

Twin Lakes andesites.

Age (?) : Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 21, No. 8, pp. 214–376, map). *Twin Lakes andesites.*—Black porphyritic quartz-bearing andesites, 1,000± ft. thick. Believed to have been poured out at about same time as Juniper andesites and before Flatiron andesites. [Mapped over large area surrounding Twin Lakes.]

Twin River formation.

Oligocene: Northwestern Washington.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52, pp. 579, 584, 604). *Twin River fm.*—Soft clay shales with occasional thin beds of ss. that wash out on the beach as flags. Thickness 2,000 ft. Occurs on N. coast of Wash. Younger than Seattle fm. Is=upper part of Astoria (Olig.).

B. L. Clark and R. Arnold, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 303–308). C. E. Weaver has apparently shown (Calif. Acad. Sci. Proc., 4th ser., vol. 6, No. 3, 1916, pp. 41–52) that the beds forming Twin Creek fm. are part of Arnold and Hannibal's Seattle fm. (*Acila gettysburgensis* zone), and they are here included in Seattle fm.

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2, pp. 245, 261–264). [See 1925 entry under *Blakeley fm.*]

Twisp physiographic stage.

Pleistocene: Central Washington (Cascade Range).

B. Willis, 1903 (U. S. G. S. P. P. 19). Interglacial. Type loc., canyon of the Twisp, Methow quad.

Two Medicine formation. (Of Montana group.)

Upper Cretaceous: Northwestern Montana (Blackfeet Indian Reservation).

E. Stebinger, 1914 (U. S. G. S. P. P. 90, pp. 62–68). *Two Medicine fm.*—Gray to greenish-gray clay and soft irregular ss., which is most abundant in lower 250 ft.; in places thin beds of red clay and nodular ls. Thickness 1,950 ft. An abundant reptilian fauna of Judith River types; at many horizons a fresh-water fauna. Overlies Virgelle ss. and underlies Bearpaw sh. Corresponds to Judith River, Claggett, and upper part of Eagle of central Mont. Exposed, together with underlying and overlying fms., on Two Medicine River btw. its mouth and Family post office.

Does not extend E. as far as Sweetgrass Hills, where a different rock classification is now used.

Twomile limestone. (In Conemaugh formation.)

Pennsylvanian: Southern West Virginia.

I. C. White, 1885 (The Virginias, vol. 6, pp. 8, 9). *Twomile ls.*—Dark-gray, sometimes earthy ls., 5 ft. thick. Occupies same relative position as marine Green Crinoidal ls. [Ames ls.] of northern W. Va., Ohio, and Pa., but appears to be of fresh-water origin. Like the Green Crinoidal ls. it is underlain by 25 to 30 ft. of dark-red marly sh. containing iron-ore nodules. Named for development on Twomile Run, below Charleston, Kanawha Co.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2). There can be no doubt the *Two Mile lss.* represent horizon of Ames or Green Crinoidal bed, though they contain only fresh-water fossils. Consists of an upper ls. 1 ft. 8 in. thick and a lower ls. 1 ft. 4 in. thick, the two separated by 6 ft. of gray sh. [Later W. Va. repts confirm this correlation.]

Tybo shale.

Cambrian: Central Nevada (Tybo district).

H. G. Ferguson, 1933 (Nev. Univ. Bull., vol. 27, No. 3, pp. 13–25). *Tybo sh.*—Dominantly fissile olive-gray to dark sh.; near top thin beds of ls. and calc. sl. with concretions of dense gray ls. Thickness 1,600± ft. Grades into overlying Hales ls. (Upper? Camb.) and into underlying Swarbrick fm. No fossils. Exposed in Tybo Canyon, near camp of Tybo.

Tye granite.

Jurassic: Central Washington (Skykomish Basin).

W. S. Smith, 1915 (School of Mines Quart., vol. 36, p. 157) and 1916 (Jour. Geol., vol. 24, p. 560). *Tye granite* (also *Tye soda granite*). Jurassic. Named for Tye River.

Tye formation. (In Clear Fork group.)

Permian: Central and central northern Texas.

W. E. Wrather, 1917 (SW. Ass. Pet. Geol. Bull. 1, pl. opp. p. 96). *Tye fm.*—Soft red clays with thin unimportant sss. in upper part. Thickness 340 ft. Is basal part of Clear Fork beds. Underlies Bullwagon dol. and overlies Wichita beds.

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, p. 47). *Vale fm.*—Red sh., some of it quite sandy, extending from top of Ferguson's Ford section to base of section at Smith place, on Bull Hollow. Thickness 154 ft. in Runnels Co.; Wrather gives thickness of 340 ft. in Taylor Co. Replaces *Tye fm.* of Wrather, which is preoccupied by an igneous fm. and also conflicts with Tyee fm. of Pacific coast. Basal div. of Clear Fork stage. Overlies Arroyo fm., of Wichita stage. Named for old post office of Vale, on Ballinger-Maverick road, on E. side of Valley Creek, Runnels Co.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 176). *Tye fm.* is preoccupied and is discarded for *Vale fm.*

Probably named for Tye, Taylor Co.

Tyee sandstone.

Eocene: Southwestern and northwestern Oregon (as far north as Tillamook County).

J. S. Diller, 1898 (U. S. G. S. Roseburg folio, No. 49). *Tyee ss.*—Massive ss. with occasional shales. Thickness 1,000 ft. in Roseburg quad. Differs from underlying Umpqua fm. in sss. being heavier-bedded and containing more conspicuous mica scales. Eocene fossils. Forms prominent escarpment from Tyee Mtn to Camas Valley.

C. W. Washburne, 1914 (U. S. G. S. Bull. 590). *Tyee ss.* (upper Eo.) is 2,000 ft. thick. Extends from type loc., in Douglas Co., southward to Rogue River Mtns and northward 120 mi. into Tillamook Co.

Harrison & Eaton (firm), 1920 (Min. Res. Oreg., vol. 3, No. 1, pp. 6–7), gave thicknesses of Tyee ss. as 2,500 ft. in Roseburg quad., 5,000+ ft. at Florence, Lane Co., and 4,000+ at Newport, Lincoln Co., and placed it below Coaledo fm., but stated that Tyee of Florence and Newport doubtless includes same horizon as Coaledo of Coos Bay.

W. D. Smith, 1924 (Econ. Geol., vol. 19, p. 458), published same statements as Harrison & Eaton regarding thickness and placed Coaledo above Tyee.

H. G. Schenck, 1928 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 1, p. 24). On basis of superposition the Tyee is to be regarded as=Coaledo fm., of Tejon age. However, characteristic Meganos fossils have been collected from typical Tyee ss. from places other than type loc. of Tyee, an obvious discrepancy that has not yet been explained.

Tyee porphyrite.

Jurassic: British Columbia.

C. H. Clapp and H. C. Cooke, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 25).

Tyende sandstone.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 66, No. 1, pp. 71–72). *Tyende ss.* is introduced as a name for "upper LaPlata" of SW. Colo. and Ariz. Named for Tyende Arroyo, a tributary of Rio San Juan, passing by north point of Black Mesa, near Kayenta settlement. In Ariz. this ss. is variously included under such titles as Navajo ss. (preoccupied), Kayenta fm. (which includes very much more), and Lohali ss. (preoccupied). Overlies Montezuma shales (middle LaPlata shaly marine strata).

Tygee sandstone. (In Gannett group.)

Cretaceous (?): Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98G, pp. 76, 83). *Tygee ss.*—Gray to buff, even-grained, and without greenish or reddish tinges of some of higher sss. Top is not exposed, and in much of region this ss., with part or all of underlying Draney ls., was eroded before deposition of Wayan fm. At type loc. about 100 ft. of this ss. is exposed. Named for Tygee Creek, E. of which, in T. 8 S., R. 46 E., the fm. is well exposed in association with Draney ls. Is top fm. of Gannett group.

Tygee erosion cycle.

Name applied by G. R. Mansfield to a Miocene erosion cycle in SE. Idaho. (See Jour. Geol., vol. 32, 1924, p. 485.)

Tyger zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 7, 12). *Tyger zone* (*Archean*) is not conspicuously separated from Anderson-Spartanburg zone, except that in addition to Carolina gneiss series it comprises the very prominent development of Roan gneiss or hornblende series. This zone comprises an irregularly shaped tract bounded on W. by Saluda zone, along a line extending southwesterly from Gap Creek toward Pendleton and thence to Tugaloo River near point where intersected by 83° long.; on N. it is limited by N. C. line; on SE. by a meandering line from a point of N. C. State line (near 82° long.) to Savannah River near Brown's Ferry; the latter river and Tugaloo River complete the bdy to 83° long. It is constituted chiefly of Carolina gneiss series with a prominent development of Roan gneiss series and some Table Rock granite. It comprises granite gneiss exposed in successive belts (coarse porphyritic prominent); granite; feldspar; porphyry; granitite; gneissoid slates; mica slates and schists; hornblende schists; graphite schists; dikes of granite, pegmatite, diabase, and diorite. Many of the rocks are garnetiferous.

Named for exposures on Tyger River.

Tyler slate.

Pre-Cambrian (upper Huronian): Northwestern Michigan and northwestern Wisconsin (Penokee-Gogebic district).

C. R. Van Hise, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, p. 338). *Tyler sl.*—The upper sl. fm. of Upper Huronian in Penokee-Gogebic dist. Named for exposures on Tylers Fork. Overlies Ironwood fm. and uncon. underlies the great basal gabbro of the Keweenawan.

Later repts give thickness 7,000 to 11,000+ ft.

Tyler red beds. (In Monongahela formation.)

Pennsylvanian: Northern West Virginia and eastern Ohio.

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, pp. 30, 44). *Tyler red beds* (also *Tyler reds*).—A widespread deposit of red beds in Ohio, 14 to 52 ft. thick; lies 18 to 46 ft. above Upper Sewickley coal, and underlies Ritchie red beds, with which it is in places continuous. Is thicker in Tyler, Ritchie, and Wood Counties, W. Va.

Tyler sandstone member (of Quadrant formation).

Pennsylvanian (?): Central southern Montana (Big Snowy Mountains, Fergus County).

O. W. Freeman, 1922 (Eng. and Min. Jour.-Press, vol. 113, No. 19, p. 827). *Tyler ss.*—White to red sss. interbedded with varicolored sandy sh. Thickness 300 ft. Beautifully exposed at E. end of Middle Bench, 1 mi. W. of post office of Tyler. On Alaska Bench is overlain by Alaska Bench ls. [according to text, but in generalized section of Quadrant fm. of central Mont. he showed 100 ft. of gray sh. btw. Alaska Bench ls. and Tyler ss.]. Rests on Otter shales, also a memb. of Quadrant fm.

H. W. Scott, 1935 (Jour. Geol., vol. 43, pp. 1028–1029). O. W. Freeman (1922) grouped, under name *Tyler sand*, the ss. beds that occur in top part of Heath fm. on NE. flank of Big Snowy Mtns. The Tyler sands occur at same strat. zone as Van Dusen sand on SE. flank of Big Snowy Mtns. They are neither a lithologic, paleontologic, or mappable unit over broad areas, and at present must be considered a memb. of Heath fm.

Tyler greensand member (of Sparta sand).

Eocene (middle): Eastern Texas.

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, pp. 1359–1360). In west-central and SW. Smith Co. there is at least 130 ft. of Sparta sand exposed. In this low area, ranging in elev. from 70 to 120 ft. above top of the Weches, is a sandy glauconitic zone which has been termed *Tyler member of the Sparta*. It is well exposed throughout city of Tyler, and W. and NW. of Swan, Smith Co., where it consists of approx. 50 ft. of very sandy, partly cross-bedded glauconite, with a few clay lumps. Weathers rapidly. No fossils yet found. Some geologists place *Tyler greensand* in Crockett fm., but writers believe it is a local memb. of the Sparta, because no similar bed has been seen to S. at normal Sparta-Crockett contact, and because the interval in Smith Co. btw. the Weches and the Tyler memb. of Sparta is not great enough to represent entire Sparta fm.

Tymochtee shale.

Silurian (Cayugan): Northern central Ohio and southeastern Michigan (?).

N. H. Winchell, 1873 (Ohio Geol. Surv. vol. 1, p. 633). *Tymochtee sl.*—Homogeneous tough thin slaty beds, 24 ft. thick, chiefly of drab color, sometimes containing so much bituminous matter as to appear like the great Black Sl. Occurs in midst of the Waterlime.

E. Orton, 1890 (Ohio Geol. Surv., 3d ser., 1st Ann. Rept.). *Tymochtee sl.*—Dark-blue shaly ls. Lies below middle of Lower Helderberg ls. or Waterlime and 100 to 200 ft. higher than Hillsboro ss. and lower than Sylvania ss.

C. S. Prosser, 1903 (Jour. Geol., vol. 11, p. 521). The limits of "Tymochtee sl." were not definitely fixed by Winchell, and further investigation may render it inadvisable to retain this name. Prof. Winchell, however, used it for the thin-bedded Waterlime in several northwestern counties and compared the beds of this character in Wood Co. with it.

C. R. Stauffer, 1908 (Ohio Nat., vol. 8, pp. 271–276), applied name *Tymochtee fm.* to 20± ft. of rather thin-bedded compact drab ls. underlying Sylvania ss. in Lucas Co., Ohio.

A. C. Lane, C. S. Prosser, W. H. Sherzer, and A. W. Grabau, 1909 (Geol. Soc. Am. Bull., vol. 19, pp. 553–556), divided "Lower Monroe or Bass Islands series" into (descending) Raisin River dolomites, 200 ft.; Put-in-Bay dolomites, 100 ft.; *Tymochtee shales and lss.;* and Greenfield dol., 100+ ft. They described the Tymochtee as something over 100 ft. thick in Wyandot Co., Ohio, "but its relation to overlying and underlying fm. is unknown. Its fauna likewise is unknown, and the fm. must be considered a tentative division of Lower Monroe. It is not impossible it represents in part one or more members recognized elsewhere."

W. H. Sherzer and A. W. Grabau, 1910 (Mich. Geol. and Biol. Surv. Pub. 2, geol. ser. 1, pp. 20, 32). *Tymochtee shales.*—Thickness 0 to 90 ft. Strat. position of *Tymochtee sl.* is unsettled. That it rests above Greenfield dol. seems certain from its geographic position, but whether it lies below or above Put-in-Bay dol. has not been determined. There is some reason for believing it lies below that fm., filling gap btw. Greenfield and Put-in-Bay.

C. S. Prosser, 1915 (Outlines of field trips in geol. for central Ohio). Pre-Sylvania part of Monroe fm. is divided into (descending) Raisin River dol., Put-in-Bay dol., *Tymochtee sh.*, and Greenfield dol.

J. E. Carman, 1927 (Jour. Geol., vol. 35, p. 488). Lower Monroe or Bass Islands fm. divided into (descending): Raisin River dol., 0 to 50 ft.; Put-in-Bay dol., 50± ft.; *Tymochtee shaly dol.*, 150± ft.; and Greenfield dol., 75 to 100 ft. The Tymochtee Creek exposure consists of gray to drab thin-bedded dol., with partings or thin layers of carbonaceous argill. material. Writer is convinced the Tymochtee should be recognized as a distinct div., even if its limits are not now definitely known. It has a meager fauna.

Named for exposures on Tymochtee Creek at Crawford, Wyandot Co., Ohio.

Tyner formation.

Upper and Middle Ordovician: Eastern Oklahoma (Tahlequah quadrangle).

J. A. Taff, 1905 (U. S. G. S. Tahlequah folio, No. 122). *Tyner fm.*—Brown ss. and thin siliceous ls. and chert above; brown thin-bedded and flaggy ss. and greenish sh. below. Thickness 60 to 100 ft. Overlies Burgen ss. and uncon. underlies Chattanooga fm. Named for exposures along Tyner Creek, near N. border of

Tahlequah quad. Occurs in but 3 places in quad., all in N. part. Has yielded fossils of Lorraine [Upper Ord.] and Trenton or Black River [Middle Ord.] age. In S. part of quad. the Chattanooga is underlain by St. Clair marble (of Niagaran, Sil., age).

J. P. Boyle, 1929 (Okla. Geol. Surv. Bull. 40KK). *Tyner sh.* [restricted].—In Okfuskee Co. is 50 to 150 ft. thick and directly overlies Burgen ls. (30 to 70 ft. thick), which rests on Burgen ss. (20 to 60 ft. thick). Is present over entire county. Directly underlies Wilcox ss. Top consists of a light-green fine-grained sand. Sandy green sh. occurs near base.

W. F. Cloud, 1930 (Okla. Geol. Surv. Bull. 40RR). In Tulsa Co. Tyner fm. [restricted] (40 to 200+ ft. thick) underlies Wilcox ss. (0 to 50 ft. thick) and overlies Burgen ss. (10 to 75 ft. thick).

I. H. Cram, 1930 (Okla. Geol. Surv. Bull. 40QQ). Tyner fm. of Taff in Cherokee and Adair Counties is here divided into (descending): Fernvale ls. (Upper Ord., Richmond) 0 to 10 ft.; Fite ls. (early Richmond), 0 to 8 ft.; *Tyner fm. restricted*, 0 to 69+ ft. The Fernvale is uncon. on Fite ls. and Fite ls. is uncon. on Tyner fm. restricted, but without discordance in dip. *Tyner fm. restricted* rests on Burgen ss., its relations to which are uncertain, as contact is seldom exposed. Fossils from upper part identified by E. O. Ulrich as Black River. Fossils from lower part suggest Chazy [Lower Ord.].

J. P. Boyle, 1930 (Okla. Geol. Surv. Bull. 40XX). *Tyner fm.* not exposed in Hughes Co., but is present everywhere beneath Wilcox sand and above Burgen ls. (30 to 70 ft. thick), which rests on Burgen ss.

The U. S. Geol. Survey has not had occasion to consider, for its publications, the restricted definitions of Tyner fm.

Tyonek formation.

Eocene: Southern Alaska (Cook Inlet region).

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 171–172, 184). *Tyonek beds.*—Clay alternating with sand and ss.; peaty brown lignite abundant. Believed to be later than Kenai series, and provisionally referred to Neocene. Uncon. underlies Cook Inlet gravels (Pleist.). Exposed along shore of Cook Inlet SW. of Tyonek.

These beds are now believed to be same as Kenai fm., but are across the bay from Kenai Peninsula.

†Tyre sandstone.

Misprint for *Tyee ss.* on p. 399 of U. S. G. S. Bull. 191.

†Tyringham gneiss.

Pre-Cambrian: Western Massachusetts.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902). *Tyringham gneiss*, Algonkian, believed to be older than Becket gneiss.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 18). [*Tyringham stretched biotite gneiss* shown as older than Becket and Washington gneisses and younger than East Lee gneiss.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 150, 155). "Tyringham gneiss" is a widely distributed facies of Becket granite gneiss, Archean.

Named for occurrence in Tyringham Twp, in which it covers a large area.

Tyrone limestone.

Middle Ordovician: Central Kentucky.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 9, 14). *Tyrone substage.*—Compact ls., light and dove-colored, with conchoidal fracture, interbedded with some clay and clay sh.; 90 ft. thick; characterized by *Helicotoma verticalis*. Top fm. of Highbridge stage. Is "Birdseye ls" of Linney. Underlies Lexington stage and overlies Oregon bed of Highbridge stage.

A. F. Foerste, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 377–385). It is proposed to remove *Tyrone ls.* from Highbridge ls., because the Tyrone is of Black River age and rest of the Highbridge of Chazy age.

Named for Tyrone, Anderson Co.

†Tyrone conglomerate.

Upper Ordovician: Central Pennsylvania (Blair County).

A. W. Grabau, 1909 (Sci., n. s., vol. 29, pp. 353, 355). *Tyrone cgl.*—Basal white beds; generally called "Oneida;" of continental origin. Underlie Juniata red beds and overlie Eden fm. Typically shown at Tyrone [Blair Co.], Pa.

A. W. Grabau, 1909 (Jour. Geol., vol. 17, p. 235). "Tyrone" preoccupied. Replaced by Bald Eagle cgl.

U. S. Geol. Survey uses *Oswego ss.*, instead of "Tyrone cgl." or "Bald Eagle cgl."

Uffington shale member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania and northern West Virginia.

I. C. White, 1903 (W. Va. Geol. Surv. vol. 2, p. 323). *Uffington sh.*—Dark sandy fossiliferous sh., 0 to 40 ft. thick, underlying Lower Mahoning ss. and overlying Upper Freeport coal. Exposed at Uffington, Monongalia Co., W. Va. Contains plants and marine fossils. In some areas replaced by ss. Is basal memb. of Conemaugh series.

W. A. Price, 1917 (Sci., n. s., vol. 46, pp. 540-542). *Uffington sh.* may then be redefined as a plant-bearing sh., frequently sandy in lower portion, of *nonmarine origin*, occupying in places the interval btw. Upper Freeport coal and Mahoning ss. Uncon. overlain by Mahoning ss. Max. reported thickness 40 ft. Absent in many places. Fossil plants abundant. At Uffington is 30 ft. thick. "Stevenson's identification of Uffington sh. as marine was due to miscorrelation with the marine Brush Creek sh."

Uinta formation.

Eocene (upper): Northeastern Utah (Uinta Basin).

O. C. Marsh, 1871 (Am. Jour. Sci., 3d, vol. 1, p. 196). The lake basin lying S. of Uintah Mtns is probably distinct from Green River Tert. basin lying N. of the mtns, and it may appropriately be called Uintah Basin. The fossils from the two basins, however, indicate synchronism of the deposits, although there is great difference in elevation.

T. B. Comstock, 1874 (Rept. reconn. NW. Wyo. made in summer of 1873 by W. A. Jones, 43d Cong., 1st sess., Ex. Doc. 285, chart opp. p. 103). *Uintah Basin beds* (*Upper Eocene*)—upper part of Bridger group of western Wyo., which overlies Green River beds. [No description of *Uintah Basin beds* or of Uintah Basin, but on p. 126 he says Prof. Marsh discovered evidence of a synchronous basin (to Green River basin) S. of Uinta Mtns.]

O. C. Marsh, 1875 (Am. Jour. Sci., 3d, vol. 9, p. 50). The deposits of Uintah Basin are of very great thickness, and fauna is essentially same as that of Green River Basin, N. of Uintah Mtns. These two lakes were contemp. for a long period at least, but there is evidence the southern lake (Uintah) continued for some time after the northern one (Green River) dried up.

C. King, 1876 (U. S. Geol. Expl. 40th Par., Atlas, map 2), showed following superposition of strata in NE. Utah (descending): Wyoming cgl. (Pliocene), *Uinta* (*Eocene*), Bridger (Eocene), Green River (Eocene), and Vermilion Creek (Eocene). *Uinta* as here used apparently included Browns Park fm. Advance copies of this map were distributed in 1875.

S. F. Emmons, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, pp. 307-320). *Uinta Eocene* (*middle and upper Eocene*) is later than Bridger, according to Marsh, and older than Wyoming cgl. [Apparently included Browns Park fm.]

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 405, 531-544). *Uinta group* (*latest Eocene*).—Lower members chiefly rough, gritty cgl., passing up into finer-grained sss. and at certain points developing creamy calc. beds. Is a shallow-water deposit, in all probability the sediment of a very restricted post-Bridger lake, wholly S. of Uinta Range, and the last memb. of that remarkable series of Eocene lakes whose great deposits are piled uncon. over one another in the region. To this group alone should *Uinta* be applied. As provisionally used on 40th Par. Atlas *Uinta group* was a term stretched for convenience to cover all Tertiaries S. of Uinta Range, of whose true subdivisions we were ignorant. Thickness 500 (?) ft.; 400 ft. only exposed. Marsh and Emmons by accident gave same name to the group. Vertebrates found in the continuation of these beds in White River Valley belong to a period higher than Bridger series. They even contain some forms closely approaching lowest Mio. types. Believed to be uncon. with all earlier Eo. groups, including Bridger. [Apparently included Browns Park fm.]

C. A. White, 1878 (U. S. Geol. and Geog. Surv. Terr. 10th Ann. Rept., pp. 20-21, 37-39). Although Mr. King has not upon his map recognized the deposits called "Brown's Park group" by Prof. Powell as separate from Green River group N. of an E.-W. line that may be made to compass through S. base of great Uinta fold, a careful comparison of deposits on both sides of Uinta Mtns has left no doubt in my mind of their identity. I therefore adopt Mr. King's name "Uinta group" instead of Prof. Powell's name "Brown's Park group."

O. C. Marsh, 1886 (U. S. G. S. Mon. 10, pp. 5-10). *Diplacodon beds*, the uppermost Eo., or the *Uinta group*, is especially well characterized by large mammals of genus *Diplacodon*. It overlies *Dinoceras* beds or Bridger series.

O. A. Peterson, 1895 (Am. Mus. Nat. Hist. Bull., vol. 7, pp. 72-75), divided the beds overlying Green River fm. in Uinta Basin, Utah, as follows (descending): (1) C, true Uinta (*Diplacodon elatus* beds), 600 ft.; B, 350 to 400 ft. of coarse brown sss. with alternating clays, transition from Bridger to Uinta; A, light-reddish stratum, 20 to 40 ft., underlain by 500 ft. of hard brown sss., Bridger fossils.

According to H. F. Osborn (U. S. G. S. Bull. 361, 1909, U. S. G. S. Mon. 55, 1929, and earlier publications as far back as 1895) the beds in Uinta Basin that are younger than Bridger fm. belong to the latest Eo. *Diplacodon* zone, and are 600 ft. thick. These latest Eo. beds have not been recognized in adjacent areas, and the U. S. Geol. Surv. therefore restricts *Uinta fm.* to its typical area. The Browns Park fm., which occurs to NE., is now considered much younger than Uinta fm., and to be of either late Mio. or early Plio. age. W. B. Scott has classified Uinta fm. as Olig., but its Eo. age seems now to be generally accepted. (For further information see explanation at end of *Bridger fm.* and also see under *Blacks Fork memb. of Bridger fm.*)

†Uinta quartzite.

†Uinta sandstone.

Pre-Cambrian: Northeastern Utah (Uinta Mountains) and northwestern Colorado.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 42, 61, 70, 138, 139, 141-145). *Uinta group* (also *Uinta ss.*).—Massive, thinly bedded sss.; some intercalated aren. shales; all of group is very ferruginous; some portions metamorphosed, becoming a qtzite. Thickness 12,500+ ft. Uncon. overlies Red Creek qtzite (white) and uncon. underlies Lodore group (shales and sss.). The Uinta Mtns are composed chiefly of this ss. About 10,000 ft. of it was deposited against the old qtzite headland before it was buried by the upper members of the Uinta group. Provisionally classified as Dev.

H. S. Gale, 1910 (U. S. G. S. Bull. 415, p. 47). *"Uinta" qtzite.*—The oldest sed. rocks of Uinta Mtns exposed in territory adjacent to the coal fields are the red and white qtzites that form so prominent a feature throughout entire length of that mtn. range. The "Uinta" qtzite forms crest and core of main axis of Uinta Mtns and extends E. into Colo. nearly as far as junction of Little Snake and Yampa Rivers. The fm. in Uinta Mtns is largely heavy-bedded ss. and qtzite with intervening bodies of sh. and some massive cgl. beds. The color characteristic throughout Uinta Range is a dark brick red or reddish brown, but some beds of light-colored or white ss. and qtzite occur. At places the rock is banded or of a gneissoid structure. Thickness is said to exceed 12,000 ft., although base of fm. is nowhere exposed. Is oldest fm. in Uinta Range. No fossils have been reported, but assigned to Algonkian (?) on basis of strat. position and suggested correlation with rocks in Wasatch Mtns. May include considerable Camb.

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24). Uinta qtzite of Gale's Bull. 415 included Powell's Uinta group and Red Creek qtzite, both of which are considered pre-Camb.

The name *Uinta* is preoccupied by the latest Eocene fm. of Utah, and is therefore not available as a name for the old red sss. and qtzites that form Uinta Mtns. In the past these rocks have been tentatively assigned to different systems, and have even been miscorrelated with Weber qtzite (Penn.). Most workers have regarded them as early Camb. or pre-Camb., or both. Because of great uncon. at their base they were on the 1935

Colo. geol. map definitely assigned to pre-Camb., and the name *Uinta Mtn group* was adopted to replace the preoccupied name "Uinta quartzite," which has also been called "Uinta ss." and "Uinta group."

†Uinta group.

Pre-Cambrian: Northeastern Utah and northwestern Colo.

See under †*Uinta ss.*

Replaced by *Uinta Mtn group.* (See also *Emmons Peak qtzite.*)

†Uinta glacial epoch.

A name applied by W. W. Atwood and K. F. Mather (Sci., n. s., vol. 35, p. 315, 1912; Jour. Geol., vol. 20, p. 388, 1912; and G. S. A. Bull., vol. 23, p. 732, 1912) to the time during which a till sheet of Wisconsin age was laid down in San Juan Mtns of SW. Colo. The name was derived from Uinta Mtns, Utah. Atwood and Mather later replaced the name with *Wisconsin glacial stage*, being satisfied of the correlation with the Wisconsin deposits to E.

†Uinta moraine.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1912 (Jour. Geol., vol. 20, pp. 392–409), mapped and described "Uinta moraine" and "Uinta outwash" in San Juan Mtns of SW. Colo., correlating the deposits with similar glacial deposits in NE. Utah, all of which are now considered by glacial specialists as belonging to Wisconsin stage of glaciation, and which are therefore now designated as *Wisconsin till* and *Wisconsin outwash*.

†Uintah Basin beds.

See second entry under *Uinta fm.* (Eocene), NE. Utah.

Uinta Mountain group.

Pre-Cambrian: Northwestern Colorado and northeastern Utah.

T. S. Lovering and others, 1935 (geol. map of Colo.), adopted *Uinta Mountain group* as the geographic name to replace the preoccupied names "Uinta ss.," "Uinta group," and "Uinta qtzite," and, because of great uncon. at base of the group, they assigned the rocks definitely to pre-Camb. This name was also used by W. H. Bradley in U. S. G. S. P. P. 185–I, 1936, to replace "Uinta qtzite" (preoccupied).

Uintan series.

A term applied by C. [R.] Keyes to part of the Lower Camb. series of Nev. and Utah, including Pioche sh. and Prospect Mtn qtzite.

†Uintatherium beds.

A paleontologic name that has been applied to middle part (*Uintatherium* zone) of Bridger fm. of western Wyo.

Ulm coal group. (In Wasatch formation.)

Eocene: Eastern Wyoming and southeastern Montana.

J. A. Taff, 1909 (U. S. G. S. Bull. 341, pp. 123–150). Eo. rocks of Sheridan coal field, Wyo., divided into (descending) Ulm coal group, Intermediate coal group [Sentinel Butte sh. memb.], and Tongue River coal group. Two workable coal beds of considerable areal extent occur 1,100 to 1,200 ft. above top of Tongue River coal group. Over larger part of Sheridan field these upper coal beds have been removed by erosion. Their remnants are found in south-central part of area mapped, near top of watershed btw. Tongue River and Clear Creek. These two coal beds are termed for convenience the *Ulm coal group*, because of their best known occurrence in vicinity of Ulm, on Burlington R. R. They are separated by about 100 ft. of sh. and soft ss. similar to the ss. and sh. lying below.

W. T. Thom, Jr., and C. E. Dobbin, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 484, 496). *Wasatch fm.* (*Ulm coal group*).—In southern Mont. and in Powder River Basin, Wyo., the Sentinel Butte sh. (Intermediate coal group) is conformably overlain by yellow coal-bearing strata belonging to *Ulm coal group*, which is correlated with

Wasatch beds of Pumpkin Buttes, Wyo. It is believed by writers that strata representative of both Sentinel Butte sh. and Ulm coal group may be included in Fort Union as mapped in Red Lodge coal field, and it is possible that one or both of them may be represented in beds now classed as Fort Union in Bull and Crazy Mtns. [This definition of Ulm coal group appears to include more than Taff included, because the two coal beds referred to are shown in diagram on p. 484 as lying a considerable distance above Sentinel Butte sh. memb.]

R. L. Nace, 1936 (Wyo. Geol. Surv. Bull. 26, p. 104), applied *Ulm fm.* to the rocks which he stated were same as Ulm coal group of Taff, 1909.

Ulm formation.

See 1936 entry under *Ulm coal group.*

†Ulsterian group.

Middle Devonian: New York.

J. M. Clarke and C. Schuchert, 1899 (Sci. n. s., vol. 10, pp. 874–878). *Ulsterian period or group* includes Onondaga ls., Schoharie grit, and Esopus grit, all of which outcrop in Ulster Co.

The 1901 geol. map of N. Y., by F. J. H. Merrill, excluded Esopus grit from Ulsterian group and placed it in Oriskany group, as did Schuchert in 1903 (Am. Geol.), Grabau in 1906, Chadwick in 1908, Schuchert in 1910, Ulrich in 1911, and Hartnagel in 1912. Although all geologists did not immediately transfer the Esopus to Oriskany group, it is now uniformly included in that group.

The N. Y. State Survey still divides the Middle Devonian series into *Erian stage or epoch* (which covers Hamilton group) and *Ulsterian stage or epoch* (in which it includes Onondaga ls. and underlying Schoharie grit). The U. S. Geol. Survey has not adopted either Erian or Ulsterian.

Ultima Thule gravel lentil (of Trinity formation).

Lower Cretaceous: Southwestern Arkansas.

H. D. Miser and A. H. Purdue, 1918 (U. S. G. S. Bull. 690B). *Ultima Thule gravel lentil of Trinity fm.*—Thickness 0 to 40 ft. Pebbles are less than 1 in. diam. Separated from underlying Dierks ls. lentil of the Trinity by variegated clays, and also separated from overlying De Queen ls. memb. of the Trinity by 70 to 600± ft. of variegated clays. Exposed near Ultima Thule, De Queen quad.

H. D. Miser, 1927. [See 1927 entry under *Pike gravel memb.*]

Ulupau tuff.

Pleistocene (late): Hawaii (Oahu Island).

C. K. Wentworth, 1926 (Bernice P. Bishop Mus. Bull. 30, pp. 85–90), described Ulupau Craters, including the tuff crater of Ulupau Head, and in several places used *Ulupau tuff*, also *tuff of Ulupau Head*, also *Ulupau alluvium*, but he mapped the tuff and the *tuff alluvium* without the geographic name. He also spoke of "*the principal Ulupau tuff.*"

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Ulupau tuff.*—Gray and brown tuff of Ulupau cone, which forms the tip of Mokapu Point. Included in lower part of Honolulu volcanic series [q. v.]. Assigned to late Pleist.

†Umbral series.

See *H. D. Rogers 1858* under †*Vespertine series* and under †*Seral series.*

†Umbral limestone.

A name applied in early repts of Pa. Geol. Survey to Loyalhanna ls. of present terminology.

Umfraville gabbro.

Pre-Cambrian: Ontario.

F. D. Adams and A. E. Barlow, 1910 (Canada Geol. Surv. Mem. 6, p. 149).

Umpqua formation.

Eocene: Southwestern Oregon (Roseburg and Riddle quadrangles and vicinity).

J. S. Diller, 1898 (U. S. G. S. Roseburg folio, No. 49). *Umpqua fm.*—Chiefly thin-bedded sss. and very thin-bedded shales with some cgls.; locally contains coal seams, also interstratified calc. siliceous beds, which, although of small extent, on account of their exceptional character are treated separately as Wilbur fm. (Wilbur tuff lentils). Contains Eo. fossils. Thickness 12,000± ft. Underlies Tyee ss. and uncon. overlies Myrtle fm. Of the igneous rocks diabase is associated almost exclusively with Umpqua fm. [Maps in this folio show Umpqua River flows through Umpqua fm.]

J. H. Smith, 1900 (Jour. Geol., vol. 8, pp. 462–463). *Umpqua fm.*, described by Diller in Roseburg folio, stretches far beyond Roseburg quad. and plays important role in make-up of whole country W. of Cascade Range.

R. E. Dickerson, 1914 (Calif. Acad. Sci. Proc., 4th ser., vol. 4, pp. 114–115). *Siphonalia sutterensis* zone is present in uppermost part of Umpqua fm. on Umpqua River near mouth of Little River.

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, and Jour. Geol., vol. 27). [See 1919 entry under *Arago group.*]

L. G. Hertlein and C. H. Crickmay, 1925 (Am. Phil. Soc. Proc., vol. 64, No. 2). [See 1925 entry under *Arago group.*] *Umpqua fm.* is well exposed near mouth of Little River at its junction with Umpqua River, near Roseburg, Oreg. Underlies Tyee ss. and uncon. overlies upturned and eroded edges of Myrtle fm. (Cret.).

J. S. Diller and G. F. Kay, 1924 (U. S. G. S. Riddle folio, No. 218). *Umpqua fm.*, chiefly yellowish sss. and shales, with some cgl. and Eo. marine fossils, is uncon. on Chico fm. (Upper Cret.).

F. G. Wells and A. C. Waters, 1934 (U. S. G. S. Bull. 850). The rocks mapped as diabase by Diller in Roseburg folio are basalt flows interstratified with sediments of Umpqua fm. Writers believe all of "diabase" is extrusive; Diller thought part of it was intrusive. In Black Butte-Elkhead area the Umpqua is uncon. overlain by beds here named *Calapooya fm.*

Umpqua group.

Eocene: Southwestern Oregon.

See under *Willamette group.*

Unadilla formation.

Upper Devonian: East-central New York.

C. S. Prosser, 1903 (Am. Geol., vol. 32, pp. 380–384). *Unadilla fm.* includes Ithaca and Sherburne members of Portage stage. Underlies Oneonta ss. and overlies Genesee sh. Named for Unadilla River below New Berlin village [Chenango Co.], where both members are present.

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 826, 829). *Unadilla fm.* was proposed by Prosser to include the practically indivisible Sherburne and "Ithaca" fms. in Unadilla Valley and to E. But since it is there impossible to separate the Sherburne and the underlying Genesee and upper Tully the base of Unadilla fm. must be redefined and placed above top of *fimbriata* zone of the Tully. Top of Prosser's Unadilla is at base of Oneonta ss. As thus defined the fm. can be easily recognized as far E. as Otego Valley, where *fimbriata* zone at top of the Tully is still well developed. East of this valley the name *Gilboa* must apply because of disappearance of *fimbriata* zone.

Uncas shale.

Permian: Central northern Oklahoma (Kay County).

D. W. Ohern and R. E. Garrett, 1912 (Okla. Geol. Surv. Bull. 16, p. 10). *Uncas sh.*—Largely more or less pure clay beds, of alternating red and lighter color, with, locally, about 10 ft. above base, 2 ft. of fossiliferous ls. which may represent Luta ls. of Kans. Thickness 50–54 ft. Underlies Herington ls. and overlies Winfield ls. Named for exposures in vicinity of Uncas, Kay Co.

Uncompahgre formation. (In Needle Mountains group.)

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Silverton folio, No. 120). *Uncompahgre fm.*—A complex of massive white or smoky qtzites and dark slates, with a few members in which those rocks alternated in thinner layers. Thickness 8,000+ ft. No fossils, but considered to be of Algonkian age. Uncon. underlies Ignacio qtzite (Camb.) and uncon. overlies schist and gneiss of probable Archean age. Well exposed in Uncompahgre Canyon, in Silverton and Ouray quads.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Uncompahgre fm.* in this quad. overlies a cgl. here named *Vallecito cgl.* These 2 fms. are here united into a group called *Needle Mtns group.*

For many years this fm. was classified as "Algonkian," but the terms "Algonkian system" and "Archean system" having been discarded by U. S. Geol. Survey the fm. is now classified as pre-Camb.

†Uncompahgre interglacial interval.

Pleistocene: Southwestern Colorado.

W. W. Atwood and K. F. Mather, 1912 (Jour. Geol., vol. 20, pp. 392–409), applied this name to interval preceding the Durango ("Bighorn") glacial stage and following the Cerro ("San Juan") glacial stage in SW. Colo. They stated: "This may not be in a strict sense an interglacial epoch but may include one or more glacial epochs as well." Later (U. S. G. S. P. P. 166, 1932) they discarded this preoccupied name and classified the post-Cerro and pre-Durango events in a different way, as including the deposition of Florida gravel followed by a period of uplift and erosion.

Underwood lava.

Tertiary (?): Southern Washington (Skamania County).

I. A. Williams, 1916 (Oreg. Bur. Mines and Geol., Min. Res. Oreg., vol. 2, No. 3, pp. 108, 115–117). *Underwood lava.*—Series of flows of dark-gray lava in vicinity of Underwood, which have come since the basalt was distorted by the folding of Cascades uplift. Underwood Mtn., and possibly other nearby hills to N. of it, was at least in part the source of these new-born lavas, which are younger by far than Columbia Gorge. Rest on Columbia River basalt. Not found in Oreg.

Unga conglomerate.

Miocene: Southwestern Alaska.

W. H. Dall and G. D. Harris, 1892 (U. S. G. S. Bull. 84, p. 234). *Unga cgl.*—Brown cgls. with *Sequoia*, occurring on Unga Island, Alaska. Rest conformably on coal-bearing Mio. beds. Are upper beds of Kenai group, of early Mio. or latest Eo. age. [Kenai fm. is now classified as Eo. and is restricted to its type region, Kenai Peninsula.]

Ungalik conglomerate.

Upper Cretaceous: Southwestern Alaska (Nulato-Norton Bay district, Lower Yukon River region).

P. S. Smith and H. M. Eakin, 1911 (U. S. G. S. Bull. 449, p. 55). *Ungalik cgl.*—Lowest Cret. sed. fm. in Norton Bay-Nulato region. Is a basal cgl. of marine origin. Exposed in steep-faced cliffs along Ungalik River and forms most of prominent range of hills btw. the river and the coastal plain from Bonanza Creek N. to 1± mi. below Camp A17. Is made up of rounded debris from the older fms., upon which it rests uncon. Conformably overlain by Shaktolik group. Most characteristic materials are variety of porphyritic rocks and abundant angular feldspar crystals in sandy matrix. Weathers red, from abundant iron content.

See also G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 395+), who applied *Melozi* to conformably overlying fm. (which he correlated with lower part of Shaktolik group), gave thickness of Ungalik cgl. as 3,000 ft., and showed it as uncon. on Paleozoic rocks.

See also U. S. G. S. P. P. 159, 1930.

Unibon shale.

Cretaceous (?): Puerto Rico.

D. R. Semmes, 1919 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 1, p. 74).

Unicoi formation.

Lower Cambrian: Southwestern Virginia, eastern Tennessee, and northwestern North Carolina.

M. R. Campbell, 1899 (U. S. G. S. Bristol folio, Va.-Tenn., No. 59, p. 3 and columnar section; name proposed by A. Keith). *Unicoi ss.*—Heavy bed of coarse feldspathic ss. or qtzite with exposed thickness of about 1,000 ft., but on its lower side bounded by a fault, so that full thickness cannot be determined. Underlies Hampton sh. Oldest fm. in area.

A. Keith, 1903 (U. S. G. S. Cranberry folio, Tenn.-N. C., No. 90, which describes an area lying E. of and not adjoining Unicoi Co., Tenn.). *Unicoi fm.*—A great series of sss. and qtzites with small interbedded shales and slates and much cgl. The sss. are light gray or white and frequently feldspathic. Very near base occur the cgl., arkose, and coarse ss. beds, and in center of fm. are layers of cross-bedded ss. A thin bed of amygdaloid is interstratified with the fm. in Iron Mtn. Interbedded shales are most frequent in upper third of fm. Thickness in Tenn. 2,000 to 2,200 ft.; in N. C. 1,500 to 2,500 ft. Underlies Hampton sh. and uncon. overlies pre-Camb. Named for Unicoi Co., Tenn., where it is prominently displayed.

A. Keith, 1907 (U. S. G. S. Roan Mtn folio, No. 151, which describes the rocks of Unicoi Co., Tenn., the type loc.). *Unicoi fm.* occupies areas in Holston and Iron Mtns E. of Elizabethton and in Unaka and Flattop Mtns. It is strongly developed along Nolichucky River in Unicoi Co., and is=Snowbird fm., Hiwassee sl., and Cochran cgl. of other parts of the quad. It underlies Hampton sh. and uncon. overlies Archean gneisses and granites. Consists of massive white ss., feldspathic ss., and qtzite, with interbedded shales and sandy shales in upper part, a thin bed of amygdaloid near middle, and cgl., arkose, and graywacke in lower part.

Union formation.

Devonian or Carboniferous: Nova Scotia.

H. M. Ami, 1900 (Can. Rec. Sci., vol. 8, pp. 154–160, and Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, pp. 207, 210).

Union shale.

Upper Devonian: Western central Montana (Elkhorn region).

W. H. Weed, 1901 (U. S. G. S. 22d Ann. Rept., pt. 2, map, pp. 434, 438). *Union sh.*—Black shales and hornstone. Upper 100 ft. consists of metamorphosed siliceous ls. altered to light-colored jaspery material; lower 30 ft. consists of black sh., in Queen Gulch altered to dark purplish-red hornstone. Horizon corresponds to Threeforks sh., Dev. Near Union mine, at head of Alpreston Gulch [Elkhorn min. dist.] it is altered to a light-colored rock.

Union formation.

Pleistocene: Western Kentucky.

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Union fm.*—Yellowish or brownish loam in Webster Co., locally a typical loess, with land shells. Thickness 8 to 20 ft. Underlies Pleist. Graves Creek fm. and overlies Plio. Lafayette fm. Assigned to Plio.

L. C. Glenn, 1922 (Ky. Geol. Surv., ser. 6, vol. 5, p. 122). The larger part of Graves Creek fm. is believed to be older than *Union fm.*, but it is probable the surface part of it is contemp. with Union fm. Named for Union Co., where it is usually a typical loess. Assigned to Pleist.

Union limestone.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 7, 13, 37). *Union ls.*—Separated from underlying Meadow ls. by 5 to 6 ft. of sh., and overlain by a series of interbedded shales and lss. Thickness 1 ft. 8 in. to 8 ft. Exposed in old quarry at Union, in valley side in NW¼ sec. 22, T. 10 N., R. 13 E.; also 1½ mi. SW. of Union, in secs. 33 and 28, T. 10 N., R. 13 E. In section at Jones Point consists of (descending): Ls., 1 ft.; carbonaceous sh., 1 ft. 2 in.; blue ls., 8 in.; bluish ls. in 5 distinct beds, 4 ft.; sh., 1 in.; brittle ls. that weathers rusty, 1 ft. 3 in.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 52, 53). Upper unit of Topeka ls. was named *Union ls.* by Condra and Bengston. This name being preoccupied the div. is here named *Coal Creek ls.*, from exposures on Coal Creek, N. of Union, Nebr. The ls. is dark blue, dense, brittle, and very fossiliferous. At places it is split in 2 or 3 beds. Overlies Holt sh. The Meadow ls. belongs down in Calhoun sh. memb.

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, 2d ser., pp. 11, 26, 28, 47). Topeka ls. memb. is divided into (descending) Coal Creek ls., Holt sh., and Du Bois ls. Meadow ls. belongs down in Stanton ls., of which it is basal memb.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Union limestone. (In Greenbrier limestone.)

Mississippian: Southeastern West Virginia and southwestern Virginia (Giles County).

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 450, 467). *Union ls.*—Gray, weathering white, hard, often crystalline and usually pure, often oolitic; very little chert or other impurities. Thickness 100 to 275 ft. Marine fossils. Underlies Greenville sh. and overlies Pickaway ls.; all members of Greenbrier series [ls.]. Type loc. at W. edge of Union, Monroe Co. Also observed in Mercer and Summers Counties, W. Va., and in Giles Co., Va.

†Union moraine.

Name used by F. Leverett in U. S. G. S. Mon. 41, pp. 475–494. Derived from Union City, Ind. Shown in part on moraine map (pl. 32) in U. S. G. S. Mon. 53, where it is called *Union City moraine*.

Union shales.

An abbreviated form of *Fort Union fm.* employed by C. [R.] Keyes.

Union City moraine.

Pleistocene (Wisconsin stage): Western Ohio and eastern Indiana. See statement under *†Union moraine*, which it replaces.

Union Corners granite.

Pre-Cambrian: Southeastern New York (New York City).

W J McGee, 1894 (Geol. map of N. Y. prepared under direction of James Hall). *Union Corners granite*, of the "ancient crystalline rocks." [Shown on map as a small patch SE. of Bronxville.]

Union Dairy member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 15). *Union Dairy ls. memb. of Hoxbar fm.* lies 400± ft. above the basal (Confederate) ls. memb. of the Hoxbar. It locally carries abundant *Fusulinae* and other fossils.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 40). *Union Dairy memb.* consists of (descending): (1) 25 ft. of fossiliferous ls. (including shaly layers), gray to cream-colored, earthy to finely and even coarsely crystalline; (2) 20 to 30 ft. of calc. sh.; (3) 5 to 20 ft. of buff ss. Lies 800± ft. below Westheimer memb. and 400± ft. above Confederate ls. memb. Named for Union Dairy Hill, in NE ¼ sec. 7, T. 5 S., R. 2 E.

C. W. Tomlinson, 1934 (A. A. P. G. Bull., vol. 18, No. 8, p. 1085). *Union Dairy memb.* is same as Crinerville ls. memb. As *Crinerville* has been in current use for many years with definite geographic significance, it is to be preferred to *Union Dairy*, which has never been in use as a geographic name and is therefore dropped.

Union Hill trap.

Upper Triassic: Southeastern New York (Rockland County).

N. H. Darton, 1890 (U. S. G. S. Bull. 67). *Union Hill trap*, 150 ft. thick, is an isolated trap ridge forming upper part of Union Hill, NE. of Suffern, N. Y. Rests on cgl. Is possibly an extension of Palisade trap sheet.

Union Pass erosion cycle.

Pleistocene: Central western Wyoming.

E. Blackwelder, 1915 (Jour. Geol., vol. 23, pp. 310–340). The oldest Pleist. erosion cycle recognized in central western Wyo. Effects of the erosion are evidenced at Union Pass.

Union Springs member (in Marcellus shale).

Middle Devonian: Central New York.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, pp. 132, 218, 219, etc.). *Union Springs memb. of Marcellus fm.*—Alternating beds of black ls. and sooty sh. overlying Onondaga ls., underlying Cherry Valley ls., and forming basal memb. of Marcellus fm. from Unadilla Valley westward to Seneca Lake. Type section is in upper part of Wood's quarry, 1 mi. S. of Union Springs, Cayuga Lake, where it is 17 ft. thick, and where its relation to Cherry Valley ls. can be studied. At Marcellus it is 13 ft. thick, at Oneida Creek above Stockbridge Falls 25 ft. and on Flint Creek, near Phelps, 9 ft. Is not known W. of Phelps [Ontario Co.].

Uniontown limestone member (of Monongahela formation).

Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_5, pp. 55–104, 286, 292). *Uniontown ls.*, 10 to 12 ft. thick. Top memb. of Pittsburg ls. group and 160 ft. above Pittsburg coal. Is older than Uniontown coal and younger than Sewickley coal. [In places called *Uniontown or Great ls.*]

E. V. d'Invilliers, 1895 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 3, pt. 2, btw. pp. 2153 and 2588), applied *Uniontown ls.* to upper 0 to 20 ft. of *Great ls.*, immediately underlying Uniontown coal; and J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18), also followed that usage. The definition adopted by U. S. Geol. Survey for Pa. in 1910, and published in Burgettstown-Carnegie folio (No. 177, 1911) and subsequent repts up to present time, applied *Uniontown ls.* to beds in Pa. which underlie Uniontown coal, or in places occur a few ft. below that coal, and which in places are separated from Benwood ls. memb. by an interval of 5 to 20 ft. of sh. with thin lenses of ls.

W. Stout, 1929 (W. Va. Acad. Sci. Proc., vol. 3, pp. 140, 143), restricted *Uniontown ls.* of Ohio and W. Va. to upper ls. of interval btw. Uniontown coal and Fulton sh., and introduced *Arnoldsburg ls.* for the lower ls., lying on or close to Fulton sh. (See *Arnoldsburg ls.*)

Named for exposures at Uniontown, Fayette Co., Pa.

Uniontown sandstone member (of Monongahela formation).

Pennsylvanian: Southwestern Pennsylvania, western Maryland, and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 58–59). *Uniontown ss.*—Massive gray ss. Occurs immediately above Uniontown coal, hence its name, although it is not prominent at Uniontown [Fayette Co., Pa.]. Lies 60 to 75 ft. below Waynesburg coal and just below Waynesburg ls.

Uniontown member. (In Monongahela formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa., No. 27, Pittsburgh quad., p. 31, 1929) to include (descending) Uniontown ss., Uniontown coal, and Uniontown ls.

Uniontown limestone.

Pennsylvanian: Southeastern Kansas.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, p. 97). [See under *Bourbon group.*]

J. M. Jewett, 1932 (p. 99 of book cited above). [See under *Bourbon group.*]

R. C. Moore and G. E. Condra, Oct. 1932 (revised chart of Penn. of Kans. and Nebr.). *Uniontown ls.* underlies Ladore sh, and is separated from underlying Dudley sh. by unnamed sh. and ss.

R. C. Moore, 1935 (Kans. Geol. Surv. Bull. 20, table opp. p. 14). Bourbon group underlies Hertha ls. and uncon. overlies Lenapah ls. It is divided into (descending): Undiff. sh. and ls.; "Uniontown" ls.; unnamed sh.; and Warrensburg channel ss.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), did not use this name and did not explain its fate.

Union Valley sandstone member. (In Wapanucka formation.)

Pennsylvanian (Pottsville): East-central Oklahoma.

R. V. Hollingsworth, 1934 (Geol. Soc. Am. Proc. 1933, p. 364). The oil-field names "Cromwell," "Lyons-Quinn," and "Pagoose" [evidently a misprint for *Papoose*] have been applied to a petroleum-producing ss. forming middle memb. of Wapanucka fm. of east-central Okla. The name *Union Valley ss.* is here proposed for this ss. memb., which crops out near Union Valley schoolhouse, Pontotoc Co., the type loc., and which there consists of light-brown massive to thin-bedded coarse- to fine-grained sss., with max. thickness of 242 ft., discon. overlain by the upper memb. of the Wapanucka, which consists of ls. and sh., and grading into lower memb. of the Wapanucka, which consists of black carbonaceous and gray shales with a few thin beds of ls. At its top the Union Valley memb. includes 4 to 6 ft. of aren. ls. containing a Morrow fauna of Brentwood affinities [listed].

D. L. Hyatt, 1936 (A. A. P. G. Bull., vol. 20, No. 7, pp. 954, 959). *Union Valley fm.* (Hollingsworth, 1934) normally consists of 2 members, a lower ss. 100 ft. thick and an upper ls. 50 ft. thick. The *Union Valley ss.* is medium- to coarse-grained ss., calc., shaly, and very lenticular in nature. Difficult to identify its contact with underlying Caney (Penn.). This fm. is known in field as *Cromwell ss.* The *Union Valley ls.* is blue shaly, sandy, and glauconitic ls., rather impure, and grades into Union Valley ss. below with here and there a sh. break, 10 to 15 ft. thick, btw. the two. The Union Valley fm. underlies Wapanucka fm.

Unionville sandstone.

Pennsylvanian: Northwestern Illinois (Whiteside County).

J. Shaw, 1873 (Ill. Geol. Surv., vol. 5, pp. 147–149). *Unionville sss.*—Soft, friable dirty-white to yellowish-red sss., 12 to 33 ft. thick, belonging to Millstone grit. Overlain by Coal Measures and uncon. underlain by Niagara ls. in Whiteside Co.

Named for outcrop at Unionville, Whiteside Co.

United Verde diorite.

Pre-Cambrian: Central Arizona (Jerome district).

L. E. Reber, Jr., 1920 (Am. Inst. Mg. Engrs), and 1922 (Am. Inst. Min. and Met. Engrs. Trans., vol. 66, pp. 3–26 and map). *United Verde diorite.*—Augite diorite. Intrusive into quartz porphyry and older rocks near Jerome. Regarded as a late phase of Bradshaw granite. [Probably named for the United Verde mine. The Bradshaw granite is pre-Camb.]

University gravel.

Pleistocene: Southeastern Pennsylvania.

See under *Philadelphia red gravel.*

University beds.

Quaternary: Central northern New Mexico (Albuquerque region).

K. Bryan, 1909 (N. Mex. Univ. Bull., Geol. ser., vol. 3, No. 1). In side gulches of second canyon of the river [Rio Grande] were deposited at time of deposition of Rio Grande gravels a series of side-wash deposits here denominated *The University beds.* They form a considerable part of Sandia Mesa within this area, extending from Menaul School S. to mouth of Power House Arroyo and to E. in a wedge shape to E. limit of area. They are reddish sandy clays, frequently cross-bedded, showing many minor unconformities and containing large angular boulders of Sandia Mtn material. They are without doubt frontal apron wash. Thickness 95 ft. Deposited by a lateral from the Sandias during deposition of Rio Grande gravels.

University Mesa marl. (In Fredericksburg group.)

Lower Cretaceous (Comanche series): Western Texas (Pecos County).

W. S. Adkins, 1933 (Univ. Tex. Bull. 3232, pp. 271, 328, 339, 347). Neritic facies of Edwards fm. occurs in form of marl at Fort Stockton, here called *University Mesa marl* (p. 339). In Fort Stockton area the top of the Fredericksburg beneath the Kiamichi marl (Edwards equivalent) is a fossiliferous marl, here called *University Mesa marl.* It is about 50 ft. thick, is underlain by Comanche Peak ls., and overlain by a thin brown ls. seam, above which the Kiamichi marl occurs. At Kent and El Paso it is clay and marly ls. (p. 347).

Unkar group.

Pre-Cambrian (Grand Canyon series): Northern Arizona (Grand Canyon).

C. D. Walcott, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pl. 60, etc.). *Unkar terrane.*—Massive beds of reddish mag. ls., lava beds, sss., lss., lava, and cgl. Thickness 6,830 ft. Underlies Chuar terrane. Lower group of Grand Canyon series.

Is now divided into (descending) Dox ss., Shinumo qtzite, Hakatai sh., Bass ls., and Hotauta cgl.

Named for outcrops in Unkar Valley.

Unkpapa sandstone.

Upper Jurassic: Western South Dakota (Black Hills).

N. H. Darton, 1899 (Geol. Soc. Am. Bull., vol. 10, p. 393). *Unkpapa ss.*—Fine-grained massive sss., pink, white, buff, or purple, 0 to 225 ft. thick, overlying Sundance fm. and underlying Beulah shales [Morrison fm.] in Black Hills, S. Dak.

N. H. Darton, 1901 (U. S. G. S. 21st Ann. Rept., pt. 4, p. 524). *Unkpapa ss.*, 0 to 250 ft. thick, was named for one of the tribes of Dakota Indians which was at one time located about SE. part of Black Hills.

J. P. Connolly and C. C. O'Harra, 1929 (S. Dak. School Mines, Depts. Geol. and Min., Bull. 16, p. 47). *Unkpapa ss.* was named for Unkpapa Peak, at head of Calico Canyon, NW. of Buffalo Gap, S. Dak.

Upland formation.

Pleistocene (Yarmouth): Southern and eastern Nebraska.

A. L. Lugn and G. E. Condra, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 190). *Upland fm.* (*Yarmouth*), clay and silt 3 to 30 ft. thick, conformably overlying Grand Island fm. (Kansan).

A. L. Lugn, 1934 (Nebr. State Mus., vol. 1, Bull. 41, pp. 319–351). *Upland fm.*—Largely fluvial inwash-outwash deposits under loess region W. of till border. Alternating greenish-gray clay and greenish sand. Of Yarmouth age. Uncon. underlies Loveland fm. and overlies Kansan gumbotil in places and in other places rests on Grand Island fm. Named for outcrops along West Branch of Thompson Creek, about 2½ mi. W. of town of Upland, Franklin Co.

Upper.

The terms *Upper* and *Lower*, connected with geographic names, have long been and still are employed in a titular sense to designate many lss., sss., and clays of Appalachian region and elsewhere. A few of these are here listed. Others are mentioned under the geographic names.

†Upper Archimedes limestone.

Mississippian: Southwestern Illinois and eastern Missouri. See under *†Archimedes ls.*

†Upper Barren Coal Measures.

A term applied in some early repts to Dunkard group (of Perm. age) of Appalachian region.

Upper Cambrian series.

Same as St. Croixan series. (See U. S. G. S. Bull. 769.)

†Upper Cambridge limestone.

A name applied in some repts to Cambridge ls. memb. of Conemaugh fm. of current usage.

†Upper Carboniferous.

A term applied in early repts to Pennsylvanian series of present nomenclature, also to Penn. and Perm. series.

Upper Clarion clay. (In Allegheny formation.)

A clay bed underlying Upper Clarion coal in Pa.

†Upper Connoquenessing sandstone.

See under *Connoquenessing ss. memb.*

†Upper Cross Timber sands.

A name applied in some early Tex. repts to Trinity group (Lower Cret.), also to Travis Peak fm. (basal fm. of Trinity group).

†Upper Cross Timbers formation.

A name applied in some early Tex. repts to Comanche (Lower Cret.) series.

Upper Devonian series.

The generally accepted definition includes all Dev. beds down to base of Tully ls.

Upper Freeport limestone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland, and northern West Virginia.

F. and W. G. Platt, 1877 (2d Pa. Geol. Surv. Rept. H_2, p. 316). *Upper Freeport ls.* substituted for *Freeport ls.* of previous repts, *Lower Freeport coal* substituted for *Middle Freeport coal*, *Lower Freeport ls.* substituted for *Middle Freeport ls.*, and *Upper Kittanning coal* substituted for *Lower Freeport coal.*

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Freeport Upper ls.*, formerly called *Freeport ls.*, consists of 8 ft. of very hard, compact grayish or white ls. in 3 layers separated by fire clay. Underlies Freeport Upper coal and lies higher in section than Freeport (Upper or Butler) ss.

Upper Freeport clay. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and Maryland and northern West Virginia.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3). *Upper Freeport clay*, 2 to 12 ft. thick, underlies Upper Freeport ls. and is separated from underlying Lower Freeport coal by 25 ft. of ss. and sh. [The 3 to 15 ft. of clay separating Upper Freeport coal from underlying Upper Freeport ls. was not given a name in this rept. but in subsequent repts the name *Upper Freeport* has been applied to the clay above and to the clay below Upper Freeport ls.]

J. P. Lesley, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 308–316). *Upper Freeport fire clay* underlies Upper Freeport coal and overlies Upper Freeport ls.

†Upper Freeport sandstone.

Replaced by *Butler ss. memb.*

†Upper Fucoidal group.

See under *Portage group.*

†Upper Helderberg group.

See under *Helderberg group.* Various limits have been assigned to this div., which has also been called "Corniferous group" and "Corniferous ls."

†Upper Helderberg limestone.

A name applied in early repts to Onondaga ls. of present terminology, also to Dundee ls. of Mich.

†Upper Homewood sandstone.

A name applied in some repts to *Homewood ss. memb.* of Pottsville fm.

Upper Kittanning limestone. (In Allegheny formation.)

Pennsylvanian: Western Pennsylvania and northern West Virginia.

J. J. Stevenson, 1878 (2d Pa. Geol. Surv. Rept. K_3). *Upper Kittanning ls.*, 6 ft. thick in Fayette and Westmoreland Counties, is separated from overlying Upper Kittanning coal by 5 ft. of clay and from underlying Lower Kittanning coal by 30 ft. of sh.

J. P. Lesley, 1879 (2d Pa. Geol. Surv. Rept. V, pp. 238–240). *Kittanning Upper ls.* of Butler Co. is same as Johnstown cement bed [Johnstown ls. memb.] of Cambria Co.

Upper Kittanning clay.

The clay bed beneath Upper Kittanning coal in Allegheny fm. of Pa.

†Upper Laramie.

A term applied, in a titular sense, in some early repts to rocks now known, in Hanna Basin, southern Wyo., as *Hanna fm.* (Eo.) and *Ferris fm.* (Eo. and Upper Cret.).

Upper Little Pittsburgh limestone.

See under †*Little Pittsburgh ls.*

Upper Little River limestone.

Lower Cretaceous (Comanche series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 111, 188). *Upper Little River ls.*—Massive semicrystalline lss. and *Gryphaea pitcheri* breccia, in strata from 1 to 5 ft. thick, forming banks and canyons of the [Little] river for some 200 ft. in height, and containing *Gryphaea pitcheri* Morton, *Requienia (Caprotina)*, and other fossils of lithologic horizon of Comanche series, which Dr. B. F. Shumard described as "Caprina ls.," and which is about midway btw. the more fossiliferous Comanche Peak and Washita horizon. Is lower part of Washita div. in SW. Ark. Underlies Cerro Gordo blue chloritic clays and overlies Fredericksburg div.

Named for exposures on Little River, SW. Ark., at Okla. State line.

Upper Madisonville limestone.

Pennsylvanian: Western Kentucky.

See under *Madisonville ls.*; also under *Kinchloe ls.*

†Upper Magnesian limestone.

A term applied in early repts on upper Mississippi Valley region to Galena dol.

†Upper Mahoning sandstone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania and Maryland and northern West Virginia.

F. Platt, 1876 (2d Pa. Geol. Surv. Rept. L), divided Mahoning ss. into *Upper Mahoning ss.*, 34 ft. thick; sh., 25 ft. thick; and *Lower Mahoning ss.*, 35 to 40 ft. thick.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, p. 33). Buffalo ss. is same as *Upper Mahoning ss.* [On pp. 303–305 of this rept J. P. Lesley also says Buffalo ss. is same as Upper Mahoning ss.]

The U. S. Geol. Survey does not use "Upper Mahoning ss." and "Lower Mahoning ss.," but treats the Mahoning as a unit, composed of an *upper ss.*, a *lower ss.*, and a middle sh. The use of "Upper Mahoning ss." and "Lower Mahoning ss." is especially undesirable because the Buffalo ss. was called "Upper Mahoning" in early repts.

†Upper Marlborough.

See under †*Piscataway sands.*

†Upper Medina.

Name applied in early repts to Albion ss. of N. Y. and to Tuscarora qtzite of Pa. and Md.

Upper Mercer iron shales. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Upper Mercer iron shales.*—Shales, dark and sandy, containing iron ore at base. Thickness 20 to 35 ft. Underlie Upper Mercer clay and overlie Lower Mercer ls.

Upper Mercer limestone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania and eastern Ohio.

I. C. White, 1879 (2d Pa. Geol. Surv. Rept. Q_2). *Upper Mercer ls.*—Generally very hard compact dark-bluish ls., often containing iron concretions. Thickness 2 to 4 ft. Overlies Upper Mercer [Mount Savage?] coal and underlies Tionesta iron shales. Is same as Mahoning ls. of Rogers and Upper Wurtemburg ls. of Lesley. During present season I have found this ls. near town of Mercer, Pa., the place after which the ls. next below was named. Owing to confusion that might result from use of Rogers' old name [Mahoning ls.] I have thought it best to drop "Mahoning" and substitute *Upper Mercer* for this ls., and change *Mercer ls. of Rogers* to *Lower Mercer.*

Upper Ordovician series.

The generally accepted definition includes (descending) Richmond group, Maysville group, Eden group, and Utica sh. The latter fm. is now excluded from Eden group by both N. Y. State Survey and U. S. Geol. Survey.

†Upper Pentamerus limestone.

A name applied in early N. Y. repts to the ls. later named *Becraft ls.*

Upper Pittsburgh limestone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q). *Upper Pittsburg ls.*—Light-gray compact ls.; breaks with conchoidal fracture; weathered surface almost white; thickness 2 ft. In Allegheny Co., Pa., it lies 65 ft. above Lower Pittsburg ls. and 20 ft. below Pittsburg coal.

See also under †*Pittsburgh ls.*

†Upper Pittsburgh sandstone.

See *Pittsburgh ss. memb.*

†Upper Productive Coal Measures.

A term applied in early repts to Monongahela fm. (of Penn. age) of Appalachian region.

†Upper Shaly limestone.

A term applied in early N. Y. repts to the ls. later named *Port Ewen ls.*

†Upper Silurian.

A term applied in early geologic repts to Silurian system of present terminology.

Upper Washington limestone member (of Washington formation).

Permian: Southwestern Pennsylvania, eastern Ohio, northern West Virginia, and western Maryland.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Upper Washington ls.*—Top memb. of Washington County group [Washington fm.]. Upper part is quite slaty and blue on fresh exposure; middle layers are almost black, frequently mottled with drab, and are exceedingly brittle; lower part is usually of light flesh color. All of the ls. weathers almost white. Thickness 30 ft. Separated from underlying Jollytown coal by 40 to 70 ft. of sh. and sss.

Upper Wurtemburg limestone.

See under *Wurtemburg ls.* and *Mercer ls.*

Upshur sandstone.

Pennsylvanian: Northeastern West Virginia.

J. A. Taff and A. H. Brooks, 1896 (U. S. G. S. Buckhannon folio, No. 34). *Upshur ss.*—White and brown ss.; some beds of cgl.; in places olive to yellow clay sh. near middle; and at least 3 coal beds. Thickness 350 to 500 ft. Covers large part of Upshur Co. Underlies Braxton fm. and overlies Pugh fm.

Corresponds to Allegheny fm. and lower part of Conemaugh fm.

Upson clay.

Upper Cretaceous (Gulf series): Southern Texas.

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 224–230). *Upson clays.*—Lower part yellow clay containing calc. nodules with *Exogyra ponderosa;* upper part clay sh. Basal fm. of Eagle Pass div. Overlies Pinto ls. (Austin chalk) and underlies San Miguel beds. Thickness 700 ft. Equivalent to Ponderosa marls of Colorado River section. [Later repts—T. W. Vaughan 1900 and J. A. Udden 1907—exclude this clay from Eagle Pass.]

L. W. Stephenson, 1928 (Am. Jour. Sci., 5th, vol. 16, p. 492), shows typical Upson clay overlain by San Miguel fm. and underlain by Austin chalk; and shows, in Anacacho Mtn, a thin development of Upson clay beneath Anacacho ls. and above Austin chalk.

Named for Upson, Maverick Co. F. M. Getzendaner says (letter of Mar. 1, 1937, to L. W. Stephenson): "Mr. Ed Smidt, who was born and raised at Eagle Pass, told me that the old Upson post office was on the present Lehman ranch, near the little Mexican village of thatched houses on the Eagle Pass-Del Rio road, where the present town of Quemado is located. This is about 15 miles north-northwest of Eagle Pass."

Urschel lime. (Buried.)

Ordovician: North-central Kansas.

J. S. Barwick, 1928 (A. A. P. G. Bull., vol. 12, No. 2, p. 185). *Urschel lime.*—Unit No. 5 encountered in wells in Salina Basin. Not exposed. Consists of few ft. to 135+ ft. of white to brown, commonly cherty dolomitic ls. Underlies Engle sh. (unit No. 4) and overlies St. Peter ss. (unit No. 6). Main producing horizon of Florence-Urschel field, Marion Co. Appears to correlate approx. with Viola ls. of Okla. and part of Plattin-Kimmswick section of Mo.

Uscari shale.

Miocene: Costa Rica.

E. W. Berry, 1921 (U. S. Nat. Mus. Proc., vol. 59, p. 169).

Utah Metals limestone.

A name applied by O. P. Peterson (Am. Inst. Min. and Met. Engrs. Trans., vol. 70, pp. 908–926, 1924) to 80 ft. of alternating qtzite and ls. beds in Bingham qtzite (Penn.) of Bingham dist., Utah. Lies 270± ft. below Highland Boy ls. memb. of Bingham qtzite. Evidently named for a mine.

Utah Queen formation.

See under *Lion Hill fm.* Name evidently derived from a mine in Utah.

Ute limestone.

Middle Cambrian: Northeastern Utah and southeastern Idaho.

C. King, 1876 (Am. Jour. Sci., 3d, vol. 11, p. 477). *Ute ls.*, 2,000 ft. thick in Wahsatch Mtns, contains fossils which show it to be chiefly or wholly of Quebec [Ord.] age, although no fossils have been obtained from its immediate summit or base. Next younger fm. is Ogden qtzite.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas), mapped the *Ute* as Silurian.

S. F. Emmons, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, pp. 340–392). *Ute ls.* (*Sil.*).—Dark, almost black compact siliceous ls., with calc. shales and argillites toward base, carrying Quebec fossils at top and bottom. Thickness 1,000 to 1,500 ft. in Wahsatch Mtns. Underlies Ogden qtzite and overlies Camb. sl.

A. Hague, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, pp. 393–419). *Ute ls.* (*Sil.*) is 1,200 to 1,500 ft. thick in northern Wahsatch region. Consists chiefly of lss. but includes some calc. and argill. sh. Named for Ute Peak, Utah.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 127–248). *Ute ls.* (*Sil.*).—Dark compact fine-grained rock, 1,000 to 2,000 ft. thick in Wahsatch Range, Utah. Toward base the ls. becomes shaly for several hundred ft. Conformably underlies Ogden qtzite and conformably overlies Camb. shales.

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804). *Ute fm.*—Blue to bluish-gray thin-bedded fine-grained lss. and shales, with some oolitic, concretionary, and intraformational cgl. layers. Thickness in Blacksmith Fork

759 ft.; in section W. of Liberty 731 ft. Abundant Middle Camb. fossils. Type loc., slopes of Ute Peak, near forks of East Fork, E. of Paradise, Cache Co., Utah. Underlies Blacksmith fm. and overlies Langston fm., all Middle Camb. This fm. was named *Ute ls.* by 40th Par. Surv., but aside from fact it was stated to overlie Camb. qtzites and to be composed of 2,000 ft. of lss. containing Camb. fossils, it was not defined or limited. The beds here referred to Ute fm. contain the fossils mentioned by 40th Par. Surv. as characterizing lower part of Ute ls.

As defined by Walcott the name *Ute* is restricted to a lower part of Ute ls. of 40th Par. Surv. This is present accepted definition. The Ute ls. of King appears to have included all the lss. (Ord. and Upper and Middle Camb.) beneath the Ord. Swan Peak qtzite, which he apparently mistook for the qtzite in Ogden Canyon, which is of Middle and Lower Camb. age.

Utica shale.

Upper Ordovician: New York, Michigan, and Ontario.

E. Emmons, 1842 (Geol. N. Y., pt. 2, div. 4, geol. 2d dist., pp. 116–118, 183, 278, 319, 397, 429). *Utica sl.*—Black shaly mass, 75 ft. thick, underlying Lorraine shales and overlying Trenton ls.

In 1911 (N. Y. State Mus. Bull. 149, pp. 10–12) J. M. Clarke separated, under name *Canajoharie sh.*, the lower part of black sh. previously included in Utica sh. of Hudson and Mohawk Valleys, which he stated thins out westward, does not reach meridian of Utica, and contains a Trenton fauna. (See further explanation under *Canajoharie sh.*) In 1912 (N. Y. State Mus. Bull. 162) R. Ruedemann stated that true Utica sh. is absent in Hudson River region, but that it is overlain by true Frankfort sh. in Utica region.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258). *Utica sh.* underlies Lorraine group and overlies Trenton ls. in Utica Basin, and overlies Canajoharie sh. [of lower Trenton age] in middle Mohawk Valley. Is 70 to 1,000 ft. thick in Utica Basin, being nearly 800 ft. thick at Utica, but only upper 250 ft. is exposed.

The present generally accepted definition of Utica sh. is for the beds beneath the Lorraine and above the Trenton.

†Utica limestone.

Silurian: Southeastern Indiana.

W. W. Borden, 1874 (Ind. Geol. Surv. 5th Ann. Rept., pp. 143, 172). *Utica ls.*—Beds of Niagara age, 52 ft. thick, overlying Clinton group and underlying Corniferous ls. in Clark and Floyd Counties. Quarried at Utica, on Ohio River [in Clark Co.].

Utica quartz monzonite porphyry.

Tertiary: Central northern Colorado (Boulder County).

P. G. Worcester, 1921 (Colo. Geol. Surv. Bull. 21, pp. 31–32). *Utica quartz monzonite porphyry* occurs as a dike extending for about ½ mi. SE. from Utica mine.

Utley metarhyolite.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Green Lake County).

S. Weidman, 1898 (Wis. Geol. Nat. Hist. Surv. Bull. 3, Sci. ser. 2, pp. 4–31). *Utley metarhyolite.*—Consists of a single rounded knoblike area more than 100 ft. high at Utley, Green Lake Co.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). Utley metarhyolite of Weidman may be supposed to be pre-Huronian.

Utopia limestone.

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). [See under *Bachelor Creek ls.* On p. 21 *Utopia ls.* is described as consisting of (1) 2.65 ft. of yellowish-brown slabby ls. interbedded with yellowish calc. sh., underlain by (2) 1.65 ft. of dark-blue massive ls. with *Cryptozoon*.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 209). *Utopia ls.*, basal memb. of Howard ls., overlies Winzeler sh. memb. and underlies White Cloud sh. memb. Type loc. just E. of village of Utopia, sec. 5, T. 25 S., R. 11 E., Greenwood Co., Kans.

Uvalde gravel.

Tertiary ? (Pliocene ?) : Southern Texas.

R. T. Hill, 1891 (Am. Geol., vol. 7, p. 368). *Uvalde fm.*—Grand detrital deposit, 50 ft. thick, of either a fresh-water lake or great embayment of gulf, occurring 400 to 1,000 ft. above Rio Grande. Composed of flint and ls. pebbles and boulders, mostly from Comanche rocks, cemented by calc. matrix. Occurs on terraces, benches, and remnantal patches around perimeter of area from San Antonio to Del Rio, thence SE. through Mexico to indefinite distance coastward beyond Lampazos, Mexico.

A. C. Trowbridge, 1923 (U. S. G. S. P. P. 131, pp. 98–100). In 1891 Hill described remnants of a fm. that consisted of coarse and fine gravel cemented by a calc. matrix and that occupied terraces 400 to 1,000 ft. above Rio Grande to N. of this region. This he called *Uvalde fm.* Dumble applied *Reynosa div.* to the series of deposits forming the plateau btw. Nueces and Rio Grande, which he called the Reynosa Plateau. He stated that "Reynosa ls." of Penrose formed top memb. of his Reynosa div., which rested on Lagarto fm. These downstream deposits to which Dumble applied name *Reynosa* are now known to be same as the upstream remnants to which Hill applied name *Uvalde*, and the necessity for discarding one of the names has become apparent. In view of fact that *Reynosa* as applied to a part of this fm. has priority over Uvalde, and that the downstream deposits perhaps afford a better type loc., the name *Reynosa* has been adopted by U. S. Geol. Survey and "Uvalde" fm. has been abandoned.

A. Deussen, 1924 (U. S. G. S. P. P. 126, p. 102). The position of the ls. at Reynosa, Mex., only 50 ft. above the streamway and 732 ft. below the ls. at Torrecillas, 100 mi. to NW., would seem to suggest that it occupies a lower terrace than Torrecillas and Realitos terraces, and that its age is Pleist. rather than Plio. However, until more definite information can be obtained as to age of the ls. at type loc. it is considered advisable to continue the use of *Reynosa* as used by Dumble and Kennedy, it being well established in literature with this significance.

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 777). *Uvalde* was name given by Hill to the upland gravel deposits of central and south Tex. Name is appropriate, applicable, and well defined. It was not generally accepted by geologists for a long time, however. Penrose had named the gravel and caliche deposits along Rio Grande *Reynosa*, for town of Reynosa, Mex. These Reynosa gravels are now thought to be Pleist., and younger than Uvalde gravel of Hill. No fossils have been found in the upland interstream deposits. The topographic position and general physiographic relationships of these deposits indicate so clearly that they antedate the river terraces that Hill's name must take precedence over others. The Uvalde gravels occur on the stream divides and in many places cap the highest hills in area S. of Edwards Plateau. They rest on fms. ranging in age from Lower Cret. to Mio. They are especially prominent in area btw. Brazos and Devils Rivers and occur in even greater thickness in northern Mex. Thickness, thin to 30 ft. Are younger than Goliad fm. and are correlated with basal part of Lissie fm. Are of late Plio. or oldest Pleist. age.

A. N. Sayre, 1934 (letter dated Dec. 29). *Uvalde fm.* is probably older than Lissie and is younger than Goliad. It is older than Reynosa at Reynosa, Mex. Name should be restored for the high-level gravels near Uvalde.

J. T. Lonsdale and J. R. Day, 1937 (U. S. G. S. W. S. P. 778). The Uvalde gravel of this rept. [on Webb Co., Tex.] is regarded as = in age to the high-level gravel near Uvalde. The materials are similar to the sand and gravel of the Goliad but are found at considerably lower altitudes and hence are probably younger.

The Tex. Geol. Survey and U. S. Geol. Survey have discontinued the use of *Reynosa* in Tex. *Uvalde gravel* (Plio.?) is present approved name of U. S. G. S. for the high-level gravels near Uvalde, and *Goliad sand* (Plio.) is the approved name for the deposits that are apparently older than the Uvalde and that overlie Lagarto clay (restricted).

Uvalde phonolite.

Eocene (?) : Southern Texas.

T. W. Vaughan, 1900 (U. S. G. S. Uvalde folio, No. 64, p. 4 and maps). *Uvalde phonolite.*—Very dark porphyry, with predominant aphanitic groundmass containing a few distinct crystals of sanidine, nepheline, brown hornblende, augite, and olivine. Occurs at Inge Mtn, near Uvalde. Unlike any other type of rock in region. [Another Eocene (?) phonolite is mapped without a geographic name.]

Named for Uvalde, Uvalde Co.

Vail slate.

Lower Cambrian: Quebec.

T. H. Clark, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 1, pp. 6, 10).

Val Brilliant formation.

Silurian: Quebec (Matapedia Valley).

G. W. Crickmay, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 368–385). *Val Brilliant fm.*—Series of alternately thin- and thick-bedded white and buff sss., 200 ft. thick. Cross-bedding common. Clinton fossils. Typically exposed along shore of Lake Matapedia from village of Val Brilliant to NW. for 1¼ mi. Overlies Shickshock fm. and conformably underlies Sayabec fm. Fossils [listed].

Valcour limestone.

Lower Ordovician: Eastern New York (Champlain Valley).

H. P. Cushing, 1905 (N. Y. State Mus. Bull. 95), adopted the subdivisions of the Chazy proposed by E. Brainerd and H. M. Seely in 1888 (Am. Geol., vol. 2, pp. 323–330), as explained under *Chazy group*, and proposed *Valcour ls.* for div. C, or Upper Chazy (which forms N. and SE. shores of Valcour Island) and *Crown Point ls.* for underlying div. B, or middle Chazy.

Foregoing definiton is still employed by N. Y. State Survey, according to N. Y. State Mus. Hdb. 10, 1931, by W. Goldring.

Valdes group.

Triassic: British Columbia.

J. A. Bancroft, 1913 (Canada Geol. Surv. Mem. 23, p. 68).

Valdez group.

Mesozoic and Paleozoic (?): Central southern Alaska.

F. C. Schrader, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 408–410, 413). *Valdes series.*—Bluish-gray and dark qtzites, arkoses, and quartz schists, interbedded with generally thin beds of dark-blue or black sl., sh., mica schist (sometimes slightly graphitic), nodular mica schist, and some stretched cgl. May be a direct continuation of Orca group to S., but more highly metamorphosed and altered. Best exposed about Port Valdes. Extend N. over the range and to region of Lake Klutina, also down into Copper River Basin, and to E. Fossils are indeterminate plant remains. Lithology suggests Dev. or Carbf., but the series may be early Tert. or Cret. Thickness great.

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, p. 64). U. S. Grant and D. F. Higgins have shown (U. S. G. S. Bull. 443, 1910, pp. 20–26) Orca group rests uncon. on Valdez group. [Valdez is approved spelling.]

According to F. H. Moffit (1924) there is evidence to support assignment of Valdez group to Mesozoic, possibly Cret., at least in part. Fossils collected at several places from rocks regarded as belonging to Valdez group, although not diagnostic, make Paleozoic age seem doubtful. There is evidence to support assignment of at least part of Orca group to Paleozoic, possibly in part as low as Sil. or Dev. Moffit excluded the greenstones from Orca group, being uncertain whether they belong to Orca or Valdez group.

G. C. Martin, 1926 (U. S. G. S. Bull. 776, p. 484). Relative sequence of Valdez and Orca groups is in doubt, and even validity of their differentiation has been questioned. There is very little fossil evidence on which to form opinion as to their ages.

Vale formation. (In Clear Fork group.)

Permian: Central and central northern Texas (Taylor and Runnels Counties).

J. W. Beede and V. V. Waite, 1918 (Univ. Tex. Bull. 1816, p. 47). [See 1918 entry under *Tye fm.*, which name it replaces.]

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 169, 176, 181). The original definition of *Vale fm.* is here modified by including in it at top the Bullwagon dol. memb., which in previous repts has been treated as a distinct fm.

Named for old post office on Ballinger-Maverick road, on E. side of Valley Creek, Runnels Co.

Valencian series.

A term introduced by C. [R.] Keyes to cover the "latest pre-Cambric succession of volcanics and granites" in N. Mex. (See his Conspectus of geol. fms. of N. Mex., 1915, pp. 4, 12.)

Valentine beds.

Pliocene (?): Northwestern Nebraska.

E. H. Barbour and H. J. Cook, 1917 (Nebr. Geol. Surv. vol. 7, pt. 19, p. 173). The *Valentine beds* are probably a lower phase than either the Snake Creek or the *Devil's Gulch*.

E. H. Barbour and H. J. Cook, 1917 (Nebr. Geol. Surv. vol. 8, pt. 18, p. 170). The 3 phases of Plio. in N. and NW. Nebr. are (ascending) *Valentine beds*, Snake Creek beds, and *Devil's Gulch beds*.

H. F. Osborn, 1918 (Am. Mus. Nat. Hist. Mem., vol. 2, pt. 1, p. 23). Valentine beds of Barbour and Cook, 1917, are upper Mio. or lower Plio.

H. J. and M. C. Cook, 1933 (Nebr. Geol. Surv. Paper No. 5, pp. 42–43). Careful systematic collecting in region about Valentine, Nebr., by R. A. Stirton, P. O. McGrew, and others indicates that at least 3 faunal phases are present in that region, to only the upper one of which the term "*Valentine*" can properly be applied. The lower memb. of this section agrees closely with typical "Ft. Niobrara;" and there is at least one distinct stage yet to be differentiated. It will undoubtedly be shown that certain beds in Valentine region agree closely with the phase of Snake Creek beds, in which the type of *Hesperopithecus* was found (on Olcott Hill). If we place beginning of Plio. at first appearance of *Hipparion*, then line btw. Plio. and Mio. will occur in Valentine beds.

F. W. Johnson, 1936 (Am. Jour. Sci., 5th, vol. 31, pp. 467–473). Ogallala fm. of Valentine area, Cherry Co., northern Nebr., is divisible into: (1) "cap-rock bed;" (2) *Burge sands* (name proposed for the fine-to coarse-grained sands and gravels containing the "Burge fauna"); and (3) *Valentine beds*. Latter consist of 175 to 225 ft. of chiefly fine-grained unconsolidated gray sss. and clay beds above, and below of loose channel sands containing the "Valentine fauna." Type loc. on S. side of a drainage cut btw. the old and new railroad grades in NE¼ sec. 17, T. 33 N., R. 27 W., Cherry Co. Were called *Fort Niobrara fm.* by Osborn, 1918. The "cap-rock bed" and Burge sands are lower Plio.; the Valentine beds are transitional Mio.-Plio., and uncon. overlie Brule (?) clay (Olig.?). [Faunas listed.]

Valentine formation.

Lower Ordovician (Chazy): Central and central southern Pennsylvania.

R. M. Field, 1919 (Am. Jour. Sci., 4th, vol. 48, pp. 404, 414–417, 422). *Valentine fm.*—Pure quarry rock, 0 to 90 ft. thick; no evidence of stratification except under high powers. Occurs as lens in upper Stones River beds. Merges into overlying Center Hall fm. (impure ls. 15 ft. thick) and rests with sharp contact on Carlim fm. Thins to E., and its beds are successively replaced by upper beds of the Carlim, the younger of which appears to be synchronous with the Center Hall at Bellefonte. Named for small hamlet and forge near Bellefonte, Center Co.

Valentine limestone member (of Sultan limestone).

Devonian: Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 10, 14, etc.). *Valentine ls. memb.*—Light-gray ls. and dol., 75 to 380 ft. thick, forming middle memb. of Sultan ls. Underlies Crystal Pass ls. memb. and overlies Ironside dol. memb. Is exposed E. of Valentine mine, in sec. 23, T. 25 S., R. 58 E. Some fossils; late Middle or early Upper Dev., E. Kirk says.

Valera shale. (In Belle Plains formation.)

Permian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 421, 426). *Valera bed.*—Clay, thin to 40 ft. thick. Memb. of Albany div. Underlies Bead Mtn bed and overlies Jagger Bend bed.

F. B. Plummer and R. C. Moore, 1922 (Univ. Tex. Bull. 2132, p. 195). *Valera sh.* is a middle memb. of Belle Plains fm. (middle fm. of Wichita group). Underlies Bead Mtn ls. and overlies Jagger Bend ls.

This definition is still recognized by Tex. Geol. Survey. (See E. H. Sellards, Univ. Tex. Bull. 3232, 1933.)

Named for Valera, Coleman Co.

Valhalla granite.

Tertiary: British Columbia.

O. E. LeRoy, 1913 (12th Int. Geol. Cong. Guidebook 9, p. 62).

Vallecito conglomerate. (In Needle Mountains group.)

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Vallecito cgl.*—A heavy cgl. exposed on both sides of Vallecito Creek for about 1 mi. N. from S. bdy of quad. Is better exposed on Pine River. Thickness 2,000 or more ft. Contact (conformable) with overlying Uncompahgre fm. is shown to E. of quad., in Pine River drainage. The Vallecito cgl. and Uncompahgre fm. compose Needle Mtns group in this area. [See also under *Needle Mtns group.*]

For many years this fm. was classified as "Algonkian," but the terms "Algonkian system" and "Archean system" having been discarded by U. S. Geol. Survey the fm. is now classified as pre-Camb.

Vallenar formation.

Middle Devonian: Southeastern Alaska (Ketchikan region).

A. H. Brooks, 1902 (U. S. G. S. P. P. 1, pp. 40–52, map). *Vallenar series.*—Bluish lss. and calc. schists, with some black slates. Named for typical exposures on Vallenar Bay. Is Middle Dev., at least in part, according to fossils identified by Schuchert. Uncon. overlies Wales group. Relations to Ketchikan series undet. Has been mapped as broad belt on W. side of Gravina Island, but was positively identified only at Vallenar Bay.

This name is now restricted to its type area, as later work proved only small part of Gravina Island is composed of Dev. rocks.

†Valley limestone.

Ordovician and Cambrian: Eastern Pennsylvania to northern Virginia.

P. Frazer, Jr., 1883 (2d Pa. Geol. Surv. Rept. C_4, pp. 99–100, 112–144), applied *Valley ls.* and *Chester Valley ls.* to the "Siluro-Cambrian? ls." of Chester Co., Pa., map accompanying this rept.

Same as Shenandoah ls. of subsequent repts, which has been subdivided and discarded in many areas.

The ls. of valley of Va. was described by W. B. Rogers in repts as early as 1839.

Named for Great Valley of Appalachian region, of which Shenandoah Valley is a part.

†Valley Forge quartzite.

Lower Cambrian: Southeastern Pennsylvania (Philadelphia region).

F. Bascom, 1904 (Am. Jour. Sci., 4th, vol. 17, p. 143), used *Valley Forge and Edge Hill qtzite (Lower Cambrian)* in tables.

Same as Chickies qtzite, older name.

Valley Head sandstone.

Upper Devonian: Eastern West Virginia (Randolph County).

D. B. Reger, 1928 (Am. Jour. Sci., 5th, vol. 15, pp. 50–57). *Valley Head ss.*—Partly greenish brown and partly reddish brown, thick-bedded, with sh. streaks; partly ripple-marked and having occasional small white quartz pebbles. Marine fossils and tree trunks. Thickness 50 to 100 ft. Included in Chemung series. Separated from underlying Elkins ss. of Chemung by 650 to 750 ft. of sh. and sss., and from overlying Hendricks ss. (top div. of Chemung) by 300 to 325 ft. of shales and sss. Good exposures at village of Valley Head, Randolph Co.

Valley Heads moraine.

Name applied to a Pleist. moraine in southern central N. Y., extending from Pa. line to Mohawk Valley. Appears to be nongeographic. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 627+, 1932.)

Valley Spring gneiss.

Pre-Cambrian (Llano series): Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. Ann. Rept., pl. 3, pp. lvi, 274). *Valley Spring series.*—Acidic and basic mica and hornblende schists, forming basal div. of Fernandan system. Underlies Iron Mtn series and overlies Burnetan system.

S. Paige, 1911 (U. S. G. S. Bull. 450, pp. 15–23). *Valley Spring gneiss.*—Dominantly acidic series, of light color, containing some altered ls. and bands of basic dark material. Lower fm. of Llano series in Llano and Burnet Counties. Grades, by transition zone, into overlying darker basic Packsaddle schist. [Adopted definition.]

Named for Valley Spring, Llano Co.

Valley Springs formation.

Miocene: Northern California (Mokelumne River Basin).

A. M. Piper, H. S. Gale, and H. E. Thomas (U. S. G. S. W. S. P. 780, in press). *Valley Springs fm.*—Pumice and fine siliceous ash, with much greenish-gray clay and some vitreous tuff, glassy quartz sand, cgl.; commonly well bedded; derived largely from rhyolitic ejectamenta thrown out in high Sierra Nevada. Thickness 75 to 525 ft. Uncon. underlies Mehrten fm. and uncon. overlies Ione fm. as restricted by V. T. Allen in 1929. The Valley Springs fm. is "Ione clay rock or tuff," forming upper memb. of Ione fm. (Eocene) as originally defined, but is now known to be of Mio age. Named for exposure on W. slope of Valley Springs Peak, 1½ mi. NW. of town of Valley Springs, near center of sec. 11, T. 4 N., R. 10 E.

Valleytown formation.

Lower Cambrian: Western North Carolina, eastern Tennessee, and central northern Georgia.

A. Keith, 1907 (U. S. G. S. Nantahala folio, No. 143, p. 4). *Valleytown fm.*—In the main consists of mica schist and fine-banded gneiss in vicinity of Valleytown and basin of Valley River. Northeastward to Nantahala River the amount of metamorphism becomes less. Mica schist gives way to mica sl. and argill. sl., and gneiss to graywacke and feldspathic ss. The mica schist passes downward into Brasstown schist, and individual layers of each fm. cannot be distinguished from those of the other. In same region numerous beds of coarse qtzite and graywacke are to be seen. Near Hiwassee River the number and thickness of coarse beds are considerably less, and bdy separating this fm. from Brasstown schist is very difficult to draw. At great bend of Nantahala River the amount of coarse material is very small and slates predominate. In each direction from that point the slates become less and less prominent. Thickness 900 to 1,200 ft. Underlies Murphy marble.

Named for exposures in vicinity of Valleytown, Cherokee Co., N. C.

Valmeyer series.

R. C. Moore, 1933 (Historical geol., pp. 261–264). *Valmeyer series* is name proposed by J. M. Weller and A. H. Sutton to include beds from Osage group to top of Ste. Genevieve ls. and strata of equiv. age. Name is derived from southern Ill., where the rocks of this series are well exposed.

Valmonte diatomite member (of Monterey shale).

Miocene (upper): Southern California (Palos Verdes Hills).

W. P. Woodring, M. N. Bramlette, and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 143). *Valmonte diatomite memb.*—Middle memb. of Monterey sh. in Palos Verdes Hills. Is chiefly diatomite and diatomaceous silt or clay. Estimated thickness 750 ft. Overlies Altamira sh. memb. and underlies Malaga mudstone memb. Type region is E. of Valmonte dist., where upper part is well exposed in quarries of Dicalite Co. Is upper Mio.

Valparaiso morainic system.

Pleistocene (Wisconsin stage): Western Michigan, northwestern Indiana, northeastern Illinois, and eastern Wisconsin. Shown in part on moraine map (pl. 32) in U. S. G. S. Mon. 53, and in part on moraine map in P. P. 106. Named for Valparaiso, Ind.

Valverde flags.

Upper Cretaceous (Gulf series): Southern Texas.

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 221, 229, 230). *Valverde flags.*—Grayish-white laminated to flaggy lss., separated into bands by laminated clays. Contain Inocerami. Thickness 600 ft. Basal fm. of Upper Cret. Overlies Vola ls. and underlies Pinto ls. Correlated with Eagle Ford shales. Named for Val Verde Co., in which they form bluffs [along Rio Grande].

Vamoosa formation.

Pennsylvanian: Central Oklahoma (Seminole County).

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 125–128, pls. 3, 27, and map. Name was also used by Morgan, but not defined, in Okla. Geol. Surv. Circ. 12, pl. and p. 15, 1923). *Vamoosa fm.*—About 230 ft. of chert cgls., massive coarse red and brown sss., and red shales, underlain by about 30 ft. of dark sh. that might easily be mapped as a separate fm. The clastic material is finer near top, and red coloration is there less pronounced. The fm. contains a greater thickness of chert cgls. than does any other fm. of area. The chert fragments are mostly angular. No fossils found, and probably none are present in the clastic beds, but the basal dark sh. is very probably fossiliferous. Overlies Belle City ls. and underlies Ada fm., which overlaps it.

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, pp. 1454, 1458, 1459), reported that N. of Stonewall quad. 225 ft. of "unclassified nonconglomeratic shales and sss." separate Vamoosa fm. from Belle City ls., and that Vamoosa fm. is there overlain by Deer Creek memb. of Pawhuska ls.

Named for exposures about ½ mi. E. of village of Vamoosa, Seminole Co. Is typically developed on main road btw. Sasakwa and Konawa.

Vamos Vamos beds.

Oligocene or Miocene: Panama.

E. Howe, 1908 (Am. Jour. Sci., 4th, vol. 26, p. 219). [Assigned to Olig., but C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 584), assigned these beds to middle Mio.]

Vanalta sand.

An oil-producing sand, 5 to 15 ft. thick, in basal part of Kootenai fm. (Lower Cret.) in Border-Red Coulee oil field of NW. Mont. and SW. Alberta. It is a fine- to medium-grained gray quartz sand, containing thin laminae of black sh. and small amounts of pyrite, and forms the upper eastward-extending tongue of Cosmos sand. Is separated from lower part of Cosmos sand by 10 to 15 ft. of gray-green pyritic siltstone. Named for discovery well.

Van Buren formation.

Lower Ordovician (Beekmantown): Southeastern Missouri.

H. S. McQueen, 1930 (Insoluble residues as a guide in stratigraphic studies, Mo. Bur. Geol. and Mines, separate). *Van Buren fm.*—The name *Gasconade* has been applied to the cherty dol. beds lying btw. Gunter ss. memb. at base and overlying Roubidoux fm. Ulrich believes, however, that two fms. occupy this interval, and for upper part he has retained name *Gasconade fm.*, but for lower part he has proposed *Van Buren*. In recent field work Bridge (Geol. of Eminence-Cardareva quads., Mo. Bur. Geol. and Mines, 2d ser., vol. in preparation) has used *Van Buren* to designate a faunal memb. lying above Gunter ss. memb. and a well-defined oolite bed in the Gasconade. Subsurface studies by writer indicate that the Mo. fms. may be distinguished on basis of their insoluble residues, and in this paper they are described separately. Base of Van Buren fm. is marked by a ss. memb. Ulrich believes this ss. is older than true Gunter and for that reason has proposed for it the name ***Van Buren ss.***

The present study would indicate, however, that the ss. is traceable in drilling over wide areas. As it occupies strat. position of Gunter memb., that name is retained in this paper. This ss. is absent at many localities, but in S. part of State it has a known thickness of at least 60 ft. Locally it contains large amount of dol. The Van Buren consists of dol., finely crystalline, dark bluish gray, often granular, with white dense porcelainlike and oolitic chert. Thickness of beds above Gunter ss. memb. 35 to 235 ft. The Van Buren is uncon. overlain by Gasconade fm. as here restricted and uncon. underlain by Proctor dol., from which it is distinguished, in absence of Gunter ss. memb., by fact that the Van Buren is cherty and the Proctor is noncherty. The character of the chert in the Van Buren is such that it can also be distinguished from overlying cherty Gasconade fm. restricted. The dolocastic chert is found only in lower 50 to 75 ft. of the Van Buren. The Van Buren contains siliceous oolite and oolitic chert in abundance. Above the dolocastic chert memb. the chert is more translucent, while below it the chert is denser and marked by quartz veinlets and incrustations. The Gasconade chert is much darker than any similar material in Van Buren or Eminence.

C. L. Dake, 1930 (Mo. Bur. Geol. and Mines, vol. 23, 2d ser., p. 137). *Van Buren fm.* does not outcrop in immediate vicinity of town of Van Buren [Carter Co.], which is built on Eminence fm. Nearest exposures are on tops of nearby hills, and no good sections are known anywhere in vicinity. But since name has appeared in print it does not seem wise to attempt to substitute another.

Vanceburg black shale.

Mississippian: Northeastern Kentucky.

E. Orton, 1880 (Review of strat. geol. of eastern Ohio, p. 21, table). *Vanceburg black sh.*, 16 ft. thick, is=Berea [Sunbury] sh. of Ohio and Orangeville sh. of Pa.

Probably named for Vanceburg, Lewis Co.

Vanceburg sandstone member.

Mississippian: Southern Ohio and northern Kentucky.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 656, 657, 665, 758, 763, 768). *Vanceburg ss. memb. of Cuyahoga fm.*—Best developed in vicinity of Vanceburg, Ky., and Buena Vista, Ohio. Here memb. is about 150 ft. thick, and on whole the sss. are thicker than intervening shales. To N. and E. the shales become relatively more important, and at Bainbridge they form much the larger part of memb. These sss. give place by transition to the shales of Scioto Valley sh. facies of Cuyahoga fm. [Cuyahoga fm. of Hyde includes lower part of Black Hand fm.] Underlies Churn Creek memb. of Cuyahoga and overlies Rarden memb. of Cuyahoga.

Is a part of Black Hand fm. of Prosser and other geologists.

Vanceburg sandstone facies.

Mississippian: Southern Ohio and northern Kentucky.

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 657, 758–763). *Vanceburg ss. facies of Cuyahoga fm. of southern Ohio.*—Sparingly fossiliferous sss. of different type from those in the cgl. area. Includes (descending): Churn Creek memb., 50 to 100 ft.; Vanceburg ss. memb., 150 ft.; Rarden sh. memb., 8½ to 58 ft.; Buena Vista memb., 1 to 30 ft.; Henley sh. memb., 5½ to 226 ft. Best developed in vicinity of Vanceburg, Ky., and Buena Vista, Ohio.

Corresponds to Cuyahoga fm. and lower part of Black Hand fm.

Vancouver series.

Triassic and Jurassic: British Columbia.

G. M. Dawson, 1887 (Canada Geol. Surv. Rept. 1886, pp. 10B, 20B, 41B). *Vancouver series*, Triassic, B. C.

The rocks in Alaska that have been called "Vancouver series" by some geologists are now considered to be Mesozoic or older. Late repts of Canada Geol. Survey assign Vancouver series of B. C. to Jurassic and Triassic.

†Vancouver group.

Upper Cretaceous: Southwestern British Columbia (Vancouver Island) and northwestern Washington (Sucia and Waldron Islands).

C. A. White, 1889 (U. S. G. S. Bull. 51, p. 33). Prof. J. S. Newberry, of Columbia College, N. Y., has placed in my hands for investigation a collection of Cret. fossils from some of small islands at S. end of Gulf of Georgia, adjacent to Vancouver Island. The islands from which these fossils came are Sucia, Waldron, and Sheep Jack. The fossils all belong to same fm., which is identical with the coal-bearing fm. at Comox and Nanaimo, on Vancouver Island, which I shall designate *Vancouver group*. Although this fm. is paleontologically equiv., at least in part, to Chico of Calif., I prefer to use for it local name *Vancouver group*.

C. A. White, 1891 (U. S. G. S. Bull. 82, p. 194). When I proposed *Vancouver group* for Cret. strata I overlooked fact that G. M. Dawson had in 1886 applied that name to rocks which he regarded as Triassic and had suggested *Nanaimo group* for the Upper Cret. strata in question. (Canada Geol. Surv. Rept. 1886, p. 10B.) Subsequently (Am. Jour. Sci., vol. 39, 1890, pp. 180–183) Dawson confirmed his selection of Nanaimo group for these Cret. strata and briefly discussed their relations and characteristics. I have therefore abandoned *Vancouver group* for the Upper Cret. strata of Vancouver dist., and adopted *Nanaimo* instead.

Vanderburg sandstone. (In Henshaw formation.)

Pennsylvanian: Western Kentucky (Webster County).

L. C. Glenn, 1912 (Ky. Geol. Surv. Rept. Prog. 1910 and 1911, p. 26). *Vandersburg ss.*—Fine-grained variable ss., possibly 25 ft. thick, in middle of Dixon [Henshaw] fm. in Webster Co.

L. C. Glenn, 1922 (Ky. Geol. Surv. ser. 6, vol. 5, p. 119). *Vanderburg ss.*—Medium- to coarse-grained, usually soft ss., 10 to 60 ft. thick. Underlies Mount Gilead shales and overlies Bald Hill shales. N. and NW. of Catesville and at Mount Pleasant Church it lies close above Dixon ss. and has probably cut out most of Bald Hill shales. Underlies crest of ridge on which Vanderburg is located.

Named for Vanderburg [correct spelling], Webster Co.

Vandever shale. (In Lee group.)

Pennsylvanian: Central Tennessee.

C. Butts, 1916 (Tenn. Geol. Surv. Res. of Tenn., vol. 6, pp. 107–110). *Vandever sh.*—Somewhat ferruginous sandy and clay sh. with heavy ss. beds in lower half. Thickness 200 ft. Underlies Rockcastle ss. and overlies Bonair ss.

C. Butts and W. A. Nelson, 1925 (Tenn. Dept. Ed., Div. Geol., Bull. 33D, pp. 14–16, pl. 4), stated that Lantana coal is at or near base of Vandever sh. and Morgan Springs coal is near top.

Named for exposures at Vandever, Cumberland Co.

Van Dusen sand.

See *Van Duzen sand*, the correct spelling.

Van Duzen sand.

Name applied to a thin calc. ss. (occurring in a series of gray and black shales and lss.) that lies 500 to 600 ft. below top of Quadrant fm. in parts of Musselshell, Fergus, and Garfield Counties of central Mont. (in Cat Creek anticline, Devils Basin dome, etc.). Lies at depth of 1,120 to 1,230 ft. Is pay sand in first well put down in Devils Basin, which was drilled by Van Duzen Oil Co. in Dec. 1919. (See U. S. G. S. Bull. 786B, 1927, pp. 68–69.)

See under *Heath fm.*, H. W. Scott, 1935.

Van Etten.

Upper Devonian: Central southern New York (Chemung and adjacent counties).

H. S. Williams, 1907 (Jour. Geol., vol. 15, pp. 97, 108, 109). *Van Etten zone of Tropidoleptus* included in Enfield sh. memb. of Nunda fm. Transferred from Chemung.

H. S. Williams, 1909 (U. S. G. S. Watkins Glen-Catatonk folio, No. 169, p. 9). In NE. corner of Watkins quad. the uppermost 100 ft. or more of Enfield sh. memb. contains first *Tropidoleptus* fauna, traces of which fauna are seen in rocks exposed along railroad cuts at Van Etten [Chemung Co.].

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 201).
Senecan series:
Ithaca-Enfield group of fms.:
(Ithaca-Enfield facies group):
(Enfield facies subgroup):
Van Etten memb., 200 ft. Presumably of West Hill age; includes 1st *Tropidoleptus* zone at its base and grades into the "transition beds" of Chenango Valley.
Grimes (?) ss. memb., 100± ft.
Hatch ss. memb., 500 ft.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, No. 4, pp. 99, 285). To E. the Enfield is divisible into 3 members (descending): *Van Etten sh.* ("first *Tropidoleptus* zone"), Juliand memb., and Kattel sh. The Van Etten underlies Cayuta memb. of Chemung fm.

G. H. Chadwick, 1935 (Am. Mid. Nat., vol. 16, No. 6, pp. 858, 862). To E. the Enfield splits into (descending): *Van Etten ("First Tropidoleptus")* zone, Juliand zone, and Kattel (*"Leiorhynchus globuliforme"*) zone.

Van Horn sandstone.

Cambrian (Upper): Western Texas.

G. B. Richardson, 1904 (Univ. Tex. Min. Surv. Bull. 9, p. 28). *Van Horn fm.*—Massive coarse red ss. and cgl. in red valley NW. of Van Horn and in southern Diablo Mtns. Thickness 0 to 500 or more ft. No fossils, but tentatively assigned to Camb. Probably younger than Bliss ss. Uncon. at base. Merges upward into varicolored ss. and white calc. ss. containing early Ord. (uppermost Calciferous) fossils.

G. B. Richardson, 1908 (Am. Jour. Sci., 4th, vol. 25, pp. 476–477), correlated Van Horn ss. with Bliss ss. and assigned both to Upper Camb.

G. B. Richardson, 1914 (U. S. G. S. Van Horn folio, No. 194). Lower 475 ft. of *Van Horn ss.* is reddish ss. and cgl., changing upward to varicolored, yellowish, and white ss.; upper 55 ft. is massive white ss. Uncon. underlies El Paso ls. (which also includes some massive white sss. near base) and uncon. overlies Algonkian (?) Millican fm.

Named for Van Horn, El Paso Co.

Vanhornsville sandstone.

Silurian (Niagaran): Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). *Vanhornsville ss.*—Red coarse hematite-quartz mixture, exposed at Vanhornsville [Herkimer Co.]. Thickness 20 ft. Fossils [listed]. Underlies Herkimer ss. and overlies Sauquoit beds. [Is a memb. of Clinton fm.]

Vann sand.

A subsurface sand, of late Penn. (?) age, in central northern Okla. In Perry pool, Noble Co., it lies at 1,587 ft. depth and is 8 ft. thick, the Ragan sand lying at 1,805 ft. and the Tonkawa at 2,714 ft.

†Van Nest Gap gneiss.

Pre-Cambrian: Northern New Jersey.

N. E. A. Hinds, 1921 (Am. Jour. Sci., 5th, vol. 1, pp. 355–364). *Van Nest Gap gneiss.*—An alkali-quartz syenite gneiss; a rather coarse, even-grained rock of dark grayish-green color and fresh unweathered appearance. Occurs at Van Nest Gap, near Oxford Furnace, Warren Co. Its chemical and lithological characters closely resemble those of certain phases of Byram gneiss, and the rock is therefore tentatively assigned to that group. Exact geol. relations of Van Nest Gap rock are unknown, but chemical composition places it with dark-colored variety of Byram gneiss.

In U. S. G. S. Raritan folio, No. 191, 1914, the gneiss around Oxford Furnace was mapped as Byram gneiss.

Vanoss formation.

Pennsylvanian: Central southern Oklahoma.

G. D. Morgan, 1924 (Bur. Geol. [Okla.] Bull. 2, pp. 133–137, pls. 3, 27, and map). *Vanoss fm.*—Alternating sss., cgls., shales, and a few thin lss., all arkosic, some sss. so arkosic as at first glance to be mistaken for granite. The sss. are less prominent in upper part than near base. Shales generally of light color, ranging through shades of green and gray; some red shales also present. Rests on nonarkosic Ada fm. and is overlain by arkosic Stratford fm. Is basal fm. of Pontotoc terrane [group]. Thickness 250 to 650 ft. Fossil plants and shells. Named for exposures in Vanoss, Pontotoc Co.

Vanport limestone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania and Maryland, eastern Ohio, and northern West Virginia.

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q, pp. 60–66). *Ferriferous ls. (Vanport ls.)*.—Massive ls., fossiliferous, 1 to 15 ft. thick. Overlain by Buhrstone iron ore. Lies 30 ft. below Kittanning ss. and sh. and 25 to 55 ft. above Clarion coal.

Named for exposures at Vanport, Beaver Co., Pa.

Van Schaick.

Middle Ordovician: Eastern New York (Mohawk Valley).

R. Ruedemann and G. H. Chadwick, 1935 (Sci., n. s., vol. 81, p. 400). *Van Schaick* introduced for lowest Snake Hill or zone of *Climacograptus caudatus* in Mohawk Valley.

Vanuxem.

Name applied to a Pleist. glacial lake in central N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, p. 615, 1932.)

Van Wert stage.

A name applied by W. H. Sherzer (Mich. Geol. Surv., vol. 7, pt. 1, 1900, pp. 133–135) to the stage of the ice at the time the Defiance moraine of Ohio and Mich. was deposited.

Vaquero sandstone.

See *Vaqueros ss.*

Vaqueros sandstone.

Miocene (lower): Southern California (Salinas and San Joaquin Valleys).

H. Hamlin, 1904 (U. S. G. S. W. S. P. 89). *Vaquero ss.*—Rather coarse, uniformly gray, white, or light-yellow quartzose ss., with an occasional stratum of granitic pebbles. In Salinas Valley it is a well-defined fm. So far as observed in this region it rests uncon. on Basement complex and on stratified terranes older than Neocene, being thus in this locality the oldest known memb. of the Neocene, but in other localities Neocene fms. are found below Vaqueros ss. Is of great thickness along E. slope of Santa Lucia Range, especially in *Los Vaqueros* Valley, hence the designation proposed by writer for this series of sss. [Lists fossils. *Los Vaqueros Creek* is shown on Hamlin's map. It is in Monterey Co.]

B. L. Clark, 1930 (Geol. Soc. Am. Bull., vol. 41, pp. 751–770). Faunas of Vaqueros and Temblor horizons have always been found in same sequence, and though they are very different they occur in similar facies of deposition (arkosic sss.). To N. the Temblor is conformable on underlying Vaqueros; in southern Calif. there is well-marked uncon. btw. them.

H. G. Schenck, 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 521–534). *Vaqueros fm.* has not been adequately defined as strat. unit and its early Mio. age is an assumption. Lower part of type Temblor is=upper part of Vaqueros at its type loc. [Long discussion. Suggests *Vaqueros group*.]

The present accepted definition of Vaqueros ss. is for oldest known Mio. deposits in southern Calif., which range in thickness from 500 to 6,000 or more ft., and which contain the *Turritella inezana* fauna. In Santa Cruz Mtn region the Vaqueros is uncon. underlain by San Lorenzo fm., of Olig. age. In Coalinga and neighboring districts it is uncon. underlain by Kreyenhagen sh., of Eo. and Olig. (?) age. In Ventura and Los Angeles Counties it is underlain, in places uncon., by Sespe fm., of Olig. and Mio. (?) age. In Salinas Valley region it is conformably overlain by Monterey (†Salinas) sh. In NW. part of Kern Co. it is overlain by Monterey (†Maricopa) sh. In parts of Ventura and Los Angeles Counties it is overlain, probably conformably, by Topanga fm., which is characterized by *Turritella ocoyana* fauna. Vaqueros ss. seems now to generally be considered as in part at least older than Temblor ss. or *Turritella ocoyana* zone. The U. S. Geol. Survey formerly included it in Monterey group, but that usage was discontinued in 1935. (See under *Monterey group*, also under *Temblor ss.*)

Named for exposures on Los Vaqueros Creek, Monterey Co.

Varennesic period.

C. [R.] Keyes, 1914 (Iowa Acad. Sci. Proc., vol. 21, p. 201). "A term proposed to take the place of A. C. Lawson's name Ontario, which is preoccupied. Is the old French designation for Ontario Province. Is probably not coextensive with term Loganian series."

Vashon drift.

Pleistocene (Wisconsin): Western Washington (Puget Sound region).

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Vashon till.*—Prevailingly sandy loam and coarse rounded gravel deposited by Vashon glacier and representing latest occupation of Puget Sound Basin by the northern ice tongue. Occurs typically, but not heavily, on Vashon Island. Is underlain by stratified blue clay along plateau face on E. side of Duwamish Valley.

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54), gave thickness of *Vashon drift* as 1 to 100 ft.

Vashon glacial epoch.

Pleistocene: Western Washington.

B. Willis, 1898 (Geol. Soc. Am. Bull., vol. 9, pp. 111+). *Vashon glacial epoch.*—Latest glacial epoch of Wash. Includes Steilacoom fm., Vashon till, Osceola till, Osceola clays, and Douty gravels. Separated by erosion uncon. from preceding Puyallup interglacial epoch.

Covers Wisconsin time and some pre-Wisconsin deposits.

Vasquez series.

Miocene(?): Southern California (Los Angeles County).

R. P. Sharp, 1935 (Pan-Am. Geol., vol. 63, No. 4, p. 314). In Ravenna quad., 18 mi. E. of Saugus, 9,000± ft. of early Tertic fangls. and 4,000± ft. of curiously interbedded basalts are exposed. They lie uncon. on pre-Tertic basement and uncon. under Mint Canyon fm. (upper Mio.). For this group of rocks *Vasquez series* is suggested, replacing "Escondido series," preoccupied. The upper part of section contains local occurrences of fine silty lacustrine beds. [Derivation of name not stated.]

Vassalboro sandstone.

Silurian: Central southern Maine (Kennebec County).

E. H. Perkins and E. S. C. Smith, 1925 (Am. Jour. Sci., 5th, vol. 9, pp. 204–228). A series of fine-grained sss., well exposed in town of Vassalboro. Typically the *Vassalboro ss.* is a massive bluish-gray ss. Locally it is recrystallized and becomes a qtzite, and the shales associated with the qtzite become altered to biotite schist. Often pyritiferous. In vicinity of China Lake the sss. terminate adjacent to Branch Pond gneiss, but no evidence found that they grade into each other. Vassalboro ss. grades into Waterville shales through a series of transition beds consisting of interbedded shales and sss. [Do not state in which fm. the transition beds are included.] No fossils, but relation to Waterville sh. indicates they are of about same age—mid-Silurian.

On 1933 geol. map of Maine, by A. Keith, these rocks are mapped as Silurian.

Vaucluse zone.

Pre-Cambrian: Northwestern South Carolina.

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in Catalogue of mineral localities of S. C., S. C. Geol. Surv. ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 6, 9, 12). *Vaucluse zone (Archean).*—The Vaucluse area is bounded on NW. by Edgefield-Chesterfield zone;

on SW. by Savannah River; the delimiting line on SE. is highly irregular by reason of variable distribution of overlapping coastal plain sands; the line which interruptedly connects the tongued projections of this area on SE., beginning near Hamburg, extends by Vaucluse, Miles Mill, Fox Bridge (Chinquepin Creek), Quattlebaum Mill (Lightwood Creek), thence by Red Bank Creek to Granby; beyond which this fm. is obscured to Granny's Quarter, whence it is successively observed at old Sumter Quarry, at Taxehaw 40-acre Rock; and at N. C. line, near Great Pee Dee River. The rocks comprise granite, granite-gneiss, gneissoid slates, mica schists, hornblende slates, qtzite, and kaolinized schists.

Named for exposures at Vaucluse, Aiken Co.

Vaurial formation.

Ordovician: Quebec (Anticosti Island).

W. H. Twenhofel, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 269), and 1921 (Canada Geol. Surv. Bull. 33, pp. 4, 5).

Veale sand.

A subsurface sand, 20 ft. thick, lying near base of Marble Falls ls. of central Tex. Was first found in Veale well, S. of Caddo, Stephens Co.

Vedder greenstone.

Carboniferous (?): Southwestern British Columbia and central northern Washington.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines Mem. 38, maps 16 and 17). [Mapped on Vedder Mtn, B. C.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, p. 522).

Vedder sand.

A name that has been applied to coarse productive sands, 40 to 85 ft. thick, lying at av. depth of 1,400 ft. below top of what is loosely identified as Temblor fm. (Mio.) in Mount Poso oil field, Kern Co., Calif. Apparently named for Vedder oil wells. (See V. H. Wilhelm and L. W. Saunders, Calif. State Min. Bur., vol. 12, No. 7, pp. 8-9, 1927.) In 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, p. 18, pl. 2), A. Diepenbrock stated that lower memb. of lower part of [so-called] Temblor fm. in Mount Poso oil field is known as *Vedder sand*, which has thickness of 290 to 750 ft. and directly underlies Jewett silt memb. of the Temblor [so-called]. He divided his Vedder sand memb. into upper Vedder zone, *Vedder silt*, and lower Vedder zone.

Vedder silt.

See under *Vedder sand.*

Velasco formation.

Upper Cretaceous: Mexico (Tampico embayment).

J. A. Cushman and E. A. Trager, 1924 (Geol. Soc. Am. Bull., vol. 35, p. 100).

Venango group.

Venango oil sand group.

Venango stage.

Venango monothem.

Devonian or Carboniferous: Northwestern Pennsylvania.

J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I₃, Atlas, pl. 11). *Venango oil sand group* (*No. 7*), 350 ft. Underlies Crawford [Meadville] shales and is separated from underlying Warren oil group by 300 to 350 ft. of shales and thin sss. Consists of (descending): (1) First ss.; (2) sh.; (3) Second ss.; (4) sh.; (5) Stray sand; (6) sh.; (7) Third ss.

I. C. White, 1881 (2d Pa. Geol. Surv. Rept. Q_4, pp. 99-116). *Venango oil sand group* (also *Venango group*).—Consists of (descending): (1) Venango Upper ss. (First oil sand) [Woodcock ss. of Chadwick, 1925, according to Chadwick], 20 ft. of sandy shales or flags, with no coarse or pebbly strata [in Erie and Crawford Counties]; (2) Venango Upper shales [Saegerstown sh. of Chadwick, 1925], 90 to 100 ft. of pale-blue sh. with occasional thin sandy layers, which sometimes thicken into sandy flags, prevailing fossils of Chemung types; (3) Venango Middle ss. (Second oil sand) [Millers ss. of Chadwick, 1925], 20 ft. of soft shales with sandy shales or flagstone layers, but nowhere is it a ss. mass and there are no layers of pebbles; (4) Venango Lower shales [Amity sh. of Chadwick, 1925], 140 ft. thick, consisting of 15 ft. of red sh. underlain by 125 ft. of blue sh.; (5) Venango Lower ss. (Third oil sand), 30 ft. thick and=LeBoeuf cgl. "I am disposed to regard Venango group as upper Chemung." Underlies Riceville sh., which contains Chemung fossils. [Chadwick's names in brackets above and their equivalents were given in Geol. Soc. Am. Bull., vol. 36, pp. 455–464, 1925.]

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69), showed *Venango group* included all beds btw. *base* of Riceville sh. down to base of Le Boeuf ss., and assigned it to *Bradfordian*. He repeated this classification in 1924 (N. Y. State Mus. Bull. 251, p. 157) and 1925 (Geol. Soc. Am. Bull., vol. 36, p. 464), when he divided *Venango group* into (descending) Woodcock, Saegerstown, Millers, Amity, and Le Boeuf.

K. E. Caster, Feb. 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Venango group (delimited "Conewango" group)*, divided into (descending): (1) Riceville fm. [restricted], including Oswayo sh. memb. (lower "Riceville"); and (2) Cattaraugus fm., including (descending) Woodcock ss. memb. (Venango 1st oil, Tuna cgl.), Saegerstown sh. memb., Millers ss. memb. (Venango 2d oil "B"), North Warren sh. memb. (in midst of the Salamanca), Watson ss. memb. (Venango 2d "A"), Amity sh., and Panama cgl. memb. (Le Boeuf, Venango 3d oil, Wolf Creek). Underlies Smethport sh. memb. (upper part of "Riceville") of Knapp fm. and overlies Chadakoin fm. of Chemung group.

G. H. Chadwick, Oct., 1933 (Pan-Am. Geol., vol. 60, p. 195), assigned Conewango of Butts to Dev. and divided it into (descending) Riceville sh. restricted, Woodcock, Saegerstown, Millers, Amity, and Panama. On p. 197 he stated: White limited his Venango fm. to the 3 sands and their 2 included shales. But his description of Riceville sh., next above these, shows its essential identity with them. Therefore I proposed to expand *Venango* to include Riceville, being then uncertain as to eventual limits of Mr. Butts' Conewango fm., defined as covering Venango and Riceville. Now that we find scope of Conewango to be correct we must apply that name to the enlarged group.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71), included in his *Venango stage (Venango monothem)* all beds btw. *base* of Riceville and base of Panama cgl., and treated the Riceville as a distinct "stage." He assigned the beds to Dev.

G. H. Chadwick, 1935 (Geol. Soc. Am. Bull., vol. 46, No. 2, pp. 328, 334), Conewango group includes Cattaraugus and Oswayo and the equiv. Venango and Riceville of Pa. Venango first sand is Woodcock ss. (and not Berea nor Corry), as long ago worked out correctly by Mr. Carll and by Dr. White and as subsequently confirmed independently by both Caster's field work and writer's surface and subsurface studies.

Named for Venango Co.

Venango formation.

Upper Devonian: Northern Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 2, pp. 1405–1406, 1438–1440, 1500–1506). My own opinion is that these intermediate [Chemung-Catskill] passage beds [btw. Lackawaxen cgl. and Allegrippus cgl.] can very well be formulated as a separate fm., and well deserve a separate name; and I propose for them the name *Venango fm.* For although it is not proven that interval btw. Allegrippus and Lackawaxen cgls. is the very interval btw. Carll's Venango Third and First oil sands, yet, as Ashburner has shown in his McKean and Cameron repts (R, R2), the increase of red rocks southeastward renders this a very probable hypothesis; and general horizon is undoubtedly the same. Therefore in speaking of Chemung fm. in northern Pa. it must be understood to include Venango fm. as its uppermost subdivision.

Venice member (of Columbus limestone).

Middle Devonian: Northeastern and central Ohio.

C. K. Swartz, 1907 (Johns Hopkins Univ. Circ. 7, p. 62). *Venice memb.*—Blue ls. with chert, 6 to 20 ft. thick; bone bed at top. Upper memb. of Columbus fm. Overlain by Delaware fm. and underlain by Marblehead memb. of Columbus fm.

Named for Venice, Erie Co.

Ventana sandstones.

A name introduced by C. [R.] Keyes in 1922 (Pan-Am. Geol., vol. 38, pp. 250, 338) for 325 ft. of sss. described as forming top memb. of his Doloresian series (late Triassic) in Apache Co., Ariz., and later applied by him in Utah and Colo. Named for Ventana Mesa, near Chinle, Apache Co., NE. Ariz.

Ventioner beds. (In Brad formation.)

Pennsylvanian: North-central Texas.

G. Scott and J. M. Armstrong, 1932 (Univ. Tex. Bull. 3224, p. 35). In Wise Co. the Adams Branch ls. is absent, and the beds below Ranger ls. memb. of Brad fm. and above Devils Den ls. memb. of Graford fm. are here named *Ventioner beds*. The beds are at least 300 ft. thick, and consist of sands and shales with 2 ls. lentils, the lower of which lies about 40 ft. above Devils Den ls. on W. side of Trinity River upstream from mouth of Ventioner Creek, and the higher of which lies about 40 ft. higher and is exposed 1 mi. W. of Ventioner Creek bridge. For convenience of mapping these beds are included in Brad fm., although lower part is of Graford age.

Ventura formation.

Triassic (?): Central northern Washington.

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137, map). *Ventura fm.* (text heading), *Ventura system* (map).—Thick-bedded sss., shales, coarse cgls., of characteristic reddish-brown color, lithologically and structurally distinct from Cret. terranes bordering them on E. and W. No fossils, but color and association with Similkameen fm. on W. and Winthrop ss. on E., both Cret., suggest that fm. belongs to Triassic. Named for abandoned mining camp in mtns bordering Methow Valley.

Ventura sands.

Pliocene and Pleistocene: Southern California (Ventura County).

C. M. Carson, 1925 (Pan-Am. Geol., vol. 43, pp. 265–270). *Ventura sands.*—The Ventura fm. of Ventura Co. is well exposed in foothills btw. Ventura and Santa Paula, in Las Posas Hills, near Camarillo, on S. and W. flanks of South Mtn, and in Simi Valley. The fm. is from 500 to 1,000 ft. thick, and is composed of coarse and fine yellowish sand, which in places becomes quite gravelly. It is in general only moderately consolidated, although locally hard beds occur. [Fossils listed.] This fauna is a cold-water facies, but its habitat is not so cold as that of the Santa Barbara fauna which follows. Assigned to Plio. Is younger than San Diego clays.

U. S. Grant, IV, and H. R. Gale, Nov. 3, 1931 (San Diego Soc. Nat. Hist. Mem., vol. 1, pp. 36, 37). Name *Ventura horizon* given by Carson is vaguely defined, without definite type loc., and its mixed Plio. and Pleist. fauna and original correlation below Santa Barbara zone rule it out of consideration for the marine Pleist. in W. part of Ventura Basin, which has been called *Saugus fm.* in some repts. The type Saugus, however, is nonmarine, and these marine deposits should not be called *Saugus*. It seems desirable to have a single name for this series of marine strata overlying Santa Barbara zone, and *lower San Pedro series*, proposed by Arnold, although lower part of the section was not originally included, seems most appropriate.

†Venus cancellata bed.

Paleontologic term applied in early repts to Plio. beds of Fla. characterized by *Venus cancellata*.

†Vera Cruz graphite schist.

Pre-Cambrian: Southeastern Pennsylvania (Easton-Reading district).

B. L. Miller, 1911 (Pa. Topog. and Geol. Surv. Rept. No. 4, p. 16). *Vera Cruz graphite schist.*—Consists of quartz, graphite, biotite, orthoclase, and some pyrite. Underlies Franklin ls.

Is a facies of Baltimore gneiss and not a distinct fm. and has been abandoned by its author and by U. S. Geol. Survey.

Veraguas crystalline series.

Age (?): Panama.

O. H. Hershey, 1901 (Calif. Univ. Dept. Geol. Bull., vol. 2, p. 247).

Verdan series.

A term employed by C. [R.] Keyes to designate "the Coconino ss. and some associated layers as well developed on Verde River, S. of Flagstaff, Ariz."

Verde formation.

Tertiary or Quaternary (Pliocene or Pleistocene): Central Arizona (Yavapai County).

L. E. Reber, 1922 (Am. Inst. Min. and Met. Engrs. Trans., vol. 66, pp. 3–26). Quat. lake beds, 1,200± ft. thick. Jenkins has recently studied and mapped the ls. deposits formed by this lake and named them *Verde fm.*

O. P. Jenkins, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 65–81, map). *Verde form.*—Chiefly white hard impure reprecipitated cavernous ls. interbedded with sands, gravels, and clays and exposed in high white bluffs along the stream courses; generally horizontal and rather evenly bedded; near the border, or shore line, of old Verde Lake, cgl. beds are in evidence, the boulders of which represent nearly all the rocks of surrounding country, including pieces of basalt. Thickness of fm. 1,400 to 2,000 ft. at least. Occurs along Verde River Basin in region about Clarkdale and Camp Verde, Yavapai Co., Ariz. Overlies greatly eroded surface of various members of the Paleozoic and earlier rocks, and also some of basic lavas which occur in abundance in this region. The fm. as a whole must not be confused with local spring deposits, although they have undoubtedly aided in its limy accumulation and alteration. It is a local deposit, but similar local deposits, formed in a like manner, may be expected to occur in same general geologic or physiographic province. It covers an area of about 300 sq. mi. No well-preserved fossils were found. Is uncon. overlain by terrace gravels which have generally been regarded as Pleist. The Verde fm. may be late Tert. or very early Pleist.

Verde Creek granite.

Age (?): British Columbia.

V. Dolmage, 1934 (Canada Dept. Mines, Geol. Surv. Mem. 171, No. 2344, p. 17).

Verden sandstone.

Permian: Central southern and southwestern Oklahoma (Grady, Stephens, and Caddo Counties).

N. Meland and R. D. Reed, 1924 (Jour. Geol., vol. 32, No. 2, pp. 150–167). *Verden ss.*—Name suggested by N. Meland in unpublished thesis, Univ. of Okla. A strikingly cross-bedded calc. red ss. 10 ft. thick. Caps a row of elongated buttes extending from a point a few mi. NW. of village of Verden, Grady Co., in a straight line to SE., a distance of somewhat more than 30 mi. from end to end. Is a supposed river-channel deposit in Perm. Red Beds of SW. Okla. Is enclosed in gypsiferous shales and fine-grained sss. of Perm. age. Max. width is 1,200 ft. Many fossils, which Beede says are probably not strictly fresh-water forms. Lies 75 to 100 ft. below base of sandy phase of Whitehorse ss.

C. N. Gould, 1924 (A. A. P. G. Bull., vol. 8, No. 3, pp. 324–341). An unusual phase of Dog Creek sh. is a channel ss. which has been named *Verden ss.*

C. N. Gould, 1925 (Okla. Geol. Surv. Bull. 35, p. 92). *Verden channel ss.* is not more than 10 ft. thick nor more than 500 ft. wide. It occurs in Grady, Stephens, and Caddo Counties, where it is exposed on a line of outcrops extending across the country like a railroad grade for 40 mi. Not yet determined whether it was originally a stream channel, tidal channel, or sea beach, or formed in some other manner. In Grady Co. it occupies upper part of Dog Creek sh.

C. D. Stephenson, 1925 (A. A. P. G. Bull., vol. 9, No. 3, pp. 626–631). Writer has carefully observed strat. position of Verden ss. and has reached conclusion that it rather definitely occurs about 35 ft. below base of Whitehorse ss. in Grady, Caddo, and Canadian Counties (the 35 ft. of overlying beds consisting of sh.); and that *although the Verden has been included in Whitehorse ss.*, it does not seem proper to include a channel ss. in the massive Whitehorse fm. It also seems to writer that Greenfield ls. is strat. equiv. of Verden ss.

C. M. Becker, 1927 (Okla. Geol. Surv. Bull. 40–I, pp. 9–13). The so-called Verden ss. occurs btw. base of Whitehorse ss. and top of Dog Creek fm. It is a long channel-like deposition.

A. J. Freie, 1930 (Okla. Geol. Surv. Bull. 48). Verden channel ss. occurs at base of Whitehorse ss.

For many years the U. S. Geol. Survey designated this fm. as *Verden channel ss.* Recent work by N. W. Bass, however, revealed the presence in it of marine fossils, showing that the ss. was deposited as a barrier beach, instead of by a stream. The name has therefore recently been changed to *Verden ss.*

Verdi beds. (In St. Louis limestone.)

Mississippian: Southeastern Iowa.

H. F. Bain, 1895 (Am. Geol., vol. 15, p. 319). *Verdi beds.*—Alternating sss. and lss. [100 ft. thick] forming middle [top now] memb. of St. Louis fm. Overlain by Pella beds [of Ste. Genevieve age] and underlain by Springvale beds [see Croton ls.].

Named for exposures in old railroad quarry near Verdi station, Washington Co.

Verdigris limestone. (In Cherokee formation.)

Pennsylvanian: Northeastern Oklahoma (Rogers County).

C. D. Smith, 1928 (Okla. Geol. Surv. Bull. 40U, map). [*Verdigris ls.* mapped in upper part of Cherokee fm. in Verdigris River region, Rogers Co. Lies higher than Chelsea ss., also mapped in upper part of Cherokee sh.]

C. L. Cooper, 1928 (Univ. Okla. Bull., Proc. Okla. Acad. Sci., vol. 7, p. 161). The most conspicuous ls. in Cherokee sh. N. of Arkansas River lies 35 to 50 ft. below Fort Scott ls. It is remarkably persistent, although only about 6 ft. thick, and extends from Kans. line S. to Arkansas River and beyond. [This appears to refer to Verdigris ls. as mapped by Smith.] The most persistent coal bed in the Cherokee lies 35 to 50 ft. below this ls. It ranges in thickness from a few inches to 4± ft. and is called Cherokee coal by the miners and also on the map that is to appear in the bulletin on Okla. coals.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 56). Same as *Ardmore ls.*, which has priority, but Verdigris ls. has been more used.

Verdigris sandstone.

A subsurface sand, of Penn. age and 28 ft. thick, in NE. Okla., lying lower than Prue sand and higher than Skinner sand.

Verdigris sandstone.

Upper Cretaceous: Southern Alberta.

S. E. Slipper and H. M. Hunter, 1931 (A. A. P. G. Bull., vol. 15, No. 10, p. 1186). The basal ss. of Foremost fm. is most persistent memb. of fm. It is proposed to call it *Verdigris ss.* because it is best exposed at 3 localities in coulee of that name. It is also fully exposed along Milk River at intervals for 7 mi. W. of town of Milk River. It does not occur in basal sections of the Foremost exposed along South Saskatchewan River W. of Medicine Hat. It is transitional into underlying Pakowki sh. to such an extent that it is difficult to place the div. line btw. them. Is buff on exposures and light-gray and medium-grained in core samples. Varies considerably in thickness but in general increases southward and southwestward, where it is 60± ft. thick.

Vergennes sandstone member (of Carbondale formation).

Pennsylvanian: Southwestern and central western Illinois.

E. W. Shaw and T. E. Savage, 1912 (U. S. G. S. Murphysboro-Herrin folio, No. 185, p. 7). *Vergennes ss. memb.*—Micaceous loose friable brownish ss. or sandy sh., 15 to 45 ft. thick, in lower part of Carbondale fm. Separated from underlying Murphysboro or No. 2 coal by 20 to 40 ft. of sh. or shaly ss. underlain by clay seam.

T. E. Savage, 1927 (Am. Jour. Sci., 5th, vol. 14, p. 309), showed *Vergennes ss.* of Fulton Co. as in part of the area overlying his Francis Creek sh. and ss. and in other parts of area as completely replacing his Francis Creek and as resting on No. 2 coal.

Named for Vergennes, Jackson Co.

†Vergent series.

Nongeographic name introduced by H. D. Rogers in 1858 (Geol. Pa., vol. 1, pp. 108, 140+, and vol. 2, p. 756). Divided into *Vergent shales* (*Chemung group of N. Y.*), 3,200 ft. thick in Huntingdon Co., Pa., and *Vergent flags* (*Portage flags of N. Y.*), 1,700 ft. thick in Huntingdon Co.

†Vergent flags.

†Vergent shales.

See under †*Vergent series.*

†Verkin shales.

Lower Triassic: Southwestern Utah (Washington County).

E. Huntington and J. W. Goldthwait, 1903 (Jour. Geol., vol. 11, pp. 46–63), divided the rocks underlying Shinarump cgl. and overlying "Super-Aubrey variegated shales and cherty ls." into *Upper Verkin* (chocolate ss. at top, red and white sh. in middle, and red sh. at base) and *Lower Verkin* (gray sss. and sh. above and red sh. below). In 1904 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 42, p. 203, pl. 7, etc.), they stated that they discarded their *Verkin shales* in favor of Ward's prior term *Moencopie* [*Moenkopi*]. The name was apparently derived from Verkin Creek, Washington Co.

Vermejo formation.

Upper Cretaceous: Southeastern Colorado and northeastern New Mexico.

W. T. Lee, 1913 (Am. Jour. Sci., 4th, vol. 35, p. 531). *Vermejo fm.* [See 1913 entry under *Raton fm.*]

W. T. Lee, 1917 (U. S. G. S. P. P. 101, pp. 40, 51–56). *Vermejo fm.*—Consists of coal-bearing ss. and sh., chiefly of fresh-water origin. The sh. is dark, carbonaceous in many places; the ss. is light gray and friable. It uncon. underlies Raton fm. (Eocene) and conformably overlies Trinidad ss. Total thickness 425 ft. Is of Montana age. Type loc. is at SE. extremity of Vermejo Park, N. Mex., where the rocks are well exposed and have max. thickness of 375± ft. [See also under *Raton fm.*]

†Vermetus rock.

Pleistocene and Recent: Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 153, 157, 337). The Vermetus rock was formed by agency of that mollusk on coast of Fla. It is the Pleist. and recent "Worm rock" of the residents of Fla.

†Vermicular sandstone.

†Vermicular sandstone and shales.

Terms applied in early Mo. repts to the beds later named *Hannibal sh.*

†Vermilion series.

†Vermilion schists.

†Vermilion group.

Pre-Cambrian (Keewatin): Northeastern Minnesota (Vermilion district).

N. H. and A. Winchell, 1887 (Minn. Geol. Nat. Hist. Surv. 15th Ann. Rept., pp. 4, 192, 355–357). *Vermilion series* (also *Vermilion group*).—Embraces the mica-hornblendic schists that appear at NW. extremity of Vermilion Lake and their equivalents at W. end of Birch Lake, as well as their extension eastward from Vermilion Lake to Basswood Lake. Belongs to lower part of Keewatin series.

C. R. Van Hise and C. K. Leith, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 401–409, map). *Vermilion series* (Archean) includes (descending): (1) intrusive granite, greenstone, and porphyry; (2) Soudan fm. (iron-bearing); and (3) Ely greenstone.

Vermilion granite.

Pre-Cambrian (pre-Huronian): Northeastern Minnesota (Vermilion district).

F. F. Grout, 1923 (Econ. Geol., vol. 18, pp. 253-269). *Vermilion granite.*—Predominantly a biotite granite of light-pink color. Along S. side it has locally a basic border facies. Intrudes Huronian schists and is supposed to be Algomian in age. Named for exposures on Vermilion Lake and along Vermilion River, northern St. Louis Co.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184). *Vermilion granite* assigned to pre-Huronian (Algoman).

Vermilion moraine.

Pleistocene (Wisconsin stage): Northern Minnesota.

W. Upham, 1894 (Minn. Geol. and Nat. Hist. Surv. 22d Ann. Rept., pl. 1, p. 51). Extends past SW. side of Vermilion Lake.

†Vermilion Cliff group.

Upper Triassic: Southwestern to northeastern Utah and northwestern Colorado.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 52-54, 151). *Vermilion Cliff group.*—Massive sss. with ferruginous layers, often with thin, irregular beds of cherty ls.; the massive beds are sometimes broken into thinner strata. In type area the sss. are of red, orange, vermilion, and light-gray colors. In Uinta Mtns region the Vermilion Cliff group is everywhere darker than the overlying White Cliff group and exhibits false bedding. Thickness 1,100 ft. Underlies White Cliff group and overlies Shinarump group. Named for Vermilion Cliffs, to S. of White Cliffs, near Paria, a little town on Paria River [Kane Co.], Utah.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 33), showed that the ss. of Vermilion Cliffs (Kane Co., southern Utah), and the Vermilion Cliff group of Powell in Uinta Mtns, NE. Utah, are Chinle fm. (Upper Triassic).

†Vermilion Cliff sandstone.

See †*Vermilion Cliff group.*

†Vermilion Creek group.

Eocene: Southwestern Wyoming, northwestern Colorado, and northeastern Utah.

C. King, 1876 (U. S. Geol. Expl. 40th Par., Atlas, maps 1, 2), divided the Tert. deposits of NE. Utah and adjacent areas into (descending) Wyoming cgl. (Plio.), Uinta (Eo.), Bridger (Eo.), Green River (Eo.), and *Vermilion Creek* (Eo.). Advance copies of this map were distributed in 1875, but Atlas is dated 1876.

Hayden and Cope originally considered Wasatch group of Hayden of NE. Utah as synchronous with the Green River deposits of SW. Wyo. (See under *Wasatch group.*)

S. F. Emmons, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, pp. 207-250), described the Tert. rocks of Green River region, Bridger Basin, Washakie Basin, and other areas in SW. Wyo. where Hayden had applied the name *Green River group*, and divided them as follows (descending): Wyoming cgl., Bridger group, Green River group, and *Vermilion Creek group.*

F. V. Hayden, 1877 (U. S. Geol. and Geog. Surv. Terr. Bull. 3, No. 1, pp. 181-185). Wasatch group of Hayden is same as Vermilion Creek group of King, and Wasatch group has priority. [On p. 608 of this Bull. C. A. White showed Green River group above Wasatch group.]

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 339, 353, 355, 360, etc.). [See 1878 entry under *Wasatch group* for reasons why he did not adopt Hayden's name *Wasatch group* for these rocks.]

According to U. S. G. S. Bull. 191, 1902, geologists seem to have unanimously adopted Hayden's name *Wasatch*, instead of King's name *Vermilion Creek*, and the U. S. Geol. Survey also has discarded latter name.

†Vermilion Lake iron-bearing series.

A term applied by R. D. Irving (U. S. G. S. 3d Ann. Rept., 1883, pl. 3, map, and 7th Ann. Rept. pp. 440–441, 1888) to the Huronian rocks of Vermilion Lake region, Minn., which were described as resting uncon. on rocks assigned to the Laurentian, but as consisting of granite, gneiss, green schist, mica schist, and hornblende schist and therefore evidently including Keewatin.

Vermilion River beds.

Cretaceous: Manitoba.

S. R. Kirk, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 123).

Vermilionville sandstone lentil (in Carbondale formation).

Pennsylvanian: Northeastern Illinois.

G. H. Cady, 1919 (Ill. Geol. Surv. Bull. 37, pp. 31, 56–58). *Vermilionville ss. lentil*, in Carbondale fm., lies higher than LaSalle (No. 2) coal and lower than Harrisburg (Springfield, No. 5) coal, in Hennepin and LaSalle quads; thickness 25 to 35 ft. Consists of micaceous sand containing much white mica and blotches and streaks of carbonaceous material. Is massive or heavy-bedded. [Columnar section on p. 31 shows base of Vermilionville ss. lentil lying 50± ft. above No. 2 coal and top underlying clay below Streator (No. 7) coal (in McLeansboro fm.), the ss. in part of area replacing sh. both above and below No. 5 coal.]

Named for exposures near Vermilionville, SW. part of LaSalle Co.

†Vermont formation.

†Vermont quartzite.

Lower Cambrian: Western Massachusetts and southwestern Vermont.

J. D. Dana, 1873 (Am. Jour. Sci., 3d, vol. 6, pp. 272–278). At Rutland, SW. Vt., massive qtzite (*Vermont qtzite*) seems to overlie Rutland ls. The fm. consists of qtzite, chlorite slates, and magnetite and hydromica slates.

T. N. Dale, 1891 (Am. Geol., vol. 8, pp. 1–7). *Vermont fm.*—Qtzite, 870 ft. thick, cropping out in Mount Greylock area only once, but possibly underlying entire mass. Underlies Stockbridge ls.

T. N. Dale, 1891 (Geol. Soc. Am. Bull., vol. 3, pp. 514–519, in description of *Vermont Valley*—Rutland, Danby Ridge, Clarendon, SW. Vt.). *Vermont fm.*—Qtzites, cgls., and schists. Underlies Stockbridge ls.

T. N. Dale, 1894 (U. S. G. S. Mon. 23, p. 190 and map, pl. 1). *Vermont fm.*—Qtzite, fine-grained, alternating with a thin-bedded micaceous and feldspathic qtzite. Associated with these qtzites, and probably at base of this horizon, is a coarse-grained micaceous qtzite, passing in places into a cgl. Thickness 800 to 900 ft. Underlies Stockbridge ls. and overlies Stamford gneiss on Mount Greylock, NW. Mass. [Derivation of name not stated, but probably named for development in southern Vt., as shown on Dale's map, pl. 1. On geol. map (by R. Pumpelly) forming pl. 2 of Mon. 23 the fm. is designated *Vermont qtzite*, and this name was also used in some subsequent repts.]

Includes, in Mass., Cheshire qtzite, Dalton fm., and some granite (see B. K. Emerson, 1917, U. S. G. S. Bull. 597, map), and has been discarded by U. S. Geol. Survey.

F. A. Burt, 1929 (16th Rept. Vt. State Geol., pp. 68–84). *Vermont fm.* consists locally, in Bennington area, SW. Vt., of 1,600± ft. of massive, brecciated, and schistose Lower Camb. qtzites called by Bain (Rept. Vt. State Geol., vol. 15, p. 230, 1925–26) *Bennington qtzite*.

F. A. Burt, 1931 (17th Rept. Vt. State Geol., pp. 115–135). *Vermont fm.* consists of Cheshire and Monkton qtzite and quartz schists with feldspathic and argill. and cgl. beds. Underlies Stockbridge ls. and overlies pre-Camb. gneisses.

Vermont.

Name applied to a glacial lake, of Pleist. age, in Lake Champlain region. Also called *Champlain*.

Vernal.

Name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to 30 ft. of late Jurassic shales in Mont. Derivation of name unknown.

Vernal Mesa granite.

Pre-Cambrian: Central western Colorado (Gunnison River region).

J. F. Hunter, 1925 (U. S. G. S. Bull. 777). Coarse porphyritic granite, resembling the coarsest phase of Powderhorn granite group. Near its borders contains numerous inclusions of biotite schist and gneiss. Is cut by many dikes of aplite and pegmatite. Intrudes the Archean schists. Occurs near NW. end of Vernal Mesa and walls adjacent portion of Black Canyon.

The terms "Algonkian system" and "Archean system" were discarded by U. S. Geol. Survey in 1934. For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

Vernon limestone.

Devonian: Western central Massachusetts and southeastern Vermont.

B. K. Emerson, 1890 (Am. Jour. Sci., 3d, vol. 40, p. 365). *Vernon ls.*, a ls. in Bernardston series, described on pp. 263–275 and 362–374 of same vol.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 276). *Vernon ls.*—Coarse granular ls., highly crystalline, of light color; contains some garnet, hornblende, and green mica. Occurs in Vernon Twp, Vt.

†Vernon gneiss.

Late Carboniferous or post-Carboniferous: Western central Massachusetts and southeastern Vermont.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 17, pl. 34). [*Vernon gneiss* shown in strat. table as underlying the Bernardston rocks. Pl. 34 states that the qtzite of Bernardston series to N. passes into Vernon gneiss.]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), discarded "Vernon gneiss." According to personal communication the rock thus designated is Pelham granite.

Named for occurrence in Vernon Twp, Vt.

Vernon shale member (of Salina formation).

Silurian: Western to east-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, pp. 18–19 and chart). *Vernon sh.*—Red and green shales, gray gypsiferous shales, and thin platten dolomites. Underlies Syracuse salt and overlies Pittsford sh.

Later repts give thicknesses of 150 ft. (at type loc.) to 700 ft. (in central N. Y.).

Next to basal memb. of Salina fm.

Type loc. is in town of Vernon, Oneida Co.

Verona iron ore.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). This ore, typically exposed in old workings N. and W. of Verona [Oneida Co.], is herein identified with the highly important oolitic lower ore of Clinton region and eastward. Fossils listed. Overlies true Sodus sh. and underlies true Wolcott ls. [memb. of Clinton fm.]. Is a much higher ore than Furnaceville ore, but was formerly called Furnaceville by Hartnagel and others. [See *Furnaceville iron ore*.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10), does not mention this ore bed. Whether it really is a separate ore bed or has been confused with one of the other ore beds of the Clinton seems uncertain.

Versailles bed. (In Richmond group.)

Upper Ordovician: Southeastern Indiana and north-central Kentucky.

A. F. Foerste, 1905 (Sci., n. s., vol. 22, p. 150). *Versailles bed.*—Proposed to include Liberty and Whitewater beds (middle Richmond), which writer found great difficulty in separating at any considerable distance from type localities; for instance, at Madison, Ind., and thence southward.

Named for Versailles, Ripley Co., Ind.

Vershire schist.

Ordovician: Northeastern Vermont (Orange County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., p. 115). U. S. G. S. has adopted *Vershire schist*, instead of *Bradford schist* (preoccupied), for the noncalc. memb. of Calciferous mica schist. [For definition see †*Bradford schist*. Richardson continued to use Bradford schist in 1908 and 1924 repts.]

C. H. Hitchcock, 1912 (8th Rept. Vt. State Geol., pp. 100-123). It will be best to drop term *Coos* as a memb. of old Calciferous mica schist and substitute *Goshen mica schist* [Sil. ?] because it has priority over suggestion of Dr. Richardson of use of *Vershire schist*.

C. H. Richardson, 1927 (15th Rept. Vt. State Geol., pp. 127-158). *Vershire schist* overlies Waits River ls.

Probably named for exposures in or near Vershire village or elsewhere in Vershire Twp, Strafford quad., in Orange Co.

†Vespertine series.

Mississippian: Appalachian region.

H. D. Rogers, 1844 (Am. Jour. Sci., 1st, vol. 47, pp. 153-158). *Vespertine series* includes the strata of Appalachian region btw. top of Ponent cgl. below and base of the great [Pottsville] cgl. under the coal measures above. [As thus defined it included Mauch Chunk sh., Loyalhanna ls., and Pocono fm. of present nomenclature.]

H. D. Rogers, 1858 (Geol. Pa., vol. 1, pp. 108, 142-144+; vol. 2, pt. 2, p. 756). Introduced *Umbral series or Middle Carbf.* for 3,000 ft. of fossiliferous red shales and argill. red sss. [Mauch Chunk sh.] underlying the coarse cgl. or millstone grit forming basal memb. of *Seral series or Coal Measures*, and applied *Vespertine series or Lower Carbf.* (also *Vespertine cgl. and ss.*) to the underlying 2,000 to 2,660 ft. of white, gray, and yellow sss., cgl's., and slates resting on *Ponent series or Catskill group*. As thus defined and used in subsequent repts "Vespertine" applied to Pocono fm. of present usage.

Named to indicate "evening period of the great Appalachian Palaeozoic day," according to Rogers, 1844 citation above.

Vestal limestone.

Lower Ordovician: Central Tennessee.

C. H. Gordon, 1924 (Tenn. Dept. Ed. Div. Geol. Bull. 28, pp. 35, 40). *Vestal ls.*—At or near base of [Ottosee fm.] is a lentil of red ls. or marble to which name *Vestal ls.* is here applied, from town on S. side of river opposite Knoxville, where these beds are well displayed. These constitute what Safford termed "Upper Marble." Thickness about 150 to 200 ft. in Knoxville area. Thins out locally but has been noted at a number of places up and down the Valley. [See also under *Meadow marble*.]

Named for exposures in town of Vestal, Knox Co.

Veta Pass limestone member.

Pennsylvanian: Southern-central Colorado (Sangre de Cristo Range).

F. A. Melton, 1925 (Jour. Geol., vol. 33, p. 812). A series of black lss. and shales, containing marine fossils of Penn. age, is present in bottom part of Sangre de Cristo cgl., interbedded with coarse arkoses and micaceous shales of continental origin. So far as known, its max. thickness, 2,100 ft., is found at Placer, near La Veta Pass, and from this exposure it has been named by writer the *Veta Pass ls. memb. of Lower Sangre de Cristo cgl.*

†Vicarya beds.

A paleontologic name applied by R. T. Hill (Biol. Soc. Wash. Proc., vol. 8, pp. 10-15, 1893) to 10 ft. of aggl. in lower part of Glen Rose ls. of Tex.

†Vicksburg fossiliferous loam.

Recent (?): Mississippi.

T. A. Conrad, 1846 (Am. Jour. Sci., 2d, vol. 2, p. 212). *Vicksburg fossiliferous loam.*—Above the Eocene of Vicksburg, Grand Gulf, Rodney, and Natchez is a deposit of loam of uniform composition and appearance, at least 50 ft. thick in many places and probably much more in others; but owing to landslides and vast accumulation of debris btw. this loam and the Eocene, the depth of the former is uncertain, and there may be a distinct deposit btw. the two. Contains land shells.

Conflicts with better-established name, Vicksburg group, of Olig. age.

Vicksburg group.

Oligocene (middle and lower): Gulf Coastal Plain.

T. A. Conrad, 1848 (Phila. Acad. Nat. Sci. Proc., vol. 3, pp. 280–299). [Describes 105 new fossils from Eocene fm. of vicinity of Vicksburg, Miss. Divides the Eo. into "Upper or Newer Eocene" and "Lower or Older Eocene," and states that *Vicksburg group* belongs to former and *Claiborne sands* to latter. Neither *Vicksburg group* nor *Claiborne sands* is described. The former he correlated with the "white ls. of St. Stephens and uppermost stratum at Claiborne, Ala."] "*Ostrea georgiana* occurs at Jackson, Miss., where its position is said to be below Vicksburg group. It is therefore the line of demarkation btw. Upper and Lower Eocene."

T. A. Conrad, 1856 (Phila. Acad. Nat. Sci. Proc., vol. 7, pp. 257–258). The following table will show order of succession of Eocene groups, but it is not pretended to be more than an exposition of my limited knowledge of them, though they are doubtless presented in true order of superposition. Further research may develop intercalated groups. When a group of corresponding fossils is to be found elsewhere, its relative position can be stated by referring to the typical subdivision which contains many identical species.

Groups of characteristic fossils

Newer Eocene, Vicksburg:

8. [Fossil lists only.] } Convenient to designate this *Vicksburg group.*
7. *Corbula alta, Natica.* }
6. *Pecten poulsoni, Orbitolites mantelli.* Is probably synchronous with Orbitolite ls. of St. Stephens, Ala., as its two most prominent fossils are very abundant in this stratum at Vicksburg. Convenient to designate this *St. Stephens group.* Limestone of Jacksonboro, Ga., is probably referable to this division.
5. Ostrea georgiana (?). Lowest bed exposed in bank of Mississippi River at Vicksburg.

Older Eocene, Jackson. Convenient to designate it *Jackson group:*

4. [Lists fossils.] Includes no Vicksburg species, and 5 only of Claiborne species. I believe the group to be newer than Claiborne deposit and certainly older than that at Vicksburg.

Older Eocene, Claiborne. Convenient to designate it *Claiborne group.*

3. [Fossil lists only.]
2. *Ostrea sellaeformis.*
1. *Cardita densata. Cyclas.*

E. W. Hilgard, 1860 (Rept. Geol. and Agric. Miss., pp. 138–147). *Vicksburg group.*—Marls and lss. 92 ft. thick, consisting of (1) 80 ft. of crystalline lss. and blue marls, underlain by (2) 12 ft. of ferruginous rock of Red Bluff; fossils listed from both divisions. Overlain by Grand Gulf group and underlain by Lignitic clay and lignite. [On p. 135 Hilgard stated that *Red Bluff group* seems to stand intermediate, by position and fossils, btw. Vicksburg and Jackson groups, but that fauna on whole seems to approach more nearly the Vicksburg than the Jackson.]

The Vicksburg group of present usage conforms to these early definitions in that it is characterized by a distinctive fauna, is overlain by Catahoula ss. (lowest fm. included in †Grand Gulf group), and is underlain by Jackson fm. In Miss. it is divided into following fms. (descending): Byram marl, Glendon fm., Marianna ls., and Forest Hill sand (=Red Bluff clay to east). In part of Ala. the Marianna ls. ("chimney rock") includes Red Bluff time. (See under *Red Bluff clay.*)

Named for exposures at Vicksburg, Miss.

Vicksburgian.

Time term used by some authors to cover the epoch during which the Vicksburg group (of Olig. age) was deposited.

Victor andesite.

A name that has been applied locally to **Mizpah trachyte** on the lower levels of Tonopah Extension mine, Tonopah dist., Nev., from Victor shaft, in this mine. (See T. B. Nolan, Univ. Nev. Bull., vol. 24, No. 4, p. 16, 1930.)

Victor moraine.

Name applied to a Pleist. moraine in N. Y. (See H. L. Fairchild, Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 627+, 1932.)

Victor formation.

Pleistocene: Northern California (Mokelumne River Basin).

A. M. Piper, H. S. Gale, and H. E. Thomas (U. S. G. S. W. S. P. 780, in press). *Victor fm.*—Sand, silt, and gravel, in small part well sorted and well stratified. Deposited by Mokelumne River and adjacent streams in building the Victor alluvial plain, on which are situated the settlements of Lodi, Lockeford, and Clements. Thickness 0 to 125 ft. Youngest Pleist. fm. in Mokelumne River Basin. Overlies Arroyo Seco gravel (Pleist.).

Victoria series.

Devonian or Carboniferous.

G. M. Dawson, 1878 (Canada Geol. Surv. Rept. 1876–77, p. 101).

†Victoria formation or clays (also Victoria shale).

Upper Cretaceous: Central Kansas.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, p. 50). *Victoria fm. or clays.*—Highly carbonaceous, almost black sticky clay sh., with a zone of frequently large "cannonball" septaria in lower part. Upper fm. of Benton div. in Kans. Overlies Russell fm. (lower fm. of Benton div.) and underlies Osborne ls., lower fm. of Niobrara div.

Same as Blue Hill sh. memb. of Carlile sh.

Named for exposures at Victoria, Ellis Co.

†Victoria amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name long in use locally. According to B. S. Butler (personal communication) this amygdaloid is same as Forest amygdaloid. The mineralized part is the Victoria lode. Named for occurrence in Victoria mine, Ontonagon Co.

†Victoria flow.

Includes †Victoria amygdaloid and underlying trap.

Victoria sandstone.

Upper Cretaceous: Alberta.

J. A. Allan, 1918 (Canada Geol. Surv. Summ. Rept. 1917, pt. C, p. 12).

Victoria quartzite.

Mississippian (lower): Central northern Utah (Tintic district).

G. F. Loughlin, 1919 (U. S. G. S. P. P. 107). *Victoria qtzite.*—Alternating beds of limy qtzite and siliceous ls., some of them conglomeratic. Thickness 0 to 85 ft. Underlies Gardner dol. and uncon. overlies Pinyon Peak ls. (Dev.). No fossils, but believed to be lower Miss. Named for Victoria mine.

Victoria limestone.

Upper Cretaceous: Mexico.

J. E. Brantly, 1924 (A. A. P. G. Bull., vol. 8, No. 1, p. 23).

Victoria Peak massive member (of Bone Spring limestone).

Permian: Western Texas (Sierra Diablo).

P. B. and R. E. King, 1929 (A. A. P. G. Bull., vol. 13, pp. 921, 922, 925). The gray ls. uncon. below Delaware Mtn ss. [a part only of Delaware Mtn fm.] has thickness of 500 to 1,000 ft., and contains *Productus ivesi* and other forms which serve to correlate it with upper part of the Leonard on one hand and with the San Andres [?] on the other. It is here proposed to call it *Victorio Peak memb. of Leonard fm.*, because of prominent exposures at summit of mtn of that name, which is a conspicuous promontory of Sierra Diablo scarp. Below it is Bone Canyon memb. Is absent in Guadalupe Mtns, but a short distance N. of Bone Canyon, on W. side of Guadalupe Mtns, it wedges into the section and separates Bone Canyon memb. from Delaware Mtn ss. [This ls. and the Bone Spring ls. were originally included in Delaware Mtn fm., but are now excluded from the Delaware Mtn.]

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 731, 755–768), designated the Victorio Peak deposits as *Victorio Peak massive memb. of Bone Spring ls.* This is designation approved by U. S. Geol. Survey.

Victory Junction shale member.

Pennsylvanian: Central eastern and northeastern Kansas.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pt. 1, pp. 76–79). *Victory Junction sh. memb.*—Brown ss. underlain by sh. Thickness 3 to 14 ft. Underlies Little Kaw ls. and overlies Olathe ls., all members of Stanton ls. in Johnson and Miami Counties. Named for hamlet (Victory Junction) in W. part of Wyandotte Co.

See also N. D. Newell, 1936 (Jour. Geol., vol. 44, No. 1, pp. 23–31).

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 135–136). *Victory Junction sh. memb.* of Kans. is possibly same as *Rock Lake sh.* of Condra in Nebr., which was originally erroneously included in Scranton sh. but which belongs in Stanton ls.

Vidrio massive member (of Capitan limestone).

Permian: Western Texas (Marathon region).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 52). *Vidrio fm.*—Very uniform dark- to light-gray dolomitic ls. or dol. with a few layers of pure dol. containing considerable chert in irregular form; in uppermost part one or two beds of reddish-brown ss. about 4 ft. thick. Thickness 2,000 ft. Underlies Gilliam fm. and overlies Word fm.

P. B. King, 1931 (Univ. Tex. Bull. 3038, pp. 73–84). *Vidrio memb. of Capitan fm.* [See 1931 entry under *Tessey dol.*]

P. B. King, 1933 (Historical geol. of R. C. Moore, p. 325). *Vidrio massive ls. memb. of Glass Mtns fm.* [See 1933 entry under *Tessey dol.*]

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 736+), designated the Vidrio deposits as *Vidrio massive memb. of Capitan ls.* This is present approved name of U. S. Geol. Survey.

This fm. is most conspicuous part of Glass Mtns. Vidrio is Spanish word for glass and is often used among local Mexican population as a name for the mtns.

Vieja series.

Upper Cretaceous: Western Texas.

T. W. Vaughan, 1900 (U. S. G. S. Bull. 164, pp. 76–81). *Vieja series.*—Interbedded lavas, pyroclastics, and unfossiliferous sss., clays, and cgls. Thickness not stated but seems to be at least 900 ft. Overlies (whether conformably or uncon. not discovered) San Carlos fm. in Presidio and Jeff Davis Counties.

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bull. 44, pp. 78–79, table opp. p. 59). *Vieja series* correlates with Navarro fm.

Named for exposures in Vieja Mtns, Presidio Co.

Viejas gabbro-diorite.

Late Jurassic or early Cretaceous: Southern California (San Diego and Imperial Counties).

W. J. Miller, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 2, pp. 115–141, map). *Viejas gabbro-diorite.*—Cuts Black Mtn volcanics and is of about same age as Alpine quartz diorite. Type occurrence in Viejas Mtn, southern Peninsular Range.

Vienna limestone. (Of Chester group.)

Mississippian: Southern Illinois and western Kentucky.

Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 281–290, and No. 5, pp. 395–416; also Ill. Geol. Surv. Bull. 41). *Vienna ls.*—Usually highly siliceous or cherty ls. Thickness 0 to 70 ft. Present in Johnson and Pope Counties. Rests, apparently conformably, on Tar Springs ss., and underlies, apparently conformably, the Waltersburg ss.

Named for excellent exposures at Vienna, Johnson Co., Ill., where it is exposed in some streets and in an old quarry just W. of the town.

Vierling sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Paoli ls. of Cumings.

Vilas shale. (Of Lansing group, Kansas.)

Vilas shale member (of Lansing formation), Missouri.

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

E. Haworth, 1898 (Kans. Univ. Geol. Surv. vol. 3, pp. 51, 103). *Vilas sh.* proposed by G. I. Adams (in field notes) for sh., 75 ft. thick, overlying Earlton ls. and underlying Iola ls. [Miscorrelation with Iola ls., the sh. exposed at Vilas really underlying Stanton ls. and overlying Plattsburg ls. See H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines, vol. 13).]

The present generally accepted definition treats Vilas sh. as a memb. of Lansing fm. in Mo., underlying Stanton ls. memb. and overlying Plattsburg ls. memb. In Kans. the Lansing is now treated as a group and the Vilas sh. as a fm.

Named for exposures in vicinity of Vilas, Wilson Co., Kans.

Village Bend limestone. (In Mineral Wells formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer, 1929 (Tex. Bur. Econ. Geol., geol. map of Palo Pinto Co.). *Village Bend ls.* lies 30± ft. below Lake Pinto ss. and 100± ft. above East Mtn sh. [restricted], all in Mineral Wells fm. [East Mtn sh. as originally defined occupied interval btw. Brazos River ss. and Lake Pinto ss., within which interval lies this ls.]

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 31–36). *Village Bend ls.*—A grayish-buff impure hard fossiliferous ls., from 6 in. to 14 ft. thick, occurring near top of East Mtn sh. memb. of Mineral Wells fm. [One section they give shows Village Bend ls. lying 60 ft. below top of the East Mtn.] Type loc. is exposure near W. end of Village Bend of Brazos River 2¾ mi. in direct line SE. of Palo Pinto, where this ls. is 6 ft. thick, very hard, and its upper part is made up of an aggl.

Villa Nueva sandstone member (of Fayette formation).

Eocene (upper): Northeastern Mexico (Tamaulipas).

W. G. Kane and G. B. Gierhart, 1935 (A. A. P. G. Bull., vol. 19, No. 9, p. 1387). *Villa Nueva ss. memb.*—Uppermost beds of Fayette fm. that admit of measurement, in section measured on both sides of Rio Grande btw. Roma and Rio Grande City, [Starr Co.], Tex. Consists of 63 ft. of coarse-grained soft gray ss. commonly weathering brown, with, at base, a fossiliferous horizon containing species of *Turritella*, *Volutocorbis*, and other fossils. [Derivation of name not stated.]

Vinales limestone.

Jurassic (?): Cuba.

E. L. DeGolyer, 1918 (A. A. P. G. Bull., vol. 2, p. 139). [Assigned to Jurassic, and thus classified by J. W. Lewis, 1932 (A. A. P. G. Bull., vol. 16, p. 536); but R. E. Dickerson and W. H. Butt, 1935 (A. A. P. G. Bull., vol. 19, No. 1), assigned it to Lower Cret., and C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 514), also assigned it to Cret.]

Vinalhaven rhyolite.

Silurian: Central southern Maine (Penobscot Bay region).

G. O. Smith, 1896 (Geology of the Fox Islands, Maine, pp. 12, 46–55). *Vinal Haven acid volcanics.*—Characterize NW. part of Vinal Haven, with exception of the strip of volcanics designated as Thoroughfare volcanics. Both lavas and pyroclastics are represented. The rocks include, in ascending order, tuffs, taxitic aporhyolite, spherulitic aporhyolites, and flow breccias, with the other tuffaceous beds as probably the highest members of the series represented. On NW. side of the area the lower members of Vinal Haven series are in contact with the more basic series [Thorofare volcanics], and the relations seem to be wholly conformable.

G. O. Smith, 1907 (U. S. G. S. Penobscot Bay folio, No. 149, p. 8). *Vinalhaven rhyolite.*—Name applied to the rocks earlier described and mapped as *Vinal Haven acid volcanics.* Assigned to Sil. Are of post-Niagara age—probably late Sil.

On 1933 geol. map of Maine, by A. Keith, these rocks are assigned to Dev.

Vincent member (of Meaford formation).

Ordovician: Ontario.

M. Fritz, 1926 (Roy. Soc. Canada Proc. and Trans., 3d ser., vol. 20, pt. 1, sec. 4, p. 93).

Vincent sand.

A subsurface unit of ss. lenses lying at or near horizon of Ames ls. memb. of Conemaugh fm. (Penn.) at places in SE. Ohio. Near Vincent, Barlow Twp, W. part of Washington Co., one of these stray sss., directly on top of Ames ls., produced gas and was named *Vincent ss.* (W. Stout et al., Geol. of nat. gas, A. A. P. G., 1935, p. 900.)

Vincentown sand. (Of Rancocas group.)

Eocene (lower): New Jersey.

W. B. Clark, R. M. Bagg, and G. B. Shattuck, 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 316–338). *Vincentown lime-sands.*—Highly calc. greensands, 20 to 100 ft. thick, forming upper part of Rancocas fm. Overlie Sewell [Hornerstown] marls. Named for Vincentown, Burlington Co.

The present classification treats *Vincentown sand* as upper fm. of Rancocas *group.*

Vindicator rhyolite.

Tertiary: Southwestern Nevada (Goldfield district).

F. L. Ransome, 1909 (U. S. G. S. P. P. 66, pp. 28, 37, etc.). *Vindicator rhyolite.*—Oldest memb. of volcanic succession, and a flow. Of white or light-gray color. Rests uncon. on alaskite and Camb. sh. and is older than Siebert [Esmeralda] fm. [which is upper Mio.]. Most extensively exposed on flanks of Vindicator Mtn. Thickness probably 200± ft.

Vinemount moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map (fig. 8) in U. S. G. S. Niagara folio (No. 190), p. 17.

Vinent formation.

Cretaceous (?): Cuba.

S. Taber, 1934 (Geol. Soc. Am. Bull., vol. 45, No. 4, p. 575). [Assigned to Cret., but C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 493) assigned it to Eocene.]

†Vineyard series.

Southeastern Massachusetts (Marthas Vineyard).

N. S. Shaler, 1888 (U. S. G. S. 7th Ann. Rept., pp. 303–363 and map). *Vineyard series.*—Reddish clays, whitish sands, brown and greenish sands, cross-bedded, composing the [supposed] Tert. deposits of Marthas Vineyard and well exposed at both extremities of the island. Thickness 15,000 ft. Believed to uncon. underlie Weyquosque series. Assigned to Tert. [but now known to include, as mapped, deposits of several ages—Plio. to Upper Cret.].

Vineyard interglacial stage (also **Vineyard formation**).

Pleistocene: Southeastern Massachusetts (Marthas Vineyard, etc.) and southeastern New York (Long Island).

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 975–988). *Vineyard erosion interval* (interglacial), accompanied by some deposits. Separates the glacial Tisbury beds [Manhasset fm.] of Marthas Vineyard from the deposits of last glacial epoch [Wisconsin stage]. [See also Geol. Soc. Am. Bull., vol. 8, pp. 197–212, 1897.]

M. L. Fuller, 1914 (U. S. G. S. P. P. 82). The *Vineyard interglacial stage* is represented on Long Island by an erosion interval and some marine and peat deposits, the deposits being called *Vineyard fm.* It separates Wisconsin morainal deposits from Manhasset fm., and is correlated with Peorian (?), Iowan (?), and Sangamon (?) stages of Mississippi Valley region.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Vineyard interglacial stage* is characterized chiefly by erosion on Block Island, Marthas Vineyard, Nantucket, and Cape Cod but is accompanied by some marine deposits, and, locally, on Marthas Vineyard, by some beds of peat.

Vinita beds.

Upper Triassic: Eastern Virginia (Richmond Basin).

N. S. Shaler and J. B. Woodworth, 1899 (U. S. G. S. 19th Ann. Rept., pt. 2, p. 435). *Vinita beds* (*Estheria beds*).—Black fissile shales carrying *Estheria ovata*, passing upward and intercalated with gray sss. Thickness 2,000± ft. Basal div. of Chesterfield group of Newark system. Underlie Otterdale sss. and overlie Tuckahoe group. Occur in James River bluff, W. of Vinita station, on Tomahawk Creek, and crop out on E. slope of Goat Hill near Vinita.

†Vinita formation.

Pennsylvanian: Northeastern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 12). *Vinita fm.*—Alternating shales and sss., with thin coals and lenticular lss., 450 to 1,000 ft. thick, uncon. overlying Miss. and underlying Claremore fm. Represents all of Muskogee group in N. part of State.

Practically synonymous with Cherokee sh.

Named for Vinita, Craig Co.

Vinland shale.

Pennsylvanian: Northwestern Missouri and eastern Kansas.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 82). A persistent coal bed occurs in Stranger fm. 8 to 10 ft. beneath its top (which is placed at base of Haskell ls.). The marine sh. btw. this coal and Haskell ls. has been called *Vinland sh.* in unpublished thesis by J. M. Patterson, from village in Douglas Co., Kans., SE. of Lawrence.

R. C. Moore and N. D. Newell, 1936 (Kans. Geol. Surv. Bull. 22, pp. 146, 150–152). *Vinland sh.* restricted to the sh. and ss., probably all marine, overlying Westphalia ls. and underlying Haskell ls. It ordinarily consists of 9 to 50± ft. of gray argill. limy or sandy sh., locally with some ss. Originally the Vinland included Westphalia ls. Type loc. is 2± mi. NE. of Vinland, Douglas Co. Best exposures in NW. part of sec. 12, T. 14 S., R. 20 E.

Vintage dolomite.

Lower Cambrian: Southeastern Pennsylvania.

G. W. Stose and A. I. Jonas, 1922 (Wash. Acad. Sci., Jour., vol. 12, pp. 359, 362, 363). *Vintage dol.*—In part a gray heavy-bedded dol. which weathers to whitish chalky surface, and in part a knotty dark-blue dol. with argill. partings. Some beds are sparkling, gray to blue mottled, with siliceous and calc. blebs that stand out on weathered surfaces. At base is a whitish schistose thin-bedded impure dol. containing muscovite flakes. Thickness 500–650 ft. Underlies Kinzers fm. and overlies Antietam qtzite. Well exposed in cut of Pa. R. R. at Vintage, 15 mi. E. of Lancaster.

Vinton member.

Mississippian: Central Ohio.

J. E. Hyde, 1912 (Hist. of Fairfield Co. and representative citizens, by C. C. Miller, pp. 206–212). *Vinton memb.*—Fine-grained yellowish sss. and sandy shales, usually

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

50 to 100 ft. thick, but in Fairfield Co. 150 ft. thick. Forms top memb. of Logan fm. Overlies Allensville memb. and uncon. underlies Maxville ls. [Logan fm. as used by Hyde included upper part of Black Hand fm. His Vinton memb. corresponds to Logan fm. of previous repts.]

J. E. Hyde, 1915 (Jour. Geol., vol. 23, pp. 771–779). Vinton memb. was named for Vinton Co., Ohio. [On other pp. in this vol. Hyde states Vinton memb. is=Logan fm. of Prosser.]

C. S. Prosser, 1915 (Outlines of field trips in geology for central Ohio, p. 13), accepted Hyde's expansion of Logan fm. and restriction of *Black Hand* to basal part of the Black Hand of previous repts, his restricted Black Hand being treated as top memb. of his expanded Cuyahoga fm.

See under *Logan fm.*

Vinton phase (of Otis limestone).

Middle Devonian: Central eastern Iowa.

W. H. Norton, 1921? (Iowa Geol. Surv. vol. 27, p. 377). *Vinton phase of Otis ls.*—Basal layers of the Otis exposed in quarries N. of Vinton [Benton Co.] along Cedar River. Probably somewhat higher in Otis terrane than Coggon phase. In all these quarries the stone is a buff, finely laminated mag. ls., remarkably homogeneous, lying in even and rather heavy horizontal beds. Chemical analysis shows it to be somewhat less mag. than Coggon phase.

Viola limestone.

Middle and Upper Ordovician: Central southern Oklahoma.

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Viola ls.*—Massive white and bluish lss., with occasional irregular bands and nodular masses of chert or flint, most abundant in lower and middle portions. Some beds coarsely crystalline, others composed chiefly of shells and shell fragments. Thickness 750 ft. Overlies Simpson fm. with transition, and underlies Sylvan sh.; all of Ord. age.

J. A. Taff, 1903 (U. S. G. S. Tishomingo folio, No. 98). *Viola ls.* is 700± ft. thick, and represents a continuous but slightly variable deposition of ls. The upper and lower parts, each approx. one-third of fm. in thickness, are composed of thicker and less evenly stratified beds than middle part. Chert is usually most abundant in lower and middle parts of fm. Texture of middle part is generally dense and fine. Some beds, especially in upper part, are uneven, earthy, and coarsely crystalline, while others are composed largely of fossil shell fragments and shells. There is gradual transition from a thin-bedded platy ls. belonging to Simpson fm. upward into the thicker beds of Viola ls., while at top there is an abrupt change from ls. to the dark-bluish or greenish clay shales of Sylvan fm. According to E. O. Ulrich the fossils of basal memb. of Viola ls. are of latest Black River and earliest Trenton age; the fossils of middle memb. are later Trenton; and the fossils of upper memb. are of Richmond age.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 27), assigned *Viola ls.* wholly to Trenton, and the beds of Black River and upper Chazy age to a new and undefined fm. called *Bromide*. He also designated the beds of Richmond age as Fernvale ls., which he showed as uncon. above his Viola [restricted] ls., with beds of Maysville and Eden age absent.

C. A. Reeds, 1926 (Am. Mus. Nat. Hist. Jour., vol. 26, pp. 470–474), listed fossils from the 3 members of Viola ls. and assigned them as follows: (1) Upper 300± ft., gray crystalline rock containing abundant Richmond fauna; (2) middle 300± ft., thin-bedded dark-gray ls. containing upper Trenton fossils; (3) basal 60 to 100 ft., massive-bedded light-colored ls. containing latest Black River and earliest Trenton fossils. He assigned entire Simpson fm. to the Chazy.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, p. 30), showed *typical Bromide*=upper part of Simpson fm. and of late Chazyan (Lower Ord.) age, and stated that the beds of Black River and early Trenton age (Middle Ord.) are "provisionally referred to Bromide fm." He also showed the rest of the Trenton and early part of Eden as absent; assigned Viola ls. [restricted] to rest of Eden epoch and early part of Maysville epoch; and showed it as uncon. overlain by Fernvale ls., of Richmond age.

F. C. Edson, 1927 (A. A. P. G. Bull., vol. 11, No. 9, pp. 967–975), stated that Taff mapped type loc. of Ulrich's Bromide as lower Viola ls., and she recognized above her Bromide ("post-Wilcox") fm. 200 ft. of lower Viola (massive dense buff-colored "lithographic" ls. of upper Black River age), 700 ft. of middle Viola (ls. carrying graptolites in base, of Trenton or Cincinnatian age), uncon. overlain by 50 ft. of Fernvale ls. (upper Viola), of Richmond age.

E. O. Ulrich, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73), assigned his *Viola ls.* to all of Maysville epoch and upper part of Eden epoch, and showed it as uncon. overlain by Fernvale ls., of Richmond age. He included in his Bromide all beds of Trenton and Black River age.

C. E. Decker, 1933 (A. A. P. G. Bull., vol. 17, No. 12, pp. 1405–1435). Evidence is given for extending Viola ls. into Atoka region, "where it has not been previously recognized." Has 40 or more separate outcrops, most of them small, in Arbuckle Mtns, Wichita Mtns, the Criner Hills, the Mansville anticline, and Atoka region, extending over an aggregate area of 45 sq. mi. The molluscoids and mollusks, as well as the graptolites, correlate parts of the Viola with Normanskill, Trenton, Utica, Lorraine, and Richmond.

C. W. Tomlinson, 1935 (Geol. of nat. gas, A. A. P. G., p. 581). Most of Viola ls. is Middle Ord., probably chiefly Trenton, with Fernvale ls. (Richmond) at top.

The U. S. Geol. Survey has not yet adopted Bromide fm. and follows original definition of Viola ls.

Named for former village of Viola, near Bromide, Johnston Co., which was located close to outcrop of fm.

Vipond series.

Pre-Cambrian: Ontario.

L. C. Graton and H. E. McKinstry, 1933 (Canadian Min. and Met. Bull. 249, pp. 3, 4).

Virgelle sandstone. (Of Montana group.)

Virgelle sandstone member (of Eagle sandstone).

Upper Cretaceous: Northwestern, central northern, and central southern Montana.

E. Stebinger, 1914 (U. S. G. S. P. P. 90, pp. 62–68). *Virgelle ss.*—Gray to buff coarse-grained massive ss., much cross-bedded, with many ferruginous concretions in upper half. In lower half slabby gray ss., becoming shaly toward base. Thickness 220 ft. on Two Medicine River btw. its mouth and Family post office. Underlies Two Medicine fm. in NW. Mont. (Blackfeet Indian Res.) and overlies Colorado sh. In central Mont. it comprises basal memb. of Eagle ss., and still farther E. it represents all of Eagle ss. that is present. Is well exposed along Missouri River from town of Virgelle, a few mi. below Fort Benton, eastward.

In Yellowstone-Bighorn Counties region the 350± ft. of transition beds underlying Virgelle ss. memb. of Eagle ss. and containing a fauna of predominantly Montana types are now known as *Telegraph Creek fm.* In that area the Telegraph Creek fm. separates Virgelle ss. memb. of Eagle from deposits of unquestioned Colorado age, carrying Niobrara fossils and designated *Niobrara sh.*

Virgen [Virgin] series.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, pp. 52 and 61). *Vergen series.*—Deposits of late Tertic age, mainly Plio. perhaps. Appear partially to fill a canyon of old Virgen [Virgin] River [SE. Nev.] that was excavated before Bonneville days, and the line of which is occupied by the lower Virgen [Virgin] River of today. In Nev. divided into Kyle sss. above and Funeral cgls. below. [In Pan-Am. Geol., vol. 41, p. 79, 1924, Keyes defined Virgen series as follows: Name applies to thick cgl. beds overlying the boraciferous clays in Virgen Valley and in Furnace Canyon, Inyo Co., Calif.]

Virgil series.

Pennsylvanian: Kansas, Missouri, Iowa, Nebraska, and Oklahoma.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Virgil series* extends from base of Americus ls. down to top of sh. uncon. overlying Iatan ls., and includes Wabaunsee group redefined, Shawnee group, and Douglas group redefined.

R. C. Moore, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, pp. 279–280). The Penn. system of Mid-Continent region is divisible into 4 major natural divisions or series, here named (descending): (1) *Virgil series,* consisting of alternating ls. and sh. with prominent ss. deposits at base, resting, with very important uncon., on (2) *Pottawatomie series* (distinguished by prominence and wide distribution of ls.); beneath it occurs an uncon. and one of most clearly defined paleontologic boundaries in the Penn., which is succeeded downward by (3) *Des Moines series*, which rests, with distinct and widespread uncon., on (4) *Bend series* [restricted to Penn. part of Bend of the literature]. [The foregoing classification discards *Missouri group*, replacing it with *Virgil series* and *Pottawatomie series*.]

M. K. Elias, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 285), reported fossil plants from "the sh. overlying the eroded surface of Stanton ls. about 6 mi. NW. of Garnett, Kans. This horizon belongs directly above the important uncon. that marks base of *Virgil series* (R. C. Moore, new), which comprises upper 1,400 ft. of Kans. Pennsylvanian (i. e., beds below Americus ls.)."

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 88, 96). It is proposed to recognize 3 major divisions or series in the Penn. rocks of Kans., designated (ascending order) *Des Moines series*, *Missouri series*, and *Virgil series*. The *Des Moines series* is essentially unchanged from previous usage, including strata from base of Cherokee sh. to an uncon. near top of Marmaton group. The *Missouri series* as formerly defined included all Penn. strata above the Des Moines. Writer now proposes to restrict this name to apply to the beds btw. the uncon. at top of Des Moines series and another important uncon. in what has previously been classed as *Douglas fm. or group*. The beds btw. the uncon. last noted and base of Perm. are defined as *Virgil series*. The uncon. btw. the Missouri and Virgil series corresponds to the time of major folding in Arbuckle Mtns, southern Okla., and probably also of deformation in Ouachita Mtns, farther E. The Virgil series includes Wabaunsee, Shawnee, and Douglas (redefined) groups. Contact btw. Virgil series and overlying Perm. (Americus ls. at base) is conformable so far as known.

R. C. Moore, 1933 (Historical geol., pp. 304–305, 319). *Virgil series*.—Uppermost Penn. in Mid-Continent region. Thickness 1,300 ft. in N. Okla.; about 700 ft. in Nebr. [On p. 319 he draws top of Penn. at base of Americus ls.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 41, 49, 50, 142). Upper bdy of *Virgil series* is located at break that occurs near horizon of Brownville ls. and within group of beds formerly known as Admire sh. [p. 41]. [Moore's diagram on p. 49 shows this uncon. as in places occurring a short distance above Brownville ls.] Named for town in E. part of Greenwood Co., Kans., located about midway btw. lower and upper limits of Virgil series outcrop in this part of State. Exposure (about 960 ft. thick) along Verdigris River, from W. of Madison to Virgil and SE. to central Wilson Co. exhibits clearly the boundaries indicated. [Page 49 shows discon. at top of Brownville ls. and includes latter ls. in Virgil series. On p. 50 he restricts *Admire group* (as he calls it) to beds from base of Towle sh. (top of Brownville ls.) up to base of Americus ls., and includes his Admire group in Perm.]

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Virgilina group.

Virgilina volcanic group.

Virgilina greenstone.

Pre-Cambrian: Central southern Virginia and central northern North Carolina (Virgilina district).

T. L. Watson, 1916 (Va. Geol. Surv. geol. map of Va.). *Virgilina group*.—Divided into 3 mapped units (descending): Gabbro; quartz porphyry; and volcanic acid and basic tuffs. Overlies pre-Camb. granite and granite gneiss.

F. B. Laney, 1917 (Va. Geol. Surv. Bull. 14, pp. 15, 19, 27–34, and map). The basic volcanics, for which *Virgilina greenstone* is proposed, were originally andesite and andesitic tuffs but have become, through intense metamorphism, chlorite-epidote schists or simply greenstone schists. These for most part retain something of their original minerals. The rocks form Virgilina Ridge and are typically developed in and near town of Virgilina [Halifax Co., Va.]. In present conditions the rock is a well-defined greenstone schist. [Mapped as Ord. (?).]

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.). [The block of pre-Camb. extrusive rocks younger than Glenarm series and designated "greenstone volcanics" is stated to "include meta-andesite in Virgilina area called *Virgilina greenstone*."]

A. I. Jonas, 1932 (Va. Geol. Surv. Bull. 38, pp. 6, 24–25, map). *Virgilina volcanic group* (p. 6); *Virgilina volcanic rocks* (text heading, p. 24); *Virgilina volcanics* (map). Acidic and basic volcanic rocks occur in a small area btw. Meherrin and Keysville, Va., which is included in Laney's map of Virgilina dist., and his rept describes these rocks in detail. They extend SW. 35 mi. to Virgilina, on Va. line, and across N. C. into S. C. Of pre-Camb. age. Older than Columbia granite, which intrudes them. Not seen in contact with Wissahickon fm. but probably overlies the Wissahickon.

Virgin limestone member (of Moenkopi formation).

Lower Triassic: Southwestern Utah (Washington County) and northwestern Arizona.

R. Bassler and J. B. Reeside, Jr., 1921 (U. S. G. S. Bull. 726C, pp. 90-92). *Virgin ls. memb.*—Earthy greenish-yellow ls., in 3 thin bands separated by greenish-yellow and reddish-brown sh. Thickness 80 to 160 ft. Lies 400 to 435 ft. below Shnabkaib sh. memb. of Moenkopi and 355 to 610± ft. above base of Moenkopi. Named for Virgin City, Utah, where it is well exposed. [See also U. S. G. S. P. P. 129D, 1922.]

Virginia slate.

Pre-Cambrian (upper Huronian): Northeastern Minnesota (Mesabi district).

C. R. Van Hise and C. K. Leith, 1901 (U. S. G. S. 21st Ann. Rept., pt. 3, pp. 353, 360). *Virginia sl.*—Dense fine-grained gray or black sl. Called Virginia sl. because in its typical form it has been found in numerous test pits and drill holes W. of town of Virginia, St. Louis Co. Top fm. of Upper Huronian in Mesabi dist. Uncon. underlies the great Keweenawan gabbro and conformably overlies iron-bearing Biwabik fm.

C. K. Leith, 1903 (U. S. G. S. Mon. 43), stated that *Virginia sl.* grades both vertically and laterally into Biwabik fm.; and C. R. Van Hise and C. K. Leith made same statement in U. S. G. S. Mon. 52, p. 174, 1911.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360) and 1911 (U. S. G. S. Mon. 52), treated Virginia sl. as younger than Biwabik fm., but assigned both to upper Huronian.

C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), assigned Virginia sl. to upper Huronian and Biwabik iron-fm. to middle Huronian.

Virginia quartz hypersthene norite.

Late Jurassic (?): Southern California (Riverside County).

P. H. Dudley, 1935 (Calif. Jour. Mines and Geol., vol. 31, No. 4, pp. 491, 501). Most important body of rock occurs near old Virginia mine, and extends W. into E. part of the Gavilan.

†Virginian.

A term introduced by A. Heilprin (Phila. Acad. Nat. Sci. Proc. 1882, pp. 183–184, 1883; also Phila. Acad. Nat. Sci. Jour., 2d ser., vol. 9, pt. 1, p. 120, 1884) for the "Middle Atlantic Miocene deposits of Va. and the newer group of Md. ('Yorktown' epoch, in part of Dana)." See under †*Carolinian*. Corresponds to an indefinite part of Chesapeake group of present nomenclature.

Virgin Valley beds.

Miocene: Northwestern Nevada.

J. C. Merriam, 1907 (Sci., n. s., vol. 26, pp. 380–382). *Virgin Valley beds.*—Mammal-bearing fm., largely volcanic ash or tuff, showing variable amount of induration and varying in color from white to green or bright red. Fauna, especially of upper beds, appears to belong to same period as Truckee Miocene. Upper beds are usually softer than the others and consist of cream-colored ash; middle beds are generally brownish or gray and weather in gently rounded knolls; lower beds are somewhat harder than the others, and where badland structure occurs in them very steep faces are frequently produced. Thickness of fm. 1,000 to 2,000 ft. Virgin Creek drains the valley in which the beds occur. There are older tuffs, ashes, and rhyolitic lavas that resemble Clarno Eocene of Oregon.

Appears to be same as Truckee fm.

Vishnu schist.

Pre-Cambrian: Northern Arizona.

C. D. Walcott, 1889 (Geol. Soc. Am. Bull., vol. 1, p. 50). *Vishnu*, bedded qtzite and schists, 1,000+ ft. thick. Uncon. underlies Grand Canyon [Unkar] group in Grand Canyon of Colorado.

C. D. Walcott, 1894 (U. S. G. S. 14th Ann. Rept., pt. 2, pl. 60, etc.). *Vishnu terrane* (Algonkian?) consists of sss., schists, etc., and overlies Archean gneisses, schists, etc.

L. F. Noble, 1910 (Am. Jour. Sci., 4th, vol. 29). *Vishnu schist*, the fundamental crystalline complex, consists of quartz, mica, and hornblende schists, invaded by quartz diorite and injected by veins of pegmatite and aplite.

L. F. Noble and J. F. Hunter, 1916 (U. S. G. S. P. P. 98–I, p. 113). The Archean complex of Grand Canyon is now known as Vishnu schist in usage of U. S. Geol. Surv. It is evident, however, from present study, that the name includes two or more very different series of rocks. Doubtless it will be advisable at some future time to restrict name *Vishnu schist* to the mica schist series and give another name or names to the gneisses, but until a more detailed study is made a change in present usage would be premature.

I. Campbell and J. H. Maxson, 1936 (Geol. Soc. Am. Proc. 1935, p. 342). Calc. concretions have been found in *Vishnu schist* (restricted by writers to include only the sed. series) on Boucher Creek in W. part of Bright Angel quad., which confirms sed. origin of the schist.

The U. S. Geol. Survey has not yet had occasion to consider the proposed restriction of Vishnu schist.

Named for Vishnu's Temple, on Colorado River, 30 mi. E. of mouth of Shinumo Creek.

Vishnuan series.

A term employed by C. [R.] Keyes instead of *Vishnu schist* of other geologists.

Vivian sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 232). *Vivian ss.*—Massive to heavy-bedded, medium-grained, micaceous, bluish gray, 0 to 35 ft. thick. Lies 0 to 5 ft. below Pocahontas No. 2 coal and rests on Pocahontas No. 1 coal. Has been quarried 300 yds. E. of East Vivian railway station, McDowell Co.

Vivien sand.

A name that has been applied by drillers to Nacatoch sand (Upper Cret.) of NW. La.

†Vola limestone. (In Washita group.)

Lower Cretaceous (Comanche series): Southern Texas.

R. T. Hill, 1889 (Am. Geol., vol. 3, p. 289; Am. Jour. Sci., 3d, vol. 37, p. 290). *Vola ls, or Shoal Creek horizon.*—Red chalk ls. At Austin 50 ft. thick. Top fm. of Lower Cret. in Burnet and Travis Counties. Overlies *Exogyra arietina* clays [Del Rio clay].

Paleontologic name. Replaced by *Buda ls.*

Volcan group.

Pre-Cambrian: Mexico (Lower California).

G. P. Merrill, 1897 (U. S. Nat. Mus. Rept. 1895, p. 985).

Volcan Peak group.

Paleozoic (?): Mexico.

S. F. Emmons and G. P. Merrill, 1894 (Geol. Soc. Am. Bull., vol. 5, p. 511).

Volga shales.

Upper Ordovician: Iowa.

C. [R.] Keyes, 1931 (Pan-Am. Geol., vol. 55, pp. 217–222), applied this name to beds underlying his Wykoff ls. and overlying his Dubuque ls. shales in Iowa. He stated that his Wykoff ls.=†Elgin ls., so that his Volga shales appear to correspond to upper part of Dubuque fm.

Volusia sh.

Upper Devonian: Western New York (Chautauqua County).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). Upper Dev. of Chautauqua Co. divided into (descending): Knapp beds; Conewango fm.; Chadakoin; Volusia sh. (=Girard sh. of Pa.); uncon.; Northeast sh.; Shumla ss.

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 153). *Volusia sh.*—Green fossiliferous sh., about 100 ft. thick E. of Volusia [Chautauqua Co.], about 180 ft. thick on the Canadaway. On approaching N. Y. line the Girard sh. becomes increasingly fossiliferous from top down, carrying specially *Camarotoechia duplicata* and changing to green sandy sh. On Chautauqua Creek the green Volusia sh. overlies about 140 ft. of normal Girard sh. On Canadaway Creek the Volusia sh. is 180 ft. thick and if normal Girard is present beneath it it cannot exceed 40 ft. in thickness. Volusia sh. is overlain by Chadakoin beds.

G. H. Chadwick, 1935 (Geol. Soc. Am. Proc. 1934, p. 71). [See 1935 entry under *Northeast sh.*]

Vulcan iron-formation.

Pre-Cambrian (middle Huronian): Northwestern Michigan (Crystal Falls, Menominee, and other districts).

C. R. Van Hise, 1899 (U. S. G. S. 19th Ann. Rept., pt. 3, p. 16; and Mon. 36, pp. xxv, xxvi). *Vulcan iron fm., containing slates.*—Highest fm. of Lower Menominee series of Menominee dist. Overlies Antoine dol. and uncon. underlies the great sl. fm. of Upper Menominee series. Correlates with Negaunee fm. of Marquette dist. and Groveland fm. of Crystal Falls dist.

C. R. Van Hise and W. S. Bayley, 1900 (U. S. G. S. Menominee folio, No. 62), defined *Vulcan fm.* as uncon. overlying Negaunee fm., as underlying Hanbury sl., and as divided into (descending) Curry ore-bearing memb., Brier sl. memb., and Traders ore-bearing memb. Thickness of fm. 0 to 700 ft.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52), treated the Vulcan rocks of Iron River dist. as a memb. of Michigamme sl. (upper Huronian).

R. C. Allen, 1915 (Jour. Geol., vol. 23, pp. 703+) and 1919 (Am. Inst. Min. and Met. Engrs. Bull. 153, pp. 2579–2594), correlated Vulcan fm. with Negaunee and assigned it to middle Huronian.

C. K. Leith, 1933 (16th Int. Geol. Cong. Guidebook 27), assigned this fm. to middle Huronian, as did C. K. Leith, R. J. Lund, and A. Leith, 1935 (U. S. G. S. P. P. 184), who called the rocks *Vulcan iron-fm.*

Named for exposures in vicinity of West Vulcan, Menominee dist.

Waban formation.

Ordovician or Cambrian: Newfoundland.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 199). The term *Waban fm.* is suggested as an appropriate designation for the iron-bearing strata of Great Bell Island.

Wabana series.

Lower Ordovician: Newfoundland.

G. Van Ingen, 1914 (Princeton Univ. Contr. to geology of Newfoundland, No. 4). *Wabana series.*—Upper part of Lower Ord. of Newfoundland. Discon. overlies Bell Island series. Divided into several fms. Correlated with Middle Arenig, Upper Arenig, and Llandeilo(?) of western Europe. [Derivation of name not stated.]

†Wabash group.

Pennsylvanian: Indiana.

G. H. Ashley, 1902 (U. S. G. S. 22d Ann. Rept., pt. 3, p. 273). *Wabash group.*—Main coal-bearing measures, 100 to 600 ft. thick. Overlain by Merom ss. and uncon. underlain by Mansfield ss.

Includes Ditney, Somerville, Millersburg, Petersburg, and Brazil fms. of Fuller, or strata of Pottsville, Allegheny, and Conemaugh age.

Named for Wabash River, Ind., which cuts through the various fms.

Wabash formation.

Pennsylvanian: Southwestern Indiana.

M. L. Fuller and F. G. Clapp, 1904 (U. S. G. S. Patoka folio, No. 105). *Wabash fm.*—Lower half heavy sss., with thin shales, lss., and coal beds; upper half alternating sss. and shales. Thickness 180 ft. Basal bed is Parker coal. Underlain by Inglefield ss. [supposed=Merom ss.] and overlain by Tert. river deposits.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 526). *Wabash fm.* of Fuller and Clapp is recognized provisionally, pending final determination of its relations to Merom ss., which in this rept is treated as terminal memb. of Penn. in Ind.

Named for exposures in bluff of Wabash River in Patoka quad.

†Wabash stage.

†Wabash beds.

Pleistocene: Central Indiana.

O. P. Hay, 1912 (Smithsonian Misc. Coll., vol. 59, No. 20, p. 13). *Wabash beds* (also *Wabash stage*).—Interglacial deposits consisting mostly of fillings of old marshes, ponds, and lakes. Underlain by Wisconsin drift. Contains Pleist. fossils.

Preoccupied.

Named for Wabash River, being especially developed in valley of that river and its tributaries. Type loc. about 4 mi. E. of Fairmount, Grant Co.

Wabash moraine.

Pleistocene (Wisconsin stage): Northwestern Ohio, northeastern Indiana, and southern Michigan. Shown in part on moraine map (fig. 8) in U. S. G. S. Columbus folio (No. 197), p. 12, and in part on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Wabash River, Ind.

Wabaunsee formation (also **group**).

Pennsylvanian: Eastern Kansas, northwestern Missouri, southeastern Nebraska, and southwestern Iowa.

C. S. Prosser, 1895 (Jour. Geol., vol. 3, pp. 688-697). *Wabaunsee fm.*—Series of alternating fossiliferous lss. and calc., argill., and aren. shales, about 575 ft. thick, underlying Cottonwood ls. and overlying Osage coal. Includes rocks from top of Swallow's bed No. 154 to base of bed No. 80.

Later restricted in repts of Kans. Geol. Surv. so as to include only beds from top of Scranton sh. of Shawnee group (a horizon considerably higher than Osage coal) to base of Cottonwood ls. This definition was adopted by E. Haworth and J. Bennett in 1908 (Kans. Acad. Sci. Trans., vol. 21, pt. 1, pp. 71–85, and Univ. Kans. Geol. Surv. vol. 9); and it was followed by Kans. Geol. Surv. until 1931, although J. W. Beede (in Univ. Kans. Geol. Surv. vol. 9, 1908) stated that in his opinion Wabaunsee should include only from top of Americus ls. down to *base* of Scranton sh.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., p. 59). The coal which Haworth and Prosser called the Osage is the Silver Lake coal, and the Topeka coal, 125 ft. lower, is the Osage. Prosser meant base of the Wabaunsee to be at Silver Lake coal, not the Osage. Later the lower bdy of fm. was placed higher, at base of Burlingame ls., which is widely persistent and a good horizon marker.

R. C. Moore, Sept. 1931 (Kans. Geol. Soc. 5th Ann. Field Conf., correlation chart), redefined *Wabaunsee group* so as to include beds below Americus ls. and above Topeka ls., and this definition was adhered to by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. of Kans. and Nebr. This definition subtracts several fms. (Eskridge sh., Neva ls., Elmdale sh., and Americus ls.) from top of Wabaunsee group and adds several (Scranton sh., Howard ls., and Severy sh.) at base. These changes have not yet been adopted by U. S. Geol. Survey.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, pp. 94, 96). *Wabaunsee group* is redefined to include the beds from top of Topeka ls. to base of Americus ls. Thus limited the Wabaunsee is a natural strat. unit consisting mainly of gray and brown shales and thin but persistent blue and brownish lss. that differ in several respects from those of underlying Shawnee. Perhaps most important of these differences is that in few or no cases can the representative divisions of the ls. cycle be recognized definitely. Nevertheless, ls. beds 1 or 2 ft. thick have been traced for distances of more than 200 mi. in some cases, and coal beds a few in. thick have been followed on the outcrop for like distances.

G. E. Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), still further restricted Wabaunsee group by drawing its top at top of his Brownville ls., which is where R. C. Moore draws top in his 1936 classification (Kans. Geol. Surv. Bull. 22). These modified definitions have not been considered by U. S. Geol. Survey for its publications.

In Kans. the Wabaunsee is now treated as a group; in Mo. and Iowa it is treated by U. S. Geol. Survey as top fm. of Missouri group.

Named for exposures in Wabaunsee Co., Kans.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Wabi formation.

Silurian: Ontario.

G. S. Hume, 1920 (Am. Jour. Sci., 4th, vol. 50, p. 303).

Wabiabi shale.

Upper Cretaceous: Alberta.

W. Purdy, 1920 (A. A. P. G. Bull., vol. 4, p. 250). Basal memb. of Benton sh.

Waccamaw formation.

Pliocene (lower): Southern and eastern South Carolina and southern North Carolina (south of Hatteras axis).

W. H. Dall, 1892 (Wagner Free Inst. Sci. Trans., vol. 3, pt. 2, pp. 209–213). For the beds exhibited in S. C. along Waccamaw River, above the Cret. marl, as sectionized by Tuomey and Johnson, the name *Waccamaw beds* may be adopted. [Fossils are listed on pp. 210–211.] Assigned to Plio.

In present usage the Waccamaw fm. represents all known Plio. beds in S. C., and it uncon. underlies Pleist. terrace deposits (so-called "Lafayette") and overlies the Miocene Duplin marl. In N. C. the Waccamaw includes all marine Plio. deposits S. of Hatteras axis, the name *Croatan sand* being applied to the Plio. deposits N. of Hatteras axis. No outcrops known N. of Neuse River, N. C. It consists of soft lss. and loose gray to buff fine quartz sands in which occasional small quartz pebbles are present; in places it contains a small number of black water-worn phosphatic pebbles that were evidently derived from the Cret. Approx. thickness 0 to 25 ft. in N. C. and 0 to 12 ft. in S. C.

Named for exposures along Waccamaw River, Horry Co., S. C.

†Wachusett gneiss.

Late Carboniferous or post-Carboniferous: Central northern Massachusetts (Worcester County region).

L. S. Burbank, 1876 (Rept. on geol. map of Mass., by W. O. Crosby, pp. 43–52), in several places called the gneiss of Wachusett Range the *Wachusett gneiss*. According to B. K. Emerson (U. S. G. S. Bull. 597, p. 233, 1917) the rocks of Wachusett and Little Wachusett Mtns consist of Fitchburg granite overlain by 600 ft. of dark granodiorite.

Waco limestone.

Silurian (Niagaran): East-central Kentucky.

A. F. Foerste, 1905 (Ky. Geol. Surv. Bull. 6, p. 145) and 1906 (Ky. Geol. Surv. Bull. 7, pp. 10, 52). *Waco ls.*—Basal part solid ls., 1 to 2 ft. thick; upper part numerous thin layers of fossiliferous lss. interbedded with clay. Thickness 8 to 10 ft. Middle memb. of Alger fm. (of Niagaran age). Overlain by Estill clay and underlain by Lulbegrud clay.

In 1931 (Ky. Geol. Surv., ser. 6, vol. 36, pp. 172, 173) Foerste assigned this ls. to Clinton epoch.

Named for Waco, Madison Co.

†Waconia moraine.

Pleistocene (Wisconsin stage): Southeastern Minnesota.

Name applied in early Minn. repts to morainal deposits which F. Leverett (U. S. G. S. P. P. 161, pp. 76–77, 1932) considers to be "only a spur formed in a recess in the ice harbor of the Gary moraine." Named for occurrence at Waconia, Carver Co.

†Wadmalaw shell marl.

†Wadmalaw phase.

Pleistocene: Southern South Carolina (Charleston County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 20–21). *Wadmalaw shell marl* (also *Wadmalaw phase*).—Immediately overlies Edisto marl (upper Ecphora Miocene). Consists of a bed of loosely matted post-Plio. shells varying from nil to 4 ft. in thickness. This phase is exhibited S. of Bees Ferry, at the Faber place, and along northerly shore of Stono and Wadmalaw inland waterway, at Cherokee, Bolton, and St. Andrews phosphate mines, and at base of Simmons Bluff; also in sundry depressions on Edisto Island. Is overlain by Bohicket marl sand. Is a marine deposit.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867, p. 151). Wadmalaw phase of Sloan is a facies of Pamlico fm.

†Wafer shale. (In Kiowa shale.)

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, pp. 361, 363, 368, 380). *Wafer sh.* is applied to Black Hill sh. because of its "peculiar method of disintegration, breaking down under the weather into small flat and thin, sharp-edged spalls resembling wafers."

Wages sand.

Drillers' name for two sands (Upper and Lower Wages) in Pottsville group of Knox Co., SE. Ky.

Wagonhound member.

Eocene: Southwestern Wyoming and northeastern Utah.

H. E. Wood, 2d, 1934. (See under *Blacks Fork memb. of Bridger fm.* The beds to which this name is applied are included in Bridger fm. by U. S. Geol. Survey and other writers, but Wood includes them in Uinta fm.)

Wagontire formation.

Eocene(?): Central southern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207–214). *Wagontire fm.*—Massive effusives of rhyolite and coarse-grained gray porphyritic andesite, of undet. thickness. Type loc. Wagontire Mtn, NE. part of Lake Co.

Wagonwheel formation.

Oligocene(?): Southern California (McKittrick-Sunset region).

H. R. Johnson, 1909 (Sci., n. s., vol. 30, pp. 63–64). *Wagonwheel fm.*—Local occurrence of sss. and several layers of white diatomaceous shales, which appear, upon paleontologic evidence, to be Olig. Underlie Vaqueros ss. and overlie Tejon ss. Occur in isolated group of hills S. of Bartons and NE. of Point of Rocks, in Devils Den dist.

G. C. Gester and J. Galloway, 1933 (A. A. P. G. Bull., vol. 17, No. 10, p. 1169), divided *Kreyenhagen group*, as he called it, into (descending) Leda sh., uncon. on *Wagonwheel*, uncon. on Kreyenhagen sh.; and assigned his Leda and Wagonwheel fms. to Olig. and his Kreyenhagen sh. to Eocene.

Named for exposures N. and SW. of Wagonwheel Mtn, Kern Co.

Wagon Yard gypsum.

Permian: North-central Texas (Stonewall County).

L. W. Storm, 1929 (Tex. Econ. Geol. Surv. map of Stonewall Co.), shows *Wagon Yard gyp.* lying 230± ft. below Quartermaster fm., 40± ft. below Ward gyp., and 150± ft. above Aspermont or Guthrie dol.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, pp. 167, 168). *Wagon Yard gyp.*, Storm, 1929; Stonewall Co.; lies about 100 ft. below Ward gyp. and about 300 ft. above Guthrie (Aspermont) dol. Is apparently same as Childress dol. and gyp. Although proposed at about same time, the term *Childress* is in more common use, and *Wagon Yard gyp.* is discarded.

Wahkiakum formation.

Miocene (lower): Southwestern Washington and Puget Sound region.

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 15, pp. 10–22). *Wahkiakum fm.*—Sss., shales, and grits, the sss. predominating. Thickness 4,000 ft. Occur on N. side of Columbia River in Wahkiakum Co. near head of Alockaman River. Fauna quite different from that of Blakeley fm. Rests uncon. on series of shales whose faunal position seems to correspond to Blakeley fm. Is largely covered by Pleist. sands.

C. E. Weaver, 1916 (Wash. Geol. Surv. Bull. 13). The fauna [listed] of Wahkiakum deposits is here called *Arca montereyensis* zone. It is distinct from Olig. and from overlying upper Mio., and is assigned to lower Mio.

Wahnapitae quartzite.

Pre-Cambrian: Canada.

A. P. Coleman, 1915 (Problems of American geology, p. 97). Included in Sudbury series.

See *Wanapitei qtzite*, Coleman, 1914.

Wahsatch group.

The approved spelling is *Wasatch*. In some early repts the name was spelled *Wahsatch*.

Wahs Creek shale. (In Moran formation.)

Permian: Central northern Texas (Shackelford County).

O. F. Hedrick, E. Owens, P. A. Meyers, 1929 (Tex. Bur. Econ. Geol., geol. map of Shackelford Co.). *Wahs Creek sh.*, 25± ft. thick, underlies Dothan ls. and overlies Camp Colorado ls.

Wahweap sandstone.

Upper Cretaceous: Central southern Utah (Kaiparowits Plateau region).

H. E. Gregory and R. C. Moore, 1931 (U. S. G. S. P. P. 164). *Wahweap ss.*—A series of buff sandy sh. and massive sss., conformably overlying Straight Cliffs ss. and underlying Kaiparowits fm. Thickness 200 to 1,300 ft. Characterized by topog. expression, the absence, so far as observed, of coal beds, and the scarcity of fossils. Upper part of Wahweap Creek, Kane Co., is cut in the fm.

Waianae volcanic series.

Tertiary and possibly early Pleistocene: Hawaii (Oahu Island).

H. T. Stearns, 1935 (Geol. and gd. water res. Island of Oahu, Hawaii: Div. Hydrog. Bull. 1). *Waianae volcanic series.*—Comprises all lava flows, intrusive rocks (dike complex), pyroclastics, breccias, and intercalated soils in Waianae Range. The basalts can be divided into a lower memb., a middle memb., and an upper memb., which have been mapped separately in most of the range. The lower basalt is correlated with Kailua volcanic series, and the upper basalt with the bulk of Koolau volcanic series. In places, however, flows of the Koolau series overlie Waianae series with erosional uncon.

Waits River limestone.

Ordovician: Northeastern Vermont (Orange, Washington, Orleans, Essex, and Caledonia Counties) and southeastern Vermont (Windsor County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., pp. 79–115). *Waits River ls.* replaces *Washington ls.* (preoccupied), which was introduced for the calc. memb. of calciferous mica schist. The fm. consists of lss. interstratified with numerous beds of phyllite schist. Three distinct phases of the ls. can be recognized in field.

The first is a beautifully banded variety closely resembling the Columbian marble of Rutland, Vt. This variety is typically developed at Waits River [NE. part of Orange Co.], Vt. [The other "phases" are described.] Uppermost members of Waits River ls. are Lower Trenton.

C. H. Richardson, 1908 (6th Rept. Vt. State Geol., pp. 265–291). *Waits River ls.*—Replaces preoccupied name *Washington ls.*, but *Washington* is here retained for one of the 3 distinct phases of Waits River ls. The first phase is the beautifully banded variety closely resembling Columbian marble of Rutland, Vt. The second, the dark steel-gray *Washington phase* (Lower Trenton) of Derby, Brownington, Newport, and Coventry. The third or *Coventry phase* is darker than the other two, more carbonaceous, sometimes shaly, and never susceptible of polish.

C. H. Richardson, 1912 (8th Rept. Vt. State Geol., pp. 162–183). Upper members of *Waits River ls.* are undoubtedly Lower Trenton. The lower members are much earlier than Trenton. The fm. is divided into 3 phases: Coventry phase, Washington phase, and *Waits River phase*. Latter is lighter-colored than the other phases and in some instances is variegated. Named for Waits River village [Orange Co.], near which it has been quarried for years. The Memphremagog sl. (Lower Trenton) and Waits River ls. are interstratified.

G. H. Perkins, 1912 (8th Rept. Vt. State Geol., pp. 21–56). Reference of Memphremagog sl. and Waits River ls. to Trenton is not certain but probable.

C. H. Richardson and H. G. Turner, 1914 (9th Rept. Vt. State Geol., pp. 283–293). No logical reason for placing Memphremagog sl. as other than Lower Trenton.

C. H. Richardson, 1916 (10th Rept. Vt. State Geol., pp. 120–146). *Waits River ls.* includes beds of quartzose marble, some calc. qtzite, and many beds of phyllite schist interstratified. Where the calc. sediments appear to predominate the area is mapped as ls.; where the non-calc. sediments predominate the area has been mapped either as sl. or phyllite schist, according to amount of secondary cleavage that has been introduced and amount of metamorphism. Age of Memphremagog sl. and Waits River ls. probably ranges from Deepkill [Beekmantown] to Lower Trenton. Author never contended they were all Lower Trenton, but advocated that deposition began fairly early in Ord. time and ceased in Lower Trenton. Paleontologic evidence now supports that view.

C. H. Richardson, 1924 (14th Rept. Vt. State Geol., pp. 77–103). The phyllites here named *Randolph phyllite*, of Memphremagog group, are interbedded and interstratified with *Waits River ls.* The Orleans phyllite of Jacobs underlies Waits River ls. and Bradford schist overlies the Waits River. The Waits River and Washington phases of the ls. are both present in Bethel Twp.

E. L. Perry, 1929 (16th Rept. Vt. State Geol.). The *Memphremagog group* of slates and phyllites occurs in and near base of Waits River ls. in northern section. Randolph phyllite is a phase of Waits River ls.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, p. 360), assigned, without discussion, *Waits River ls.* to Lower Ord. (Chazy); Randolph phyllite to Middle Ord. (Black River); and Memphremagog sl. to the Beekmantown; and stated that Waits River ls. had yielded Chazy fossils and that Memphremagog sl. had yielded Beekmantown fossils.

Waits River phase (of Waits River limestone).

See 1912 entry under *Waits River ls.* In many subsequent Vt. repts Richardson continued to use this term.

Wakarusa limestone. (In Wabaunsee group.)

Pennsylvanian: Northeastern Kansas and southeastern Nebraska.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 30). *Wakarusa ls.*—Very fossiliferous ls., 2 to 4 ft. thick, included in Upper Coal Measures of Shawnee Co. Named for fine exposure on Wakarusa Creek immediately S. of Auburn. [From statement on p. 28 it appears to underlie Auburn sh. and overlie Soldier Creek sh.]

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser.). *Wakarusa ls.* underlies Auburn sh. and overlies Soldier Creek sh. Was named by Beede in 1898. Is same as "Fargo" ls. of Condra and Bengston. In places it is one solid ls. 6± ft. thick; in other places it is 2 dense blocky bluish lss. separated by 1 to 4 ft. of argill. sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 49, 218–225). *Wakarusa ls.* underlies Auburn sh. and overlies Soldier Creek sh. [p. 49]. Beede's original Wakarusa ls., however, is identified as Reading ls.; and Wakarusa ls. as now defined by usage, mainly by Condra, was included in upper part of Beede's "Stanton" (=Burlingame) ls. [p. 219]. Condra's 1927 usage of *Wakarusa ls.*

seems to agree with Beede's original definition, but when the ls. called Wakarusa by Condra is traced to southern Shawnee Co., Kans., it is found to comprise upper memb. of Beede's "Stanton" ls. It is desirable to separate this unit from Burlingame ls., and because Condra's use of *Wakarusa* is the only one since original publication, and because this name has been extensively employed recently with application given it by Condra, it is here retained with Condra's definition. This is case where usage desirably takes precedence over priority. The beds called *Wakarusa ls.* by Condra and here designated by that name are present along Wakarusa Creek S. of Auburn, but much better exposures are on Kansas Highway 10 W. of Topeka, in sec. 35, T. 11 S., R. 13 E., and along the creek N. of the highway near this place [p. 220].

Wakefield marble.

Commercial term substituted for *Winooski marble* of Vt. by company quarrying the marble. (See G. H. Perkins, Am. Nat., vol. 19, 1885, pp. 128–136.)

†Wakulla formation.

Miocene (lower): Northern Florida.

L. C. Johnson, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 128–132). Defined in a more extended sense, the Chattahoochee embayment will stretch out almost to basin of Suwanee River, or at least to about middle of Madison Co., Fla. The rocks found in this extension present quite another aspect. When collections were first made in this part of Fla. a few years ago, the leading type was called [in unpublished ms.?] *Wakulla fm.*, because it abounds in vicinity of springs of that name [in Wakulla Co.]. The material was taken out of a deep well 2 mi. SW. of Tallahassee. The leading features of this rock were an abundant *Hemicardium* (species not determined so far as writer is aware) and the large *Orbitulites floridana*, together with many land shells. The rocks vary greatly in material; sometimes a quite pure ls., at other places, or in other layers, aluminous and siliceous. The collection from the well shows a good ls., with calcite filling the cavities left by removal of the substance of the shells, and with some lumps or streaks of chert; the deposit was said to be 80 ft. thick. Assigned to Mio.

The deposits above described are now regarded as belonging to Tampa ls. (See C. W. Cooke and S. Mossom, Fla. Geol. Surv. 20th Ann. Rept., pp. 92–93, 1929.)

†Walden sandstone. (In Pottsville group.)

Pennsylvanian: Southeastern Tennessee, northeastern Alabama, and northwestern Georgia.

C. W. Hayes, 1892 (Ala. Geol. Surv. Bull. 4, pp. 49–51). *Walden ss.*—Sss. and shales, with beds of coal and fire clay. Overlies heavy cgl. [Sewanee cgl.] constituting top memb. of Lookout ss., and forms top part of Coal Measures in NE. Ala. and adjacent portions of Ga. and Tenn. Thickness 500 or more ft. More homogeneous than underlying Lookout ss. Contains most of coal of region. Is=Upper Coal Measures of Smith.

Comprises upper part of Pottsville group of this region. Is=Rockcastle ss., Vandever sh., Bonair ss., and Whitwell sh. of present classification of central Tenn.

Named for exposures on Walden Ridge, Chattanooga, Pikeville, and Kingston quads., SE. Tenn.

†Walden Ridge sandstone.

A name applied, probably inadvertently, by S. W. McCallie (Ga. Geol. Surv. Bull. 17, 1908, p. 47) to *Walden ss.*

†Waldo formation.

Miocene (lower): Northern Florida.

L. C. Johnson, 1888 (Am. Jour. Sci., 3d, vol. 36, pp. 230–236). The *"Chimney rock," or Waldo fm.*, having Mio. fossils, and generally phosphatic. Is the site and source of phosphatic rocks of this part [northern and central] of Fla. Thickness not less than 10 ft. and possibly 50; average 30 ft. In places has suffered much erosion, and the reworked material has often been redeposited in beds of uncertain age, making a cgl. with clay, bones, and nodules of the rock. Undisturbed and in situ it may be seen, among other places, near Waldo [Alachua Co.], at old Fort Harlee, in Preston's marl bed. Fossils at this locality innumerable.

Replaced by *Hawthorn fm.* (See C. W. Cooke and S. Mossom, Fla. Geol. Surv. 20th Ann. Rept., pp. 129–130, map, 1929.)

Waldoboro moraine.

Pleistocene (Wisconsin): Central southern Maine.

G. H. Stone, 1887 (Am. Jour. Sci., 3d, vol. 33, pp. 381–385). *Waldoboro moraine.*—Named for occurrence about 3 mi. N. of Waldoboro, Lincoln Co.

†Waldrip division.

Pennsylvanian: Central Texas.

E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, p. lxvii). *Waldrip-Cisco series.*—Alternating clays, shales, fire clays, and lss., with coal seams, overlying Brownwood-Ranger series and underlying Coleman-Albany series.

R. S. Tarr, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 207–210). *Waldrip coal div.*—Alternating clays, shales, sss., and lss., 300 ft. thick, with basal ss. 100 to 500 ft. thick. Overlies Brownwood div. and underlies Coleman div.

Same as Cisco group.

Named for Waldrip, McCulloch Co.

†Waldrip bed.
†Waldrip formation. } (In Cisco group.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 412). *Waldrip bed.*—Chiefly blue clays, but locally ss. of considerable thickness, three well-marked and persistent lss., and some shaly clay, carbonaceous sh., and a coal bed. Thickness 100 to 200 ft. Memb. in middle of Cisco div. Underlies Saddle Creek bed and overlies Chaffin bed.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Waldrip fm.*—Is characterized by a coal bed below *Waldrip ls.* (top memb. of Waldrip fm.) which forms a conspicuous scarp throughout its outcrop. At Cisco the ls. is a dense crystalline and dark-gray fossiliferous bed, but in N. part of Shackelford Co. W. of Breckenridge it changes to ss. and disappears. Another ls., however, occurs about 40 ft. lower and can be traced farther N. To NE. of Newcastle the fm. is composed largely of sand. In places where the coal does not outcrop the Waldrip ls. can be identified by the large numbers of large crinoids on its surface and the characteristic fossils from the sh. just below. Underlies Pueblo fm. and overlies Breckenridge fm.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132), replaced their Waldrip fm. with *Harpersville fm.* and correlated their Waldrip ls. memb. with Saddle Creek ls. of Drake and the remainder of Harpersville fm. with Waldrip bed of Drake.

Named for Waldrip, McCulloch Co.

†Waldrip limestone member (of Harpersville formation).

Pennsylvanian: Central northern Texas.

F. B. Plummer, 1919 (A. A. P. G. Bull., vol. 3, pp. 133–145). *Waldrip ls.*, a memb. of Waldrip fm. [See 1919 entry under †*Waldrip bed.*]

In 1922 Plummer and R. C. Moore replaced this name with *Saddle Creek ls. memb.*, finding it to be same as Drake's older name *Saddle Creek bed.*

Waldrip member. (In Harpersville formation.)

Pennsylvanian: Central Texas (McCulloch County, Colorado River region).

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 238–244). Drake applied *Waldrip beds* to all strata btw. top of Breckenridge ls. below and base of Saddle Creek ls. above, which makes it nearly synonymous with Harpersville fm., since it covered all of the Harpersville except the thin Saddle Creek ls. In this paper (on McCulloch Co.) the name *Waldrip beds* is restricted to the 65± ft. of strata (sh., ss., coal beds, and 3 thin lss.) from base of Waldrip ls. No. 1 of Drake up to base of Saddle Creek ls. memb. The beds underlying this *Waldrip memb.* are here designated as *Lower Harpersville*. They consist of 90 ft. of reddish to yellowish clay beds separated by relatively thin red to brown sss. The Waldrip ls. No. 1 lies 2 to 3 ft. above a thin impure coal bed near top of Lower Harpersville beds.

Waldron shale. (In Indiana.)

Waldron clay member (of Wayne formation) in Tennessee.

Silurian (Niagaran): Indiana and west-central Kentucky and Tennessee.

M. N. Elrod, 1883 (Ind. Dept. Geol. and Nat. Hist. 12th Ann. Rept., pp. 106–111). *Upper Niagara or Waldron sh.*—Calc. clay, sh., and thin strata of ls., 10 in. to 6 ft. thick, overlying the quarry stone and closing Niagara period or group in Decatur and Shelby Counties, central Ind. Overlain by Lower Corniferous ls. and underlain by quarry stone of Niagara age.

Adopted by U. S. Geol. Survey as a distinct fm. in Ind. and north-central Ky., and as *Waldron clay memb.* of Wayne fm. in west-central Tenn. In southern Ind. is discon. overlain by Louisville ls. (35 ft. thick and forming top fm. of Niagaran age in that region) and is underlain by Laurel ls. In west-central Tenn. *Waldron clay memb.* is overlain by two ls. members of Wayne fm. and underlain by Laurel ls. memb. of the Wayne.

For occurrence of Waldron fauna in Ohio see *Massie clay.*

Named for Waldron, Shelby Co., Ind.

†Waldron sandstone. (In Douglas formation.)

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., p. 52), mentioned "Waldron ss. alternating with sh." as occurring in interval btw. coals Nos. 4 and 5 near Weston, Mo. Is now considered to be a channel deposit in Lawrence sh. memb. of Douglas fm.

Named for exposures at Waldron, Platte Co.

Wales group.

Pre-Ordovician to Devonian: Southeastern Alaska (Prince of Wales Island).

A. H. Brooks, 1902 (U. S. G. S. P. P. 1, pp. 40–52, map). *Wales series.*—Crystalline white lss. and argillites or phyllites, with closely associated greenstones. The lss. alone are probably several thousand ft. thick. Lower part is chiefly argill. and upper part calc. Occupies large area on Prince of Wales Island. Uncon. underlies Vallenar series. Believed to be of Sil. and presumably older Paleozoic age.

Walker shale.

Upper Devonian: Southwestern Virginia.

M. R. Campbell, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 171, 177, pl. 4). *Walker black sh.*—Constitutes lower portion of great series of Dev. shales [in Wythe, Montgomery, and Pulaski Counties, Va.] and is separated entirely by its color. Is black carbonaceous sh., and the passage from this into the green sh. above is very gradual and is accomplished by interbedding, so that it is impossible to determine exactly where the line should be drawn. It is arbitrary at best and serves only to show that base is essentially a black sh. which, in a broad way, is clearly distinguishable from green sh. above. Overlies Giles fm. and underlies Kimberling sh.

Named for Walker Mtn, Giles Co.

†Walker beds.

Lower Cretaceous (Comanche series): Central southern Kansas.

F. W. Cragin, 1895 (Am. Geol., vol. 16, p. 359). *Walker beds* is suggested as substitute for *Belvidere beds in broad sense* (i. e., to include Cheyenne ss., Champion shell bed, and Kiowa shales), in case conflicting uses of *Belvidere* should make that name not acceptable. But *Belvidere* seems preferable to *Walker.*

Named for Walker's Draw, a well-known branch of Medicine Lodge River S. of Belvidere, Kiowa Co.

Above is only known use of *Walker* for this unit. *Belvidere* and *Walker* were discarded by U. S. Geol. Survey in 1921, the Cheyenne ss. and Kiowa sh. being treated as fms. and the Champion shell bed being included in Kiowa sh.

Walker conglomerate and sandstone.

Pennsylvanian: Western Missouri (Vernon County).

F. C. Greene and W. F. Pond, 1926 (Mo. Bur. Geol. and Mines vol. 19, 2d ser., pp. 62–65). *Walker cgl. and ss.*—This fm. includes the uncon. cgl. near Walker and the coarse ss. into which it grades. It consists of cgl. at base, very coarse ss. above, and coarse ss. at top, the three types of rock grading into each other. The cgl. at base is very coarse, consisting chiefly of ls. pebbles derived from Rich Hill ls. memb. of Cherokee fm., with a liberal sprinkling of angular to subangular quartz pebbles. The Walker fm. has been found at only one place, the crest of the ridge which extends to NW. on Walker Mound (sec. 8, T. 36 N., R. 30 W.). About 20 ft. of the material is in place at NW. end of outcrop. It rests uncon. on lower part of the sh. memb. of Cherokee fm. that overlies the Williams coal. Evidence indicates it is southern continuation of Warrensburg channel ss., of late Pleasanton age. No fossils except a few in the ls. fragments of the basal cgl.

Walker formation.

Miocene: Southern California (Kern County).

V. H. Wilhelm and L. W. Saunders, 1927 (Calif. State Min. Bur. vol. 12, No. 7, p. 9, pl. 1). *Walker fm.*—A series of land-laid beds, consisting of sands and shales of characteristic greenish color. The fm. changes rapidly in type from bed to bed and may be considered to be formed from variable proportions of 2 types of constituents—(1) granitic, including widespread unsorted angular quartz grains and white decomposed feldspar grains, large biotite flakes, and dark-green and red opaque clays; (2) volcanic, including white clays and ashy materials, and shales, also green soapy clays which form the matrix for fragmentary granitic debris. The fm. has widespread distribution in area and is characteristically continental in origin. Its deposition represents first stage of erosion of old granitic land mass to E. Only 3 wells have penetrated this fm., the thicknesses encountered being 370, 555, and 594 ft. Uncon. underlies Temblor fm. (middle Mio.) and rests uncon. on granitic basement. [Derivation of name not stated; no indication of age or whether or not exposed.]

H. A. Godde, 1928 (Calif. Oil Fields, Div. Mines and Min., vol. 14, No. 1, pp. 5–10). *Walker fm.* is lower memb. of Temblor group; is probably lower Mio. and may be = Vaqueros fm. Thickness 0–1,200 ft.; av. 700± ft. Uncon. underlies Temblor fm. and rests uncon. on granite. [Derivation of name not stated. Appears not to be exposed on surface.]

A. Diepenbrock, 1933 (Calif. Oil Fields, Div. Oil and Gas, vol. 19, No. 2, p. 19). There is little evidence as to age of *Walker fm.*, other than that Vedder sands grade into it. Basinward the fm. decreases in thickness, and it is possible it is a facies of Vedder sand. Rests on granite.

Walker sand.

A subsurface sand, of Penn. age and 15± ft. thick, in central northern Okla., correlated with part of Sand Creek fm. In Garber pool, Garfield Co., this sand lies at 1,500 ft. depth, the Hotson sand at 1,430 ft., and the Belveal at 1,600 ft.

Walker Ridge sandstones.

Post-Franciscan and pre-upper Miocene: Northern California (Humboldt County).

W. Stalder, 1915 (Calif. State Min. Bur. Bull. 69, pp. 447–449). *Walker Ridge sss.*, upper fm. of Rainbow series in Humboldt Co. Overlie Walker Ridge shales. Thickness 50 to 750 ft. Mostly siliceous and well cemented. Vary in color from green to gray; weather yellowish. Older than upper Mio. Named for exposures on Walker Ridge, Humboldt Co.

Walker Ridge shales.

Post-Franciscan and pre-upper Miocene: Northern California (Humboldt County).

W. Stalder, 1915 (Calif. State Min. Bur. Bull. 69, pp. 447–449). *Walker Ridge shales.*—Bluish to black to gray soft sh. beds alternating with fine- to medium-grained gray to bluish sss. varying from 3 in. to 10 ft. Minor bands of ls., some chert, and lenses of calcite at a few localities. Thickness 500 to 1,500 ft. Basal fm. of Rainbow series. Underlies Walker Ridge sss. Named for Walker Ridge.

Walkup clay.

Eocene: Northern California (Chico quadrangle).

V. T. Allen, 1929 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 18, No. 14, pp. 364, 403). *Walkup clays.*—Crudely bedded gray clays, which in some places become shaly and contain thin lenses of ls.; weather buff or yellowish. Less than ½ mi. E. of Gladding McBean pit these clays appear at surface at Walkup pit. Fossils listed. Rest on Cret. ss. Limited evidence points to Eo. age of Walkup clays. Contact with overlying Ione fm. not exposed. Walkup clay is somewhat different from clays of Ione fm., and there is marked difference in ceramic qualities. So even though no sharp break is known to separate the 2 fms. in field, it seems desirable to use name *Walkup* (already in use locally) to denote this transitional stage to Ione conditions.

Wallace formation.

Pre-Cambrian (Belt series): Northeastern Idaho (Coeur d'Alene district) and western Montana (Cabinet Mountains and Philipsburg district).

F. L. Ransome, 1905 (U. S. G. S. Bull. 260, pp. 277–285). *Wallace fm.*—Upper part, thin-bedded sandy shales; middle part, rapidly alternating thin beds of argillite, calc. ss., impure ls., and indurated calc. sh.; lower part, green siliceous argillites. Shallow-water features throughout; slaty cleavage common. Thickness 2,500± ft. Underlies Striped Peak fm. and overlies St. Regis fm. Well exposed at town of Wallace, Coeur d'Alene dist., Idaho, particularly at Northern Pacific R. R. station. Description of general geology of region is based almost wholly on work of F. C. Calkins.

Wallace Creek formation.

Southern Quebec and northwestern Vermont.

See under *Morgan Corners fm.*, also 1931 entry under *Philipsburg series.*

†Wallala beds.

†Wallala group.

Upper Cretaceous: Northwestern California (Mendocino County).

G. F. Becker, 1885 (U. S. G. S. Bull. 19, pp. 7–17). *Wallala beds.*—A series of sss. and cgls. extending along the coast from near Fort Ross at least to Wallala. In some places they rest uncon. on metamorphosed rocks thought to belong to Knoxville group. Fauna not decisive as to age. Fossils collected near Wallala are regarded by C. A. White as probably pre-Chico and younger than Knoxville.

C. A. White, 1885 (U. S. G. S. Bull. 22, p. 8). *Wallala group.*—Since so little is known of strat. relations of Wallala and San Diego beds with other fms. I cannot now discuss them fully, but I shall give them the provisional name *Wallala group,* referring those of both localities to one and same fm.

The beds referred to belong to lower part of Chico fm.

Wall Creek sandstone member (of Frontier formation).

Upper Cretaceous: Eastern Wyoming.

C. H. Wegemann, 1911 (U. S. G. S. Bull. 452, pp. 43, 45). *Wall Creek ss. lentil of Benton sh.*—Buff ss., ripple-marked and cross-bedded, firmly cemented, and of medium grain. Thickness 80 to 100 ft. Contains petrified wood, marine shells, and fish teeth. Is principal oil sand of Salt Creek field. Lies 220 ft. below Niobrara sh. and 800 ft. above Mowry sh. Not exposed in Salt Creek field but reaches surface in an escarpment 12 mi. W. of Salt Creek, which rims Powder River dome, forming the lofty escarpment known locally as "The Wall," and is best exposed above Wall Creek, a little stream named for it. Is 80 to 100 ft. thick along Wall Creek, but in Salt Creek dome thicknesses as great as 150 ft. are reported in some wells.

Later work resulted in tracing this ss. over considerable area, and the name was therefore changed to *Wall Creek ss. memb.* Subsequently the deposits of Benton age in this part of Wyo. were differentiated into (descending) Carlile sh., Frontier fm., Mowry sh., and Thermopolis sh., and the Wall Creek ss. was found to form top memb. of Frontier fm. The drillers in this part of Wyo. began to identify sands in this part of the geol. column as (descending) "First Wall Creek sand," "Second Wall

Creek sand," and "Third Wall Creek sand." Of these, the "First Wall Creek sand" is Wall Creek ss. memb. as defined. The "Second Wall Creek sand" has also been called "Lower Wall Creek sand."

Wall Creek sands of drillers.

See explanation at end of *Wall Creek ss. memb.*

Wallingford dolomite.

Lower Cambrian: Southwestern Vermont (Rutland County).

A. D. Hager, 1861 (Rept. geol. Vt., vol. 2), mentioned *Wallingford marble*, trade name.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 397). *Wallingford dol.*—Mainly light- and dark-gray dolomites like those of Rutland dol. Interstratified are thin beds of dolomitic or qtzitic light-gray ss. Thickness 300± ft. Bdy btw. Wallingford dol. and underlying Danby fm. is not sharp and is mainly marked by close of the strong qtzite sedimentation, the variable colors of the dol., and the sl. beds. Type loc. is Wallingford Twp, where it is well exposed. Is older than Clarendon Springs dol.

†Wallkill limestone.

Lower Ordovician and Upper Cambrian: Northern New Jersey.

J. E. Wolff and A. H. Brooks, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, pp. 443–454). *Wallkill blue ls.*—Normally a blue ls., fine-grained, homogeneous, becoming aren. or shaly as it merges into underlying Hardistonville [Hardyston] qtzite. One belt of it occupies Wallkill Valley S. of Franklin Furnace.

H. B. Kümmel, 1901 (N. J. Geol. Surv. Ann. Rept. State Geol. 1900, p. 31). In recent rept (U. S. G. S. 18th Ann. Rept, pt 2, p. 443) upon Kittatinny ls. in vicinity of Franklin Furnace and Hamburg, Wolff and Brooks used *Wallkill ls.* for that part of this fm. included in their studies. The term Kittatinny is, however, preferable, as the ls. is on the whole not well exposed along Wallkill River, and it is preeminently the great ls. fm. of Kittatinny Valley.

Walloomsac slate.

Middle or Lower Ordovician: Eastern New York (Rensselaer County), southwestern Vermont (Bennington County), and northwestern Massachusetts.

L. M. Prindle and E. B. Knopf, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 268–269 (map), 274–275). *Walloomsac sl.*—Thick series of dark smooth shales and soft slates that carry graptolites and rest on Ord. lss. Actual contact not seen, but areal relations of the 2 fms. in and near valley of Hoosic River make it likely the black sl. rests conformably upon the uppermost dark-blue crinoidal lss. of the calcitic lss. and marble beds. Overlies lss. of Chazy age, and is=upper Normanskill zone of Capitol dist., which is of Chazy and possibly Black River age. Named for extensive distribution in valley of Walloomsac River, W. and NW. of Bennington, Vt., in both Bennington Co., Vt., and Rensselaer Co., N. Y.

Walnut clay. (In Fredericksburg group.)

Lower Cretaceous (Comanche series): Eastern Texas.

R. T. Hill, 1891 (Geol. Soc. Am. Bull., vol. 2, pp. 504, 512). *Walnut clays* is name proposed for yellow laminated clay marls containing *Exogyra texana* and overlying and underlying the *Gryphaea* rock in Tex.-Ark. region. These clays are not always present where the *Gryphaea* rock is. The *Gryphaea* rock consists of grypheate oysters, occurring sometimes in solid masses 10 to 50 ft. thick, in some places embedded in calc. matrix. The Walnut clays overlie Paluxy sand and underlie Comanche Peak chalk. Included in Fredericksburg. [He also calls them *Walnut clays or Exogyra texana beds*. Later repts give thicknesses of 0 to 130 ft.]

Basal fm. of Fredericksburg group. See under *Fredericksburg group*. Named for Walnut (also called Walnut Springs), Bosque Co.

†Walnut shale.

Pennsylvanian: Eastern Kansas and northeastern Oklahoma.

E. Haworth and J. Bennett, 1908 (Kans. Acad. Sci. Trans., vol. 21, pt. 1, p. 74). *Walnut sh.*—Shales overlying Altamont ls. and underlying Coffeyville [Lenapah] ls.

Preoccupied. Replaced by *Nowata sh.*

Named for Walnut, Crawford Co., Kans., around which it is the surface rock.

Walnut shaly member (of Goodland limestone).

Lower Cretaceous (Comanche series): Northeastern Texas (Grayson County) and southern Oklahoma.

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120H, pp. 135–137). The basal 3 to 6 ft. of Goodland ls. consists of layers of persistent hard thin-bedded coquina-like ls. with interbedded thin layers of dark marly sh., which in this paper are called *Walnut shaly memb.* These beds were not recognized by Hill (Geol. Soc. Am. Bull., vol. 2, pp. 502–514, 1891) in type section [of Goodland ls.] at Goodland, Choctaw Co., Okla. In 1894, and again in 1901, Hill restricted Goodland to massive ls. btw. Walnut clay below and Kiamichi clay above. In Atoka and Tishomingo folios Taff included Walnut clay in the Goodland, and this usage has subsequently been followed by Taff and other authors. Although U. S. Geol. Survey has adopted Taff's usage of Goodland, the present writer is of opinion future investigations will demonstrate appropriateness of restricting Goodland to the massive ls. above the interbedded shaly clay and coquina-like ls. here called *Walnut shaly memb.*, in accordance with Hill's original usage. The Walnut shaly memb. is correlated with Walnut clay of central Tex.

Some geologists have expressed belief that this bed is younger than any part of typical Walnut clay, and some geologists now exclude the bed from Goodland ls. (See W. M. Winton and W. S. Adkins, Univ. Tex. Bull. 1931, 1920, who called the beds *Walnut shell cgl. and clays*; also see G. Scott and J. M. Armstrong, Univ. Tex. Bull. 3224, 1932, who called the beds *Walnut shell aggl.*)

See also under *Goodland ls.* and *Fredericksburg group.*

Walsingham formation.

Pliocene: Bermuda Islands.

A. E. Verrill, 1907 (Conn. Acad. Arts and Sci. Trans., vol. 12, p. 68). [Assigned to Plio., and thus classified by several other geologists, but Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 740), assigned it to Pleist.]

Waltersburg sandstone. (Of Chester group.)

Mississippian: Southern Illinois and western Kentucky.

S. Weller, 1920 (Jour. Geol., vol. 28, No. 4, pp. 281–290, and No. 5, pp. 395–416; also Ill. Geol. Surv. Bull. 41). *Waltersburg ss.*—Massive cliff-making ss. that resembles the other sss. of Chester group. Thickness 0 to 70 ft. Absent in Mississippi River counties. Present in Pope and Johnson Counties. Underlies, apparently conformably, Menard ls. [restricted]; overlies, also apparently conformably, Vienna ls.

Named for exposures at Waltersburg, Pope Co., Ill.

Waltham gneiss.

Pre-Cambrian: Eastern Massachusetts.

L. LaForge, 1932 (U. S. G. S. Bull. 839). *Waltham gneiss.*—A complex of gneisses of several varieties, probably mainly if not wholly of igneous origin. Comprises several varieties of biotite-bearing and hornblende-bearing gneiss, some aplitic gneiss, and a few porphyroid gneisses containing conspicuous crystals of feldspar in a matrix composed largely of biotite. The aplitic varieties appear to be intrusive into rest of complex and may be part of a much younger intrusive group. Oldest fm. in Boston quad. Age indeterminate but is regarded as probably pre-Camb., and quite possibly it is Archean. Occupies much of northern Waltham, SE. Lexington and Burlington, and NW. Woburn. Extends NE. into Lawrence and Salem quads. and SW. into Framingham and Franklin quads.

Wamsutta formation.

Carboniferous: Southeastern Massachusetts and eastern Rhode Island.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, pp. 134, 141–158 and pl. 17). *Wamsutta series* (also *Wamsutta group of red beds*).—A lithological unit of red beds, which in southern parts of Narragansett and Norfolk Basins are in part represented by ordinary gray and carbonaceous sediments of lower part of overlying Rhode Island Coal Measures. Along northern margin the red series underlies the Coal Measures; at Pawtucket it is interstratified with them. The beds consist of slates, shales, sss., arkose, and cgls. Includes flows of felsite and aggls. of felsitic material. Thickness 1,000+ ft. Rests on Pondville cgl. Wamsutta is a name proposed but not actually adopted for North Attleboro, Mass., where the Wamsutta Mills are located.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 54 and map). *Wamsutta fm.*—A group of characteristically red beds, composed of sss., felsite, aggls., arkose, and sh. The sediments, which include both felsites and melaphyres, are interbedded with some tuffs and flows of volcanic rock. Overlies Pondville cgl. where present, or rests on older rocks.

†Wamsutta volcanics.

A term applied by J. B. Woodworth (U. S. G. S. Mon. 33, pp. 155-156, 1899) to the volcanic flows interbedded in Wamsutta fm. of SE. Mass. and R. I.

Wanakah shale.

Middle Devonian: Western and central New York.

A. W. Grabau, 1917 (Jour. Geol., vol. 25, p. 338, footnote). The lower Hamilton shales, underlying the Encrinal ls. of western N. Y., are now designated *Wanakah shales* by me.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, p. 225). *Wanakah memb. of Ludlowville fm.*—Grabau in 1917 proposed this name for the sh. below the "Encrinal" of Eighteenmile Creek (Tichenor of this paper), but did not define it further. In this paper his name is used for the sequence beginning [below] with the *Strophalosia* and *Pleurodictyum* beds of Grabau and terminating at top with base of Tichenor. Type section is in Wanakah and Lakewood Beach Cliffs, Lake Erie. Thus defined it can be traced E. to Seneca Lake. Is chiefly light and dark blue-gray shales but contains a number of thin bands of ls. (Trilobite beds), which are remarkable for their persistence for nearly 100 mi. The Wanakah memb. overlies Ledyard memb. [Thickness of Wanakah not stated, but it appears, from section on p. 218, to range from 30 ft. at Lake Erie to 60± ft. at Seneca Lake, to E. of which it corresponds to lower part of Kings Ferry memb.]

Wanakah member (of Morrison formation).

Upper Jurassic: Southwestern Colorado (Ouray district).

W. S. Burbank, 1930 (Colo. Sci. Soc. Proc., vol. 12, No. 6, p. 172). *Wanakah memb. of Morrison fm.*—Basal memb. of Morrison fm. in Ouray dist. Thickness 124.9 ft. Divisible into 3 lithologic units (descending): (1) Sh. div. (the basal "McElmo" of Cross), 47 ft.; (2) ss. ("Upper La Plata" ss. of Cross), 19 ft.; (3) basal sh., ls., and breccia (the "Pony Express beds," called by miners "Pony Express ls." and "Pony Express contact"), 58½ ft. Rests on Upper(?) Jurassic ss. and underlies the thick ss. memb. of the Morrison. Named for exposures in Wanakah mine.

Wanapitei quartzite.

Pre-Cambrian: Ontario.

A. P. Coleman, 1914 (Ont. Bur. Mines Ann. Rept., vol. 23, pt. 1, p. 213).

See *Wahnapitae qtzite*, Coleman, 1915.

†Wando clays and sands.

Pleistocene: Southern South Carolina (Charleston County).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908 publication cited below); 1907 (Summary of mineral resources of S. C., table on p. 12); 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, p. 484, definition). *Wando clays and sands.*—White sands and a layer of drab clay (frequently stained red); successively overlie Accabee gravels. This sequence is established at Corn Hill, above Accabee Flats, on the Ashley, and elsewhere; it occurs most extensively developed along Foster's Creek and Wando River. The base of the drab clay, along its upper limits on the Cooper, attains elevation of 50 ft. (M. L. T.), which declines to low-tide level at Dean Hall, and is exhibited near tide level along Foster's Creek and Goose Creek, from which area it probably sweeps around by Accabee Flats, on the Ashley, and proceeds irregularly to

SW., while from the Cooper exposures it extends northeasterly. The clay fm. is generally missing, but the Wando sands are widely distributed. They are characterized by abundant enclosure of fine black particles, as may be observed at Simmons' Bluff and at base of the bluff along southerly side of Wappoo Cut. Is a marine Pleist. fm.

C. W. Cooke (personal communication, 1935). The beds described are a facies of Pamlico fm.

Named for exposures along Wando River, btw. Charleston and Berkeley Counties.

Wanipigow series.

Pre-Cambrian: Ontario and Manitoba.

W. G. Miller and C. W. Knight, 1914 (Ont. Bur. Mines Rept., vol. 22, pt. 2, p. 138).

†Wann formation.

Pennsylvanian: Northeastern Oklahoma.

D. W. Ohern, 1910 (Okla. State Univ. Research Bull. 4, p. 28). *Wann fm.*—Shales, sss., and lss. occupying interval btw. top of Curl fm. below and top of Stanton ls. memb. above. Divided into Stanton ls. memb., Copan memb., and Hogshooter ls. memb.

These rocks are now divided into (descending) Ochelata fm., Dewey ls., Nellie Bly fm., and Hogshooter ls.

Named for Wann, Nowata Co.

Wanswangoning quartzite.

A misprint (on p. 410 of U. S. G. S. Bull. 191) for *Wauswaugoning qtzite.*

Wapanucka limestone.

Pennsylvanian (Pottsville): Central southern Oklahoma (Arbuckle Mountains) and southeastern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Wapanucka ls.*—In descending order: (1) White massive and often oolitic ls.; (2) cherty sandy lss. and shales; (3) massive white ls., absent in places; (4) calc. and cherty sss. grading into shales and into nearly pure ferruginous sss. Thickness 30 to 200 ft. Underlies Atoka fm. and overlies Caney sh.

E. O. Ulrich, 1927 (Okla. Geol. Surv. Bull. 45, pp. 24–25, 30), proposed redefining Wapanucka ls., stating that it should include the shaly lower beds with essentially the same early Penn. fauna that Morgan (1924) described in his rept on Stonewall quad. as "Upper Caney," and that Caney sh. should be restricted to the Miss. part (middle Meramec) of Caney sh. of the literature. Also that the Wapanucka is of lower Pottsville age and is separated from underlying Caney sh. by a hiatus representing Chester group and upper Meramec.

The fm. that underlies Wapanucka ls. is now known as *Springer fm.*; it was formerly included in Caney sh. The fm. that overlies the Wapanucka is Atoka fm. (See H. D. Miser, A. A. P. G. Bull., vol. 18, No. 8, 1934, pp. 971–1009.)

Named for Wapanucka, Johnston Co., which is located along N. border of the outcrop.

Wapellan series.

A term employed by C. [R.] Keyes to cover most of the pre-Wisconsin Pleist. deposits of Iowa. (See Pan-Am. Geol., vol. 56, p. 349, 1931.)

Wapiabi shale.

Upper Cretaceous: Alberta.

G. S. Malloch, 1911 (Canada Geol. Surv. Mem. 9, p. 37). [Assigned to Cret. Later repts, by other geologists, assign it to Benton, Upper Cret.]

Wapiti formation.

Upper Cretaceous: British Columbia and Alberta.

F. H. McLearn, 1919 (Canada Geol. Surv. Summ. Rept. 1918, pt. C, p. 5). *Wapiti fm.*, Cret., Alberta.

Later writers use the name in B. C. also and assign the rocks to Upper Cret.

Wapiti River sandstones.

Upper Cretaceous: British Columbia and Alberta.

G. M. Dawson, 1881 (Canada Geol. Surv. Rept. 1879–80, p. 15B). *Wapiti River ss.*, Cret., B. C., included in Fox Hill and Laramie.

†Wappinger limestone.

†Wappinger Valley limestone.

Middle Ordovician to Lower Cambrian: Southeastern New York. See under *Barnegat ls.*

Wapsipinicon limestone.

Middle Devonian: Eastern Iowa and southwestern Illinois (Calhoun and Jersey Counties).

W. H. Norton, 1895 (Iowa Geol. Surv. vol. 4, pp. 127, 155–166). *Wapsipinicon stage.*—Various lower beds of Dev. series in Iowa, including (descending) Upper and Lower Davenport beds (described as *Fayette breccia*), Kenwood beds (including Independence sh.), and Otis beds, with possibility future investigations may add to the stage the underlying Coggon beds (here tentatively placed in Sil.) [but in later repts included in Wapsipinicon ls.]. Underlies Cedar Valley ls.

See second entry under *Davenport beds.*

T. E. Savage, 1925 (Jour. Geol.), classified *Wapsipinicon ls.* as Upper Dev.; E. O. Ulrich (1911) as Middle Dev., correlating it with Marcellus and lower Hamilton of N. Y.

Rept. 9th Ann. Field Conf. Kans. Geol. Soc., 1935, fig. 1, divided *Wapsipinicon ls.* into (descending) Davenport, Spring Grove (new name), Kenwood, Otis, and Coggon members and treated Independence sh. as a distinct fm. overlying the Wapsipinicon. "It is not yet certainly known whether Wapsipinicon beds are Upper or Middle Dev. (Stainbrook, p. 248 of this Guidebook)."

Named for Wapsipinicon River, btw. Troy Mills, Linn Co., and Central City, Linn Co., Iowa.

Wapta formation.

Ordovician: Canada.

H. M. Ami, 1900 (Roy. Soc. Canada Proc. and Trans., 2d ser., vol. 6, sec. 4, p. 202).

Wapussakatoo group.

Pre-Cambrian: Labrador.

J. E. Gill, 1935 (Geol. Soc. Am. Proc. 1934, p. 78).

Warclub Lake series.

Pre-Cambrian: Ontario.

E. M. Burwash, 1934 (Ont. Dept. Mines 42d Ann. Rept., pt. 4, p. 47).

Ward limestone.

Middle Ordovician: Central Tennessee.

P. M. Jones, 1892 (Geol. of Nashville and immediate vicinity, pp. 36–38, Univ. Press, June 1892). *Ward ls.*—Dark-blue coarsely crystalline ls., cross stratification shown at a few places. Thickness 25 to 28 ft. Underlies False Dove ls. or *Cyrtodonta* bed. Overlies Dove ls. Contains few fossils. Named for fine exposure in Mrs. Ward's quarry, near the Hudson place on Addison Ave. and Pearl St., Nashville.

These beds were formerly included in Bigby ls., but R. S. Bassler, 1932 (Tenn. Dept. Ed., Div. Geol., Bull. 38), included them and underlying †Dove ls. in Cannon ls.

Ward gypsum.

Permian: Central northern Texas (Stonewall County).

L. W. Storm, 1929 (Tex. Bur. Econ. Geol., geol. map of Stonewall Co.). *Ward gyp.* lies lower in section than Croton gyp. and 40± ft. above Wagon Yard gyp.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 167). Ward gyp. of Storm lies about 300 ft. below Croton gyp. and about 100 ft. above Childress (Wagon Yard) gyp. It may be Eskota gyp. The name *Ward* is preoccupied and is discarded.

Wardner limestone.

Mississippian: British Columbia.

S. J. Schofield, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 160).

Ware schist.

Carboniferous: Central Massachusetts.

E. Callaghan, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, p. 230). A part of Brimfield schist is here designated tentatively as a separate fm., the *Ware*, because it was found to lie below the Paxton schist, which becomes thinner to W. and is feldspathic. The Paxton, Brimfield, and Ware may be Carbf.

E. Callaghan, 1931 (N. Y. Acad. Sci. Annals, vol. 33, pp. 29, 63, 64, 67, 74). *Ware fm.* is proposed for the biotite schist which underlies the Paxton feldspathic schist in anticline in W. part of Wachusett-Coldbrook tunnel. Formerly included in Brimfield schist. Occurs along Ware River near village of Coldbrook, hence name. The area of Brimfield schist (on Emerson's geol. map of Mass.) in which Oakham is located is roughly the area of Ware fm. [*Ware schist* on map.] May be Carbf. Thickness 1,900+ ft.

War Eagle sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 216). *Lower War Eagle ss.*—Massive aren. stratum, 20 to 30 ft. thick, underlying Little Cedar coal and separated from underlying Lower War Eagle coal by 2 to 10 ft. of black laminated sl. Named for association with War Eagle coal. [No Upper War Eagle ss. was described.]

Wark diorite.

Age (?): British Columbia.

C. H. Clapp, 1912 (Canada Geol. Surv. Mem. 13, p. 96).

Wark gneiss.

Jurassic: British Columbia.

C. H. Clapp, 1913 (Canada Geol. Surv. Mem. 36, p. 57).

†Warley Hill marl.

†Warley Hill phase.

Eocene (middle and upper): Western and central South Carolina (Barnwell and Orangeburg Counties).

E. Sloan, 1905 (S. C. Geol. Surv. geognostic map of S. C., advance copies; published in 1908, in S. C. Geol. Surv., ser. 4, Bull. 2); 1907 (Summary of mineral resources of S. C., pp. 12, 16). *Warley Hill marl*, also *Warley Hill phase*.—Along marginal line of Middle Eocene marls this fm. is exhibited in form of a fine-grained argill. yellow-green marl at base of Shell Bluff (observed at extremely low water), at Kennedy's scarp on Tinkers Creek, and along South Fork of the Edisto; in its more typical form it is exposed perhaps at Caw Caw Swamp, then at type loc., Warley Hill, beyond which it is observed slightly N. of Weeks Landing, and at Cave Hill and Poplar Creek. It is exhibited approx. conforming to water level of Edisto River from Tuckers Bridge (near Branchville) to Sullivan's Bridge (about 14 mi. N. of Jacksonboro); its seeming equivalent is also observed underlying Santee marl in bed of Lower Three Runs, at Usserys Bluff (Barnwell Co.). The typical materials consist of highly glauconitic harsh marls.

In a later rept (S. C. Geol. Surv., ser. 4, Bull. 2, pp. 449, 454, 457–459, 1908) Sloan divided his Warley Hill phase into †Upper or Warley Hill fm. and †Lower or Caw Caw fm. and showed it as overlain by Santee and underlain by his Congaree phase.

The Warley Hill phase of Sloan as interpreted by C. W. Cooke (U. S. G. S. Bull. 867, 1936) is partly=McBean fm. (middle Eocene) and partly=Cooper marl (upper Eocene).

Named for exposures at Warley Hill, in E. part of Orangeburg Co.

Warm.

Name applied by C. [R.] Keyes (Pan-Am. Geol., vol. 46, 1926) to 25 ft. of cgl. at base of Kootenai fm. of Mont. Derivation of name unknown.

Warm Creek shale. (In Colorado group.)

Upper Cretaceous: Central northern Montana (Little Rocky Mountain region).

A. J. Collier and S. H. Cathcart, 1922 (U. S. G. S. Bull. 736F, p. 172). *Warm Creek sh.*—Includes all of Colorado group of Little Rocky Mtn region above Mowry sh. The upper 775 ft. consists of dark bluish-black marine sh. containing *Baculites*, *Inoceramus*, etc. The basal 360 ft. consists of dark-blue marine sh. containing very few fossils. Between these two parts lies Mosby ss. memb., a calc. ss., 5 ft. thick, containing many periwinkle-like fossils. The fm. is overlain by Eagle ss. Named for exposures along Big Warm and Little Warm creeks.

Warner basalt.

Tertiary: Northeastern California (Modoc County).

R. J. Russell, 1928 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 17, No. 11, pp. 416–425 and map). *Warner basalt.*—A thin sheet of basalt flows. The most widespread surface rock in Modoc Co., probably covering half the county. Thickness 0 to 600 ft. Named for exposures on sides of Warner Valley and for widespread distribution in Warner Lakes Range and Warner Range. Underlies rhyolite and overlies Cedarville series, the upper part of which contains flora considered to be Mascall (Upper and Middle Mio.). The Warner basalt is therefore considered much younger than Columbia River basalt.

R. E. Fuller, 1931 (Univ. Wash. Pub. in Geol., vol. 3, No. 1, pp. 15–45). Warner basalt of R. J. Russell was indicated by strat. relations to be lower Plio.

Warner sandstone member (of McAlester shale).

Pennsylvanian: Eastern Oklahoma (Muskogee, Haskell, McIntosh, and adjacent counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Warner ss. memb. of McAlester sh.*—Massive, very irregularly bedded ss., of medium texture; friable; brown; cross-bedded; contains clay blebs; very ferruginous; white mica common. Fossil plants. Thickness 40 ft. Overlies McCurtain sh. memb. and lies 8 to 40 ft. below Lequire ss. memb. Named for exposure W. of Warner.

Warren sandstone.

Mississippian: Northeastern Ohio.

H. P. Cushing, 1888 (Am. Ass. Adv. Sci. Proc., vol. 36, pp. 214–215). *Warren ss.*, 6 to 50 ft. thick, underlies Cuyahoga sh. and overlies [so-called] Berea sh. in Ashtabula and Trumbull Counties. Certain equiv. of Sharpsville ss. of I. C. White in Crawford Co., Pa.

Named for Warren, Trumbull Co.

†Warren beds. (In Richmond group.)

Upper Ordovician: Southwestern Ohio, southeastern Indiana, and west-central Kentucky and Tennessee.

J. M. Nickles, 1902 (Cincinnati Soc. Nat. Hist. Jour., vol. 20, p. 86). *Warren or Homotrypa bassleri beds.*—Interbedded lss. and dark-bluish, rather marly shales, the lss. and shales becoming rough and nodular toward top. Thickness 80 ft. Overlain by Richmond group and underlain by Mount Auburn or *Platystrophia lynx* beds [upper part of McMillan fm.].

Preoccupied. Replaced by *Arnheim sh.*, which for many years has been included in Richmond group.

Named for Warren Co., Ohio.

Warren gravel.

Pleistocene: Ontario.

A. P. Coleman, 1909 (Ont. Bur. Mines Ann. Rept., vol. 18, pt. 1, p. 297).

Warren.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Warren stage.

Name applied by W. Upham (Am. Geol., vol. 16, 1895, p. 105) to the stage of the ice during the formation of glacial Lake Warren, of Lake Superior region.

Warren oil sand group.

Drillers' term for a series of sands of Chemung age (Upper Dev.) in NW. Pa. As originally defined by J. F. Carll, 1880 (2d Pa. Geol. Surv. Rept. I_5, Atlas, pl. 11), they are 300 ft. thick, are separated from overlying Venango oil sand group by 300 to 350 ft. of shales and sss. and from underlying Bradford Third oil sand by 400 to 450 ft. of shales and sss. Include Stoneham oil sand at base. The sands have also been called (descending) Warren First sand, Warren Second sand, and Warren Third sand, and these names have been carried S. into W. Va. Named for Warren, Warren Co., Pa.

Warren County stone.

Trade name of a Carbf. ss. quarried in Warren Co., Ind. (See S. S. Gorby, Ind. Dept. Geol. and Nat. Hist. 15th Ann. Rept., 1886, p. 86.)

†Warrendale formation.

Tertiary (lower Miocene or Oligocene): Central northern Oregon (Dalles region).

W. D. Smith and E. L. Packard, 1919 (Univ. Oreg. Bull., vol. 16, No. 7, pp. 97–99; and Jour. Geol., vol. 27, pp. 97–98). *Warrendale fm.* replaces Mio. Eagle Creek fm., preoccupied. [They do not give reference to publication that constitutes priority, and compiler has been unable to find it. U. S. G. S. uses *Eagle Creek fm.* for this Tert. deposit and has discarded *Eagle Creek* as a name for the Triassic fm.] Consists of terrestrial beds of hardened ashy clay, and occurs at or near base of Columbia [River] lavas at Eagle Creek, a tributary of the Columbia in Multnomah Co. Named for town of Warrendale, near Eagle Creek. Thought to be upper Mio.

Warren Point sandstone member (of Gizzard formation).

Pennsylvanian: Southeastern Tennessee (Bledsoe, Franklin, Grundy, Hamilton, Marion, and Sequatchie Counties).

W. A. Nelson, 1925 (Tenn. Dept. Ed., Div. Geol., Bull. 33A, pp. 43, 44, 148–149, and 184). *Warren Point ss. lentil.*—A ss. in upper part of Gizzard fm., varying in thickness from 25 to 175 ft. Is first ss. beneath Sewanee cgl., from which it is in places separated by as much as 135 ft. of beds. In other places the beds btw. Warren Point ss. and overlying Sewanee cgl. thin out, and the Warren is in contact with the Sewanee. The lower ss. members of the Warren Point vary greatly, some being thick and heavy cross-bedded sss., while others are thin, slablike, very fine-grained ripple-marked micaceous sss., often containing partings of yellowish-gray or gray fissile sh. containing white or pink plastic clay bands. Around Sewanee the Warren Point is a fine-grained hard nonconglomeratic ss. In E. part of plateau and N. part of Southern Tenn. coal field it becomes conglomeratic. On Tenn. River it is very conglomeratic in lower part. There is marked erosional uncon. at base of the Warren Point at widely scattered places over entire field. In extreme S. part of field the Etna coal lies at base of the ss. It was called cliff ss. by Safford, as it forms prominent bluffs in southern and central parts of the plateau. The name Warren Point is taken from a point ½ mi. N. of Monteagle, Grundy Co., where this ss. forms a prominent bluff 65 ft. thick.

†Warrensburg group.

Pennsylvanian: Central western Missouri.

G. C. Broadhead, 1873 (Mo. Geol. Surv. Prel. Rept. on Iron Ores, pt. 2, pp. 169, 182). *Warrensburg group.*—Shales and lss. with ss. near top; 75 to 100 ft. thick, including beds 33 to 43 of detailed section of lower Coal Measures from Sedalia to Kansas City. Underlies Lexington group and overlies Knob Noster group.

Comprises upper part of Cherokee sh.

Named for exposures at Warrensburg, Johnson Co.

Warrensburg channel sandstone.

Pennsylvanian: Central western Missouri.

A. Winslow, 1892 (Mo. Geol. Surv. Sheet Rept. 1 (vol. 9), pp. 22, 45–54). *Warrensburg ss.*—Yellowish-gray micaceous ss., aren. and micaceous sh., and in places shaly ss., 200 ft. thick; cuts across Coal Measures in Lafayette Co., and apparently occupies depression which once existed where the ss. now is.

Is channel deposit in Pleasanton fm., and probably of Pleasanton age and= Moberly channel ss. of central Mo.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 43), applied *Warrensburg channel ss.* in Kans., and treated it as=lower part of his Bourbon fm. and as cutting down into basal part of Fort Scott ls. This would make it=lower part of Pleasanton and all of Henrietta of U. S. Geol. Survey and Mo. Geol. Survey.

Named for exposures at Warrensburg, Johnson Co., Mo.

Warrior limestone.

Upper Cambrian: Central Pennsylvania (Huntingdon to Center Counties).

C. Butts, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 528, 534, 537). *Warrior ls.*—Thick- and thin-bedded blue ls. with thin siliceous shaly layers and partings, a few thin qtzite layers, and an occasional bed of ls. full of large rounded quartz grains; some oolite. Fossiliferous. Thickness 250 [1,250] ft. Underlies Gatesburg fm. and overlies Pleasant Hill ls. Named for exposures on Warrior Run, along river bluff 1 mi. W. of Williamsburg, Blair Co., and on Warrior Creek, E. of Warriors Mark, in northern part of Huntingdon Co.

Warsaw shale (also **Warsaw limestone**). (Of Meramec group.)

Mississippian: Iowa, Illinois, Indiana, Kentucky, Tennessee, eastern Missouri, northern Alabama, and northeastern Mississippi.

J. Hall, 1857 (Am. Ass. Adv. Sci. Proc., vol. 10, pt. 2, pp. 54–56). *Warsaw or Second Archimedes ls.*—Series of highly fossiliferous beds of blue "marlites" with intercalations of impure lss., or in some places impure lss. separated by seams of blue marl. Overlain by an aren. bed that sometimes contains small pebbles and is in turn overlain by St. Louis ls. [includes Spergen ls.]. Underlain by 10 ft. of mag. ls. (of local occurrence, probably) succeeded below by "Geode bed" (soft shaly or marly beds with geodes of quartz chalcedony), which rests on Keokuk ls.

Adopted by U. S. Geol. Survey as basal fm. of Meramec group, overlain by Spergen ls. and underlain by Keokuk ls. As defined it includes at base the "geode bed," which in some repts has been included in Keokuk ls. In western Ky. and southern Ind. the Warsaw (formerly called "Harrodsburg ls.") is chiefly ls. and is called *Warsaw ls.*

J. M. Weller, 1934 (Ill. Acad. Sci. Trans., vol. 26, No. 3, p. 106), proposed "to restore *Warsaw fm.* to its early status," assigning to it all beds btw. Keokuk ls. and St. Louis ls. as these are now limited. This definition would include Spergen ls. in the Warsaw. The classification adopted by 9th Ann. Field Conf. Kans. Geol. Soc., Sept. 1935, did not include Spergen ls. in Warsaw, and this proposed change has not been considered by U. S. Geol. Survey for its publications.

See also under *Spergen ls.*

The Ill. Geol. Survey and Rept. 9th Ann. Field Conf. Kans. Geol. Soc. (1935) include the Warsaw in Osage group.

Named for exposures at Warsaw, Hancock Co., Ill. A typical exposure occurs along creek known as Soap Factory Hollow, which joins the Mississippi from the E. about ½ mi. S. of Lower Warsaw, Ill.

Wartburg sandstone. (In Pottsville group.)

Pennsylvanian: Northeastern Tennessee.

A. Keith, 1896 (U. S. G. S. Briceville folio, No. 33). *Wartburg ss.*—Interbedded sss., sandy shales, argill. shales, and coal beds. Perhaps as much as half of fm. is ss., the two beds at top and bottom being specially conspicuous. As many as 5 seams of coal occur with these strata. The ss. beds vary in thickness from a few in. to 50 ft., and sh. beds are of similar size. Thickness of fm. 500 to 650 ft. Underlies Scott sh. and overlies Briceville sh. Named for town of Wartburg, Morgan Co., which is situated upon this ss.

According to L. C. Glenn (Tenn. Geol. Surv. Bull. 33B, pp. 19, 310, 311, 1925) the ss. upon which town of Wartburg is located is a bed, 30 to 40 ft. thick, just below middle of Briceville sh. and from a few ft. to 30 or 40 ft. beneath Poplar Creek coal. He therefore introduced new name *Jellico fm.* for the rocks overlying Briceville sh. and underlying Scott sh., and restricted the name *Wartburg ss.* to the ss. at Wartburg. (See *Wartburg ss. memb.*)

Wartburg sandstone member.

Pennsylvanian: Northeastern Tennessee.

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, p. 311). *Wartburg ss. memb.*—A ss. near middle of Briceville fm., "more massive and more persistent than usual," lying from a few ft. to 30 or 40 ft. below Poplar Creek coal and being the ss. upon which is located the town of Wartburg, Morgan Co. Thickness of ss. 30 to 40 ft. Is basal ss. memb. of Keith's Wartburg ss., but latter name is here abandoned.

Warwick limestone.

Lower Ordovician: New York.

W. W. Mather, 1843 (Geol. N. Y., vol. 1, p. 367), stated that *Warwick ls.* is a synonym of Calciferous group, but compiler has not found any definition of Warwick ls.

Wasatch group.

Wasatch formation.

Eocene (lower): Wyoming, central southern Montana, southeastern Montana, southwestern North Dakota (?), western Colorado, Utah, and northwestern New Mexico.

F. V. Hayden, 1869 (U. S. Geol. Surv. Terr. 3d Ann. Rept., p. 191 of 1873 ed.). Immediately W. of Fort Bridger (Wyo.) commences one of most remarkable and extensive groups of Tert. beds seen in West. They are wonderfully variegated, some shade of red predominating. This group, to which I have given name *Wasatch group*, is composed of variegated sands and clays; very little calc. matter is found in it. In Echo and Weber Canyons (Utah) are wonderful displays of cgls., 1,500 to 2,000 ft. thick. Although this group occupies vast area and attains thickness of 3,000 to 5,000 ft., yet I have never known any remains of animals to be found in it. I regard it, however, as of middle Tert. age. [Does not explain relations to Green River shales, but assigns both to middle Tert. and appears to consider them as in part at least equiv.]

F. V. Hayden, 1871 (U. S. Geol. and Geog. Surv. Terr. 4th Ann. Rept., pp. 147–156). Soon after leaving Carter station [Wyo.] toward the W. the Wasatch group of beds come in. They seem to rise from beneath Bridger group. They consist of red indurated aren. clays, with beds of grayish and reddish-gray sss. alternating. Pinkish and purplish clays are dominant features and give lithological character to the groups as far W. as Echo Canyon [Utah], where cgls. prevail. I have included in this group all variegated beds we have observed W. of Carter's station.

E. D. Cope, 1874 (U. S. Geol. and Geog. Surv. Terr. 7th Ann. Rept., btw. pp. 435 and 444). Hayden named deposits of western area *Wasatch group*, and regarded it as synchronous with Green River group of eastern area. Writer has attained same opinion on paleontological grounds and hence has applied name *Green River* in both areas.

C. King, 1876 (U. S. Geol. Expl. 40th Par., Atlas), divided the Tert. deposits of NE. Utah and adjacent areas into (descending) Wyoming cgl. (Plio.), Uinta (Eo.), Bridger (Eo.), Green River (Eo.), and *Vermilion Creek (Eo.)*. Advance copies of this map were distributed in 1875.

A. C. Peale, 1876 (U. S. Geol. Surv. Terr. 8th Ann. Rept.). I shall use name *Green River group* to include also Wahsatch group of Hayden. Cope restricts name to Green River shales. The Wahsatch group and Green River group occupy two distinct basins, but are considered synchronous by Dr. Hayden and Prof. Cope. [This usage of *Green River* did not prevail, and Peale himself abandoned it in 1878.]

S. F. Emmons, 1877 (U. S. Geol. Expl. 40th Par., vol. 2, pp. 207–250), described the Tert. rocks of Green River region, Bridger Basin, Washakie Basin, and other areas in SW. Wyo. where Hayden had applied the name *Green River group*, and divided them as follows (descending): Wyoming cgl., Bridger group, Green River group, and *Vermillion Creek group*.

F. V. Hayden, 1877 (U. S. Geol. and Geog. Surv. Terr. Bull. 3, No. 1, pp. 181–185). *Wasatch group* of Hayden is same as *Vermilion Creek group* of King, and Wasatch group has priority.

C. A. White, 1877 (p. 608 of Bull. 3 cited just above), gave following sequence of Tert. fms. in Green River region (descending): Brown's Park group, Bridger group, Green River group, and Wasatch group.

C. King, 1878 (U. S. Geol. Expl. 40th Par., vol. 1, pp. 339, 353, 355, 360, etc.). *Vermilion Creek group.*—Same as Wasatch group of Hayden. A conformable series of fresh-water lake deposits of reddish sss., cgls., and clays, 0 to 5,000± ft. thick, uncon. underlying Green River group and uncon. overlying Laramie group (Cret.) except at Black Butte, Wyo., where it is conformable with Laramie. The term *Wasatch* was originally applied by Hayden to the group of cgls. and sss. displayed in Echo Canyon and in the Narrows and at other points in immediate neighborhood of the Wasatch. In attempting to follow his nomenclature in this region [of 40th Par. Surv.] I have been led to reject this name and to apply to these rocks the name *Vermilion Creek group*, because upon Vermilion Creek [SW. Wyo. and NW. Colo.] was exposed the whole thickness of the series, while at the Wasatch the full volume of the group was never seen. Base of Vermilion Creek group is base of Tert.

F. V. Hayden, 1878 (U. S. Geol. Surv. Terr. Mon. 7, pp. iii–ix). It is probable Wasatch group as now defined and Fort Union group are identical as a whole, or in part at least. [Although deposits now recognized as belonging to the true Fort Union fm. have in the past been included in both Wasatch fm. and so-called Laramie fm. of southern Wyo. and NW. Colo., the Wasatch fm. as now recognized overlies Fort Union fm. as now interpreted. See under *Fort Union fm.*]

According to U. S. G. S. Bull. 191, 1902, geologists seem to have unanimously adopted Hayden's name *Wasatch*, instead of King's name *Vermilion Creek*, and the U. S. Geol. Survey has discarded latter name. In SW. Wyo. the Wasatch deposits are now called *Wasatch group*, having been divided by A. C. Veatch (U. S. G. S. P. P. 56, 1907) into 3 fms. (descending)—Knight fm., Fowkes fm., and Almy fm. In other areas they are treated as a single unit and are called *Wasatch fm.* In SW. Utah the southern development of the Wasatch fm. was called "Pink Cliff series" by Dutton.

See under *Green River fm.* for explanation of intertonguing of Green River and Wasatch fms. in Moffat Co., Colo., and Sweetwater Co., Wyo.

Named for exposures in Echo and Weber Canyons, Wasatch Mtns, Utah.

†Wasatch limestone.

Mississippian, Devonian, Silurian, and Upper Ordovician: Northeastern Utah (northern Wasatch Mountains).

C. King, 1876 (Am. Jour. Sci., 3d, vol. 11, pp. 477–479). *Wasatch ls.*—Carbf. and Dev. lss., consisting of: (1) 4,000 ft. of ls. carrying Coal-measure fossils; (2) 1,000 to 1,200 ft. of sub-Carbf. lss. underlain by beds containing fossils that have close resemblance to Waverly group but which are considered by Hall and Whitfield as closely allied to Upper Dev.; (3) lower 1,200 to 1,400 ft. characterized by Dev. (Upper Helderberg and Chemung) fossils and a single group of fossils that seem to have the facies of both Upper and Lower Helderberg. Total thickness in Wasatch Mtns, Utah, 7,000 ft.; in middle Nev. over 8,000 ft.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, p. 407), divided the Wasatch ls. of King in N. part of Wasatch Mtns into (descending): Brazer ls. (upper Miss.), 800 to 1,400 ft.; Madison ls. (lower Miss.), 600 to 1,600 ft.; Threeforks ls. (Upper Dev.), 200 ft.; Jefferson dol. (Middle Dev.), 1,200 ft.; Laketown dol. (Sil.), 1,000 ft.; and Fish Haven dol. (Upper Ord.), 500 ft. The Fish Haven dol. rests on Swan Peak qtzite (Lower Ord.), evidently mistaken by King for the Camb. qtzite in Ogden Canyon.

Wasatchan series.

A term employed by C. R. Keyes instead of *Wasatch group* or *Wasatch fm.* of other geologists.

†Washakie formation.

Eocene (middle and upper?): Southwestern Wyoming (Washakie Basin, Sweetwater County).

F. V. Hayden, 1869 (U. S. Geol. Surv. Terr. 3d Ann. Rept., p. 190 of 1873 ed.; 1869 ed. not available). *Washakee group.*—A series of purely fresh-water beds, with some beds of impure lignite and vast quantities of fossils. The strata are nearly horizontal. I have regarded these beds as separated from the lower tertiary Fort Union or true lignite group.

F. V. Hayden, 1871 (U. S. Geol. and Geog. Surv. Terr. 4th Ann. Rept., pp. 71–73). I am now inclined to believe *Washakie group* is either an extension eastward of Bridger group or synchronous with it.

F. B. Meek, 1873 (U. S. Geol. and Geog. Surv. Terr. 6th Ann. Rept., pp. 455–462). *Washakie group* (Tert.) overlies Bitter Creek group and underlies Green River group.

F. V. Hayden, 1877 (U. S. Geol. and Geog. Surv. Terr, Bull. 3, No. 1, pp. 181–185). *Washakie group.*—E. limit of group is near Creston, extending to point just W. of Bitter Creek Station. Exposures consist of soft clays and sands of various shades of brown and yellow, with here and there a hard ss.; in several places beds of impure lignite occur. Is probably same as Vermilion Creek of King and Wahsatch group of Hayden. [Now known to be much younger than Wasatch group.]

C. King, 1878 (U. S. Geol. Expl. 40th Par. vol. 1, p. 394). Bridger group was deposited in lake which is here named Washakie Lake.

See also W. Granger and W. J. Sinclair, 1909 (Am. Mus. Nat. Hist. Bull., vol. 26, art. 3 and art. 4, pp. 17–27).

H. F. Osborn, 1909 (U. S. G. S. Bull. 361). Typical Bridger fm. of Bridger Basin, Wyo., contains some earlier deposits than Bridger fm. of Washakie Basin.

Now considered essentially same as Bridger fm. (See U. S. G. S. Bull. 702, 1920, by A. R. Schultz.)

Named for exposures at Washaki station, btw. Creston and Bitter Creek, on Union Pacific R. R., in Sweetwater Co. Comprises the Eo. sediments of Washakie Basin (approved spelling).

Washburn sandstone.

Pennsylvanian: Western Arkansas coal field and central eastern Oklahoma.

A. Winslow, 1896 (N. Y. Acad. Sci. Trans., vol. 15, p. 51). *Washburn sss.*—Sss., 500 to 600 ft. thick, forming basal part of Appleton stage. Overlie Danville stage and underlie Russellville shales.

Is a part of Atoka fm.

Probably named for Washburn, Sebastian Co., Ark.

Washburn beds.

Pre-Cambrian (upper Keweenawan): Northwestern Wisconsin (Bayfield County).

F. T. Thwaites, 1912 (Wis. Geol. Nat. Hist. Surv. Bull. 25, p. 34). *Washburn beds.*—Soft red and white sss., with much banding and mottling of colors; beds usually thin, with few pebbles or sh. layers which sometimes show mud cracks. Top memb. of Chequamegon ss. Overlies Quarry or Brownstone beds. Named for exposures in shore cliffs S. of Washburn, Bayfield Co.

Wash Creek slate.

Pre-Cambrian or Paleozoic: Central Alabama.

C. Butts (U. S. G. S. Montevallo-Columbiana folio, No. 226). *Wash Creek sl.*—Chiefly sl., very similar to Waxahatchee sl., but a considerable thickness at bottom is rather more sandy than most slates of the region and has appearance of thin-bedded ss. Generally contains many quartz veins. About 1,000 ft. above bottom is a persistent ferruginous ss. 130± ft. thick. At or near top is a thick stratum of conglomeratic qtzite that may belong to Weisner fm. Thickness of fm. probably 5,000 ft. Overlies Brewer phyllite and underlies Weisner fm.

Named for exposures on Wash Creek, Chilton Co., in Columbiana quad.

Washington formation. (In Dunkard group.)

Permian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K, pp. 44–56). *Washington County group.*—Includes all beds btw. top of Upper Washington ls. and top of Waynesburg ss. below. Thickness 150 to 450 ft. Is an important fm. in Washington Co., Pa. [For many years the Waynesburg ss. and underlying Cassville sh. have been included in *Washington fm.* (the shorter name), the base of which has been drawn at top of Waynesburg coal.]

Is lower fm. of Dunkard group.

The present Pa. Geol. Survey classifies the Washington as a *group* and the Dunkard as a *series*.

Named for exposures in highlands of Washington Co., Pa.

Washington sandstone member (of Washington formation).

Permian: Southwestern Pennsylvania, northern West Virginia, and western Maryland.

J. J. Stevenson, 1876 (2d Pa. Geol. Surv. Rept. K). *Washington ss.*—Thinly laminated micaceous dark-gray to bluish-gray ss., 12 to 18 ft. thick. Included in Washington County group [Washington fm.]. Underlies Washington coal and overlies Little Washington coal.

Washington limestone.

A name that has been applied for many years to 3 lss. in upper part of Washington fm. (Perm.) of western Pa., W. Va., Md., and eastern Ohio, which have been designated *Upper Washington ls.* (top bed of Washington fm.), *Middle Washington ls.*, and *Lower Washington ls.* For definition see under *Upper*, *Middle*, and *Lower*.

†Washington greensand.

Upper Cretaceous (Gulf series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72–75, 188). *Washington or High Bluff greensand beds.*—Dull-brown sands with occasional bands of ss., differing in lithologic character from great series above it, being coarser, less argill., free from stratified clay bands, more or less rich in greensand, and containing occasional beds of firmer dark-colored crystalline calc. strata 1 to 2 ft. thick, or round boulderlike sss. resulting from local hardenings and filled with cylindrical tubelike casts of fossils and impressions of *Baculites*. One section shows 120 ft. of the beds. Uncon. underlies Arkadelphia shales and rests conformably on High Bluff blue sands.

C. H. Dane, 1929 (Ark. Geol. Surv. Bull. 1). "Washington greensand beds" are now included in Nacatoch sand [p. 46]. An examination of Hill's rept leaves no doubt that most of the beds included by him in the "Washington or *High Bluff greensand* beds," as well as the underlying "*Blue sands of High Bluff* and of Pate's Creek," were included by Veatch (U. S. G. S. P. P. 46, p. 27, 1906) in upper part of his Marlbrook fm. [p. 115].

Named for exposures in Town Creek Valley at Washington, Hempstead Co.

†Washington shale and sandstone.

Pennsylvanian: Northwestern Arkansas and eastern Oklahoma.

F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. 26, 75–82). *Washington sh. and ss.*—Sh. below and ss. above; or there may be a gradual passage from the sh., through flagging, into the ss. Thickness 40 to 75 ft. Included in Lower Carbf. Overlies Archimedes [Pitkin] ls. and underlies Pentremital [Brentwood] ls.

Preoccupied. Replaced by Hale fm. Is of Penn. age.

Named for Washington Mtn, Washington Co., Ark.

Washington gneiss.

Pre-Cambrian: Western Massachusetts and northern Connecticut.

B. K. Emerson, 1892 (U. S. G. S. Hawley sheet, i. e., proof sheets of geol. maps and text intended for a geol. folio, but never completed and published in that form, although cited in U. S. G. S. Bull. 191, 1902).

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pp. 18, 20, 31–32, pl. 34). *Washington gneiss.*—Rusty biotite gneiss carrying blue quartz, slightly fibrolitic, with thick beds of coarse and highly crystalline lss. Thickness 2,000 (?) ft. Uncon. underlies Becket gneiss. [See also B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 23–24, 150, and map).]

Named for occurrence at Washington and Washington Center, Berkshire Co., Mass.

†Washington limestone.

Ordovician: Northeastern Vermont (Orange, Washington, Windsor, Orleans, Essex, and Caledonia Counties).

C. H. Richardson, 1898 (Am. Ass. Adv. Sci. Proc., vol. 47, pp. 295–296). *Washington ls.*—This name is proposed for the more calc. memb. of Calciferous mica schist of C. H. Hitchcock, which in Washington [Orange Co.], Vt., is sufficiently pure and compact to be catalogued as a crystal-like marble of great economic value. Thickness 2,000–5,875 ft. The noncalc. memb. of Calciferous mica schist is Bradford schist [now known as *Vershire schist*]. In Mass. the calc. memb. is known as *Conway schist.*

C. H. Richardson, 1902 (3d Rept. Vt. State Geol., pp. 61–98). *Washington ls.*, 5,000–6,000 ft. thick, is in general dark-gray siliceous ls., interstratified with 14 bands of sl., outside of the 2 large belts. It is the calc. memb. of old "calciferous mica schist." Contains Lower Trenton fossils and is intimately interstratified with Bradford schist, the noncalc. memb. of the old "calciferous mica schist."

C. H. Richardson, 1906 (5th Rept. Vt. State Geol.). *Waits River ls.* replaces *Washington ls.* (preoccupied).

See *Waits River ls.*

†Washington reds. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania.

J. J. Stevenson, 1906 (Geol. Soc. Am. Bull., vol. 17, btw. pp. 65 and 216). *Washington reds*, the "Big Red" of drillers; lies btw. Ames ls. and Elk Lick ls.

J. J. Stevenson, 1912 (Am. Phil. Soc. Proc., vol. 51). Birmingham sh. replaces *Washington reds* in Pa.

Washington phase (of Waits River limestone).

See 1908 entry under *Waits River ls.* In many subsequent Vt. repts Richardson continued to use this term.

Washington fire clay shale. (In Washington formation.)

Permian: Northern West Virginia.

C. E. Krebs, 1911 (W. Va. Geol. Surv. Rept. Jackson, Mason, and Putnam Counties, p. 117). *Washington fire clay sh.*—Dark greenish yellow, 1 to 8 ft. thick. Lies 5 to 10 ft. below Washington coal.

†Washington County group.

Same as *Washington fm.* (Perm.), the shorter name.

Washingtonville member (of Allegheny formation).

Pennsylvanian: Eastern Ohio, western Pennsylvania, northern West Virginia.

W. Stout and R. E. Lamborn, 1924 (Ohio Geol. Surv., 4th ser., Bull. 28, pp. 175–181). *Washingtonville memb. of Allegheny fm.*—Bony carbonaceous sh., of dark slaty-gray to nearly black color; hard, tough, resistant. Carries marine fauna. Occurs in Allegheny fm. In places lies on and in other places as much as 10 ft.

above Middle Kittanning coal, the average interval being 4 ft. 4 in. of dark fissile sh. or gray siliceous sh. Thickness of Washingtonville memb. varies from 6 in. to 6 ft.; average 2 ft. 2 in. Extends from Muskingum Co., Ohio, to Beaver Co., Pa., and from Mahoning Co., Ohio, to Panhandle of W. Va.

Named for exposures at Washingtonville, Columbiana Co., Ohio.

†Washita limestone.

Lower Cretaceous (Comanche series): Texas and southern Oklahoma.

B. F. Shumard, 1860 (St. Louis Acad. Sci. Trans., vol. 1, pp. 583, 586). *Washita ls.*—Fossiliferous ls. of nearly white, yellow, gray, and blue color; some layers moderately hard, others disintegrating rapidly on exposure. Good exposures near Austin and in Grayson, Fannin, and Red River Counties, Tex. According to G. G. Shumard finely developed at Fort Washita. Underlies *Exogyra arietina* marl [Del Rio clay] and in Grayson Co. overlies Blue marl.

Named for old Fort Washita, T. 5 S., R. 7 E., about sec. 23, Bryan Co., Okla.

Washita group.

Lower Cretaceous (Comanche series): Texas, southwestern Arkansas, southern Oklahoma, and northwestern Louisiana.

R. T. Hill, 1887 (Am. Jour. Sci., 3d, vol. 33, p. 298). *Upper or Washita div. of Comanche series or Lower Cret.*—Lss., sss., shales, and marls uncon. underlying Timber Creek group [Woodbine sand] and overlying Fredericksburg div. of Lower Cret.

In Am. Jour. Sci., 3d, vol. 34, p. 303, Oct. 1887, Hill placed provisional line of demarcation btw. Washita and Fredericksburg groups at top of "Caprina" (Edwards) ls., which is present generally recognized bdy. In Austin and vicinity Washita group has for many years been divided into Buda ls. (top), Del Rio clay, and Georgetown ls.; in northern Tex. it has usually been divided into Denison fm. (top), Fort Worth ls., Duck Creek fm., and Kiamichi clay. Underlies Woodbine sand and overlies Fredericksburg group.

Named for old Fort Washita, T. 5 S., R. 7 E., about sec. 23, Bryan Co., Okla.

Washita stone.

Commercial term. Same as *Ouachita stone*. Lower Dev., SW. Ark. and SE. Okla.

Wassonville limestone. (In Osage group.)

Mississippian: Southeastern Iowa.

H. F. Bain, 1895 (Am. Geol., vol. 15, p. 322). *Wassonville ls.*—Earthy mag. ls., in places aren.; 35 ft. thick; forms top memb. of Kinderhook in SE. Iowa. Underlies Augusta fm. and overlies English River grits (middle memb. of Kinderhook).

Is of Fern Glen age, according to R. C. Moore, 1928 (Mo. Bur. Geol. and Mines vol. 21, 2d ser.) and 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 245), and younger than Chouteau ls., which is shown as much younger than English River ss. The Fern Glen is now generally included in Osage group, but L. R. Laudon, 1931 (Iowa Geol. Surv. vol. 35, p. 347), called these beds *Wassonville dol. memb. of Hampton fm.*, and included the Hampton in the Kinderhook.

Named for outcrops at old Wassonville mill, Washington Co.

†Watauga shale.

Lower Cambrian: Southwestern Virginia, western North Carolina, eastern Tennessee, and northwestern Georgia.

A. Keith, 1903 (U. S. G. S. Cranberry folio, No. 90, p. 5). *Watauga sh.*—A series of interbedded lss., red, green, and variegated shales, and red sss. The lss. are blue and blue gray in color and show all grades in transition from pure ls. to red sh. Thickness of ls. beds seldom exceeds 10 ft., being usually from 1 to 2 ft. Much the greater part of the fm. is made up of red, brown, purple, and yellow sh., in places calc., in places sandy, and usually argill. When perfectly fresh much of the sh. appears as a blue or drab ls.; slight exposure produces in this the reddish colors and the shaly partings. The beds of red ss. are local and argill. and differ from the sandy sh. chiefly in being more massive. Rather unusual in appearance are a few layers of white ss. near Stone Mtn. The sss. range in thickness up to 6 ft. and are closely interbedded with the sh. Thickness 1,000 to 1,100 ft. Overlies Shady ls. through a few beds of red sh. in upper layers of the Shady. Highest Camb. fm. present. [In other areas this fm. is overlain by Honaker ls.]

Replaced by Rome fm., which has priority, and, according to C. Butts, is same as Watauga sh. of Keith.

Named for development in drainage area of Watauga River, in Carter Co., Tenn.

Watchung basalt. (In Newark group.)

Upper Triassic: Northern New Jersey (Watchung Mountains).

N. H. Darton, 1889 (Am. Jour. Sci., 3d, vol. 38, pp. 134–139) and 1890 (U. S. G. S. Bull. 67). *Watchung trap sheets.*—Three thick sheets of extrusive lava interbedded with the sediments of Newark system [group] in Watchung Mtns.

Being interbedded flows, the Watchung basalt is treated as part of Newark group.

Waterbury gneiss.

Ordovician: Central Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 86, 100, and map). *Waterbury gneiss* is not a distinct geological fm. but a complex of schists, which have been intricately injected with granite and pegmatite and occasionally amphibolite. It is Hartland (Hoosac) schist modified by igneous injections. Occurs in Waterbury and other towns.

Waterford slate.

Ordovician (?): Northeastern Vermont (Caledonia County).

C. H. Richardson, 1906 (5th Rept. Vt. State Geol., p. 97). *Waterford sl.* is here used to locate a narrow belt of sl. that may or may not be = Montpelier sl. It flanks Bradford schist on E. and is separated from the pre-Camb. metamorphic series by a fault. Lithologically it is a sl. graduating into a fine-grained phyllite of the Bradford series to W. In Waterford [village or twp.?] it reaches max. thickness, 400 ft. of workable sl.

†Waterlime.

†Waterlime series.

†Waterlime group.

Terms (lithologic) applied in early N. Y. repts to Helderberg group and underlying lss. above Salina fm.; also to the beds btw. top of Manlius ls. and top of Salina fm. of modern nomenclature. In some repts it included upper part of Salina fm. In other repts it was included in Salina fm. In still other repts it included Manlius ls., Cayuga group, and Lockport dol., and in still other repts it applied to Rondout ls. only. Name derived from fact that hydraulic lime is made from part of the rocks, especially from Rondout ls.

Waterloo quartzite.

Pre-Cambrian (middle? Huronian): Central southern Wisconsin (Jefferson County).

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, pp. 252–256). *Waterloo qtzite.*—Hard, thoroughly metamorphosed red and gray qtzites; metamorphic cgls. in certain portions; in others there is a foliated material of talcose appearance, but seldom sufficient to give the rock a schistose structure. The gray variety of qtzite predominates, especially in more westerly outliers. Exposed at foot of a ridge on border of a marsh in town of Waterloo.

J. H. Warner, 1905 (Min. World, vol. 22, pp. 420–422). *Waterloo qtzite* is a pre-Camb. outlier in the Paleozoic of southern Wis. The several outcrops dip steeply under flat-lying Paleozoic sediments that surround them. The main groups of exposures are separated by distances of a few miles; in all forming a range about 12 mi. long. These knobs lie 30 mi. E. and 10 mi. S. of Baraboo qtzites, with which they have been correlated. The qtzite is in every way similar to Baraboo qtzite. Assigned to middle Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598). *Waterloo qtzite* is possibly middle Huronian.

Waterloo moraine.

Pleistocene (Wisconsin stage): Southern Ontario. Shown on moraine map in Smithsonian Inst. Ann. Rept. 1912, p. 297, 1913.

Waterton dolomite.

Pre-Cambrian: Southern Alberta, Canada.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 50, 178). *Waterton fm. or dol.*—Siliceous dol., massive, dark gray. Thickness 200+ ft. Seen at only one place in Clarke Range, viz, at cliff over which waters of Oil Creek (Cameron Falls Brook of older maps) tumble from hanging valley of Oil Creek into Waterton Lake. [See also R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines Mem. 38, map 1).]

C. L. and M. A. Fenton, 1931 (Jour. Geol., vol. 39, No. 7, pp. 670–679). *Waterton fm.* (massive dol.) underlies Altyn fm. at Cameron Falls and other localities near Waterton Lake, Alberta.

Watertown limestone. (Of Black River group.)

Middle Ordovician: Central New York

R. Ruedemann, 1910 (N. Y. State Mus. Bull. 138, p. 72). Black River group as now understood by this [N. Y.] survey, comprises [ascending] Lowville ls., *Watertown ls.* (formerly Black River ls.) and *Amsterdam ls.*

R. Ruedemann, 1910 (N. Y. State Mus. Bull. 145, pp. 79, 84–90, 97). *Watertown ls.*—Massive dark bluish-gray to black ls., 10 ft. thick in Thousand Islands region. Is "Seven-foot tier" or Black River ls. of Hall. Uncon. underlies Trenton ls. and uncon. overlies Lowville ls., the top memb. of which is here named *Leray ls. memb.* Is next to top fm. of Black River group, being older than Amsterdam ls., the top fm. of Black River group in Mohawk and Champlain Valleys and Saratoga region. Named for exposures at Watertown, Jefferson Co.

See also under *Black River group* and *Lowville ls.*

Watertown moraine.

Pleistocene (Wisconsin stage): Northwestern New York. Named for Watertown, Jefferson Co. (See Jour. Geol., vol. 32, pp. 645, 659, 1924.)

Watertown formation.

Pre-Cambrian: Alberta and British Columbia.

G. S. Hume, 1933 (Canada Geol. Surv. Summ. Rept. 1932, pt. B, p. 5).

Waterville shale (also slate).

Silurian: Central southern Maine (Kennebec County).

C. H. Hitchcock, 1861 (Maine Bd. Agric. 6th Ann. Rept., p. 232), mentioned *Waterville slates.*

E. H. Perkins and E. S. C. Smith, 1925 (Am. Jour. Sci., 5th, vol. 9, pp. 204–228). *Waterville shales* [also called *Waterville sl.*].—A series of shales, fine-grained sss., and impure lss.; often pyritiferous. Named for fine exposures at Waterville. On SE. the shales pass into Vassalboro ss. through a series of transition beds consisting of interbedded shales and sss. [Do not state in which fm. they include the transition beds.] Two phases are typical of fm.; the first consists of interbedded bluish calc. shales and gray aren. shales; the second consists of dark-bluish slates interbedded with coarser qtzitic layers. Fossils consist of trails, sea weeds, and graptolites. Ruedemann has determined the graptolites to be of mid-Silurian (Clinton or Lower Wenlock) age, which makes the Waterville the time equiv. of Quoddy sh. of Eastport region.

Watsi shale.

Oligocene: Panama and Costa Rica.

D. F. MacDonald et al., 1919 (A. A. P. G. Bull., vol. 3, p. 364).

Watson limestone.

Silurian (early): Northeastern Missouri (Pike County).

R. R. Rowley, 1916 (Am. Jour. Sci., 4th, vol. 41, pp. 317–320). *Watson ls.*—Brown ls., coarser and heavier than Cyrene ls.; locally bluish and massive. Of considerable thickness. Half a mi. SW. of Vera or Watson station, in first cut along C. & A. R. R., the Cyrene beds are replaced by Watson horizon, which rests on Ord. sh. and yields abundance of fossils. The Watson bed is either very base of Bowling Green ls., with which it agrees lithologically, or should be regarded as another memb. of Edgewood fm.

†Watson sandstone member.

Devonian or Carboniferous: Northwestern Pennsylvania.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Watson ss. memb. of Cattaraugus fm. (Dev.)* is Venango 2d "A." Underlies North Warren sh. memb. (new name) and overlies Amity sh. memb. [All of definition. The U. S. Geol. Survey classifies Cattaraugus fm. as *Dev.* or *Carbf.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 86), replaced this preoccupied name with *Bimber Run cgl. memb.*

Watts Creek shale member (of Moran formation).

Permian: North-central Texas (Colorado River region).

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 387, 419). *Watt's Creek bed.*—Mostly bluish and reddish sandy clay, with thin strata of ls. and ss. Thickness 50 to 75 ft. Memb. of Cisco div. Underlies Horse Creek bed and overlies Camp Colorado bed.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 177, 181, 182, and charts). *Watts Creek sh. memb.*, 50 to 75 ft. thick, is basal memb. of Moran fm. in Colorado River Valley. Underlies Horse Creek ls. memb. of Moran and overlies Camp Colorado ls. memb. of Pueblo fm. Named for Watts Creek, Coleman Co.

Moran fm. was transferred to Permian in 1933.

Waubakee dolomite.

Silurian (Cayugan): Southeastern Wisconsin.

W. C. Alden, 1906 (U. S. G. S. Milwaukee folio, No. 140). *Waubakee fm.*—Gray to brownish-gray, finely laminated mag. ls. splitting readily into slabs ½ to 4 in. thick. The lower strata are more evenly bedded and contain streaks of blue clay. A thickness of 10 to 12 ft. is exposed. The beds lie stratigraphically above Racine ls. and below Milwaukee fm. and are correlated with certain beds exposed about 20 mi. N. of Wauwatosa, near village of Waubakee, Ozaukee Co., which have been correlated on faunal evidence with a portion of Cayuga group of N. Y. Few fossils in Milwaukee quad.

Waucoba series.

A variant of *Waucoban series* proposed by G. H. Ashley, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 1106–1108).

Waucoban epoch (or series).

Geographic name for Lower Cambrian. Proposed by C. D. Walcott (Smithsonian Misc. Coll., vol. 57, No. 10, pp. 305–306, 1912). Replaces †Georgian. For definition see U. S. G. S. Bull. 769, pp. 100–101.

Waucoma limestone.

Silurian (pre-Niagaran): Northeastern Iowa and northwestern Illinois.

T. E. Savage, 1914 (Am. Jour. Sci., 4th, vol. 38, pp. 35–36). *Waucoma ls.*—Fossiliferous light-gray nonmag. ls., 10 to 20 ft. thick, overlying Winston ls. and representing time interval of Sexton Creek ls., but may represent deposition in a northern province. Upper fm. of Alexandrian series.

T. E. Savage, 1916 (Geol. Soc. Am. Bull., vol. 27, pp. 305–324), introduced *Kankakee ls.* for 20 to 39 ft. of hard gray to brown ls. in NE. Ill., western Ill., and eastern Mo. N. of St. Louis, which he stated is contemp. with Sexton Creek ls. but deposited in separate basin.

T. E. Savage, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 526+). At time writer introduced "Waucoma ls." and "Winston ls." he believed these strata were deposited in basin that had a northern sea connection; but with a better knowledge of the Sil. he now believes all of Alexandrian strata in Ill. and Iowa were deposited in a sea that advanced from S., and thus belong to same province as Alexandrian strata of corresponding age in SW. Ill. "Waucoma ls." is same as *Kankakee ls.* [which he previously stated is same as Sexton Creek ls., an older name] and "Winston ls." is same as *Edgewood ls.*

Named for Waucoma, Fayette Co., Iowa.

Waugh sand.

Drillers' name for a sand of Upper Dev. (Portage?) age in western Pa., southern N. Y., and W. Va. Considered same as Elk sand.

Waukesha limestone.

Silurian (Niagaran): Southeastern Wisconsin (Waukesha County).

I. A. Lapham, 1851 (Rept. of J. W. Foster and J. D. Whitney on geology of Lake Superior dist., pt. 2, S. Ex. Doc. 4, U. S. 32d Cong., special sess., pp. 168–171). *Waukesha ls.*—Hard white or bluish-white ls. occurring throughout Waukesha Co. Few fossils (of Niagara age, according to James Hall). Extends E. along Menomonee River to within 3 mi. of Milwaukee, where it is quarried. Underlies soft yellow ls., which also occurs near Racine.

J. Hall, 1862 (Wis. Geol. Surv. Rept. 1, p. 67). *Waukesha ls.* is overlain by Racine ls. at Waukesha. It consists below of thin-bedded ls. and above of heavy-bedded ls. of same general character but less argill. Thickness 200 to 250 ft. Included in Niagara group. Rests on Geodiferous or Pentamerus and Coralline ls. of Niagara group.

T. C. Chamberlin, 1877 (Geol. Wis., vol. 2, pp. 357–360). *Waukesha beds.*—For the strata that lie btw. Mayville beds below and Racine beds above in southern part of Wis. the term *Waukesha ls.*, which has previously been applied to a portion of them, has been adopted with modifications. The term was selected many years ago by Dr. Lapham to designate the thin-bedded strata that occur at Waukesha and their equivalents elsewhere. Typical Waukesha beds consist of regular even beds of hard, compact, fine-textured crystalline dol., of gray color and conchoidal fracture, characterized by much chert in form of nodules, distributed chiefly in layers. The Waukesha beds seem to be = Upper Coral beds, Lower Coral beds, and Byron beds of Sheboygan region. [The equivalency of Byron beds to basal part of Waukesha beds was published in many subsequent Wis. repts. by different authors.]

E. O. Ulrich, 1924 (Wis. Acad. Sci. Trans., vol. 21, pp. 71–93). *Waukesha dol.* of eastern Wis., 250 to 300 ft. thick, is younger than Byron dol., 100 ft. thick, but both are of Lockport age. [This was a restriction of Waukesha dol.]

A. H. Sutton, 1935 (Rept. 9th Ann. Field Conf. Kans. Geol. Soc., p. 278), states lower part of Waukesha is probably pre-Niagaran, and of Alexandrian age, but fig. 1 of this rept assigns all of Waukesha to Lockport epoch.

Waukesha ls. is now considered by Savage and others as overlying Joliet ls. of Ill. Geol. Survey. (See under *Joliet ls.*)

Waukon sandstone.

Upper Cambrian: Northeastern Iowa.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 320–321, 326). In substituting *Waukon ss.* for the older title Jordan ss., as used in Iowa (not typical Jordan terrane), it is with a keen sense of necessity, because of fact that the term Jordan as originally proposed refers to an entirely different strat. unit. The Waukon ss. underlies Oneota dol. as exposed in NE. Iowa, SE. Minn., and SW. Wis., and uncon. overlies Allamakee dol. [Keyes correlated typical Jordan ss. with New Richmond ss. of Iowa repts.]

Named for exposures in vicinity of Waukon, Allamakee Co.

Waupecan sandstone.

Pennsylvanian: Northeastern Illinois (Morris quadrangle, comprising parts of Kendall and Grundy Counties).

H. E. Culver, 1922 (Ill. Geol. Surv., Extract from Bull. 43, 1923, pp. 53–56). *Waupecan ss.*—Shaly ss. or sandy sh. above and ss. below. Thickness 10 to 25 ft. A development of "millstone" concretions is common if not characteristic of this memb. There seems little doubt this ss. is contemp. with Vermilionville ss.

lentil of Carbondale fm., but it may possibly belong to McLeansboro fm., which, however, so far as known is absent in Morris quad. Uncon. overlain by Pleist. deposits, and underlain by 15 to 25 ft. of sh. belonging to Carbondale fm.

Named for exposures along Waupecan Creek, Grundy Co.

Waupun moraine.

Pleistocene (Wisconsin stage): Southeastern Wisconsin. Shown on moraine map (pl. 23) of U. S. G. S. P. P. 106. Named for Waupun, Fond du Lac Co.

Wausau graywacke.

Pre-Cambrian (middle Huronian): Central northern Wisconsin (Marathon County).

S. Weidman, 1907 (Wis. Geol. Nat. Hist. Surv. Bull. 16, p. 55). *Wausau graywacke.*—Feldspathic qtzite and graywackes occurring in isolated masses within a few miles NE. and NW. of Wausau. Believed to have considerable thickness. It is likely it is conformable with and a part of Hamburg sl. to NW. and with Rib Hill qtzite to SW. Assigned to lower Huronian(?).

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, chart opp. p. 598), assigned this fm. to middle Huronian.

Wausau granite.

Pre-Cambrian: Wisconsin.

C. C. Wang, 1932 (Geol. Soc. China Bull., vol. 11, No. 4, p. 427).

Waushara granite.

Pre-Cambrian (pre-Huronian?): Central southern Wisconsin (Waushara County).

S. Weidman, 1898 (Wis. Geol. Nat. Hist. Surv. Bull. 3, Sci. ser. 2, pp. 47–64). *Waushara granite.*—Fine-grained dull-red granite consisting of feldspar and quartz and a very small amount of fine mica. Outcrops at several places in Marion and Warren Twps, SE. part of Waushara Co., in dist. of Fox River.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 365). *Waushara granite* may be supposed to be pre-Huronian.

Wauswaugoning quartzite.

Pre-Cambrian (Huronian): Northeastern Minnesota.

N. H. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept.). *Wauswaugoning qtzite*, at head of Wauswaugoning Bay, apparently lies at same horizon as Pewabic qtzite, near top [?] of the Animikie.

N. H. Winchell, 1893 (Minn. Geol. Nat. Hist. Surv. Bull. 8, btw. pp. vii and xxxiv). *Wauswaugoning qtzite*, with its slaty qtzites, is probably on same horizon as Pewabic qtzite.

C. R. Van Hise and C. K. Leith, 1909 (U. S. G. S. Bull. 360, p. 409), correlated this qtzite with Pokegama qtzite, which is now classified as middle Huronian by C. K. Leith and other geologists.

†Wautubbee marl. (In Claiborne group.)

Eocene (middle): Mississippi.

E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14, p. 78). *Wautubbee marl.*—Highly calc. and fossiliferous marine marls, gray to almost white, or dark-bluish and greenish tints, due to presence of glauconite. Thickness about 100 ft. in SE. Miss. Underlies Cockfield memb. of Lisbon fm. and overlies, perhaps uncon., Decatur sand memb. of Lisbon.

Later work has shown that these rocks comprise upper and major part of Lisbon fm., and that geographic name is not necessary, because the rocks closely resemble typical Lisbon deposits. (See L. W. Stephenson, W. N. Logan, and G. A. Waring (U. S. G. S. W. S. P. 576, p. 51, 1928.)

Named for exposures near Wautubbee, Clarke Co., on Northeastern R. R., in deep cut beneath highway bridge on Highway 11, sec. 10, T. 3 N., R. 14 E.

†Waverlian.

A variant of †Waverlyan.

†Waverly group.

Mississippian and Devonian (?): Ohio and Kentucky.

W. W. Mather, 1838 (Am. Jour. Sci., 1st, vol. 34, pp. 356, 363); C. Briggs, Jr., 1838 (Ohio Geol. Surv. 1st Ann. Rept., pl. 1, p. 79). *Waverly ss. series.*—Alternating fine-grained ss. and sh., 250 to 300 ft. thick, overlying 200 to 300 ft. of grayish to black slaty argill. rock and underlying 40 to 80 ft. of cgl. [Pottsville] beneath the lower coal series.

This term has been variously used, to include Logan, Black Hand, Cuyahoga, Sunbury, and Berea fms.; Bedford fm. (of Dev. or Carbf. age) also has been included by some writers; and many writers have included the still older Cleveland sh.

Named for Waverly, Pike Co., Ohio.

See also U. S. G. S. Bull. 769, pp. 75–78.

†Waverly conglomerate.

Mississippian: Ohio.

E. B. Andrews, 1871 (Ohio Geol. Surv. Rept. Prog. 1870). *Waverly cgl.*—Coarse ss., often cgl.; exposed at Black Hand; total thickness 50 to 85 or more ft. Underlies Logan ss. (Upper Waverly ss.) and overlies lower sss. and shales of Waverly ss. group. [See also E. B. Andrews, 1870 (Ohio Geol. Surv. Rept. Prog. 1869, pp. 75–80, 135, and "Section of Hocking River," on map of Lower Coal Measures).]

Replaced by *Black Hand fm.*

Named for occurrence within †Waverly group.

†Waverly sandstone series.

Same as †Waverly group. (See U. S. G. S. Bull. 769, pp. 75–78.)

†Waverly black shale.

†Waverly black slate.

Names applied in some early Ohio repts to the Mississippian fm. later named *Sunbury sh.* Named for occurrence in †Waverly group.

†Waverly brownstone.

A term applied in some early Ohio repts to a part of Buena Vista ss. memb. of Cuyahoga fm.

†Waverly shale.

†Waverly blue shale.

Names applied in some early Ohio repts to *Bedford sh.*

†Waverly quarries.

†Waverly sandstone.

Names applied in some early Ohio repts to *Berea ss.*

Waverly formation.

Mississippian: British Columbia.

W. A. Johnston and W. L. Uglow, 1926 (Canada Geol. Surv. Mem. 149, p. 21).

†Waverly flags.

Pennsylvanian: Eastern Kansas, southeastern Nebraska, and northwestern Missouri.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 36, 39, 45). [See 1st entry under *Kereford ls.*]

†Waverlyan system.

E. O. Ulrich, 1905 and 1911. (See explanation under †*Tennesseean system.*)

Has also been called *Waverlyan series* and *Waverlian series.*

Wawa tuff.

Pre-Cambrian (Keewatin): Western Ontario (Michipicoten district).

A. P. Coleman and A. B. Willmott, 1902 (Toronto Univ. Studies, geol. ser., No. 2, p. 9; Ont. Bur. Mines Ann. Rept. 1902, p. 156). *Wawa tuffs*, Huronian.

C. R. Van Hise and C. K. Leith, 1911 (U. S. G. S. Mon. 52, p. 151), included *Wawa tuff* in Keewatin.

Waxahatchee slate.

Pre-Cambrian or Paleozoic: Central Alabama.

C. Butts (U. S. G. S. Montevallo-Columbiana folio, No. 226). *Waxahatchee sl.*—Chiefly grayish, greenish, and bluish sl., including, near top, Sawyer ls. memb. and a bed of ss., also several beds of ss. at lower horizons. Contains much bluish fine-grained sl. Thickness probably about 5,000 ft. Underlies Brewer phyllite and is oldest fm. exposed in these quads. Named for exposures on Waxahatchee Creek, Shelby Co., in Columbiana quad.

Wayan formation.

Upper Cretaceous (and Lower Cretaceous ?): Southeastern Idaho.

G. R. Mansfield and P. V. Roundy, 1916 (U. S. G. S. P. P. 98G, p. 83). *Wayan fm.*—Sss., shales, lss., and some cgls. Neither top nor bottom of fm. is known, but 11,800± ft. appears to be exposed thickness. Confined to NE. part of Wayan quad. and region to N. Rests uncon. on Gannett group. Named for settlement of Wayan, Bannock Co., in NW. part of Wayan quad. Occupies hills immediately E. of Wayan and appears to be broadly divisible into two units, the upper 9,000± ft. being composed chiefly of alternating sss. and shales with some conglomeratic beds, and the lower 2,800 ft. comprising some 8 subdivisions, including several thick beds of ls. Assigned to Cret. (Lower? Cret.).

Later definitely Upper Cret. fossils were found in upper part of Wayan fm., and the accumulated evidence (mainly physical) regarding the lower part suggested that that part also is Upper Cret. Age was therefore changed (in March 1936) to *Upper Cret. (and Lower Cret.?)*. (See American Cret. ferns of genus *Tempskya*, by C. B. Read and R. W. Brown, U. S. G. S. P. P. 186F, 1937.)

Wayland shale member (of Graham formation).

Pennsylvanian: Central and central northern Texas.

F. B. Plummer and R. C. Moore, 1922 (Jour. Geol., vol. 30, pp. 24, 31; Univ. Tex. Bull. 2132, pp. 127–158). *Wayland sh. memb. of Graham fm.*—Very fossiliferous sh. composing top memb. of Graham fm. in most places in Brazos River and Colorado River Valleys. Varies in thickness from 0 to 100 ft. In section 1½ mi. E. of Avis, Jack Co. [Brazos River region], it consists of 75 ft. of light-gray sandy sh. underlain by 10 ft. of yellowish-gray sh. with ferruginous concretions. In some sections the basal bed is black carbonaceous sh. 5 ft. thick. Discon. underlies Avis ss. memb. of Thrifty fm. and overlies Gunsight ls. memb. of Graham fm.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 103), treated *Wayland sh.* as top memb. of Graham fm., overlain by Avis ss.

F. M. Bullard and R. H. Cuyler, 1935 (Univ. Tex. Bull. 3501, pp. 197+), expanded *Wayland sh.* to include, in Colorado River region, all beds up to base of Speck Mtn ls. and defined it as resting on Gunsight ls.

Wallace Lee and C. O. Nickell (rept completed and soon to be published by Tex. Geol. Surv.) define Wayland sh. of type region (Brazos River) as underlying Avis ss. and as in places separated from Gunsight ls. memb. by 200± ft. of deposits.

Named for exposures at and near Wayland, Stephens Co., Brazos River region.

Wayne formation.

Silurian (Niagaran): Western Tennessee and northeastern Mississippi.

N. F. Drake, 1914 (Tenn. Geol. Surv. Resources of Tenn., vol. 4, No. 3, p. 103). *Wayne fm.*—Name proposed by H. D. Miser from fact the rocks to which it is applied are widely exposed and typically developed in Wayne Co. Consists of 5 members (descending): Dixon earthy ls. memb. (10 to 45 ft. thick); Lego ls.

memb. (25 to 36 ft. thick); Waldron clay memb. (2½ to 5 ft. thick); Laurel ls. memb. (19 to 32 ft. thick); and Osgood earthy ls. memb. (10 to 17 ft. thick). Underlies Brownsport fm. and overlies Brassfield ls.

Named for Wayne Co., Tenn., in NW. part of which all of the members are well developed.

Wayne.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Waynesboro formation.

Lower Cambrian: Central and southern Pennsylvania, western Maryland, and northern Virginia north of Rockbridge Co.

G. W. Stose, 1906 (Jour. Geol., vol. 14, p. 209). *Waynesboro fm.*—Purple sh. and flaggy calc. sss., hard, siliceous, and ripple-marked. About 600 ft. thick. Underlies Elbrook ls. and overlies Tomstown ls. Outcrops in ridge just N. of Waynesboro, Franklin Co., Pa.

G. W. Stose, 1909 (U. S. G. S. Mercersburg-Chambersburg folio, No. 170), gave thickness of Waynesboro fm. as 1,000 ft., and later repts give thickness up to 1,750 ft.

Waynesburg group.

H. D. Rogers, 1858 (Geol. Pa., vol. 2, pt. 1, pp. 474–477), mentioned, but did not define, *Waynesburg group.*

Waynesburg sandstone member (of Washington formation).

Permian: Southwestern Pennsylvania, southeastern Ohio, northern West Virginia, and western Maryland.

J. J. Stevenson, 1873 (Am. Phil. Soc. Trans., vol. 15, n. s., p. 16). The "Upper Barren group" [Dunkard group of present nomenclature] includes all above the *Waynesburg ss.*, if I may so term it. This ss. is separated from underlying Waynesburg coal by 1 to 15 ft. of sh. [later named Cassville sh. memb.]. [For many years the Waynesburg ss. and Cassville sh. have been included in Washington fm., the lower fm. of Dunkard group, although they were excluded in this original definition. W. M. Fontaine and I. C. White transferred them to the higher fm. in 1880 (2d Pa. Geol. Surv. Rept. P_2).]

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 40, 41). *Waynesburg ss.*—Generally massive and conglomeratic grayish-white ss., but in places represented by sandy shales and flaggy sss., with an occasional ls. stratum. Thickness 50 to 100 ft. Lies 2 to 5 ft. below Mount Morris ls. and rests on Cassville plant sh. Named for fine development near [on Tenmile Creek just E. of] Waynesburg, Greene Co., Pa.

Waynesburg limestone member (of Monongahela formation).

Pennsylvanian: Southwestern Pennsylvania, western Maryland, eastern Ohio, and northern West Virginia.

J. J. Stevenson, 1877 (2d Pa. Geol. Surv. Rept. K2). In Fayette and Westmoreland dist. of Pa. the *Waynesburg ls.*, 8 to 35 ft. thick, underlies Little Waynesburg coal and is separated from underlying Uniontown coal by 50 to 80 ft. of sh. and shaly ss. [the ss. is Uniontown ss. memb.].

Named for Waynesburg, Greene Co., Pa.

Waynesburg clay.

Name applied to the clay associated with Waynesburg coal, the upper bed of Monongahela fm. (Penn.) in southwestern Pa., northern W. Va., and eastern Ohio.

Waynesburg member. (In Monongahela formation.)

A term employed by Pa. Geol. Surv. (M. E. Johnson, Topog. and Geol. Atlas Pa. No. 27, Pittsburgh quad., p. 31, 1929) to include (descending) Waynesburg coal, Browntown ss., Little Waynesburg coal, and Waynesburg ls.

Waynesville shale. (In Richmond group.)

Upper Ordovician: Southwestern Ohio, southern Indiana, and north-central Kentucky.

J. M. Nickles, 1903 (Am. Geol., vol. 32, p. 205). *Waynesville or Bythopora meeki beds.*—Dove-colored to blue lss. interbedded with blue or greenish-blue clay; 50 ft. thick. Conformably overlies Warren beds [Arnheim fm.] and underlies Liberty beds.

Adopted by U. S. Geol. Survey to exclude at base beds called by A. F. Foerste *Fort Ancient div. of Waynesville,* which according to E. O. Ulrich and C. Butts more appropriately belong to underlying Arnheim sh. In introducing *Fort Ancient,* Foerste also stated that the lamellibranchs suggest that Fort Ancient belongs to Arnheim. In his subsequent repts, however, he included it in Waynesville and placed an uncon. at its base. According to E. O. Ulrich and C. Butts there is an uncon. at top of Fort Ancient of Foerste. In SW. Ohio the Waynesville is chiefly sh. and is called *Waynesville sh.;* in southern Ind. and north-central Ky. it is chiefly ls. and is called *Waynesville ls.*

Named for Waynesville, Warren Co., Ohio.

Waynesville limestone. (In Richmond group.)

Upper Ordovician: Southern Indiana and north-central Kentucky.

See under *Waynesville sh.*

Wayside sandstone and shale member. (In Pottsville formation.)

Pennsylvanian: Southwestern Illinois (Carbondale quadrangle).

J. E. Lamar, 1925 (Ill. Geol. Surv. Bull. 48, pp. 23, 84–85, and map). *Wayside ss. and sh. memb.*—The Wayside memb. of the Pottsville in Carbondale quad. is defined as the strata lying above the ls. beds of the Kinkaid and below the massive conglomeratic ss. beds of the Lick Creek memb. Most of its beds seem to be lenticular. The sss. vary from thin-bedded to massive, from fine to locally coarse-grained, and from relatively pure to very argill. The shales show wide textural and compositional range. In places thin bands of quartz-pebble cgl. occur. A few small thin lenses of coal are present. Argill. dark-colored ls. found in places also probably belongs to this memb. Contains one massive ss. about 45 ft. thick, which forms waterfalls and cliffs. Average thickness of the Wayside is probably about 70 ft. Lies uncon. on Kinkaid ls. and is overlain, probably conformably, by Lick Creek ss. memb. of the Pottsville. Named for village of Wayside, Union Co., which is a few mi. NW. of best exposures.

Wayside sand.

A subsurface sand, of Penn. age, in central northern Okla., that is correlated with Cleveland sand and with part of Nowata sh. In Wiser pool, Osage Co., it is 20 to 25 ft. thick and lies at 750 ft. depth, the Bartlesville sand lying at 1,475 ft. Is supposed to be same as Wayside sand of Wayside, Kans.

Wea shale.

Pennsylvanian: Eastern Kansas, northwestern Missouri, and southwestern Iowa.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 91, 97). *Wea sh. memb.* underlies DeKalb ls. and overlies Block ls., all members of Cherryvale sh.

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, pp. 18, 38). *Wea sh.*—Argill. or calc. sh., greenish or gray, 10 to 30+ ft. thick, overlying Block ls. and underlying Westerville ls., all in Kansas City group. Named for Wea Creek, in NE. part of Miami Co. Type exposures at SE. cor. sec. 31, T. 16 S., R. 24 E., and at center of E. side of sec. 12, T. 18 S., R. 22 E.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

Weatherford dolomite.

Permian: Northwestern Oklahoma (Dewey and Custer Counties).

R. L. Six et al., 1930 (Okla. Geol. Surv. Bull. 40UU, map). "*Day Creek or Weatherford dol.* (Not always present.) Weatherford horizon is 50± ft. below the Day Creek."

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4). *Weatherford dol.* closely resembles Relay Creek dolomites. It lies 25 to 60 ft. below Cloud Chief gyp. and in Rush Springs ss. It was called *Day Creek dol.* by Gould in 1924, when he first defined Cloud Chief gyp.

See also under *Day Creek dol.* and *Cloud Chief gyp.*

D. A. Green, 1936 (A. A. P. G. Bull., vol. 20, No. 11, p. 1472). Evans (1931) [publication cited above] described Weatherford dol. as in upper part of Rush Springs ss., with which all geologists who have worked in Weatherford area agree. From Weatherford N. and W. through Custer Co. the Weatherford dol. horizon occurs as a gyp. bed 3 to 5 ft. thick, except a few local patches in vicinity of Arapaho, where it is a thin dol.

Weatherford lime rock.

A term applied by drillers to Lower Cret. lss. occurring at various horizons in Main Street ls., Denton clay, and Goodland ls. of Dallas Co., NE. Tex. (See E. W. Shuler, Tex. Univ. Bull. 1818, pp. 11-26, 1918.)

Weaver rhyolite.

Triassic (Middle?): Northwestern Nevada (Rochester district).

A. Knopf, 1924 (U. S. G. S. Bull. 762). *Weaver rhyolite.*—Chiefly flows of rhyolite lavas, with small amount of intercalated tuffs and breccias. In places rests on rhyolite tuff and in places on the lower (70± ft.) Nenzel rhyolite breccia. Thickness 720+ ft. Of Triassic (Middle? Triassic) age. Exposed at head of Weaver Canyon.

Weaverton sandstone.

Same as Weverton ss., the approved spelling.

Weaverville formation.

Eocene: Northern California (Klamath Mountains).

N. E. A. Hinds, 1933 (Calif. Jour. Mines and Geol., vol. 29, Nos. 1 and 2, pp. 79, 115). Diller, Hershey, and MacDonald have described deposits of "auriferous gravels" from a number of small basins in western Klamath Mtns. Under this heading of "auriferous or gold gravels" deposits of such different ages and types are included that the term has no strat. significance. The *earliest or first-cycle group*, for example, are the Cret. marine cgls. which at certain localities contain detrital gold. The *second series* includes fine-textured flood-plain sediments (ss., shaly sss., and sandy shales), lake beds, lignitic shales and lignites, tuffs, and coarse stream gravels. The fossil plants present toward base of the series at various localities are of Eo. age, but whether all the beds belong to a single sequence has not been determined. For this series of beds writer proposes *Weaverville fm.* from extensive exposures near Weaverville, Trinity Co. The gravels most important as a source of gold are coarse channel deposits of Pleist. age. The deposits of second cycle have been preserved by down-faulting of small blocks into the much more resistant bedrock of the region, and in these basins the soft unconsolidated sediments were protected from rapid erosion. The principal deposit extends from short distance S. of Weaverville for about 20 mi. to NNE., and has width of 1 to 3 mi. Plants found in the tuff and tuffaceous sediments on Redding Creek and near Hayfork and Hyampon were considered by F. H. Knowlton to be Mio. and = fossil floras of Sierra Nevada auriferous gravels. According to H. MacGinitie (personal communication), who has worked on this flora under direction of R. W. Chaney, the fossil plants are Eo. and probably to be correlated with the floras of auriferous gravels of Sierra Nevada.

In 1935 (Geol. Soc. Am. Proc. 1934, p. 316) Hinds assigned this fm. to Eo. or Mio.

†Webb Bluff.

Eocene: Southern Texas.

E. T. Dumble, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 224, 228, 230). *Webb Bluff Tertiary.*—Underlies Reynosa beds (Neocene) and overlies Escondido beds. Assigned to Eocene. [Not fully described, but seems to consist of 7 to 8 ft. of greensand marls with many Tert. fossils, nodules of carbonate of lime, and specks of glauconite.]

Same as Midway fm.

Named for Webb Bluff, Webb Co., 3 mi. below Maverick Co. line.

Webbers Falls sandstone member (of Atoka formation).

Pennsylvanian: Eastern Oklahoma (Muskogee and McIntosh Counties).

C. W. Wilson, Jr., 1935 (A. A. P. G. Bull., vol. 19, No. 4, pp. 503–520). *Webbers Falls ss. memb. of Atoka fm.*—Impure bluish limy ss., containing angular quartz grains and argill. and carbonaceous matter. In S. part of area the lower part outcrops as a thin-bedded blocky impure ss. of fine texture and dark-blue color. Fossils. Thickness 35 ft. Separated from underlying Dirty Creek ss. memb. by 40 ft. of dark-blue sh. and from overlying Blackjack School ss. memb. by 150 to 350 ft. of sh. Named for exposures in secs. 10 and 15, T. 15 N., R. 20 E., about 2 mi. W. of Webbers Falls.

†Webberville beds.

Upper Cretaceous (Gulf series): Central Texas (Travis and Burnet Counties).

R. T. Hill, 1889 (Tex. Geol. Surv. Bull. 4, pp. xiii, xxx). *Navarro-Webberville beds* of *Exogyra ponderosa* marls or Blue Bluffs div.; seen in Colorado section from Montopolis Bridge to Webberville, especially at blue bluffs of Colorado River. Consist of clays underlying the Glauconitic div. of the Cret. or the Lignitic or Basal div. of Eo. Exposed at and near Webberville [Travis Co.].

R. T. Hill, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. 115, 132). *Webberville beds* [on p. 115] also *Navarro-Webberville beds* [on p. 132 and included in *Exogyra ponderosa* marls or Blue Bluffs div. (Taylor marl)].—Slightly aren. and very fossiliferous concretionary clays indicating transition into Glauconitic div. Along Colorado River overlain by Eocene Lignitic deposits.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 124–127, 344). *Webberville beds.*—Black clay shales with occasional aren. layers and indurations. Thickness 400 ft. Differs from underlying Taylor marl in presence of many glauconite or greensand grains and by different fossils. The beds represent Navarro fm., which author in previous repts has called *Glauconitic div.* They grade into Taylor marl.

Now considered to be essentially the same as Navarro fm., the older name.

Weber quartzite.

Pennsylvanian: Northeastern Utah (Weber Canyon region).

C. King, 1876 (Am. Jour. Sci., 3d, vol. 11, pp. 477–479). *Weber qtzite.*—Qtzite with a few beds of red ss. at base and occasional fine beds of sh. interspersed at 3 or 4 horizons, varied to considerable extent by thin sheets of cgl. and rounded quartz pebbles. Named for Weber Canyon of Wasatch Range. No fossils but is certainly referable to middle of Coal measures. Rests conformably on Wasatch ls. and is conformably overlain by Upper Coal measures. Thickness 6,000 to 10,000 ft. [The use of the name *Weber* was extended by the early workers into Colo. and Wyo., to include great thicknesses of rocks that are probably older than Weber qtzite.]

E. Blackwelder, 1910 (Geol. Soc. Am. Bull., vol. 21, pp. 517–542). In upper canyon of Weber River the conspicuous *Weber qtzite* is separated from the dark Miss. lss. by a Penn. fm. of red ss. and sh. with intercalated thin lss., having a total thickness of about 500 to 2,000 ft. This fm. was noted by geologists of Survey of 40th Par. but was not named. Weeks [F. B.], in an unpublished ms. on geol. of NE. Utah and adjacent regions, calls it *Morgan fm.*, and in present paper that name is adopted. In Weber Canyon the Park City fm. overlies Weber qtzite. Writer traced Weber qtzite N. from its type loc. and found that it grows thinner and finally disappears 7± mi. N. of Weber River, and that it is missing where the Penn. rocks reappear 4 to 5 mi. to NW., where the Penn. phosphatic series (Park City fm.) rests on Miss. ls. In Big Cottonwood Canyon the Weber is 1,200 to 1,500 ft. thick. It is uncertain whether Weber qtzite is a fm. of local extent, or once far more extensive than now and removed by erosion from N. part of Wasatch region. There is probably an uncon. btw. Weber qtzite and overlying Park City phosphatic series. [The Morgan fm. was included in Weber qtzite of King.]

In repts of early geologists the name *Weber* was applied to Carbf. rocks in Colo. whose relations to the type Weber still remain undet., but which are believed to be older; and it was also applied in some areas to rocks now known to be Camb. The typical rocks in Weber Canyon are of Penn. age, but in many parts of northern Utah the name has in recent years been incorrectly used to include at base several hundred ft. of lss., sh., and sss. that apparently correspond to Morgan fm. of NE. Utah and are older than the typical Weber qtzite.

†Weber grits.

Pennsylvanian: Central Colorado (Leadville and neighboring regions).

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215-230), 1883 (U. S. G. S. Leadville Atlas), and 1886 (U. S. G. S. Mon. 12). [A name applied, on questionable correlation with Weber qtzite of Utah, to 940 ft. of coarse-grained arkose, micaceous sss., and qtzites alternating with beds of sandy micaceous, argill., and sometimes bituminous sh., overlying so-called "Weber shales." The name was also used by Emmons to include "Weber grits" and "Weber shales."]

†Weber shales.

Pennsylvanian: Central Colorado (Leadville and neighboring regions).

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215-230), 1883 (U. S. G. S. Leadville Atlas), and 1886 (U. S. G. S. Mon. 12). [A name applied, on questionable correlation with Weber qtzite of Utah, to 300 ft. of thin-bedded black bituminous sh. underlying so-called "Weber grits" and overlying "Blue" (Leadville) ls.]

G. H. Girty, 1903 (U. S. G. S. P. P. 16). *Weber* should be abandoned in Colo. Correctness of correlation of shales and grits in Colo. with Weber qtzite (the type fm.) of Wasatch Mtns, Utah, is very doubtful.

Weber conglomerate.

A name applied in some repts to a cgl. in Eureka and other dists of Nev. that is doubtfully correlated with Weber qtzite of Weber Canyon, Salt Lake region, Utah.

†Weberan series.

†Weberian series.

Terms applied by C. [R.] Keyes to Weber qtzite of Utah and supposedly contemp. deposits.

Webster group.

Devonian: Southwestern Missouri (Greene County).

E. M. Shepard, 1905 (Drury Coll. Bradley Geol. Field Sta. Bull. 1, p. 57). *Dev. (Webster group) cherts.*—Very hard chert, passing from ss. on one side into qtzite on the other, imperfectly banded and agatized, rarely oolitic (containing minute egg-shaped particles), in extremely irregular layers or masses. [Derivation of name and strat. position of the cherts not stated.]

Webster formation.

A term proposed by E. O. Ulrich in an unpublished chart exhibited before Geol. Soc. Am. in Dec. 1932, for beds in Okla. said to be of late Black River and early Trenton age and to overlie his Bromide fm. [restricted] and underlie Viola ls. The term has not been defined or published by Ulrich, but has been published by F. C. Edson (A. A. P. G. Bull., vol. 19, No. 8, pp. 1122–1130, 1935), who asks "What is the Webster fm?"

Webster sand.

A subsurface sand, 30 ft. thick, in Eocene Cook Mtn fm. (of Claiborne group) of southern Tex. Lies 500 ft. below Mirando sand and higher than Carolina-Texas sand.

Webster Springs sandstone. (In Bluefield formation.)

Mississippian: Southern West Virginia.

D. B. Reger, 1920 (W. Va. Geol. Surv. Rept. Webster Co., pp. 214, 227–228). *Webster Springs ss.*—Massive current-bedded greenish-gray micaceous medium-hard ss., 20 to 150 ft. thick. Basal memb. of Mauch Chunk. Rests on Greenbrier ls. and is separated from overlying Hinton ls. by 20 to 50 ft. of red or green sh. with lenticular sss. Exposed on N. side of Elk River at SE. edge of town of Webster Springs. May be same as Hinton ss. of Krebs.

D. B. Reger, 1926 (W. Va. Geol. Surv. Rept. Mercer, Monroe, and Summers Counties, pp. 301, 432). *Webster Springs ss.* is underlain by Glenray ls. (44 to 125 ft. thick) and overlain by Bickett sh.

Weches greensand member (of Mount Selman formation).

Eocene (middle): Eastern Texas (Houston to Sabine Counties) and northwestern Louisiana.

A. C. Ellisor, 1929 (A. A. P. G. Bull., vol. 13, pp. 1339–1346). *Weches memb. of Claiborne fm.*—Name proposed by E. A. Wendlandt and G. M. Knebel, for the massive greensand beds below Sparta sand memb. and above Queen City sand memb. The following section is exposed on Crockett road 1½ mi. SW. of Weches, in Houston Co., Tex. (descending): (1) Glauconitic, calc. fossiliferous clays, with small calc. concretions, 28 ft.; (2) very light fine quartz sand, clay, and sandy clay with ferruginous partings, 5 ft.; (3) much weathered greensand, sandy near top, 5 ft.; (4) gray to chocolate-gray glauconitic clay, 4 ft.; (5) greensand with fossil casts and streaks of clay, ironstone concretions at top, 4 ft.; (6) glauconitic gray sh. with sand streaks and fossil casts, 7 ft. Thickness 160 ft. in Angelina, Trinity, and Houston Counties; disappears opposite Sabine River in La.; in Cherokee and Smith Counties is 40 or less; in NW. La. it is 80± ft. thick in Palmer Corp. Crichton No. 1 well. Writer has found this memb. in wells in Cleveland and Bradley Counties, Ark. Not observed in wells in La. to E. and SE. of Sabine uplift. In some areas *Ostrea sellaeformis* and *Scutella caputsinensis* characterize this memb., especially near *San Augustine*, Tex., "which name formerly was applied to this memb. but dropped because of priority." In NW. La. the Queen City beds are absent and Weches memb. underlies Sparta sand and overlies Reklaw memb.

E. A. Wendlandt and G. M. Knebel, 1929 (A. A. P. G. Bull., vol. 13, pp. 1351, 1356–1360). *Weches memb. of Mount Selman fm.*—A remarkable deposit of rather pure clayey glauconite whose av. thickness is approx. 50 ft. throughout basin proper, but thicker in Nacogdoches and San Augustine Counties. At top is a zone of laminated iron ore few in. to 4 ft. thick. To NE., particularly in Cass Co., the Weches greensand becomes more sandy and cross-bedded and the iron ore occurs irregularly throughout the fm. It is this fm. which gives to East Texas its characteristic red color. Overlies Queen City memb., and underlies Sparta sand. Is top memb. of Mount Selman fm.

Adopted as *Weches greensand memb. of Mount Selman fm.* In NW. La. these beds form upper part of Cane River fm.

Wedington sandstone member (of Fayetteville shale).

Mississippian (Chester): Northern Arkansas and northeastern Oklahoma.

G. I. Adams, 1904 (U. S. G. S. P. P. 24, p. 27). *Wedington ss.*—A ss. fm., 50 to 150 ft. thick, thin-bedded and heavy-bedded, carrying some interstratified sh. Overlies Fayetteville sh. [restricted sense].

E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, p. 108). According to available evidence the Wedington ss. is a wedge, thickening westward and possibly eastward, lying on Fayetteville sh. Whether these underlying shales are of upper or lower part of Fayetteville fm. is not known. If upper bed is not present in any sections containing the Wedington ss., then this ss. must be a later fm., probably overlapping northwardly and westwardly, during time there represented by uncon. btw. the Fayetteville and Pitkin. On other hand, it may be an extension and expansion of the fossiliferous intermittent ss. memb., 3 to 60 ft. thick, which divides Fayetteville fm. into three parts, and if so it should be treated as memb. of Fayetteville. Writer inclines to latter interpretation. Same as Batesville ss. of Simonds [not true Batesville ss.].

G. I. Adams and E. O. Ulrich, 1905 (U. S. G. S. Fayetteville folio, No. 119), treated Wedington ss. as a memb. of Fayetteville sh. This is still the approved definition of Wedington ss. In Okla. this ss. lies near middle of the Fayetteville; in Ark. it lies 0 to 70 ft. below top of the Fayetteville.

Named for Wedington Mtn, Washington Co., Ark.

Wedowee formation.

Cambrian to Carboniferous: Eastern Alabama.

G. I. Adams, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, p. 36). *Wedowee fm.*—Slates, phyllites, qtzites, and schists, characterized in many places by occurrence of amorphous graphite, which renders the rocks black or grayish black where weathered. Much of fm. is without graphite but contains such metamorphic minerals as mica, garnet, staurolite, and cyanite. No calc. rocks have been found in the fm. May comprise upward of 10,000 ft. of variable altered sediment. The black graphitic phase reaches thickness of 2,000 ft. in places. Age tentatively placed from Carbf. downward into Camb., but lower limit cannot be stated with any definiteness. [Adams repeated this age designation in Jour. Geol., vol. 41, No. 1, p. 166, 1933, but A. I. Jonas considers the fm. to be pre-Camb., and it is thus tentatively mapped on 1932 geol. map of U. S.]

Named for exposures at and around Wedowee, Randolph Co.

Weedon schist.

Ordovician (?): Quebec.

F. R. Burton, 1931 (Quebec Bur. Mines Ann. Rept. 1930, pt. D, p. 111).

Weed Patch member.

Mississippian: Southern Indiana.

P. B. Stockdale, 1931 (Ind. Dept. Cons., Div. Geol., Pub. 98, pp. 76, 119, 189, 202, 218, 280, etc.). *Weed Patch memb. of Edwardsville fm.*—Calc. zone, very sandy, irregular, buff to chocolate-colored, with chert. Thickness 5 to 8½ ft. At Kelly Hill lies 17 ft. below top of Edwardsville fm. and 21 ft. above base of Edwardsville. Along road SE. of Weed Patch Hill, 3½ mi. SE. of Nashville, it is 5 ft. thick and lies 17 ft. above Floyds Knob ls. and 81 ft. below top of Edwardsville fm. The underlying beds are ss., the lower part of which is in thick, irregular, wavy beds; the immediately overlying beds consist of 45 ft. of siltstone. [In pl. 5, opp. p. 212, author places Weed Patch memb. 6± ft. above Cutright ss. memb.]

Weeks limestone.

Upper Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 10). *Weeks fm.*—Thin-bedded shaly lss. with a few bands of oolitic and aren. lss., 1,390 ft. thick. Underlies Orr fm. and overlies Marjum fm. Type loc. is N. side of Weeks Canyon, N. of Orr Ridge.

Weeping Water limestone. (In Oread limestone.)

Pennsylvanian: Southeastern Nebraska, eastern Kansas (?), and northwestern Missouri.

C. S. Prosser, 1897 (Jour. Geol., vol. 5, pp. 154–172). *Weeping Water ls.*—Massive light-gray ls., 9 ft. thick, forming top memb. of Wabaunsee fm. in Cass Co.

G. E. Condra and N. A. Bengston, 1915 (Nebr. Acad. Sci. Pub., vol. 9, No. 2, pp. 6, 10, 19). *Weeping Water ls.*, lying 18 ft. below top of Andrew (Lawrence) sh. and 16 to 18 ft. above Oreapolis ls. memb. of the Andrew, is 11 to 12 ft. thick in exposures W. of La Platte and Oreapolis, in Platte section, and 6 to 8 ft. thick near Plattsmouth, in Missouri River section. Is light-colored. In Platte section it consists of 2 beds separated by 1 ft. of light-colored calc. sh.

R. J. Scarborough, 1915 (p. 34 of book cited above). *Weeping Water ls.* (in Andrew sh.), is exposed in valley sides of Weeping Water Creek in secs. 4, 5, 6, 9, and 10, T. 10 N., R. 12 E., and along W. side of North Branch Valley about

1 mi. NW. of Nehawka [Cass Co., Nebr.]. Thickness 6 ft. Is light-colored, massive, breaks down in large blocks, and shows tendency to weather into rough, nodular forms. Is overlain and underlain by sh.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 32, 36). *Weepingwater ls.* is now known to be lowest unit of Oread ls. The overlying sh. is here named *Snyderville sh.* The underlying beds are Lawrence sh. [This definition was adhered to by R. C. Moore and G. E. Condra in their Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans., and by Condra in his 1935 classification (Nebr. Geol. Surv. Paper No. 8, p. 12).]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 163). There is sufficient doubt as to equiv. of "lower Oread" ls. of Kans. and Weeping Water ls. of Nebr. to make use of latter name undesirable for a subdivision of Kans. Oread. The basal memb. of Kans. Oread is therefore here named *Toronto ls. memb.*, a name introduced by Haworth and Piatt in 1894.

Wehrum flint clay.

A clay bed in lower part of Mahoning ss. memb. of Conemaugh fm. in western Pa. Lies lower than Mahoning ls. Probably named for occurrence at Wehrum, Indiana Co.

Weir sand.

An oil-bearing ss., 30 to 60 ft. thick, in New Providence fm. (Miss.) of eastern Ky. The name has also been applied to a sand of Miss. or Upper Dev. age in Kanawha Co., W. Va., and it has been misspelled Wier. It is first producing sand (oil and gas) near Weir, Kanawha Co., W. Va.

Weiser sand.

See *Wiser sand.*

Weisner quartzite (also **formation**).

Lower Cambrian: Northern central and northeastern Alabama and northwestern Georgia.

E. A. Smith, 1890 (Ala. Geol. Surv. Rept. Cahaba coal field, p. 149). *Weisner quartzite.*—Great beds of qtzite and cgl. in E. part of Coosa Valley, many hundred ft. thick, but often of very limited extent geographically. Interpolated in Coosa and Montevallo shales, at no definite horizon but most commonly in their lower parts, as local masses of lenticular shape and often of very great thickness. The qtzites always form high and rugged mtns, sometimes stretching for miles in an unbroken range, but as often forming detached and isolated peaks.

C. W. Hayes, 1891 (Geol. Soc. Am. Bull., vol. 2, geol. section of NW. Ga. on p. 143), showed *Weisner qtzite* underlying Rome ss. and overlying Coosa sh.

E. A. Smith, 1894 (Ala. Geol. Surv. geol. map of Ala. with explanatory text), excluded Weisner qtzite from †Montevallo sh., treated it as a distinct fm. overlying the crystalline rocks, and described it as consisting of 2,000 to 4,000 ft. of massive light-colored cgls., sss., and sandy yellowish sh.

C. W. Hayes, 1895 (U. S. G. S. 16th Ann. Rept., pt. 3, pp. 554–559), described Weisner qtzite as in places separated from overlying Rome fm. by a blue siliceous ls., which he correlated (erroneously) with Beaver ls. of Tenn. This ls. is now known as *Shady dol.*, 800 to 1,200 ft. thick. This is present approved definition of Weisner qtzite, which in parts of Ala. attains a thickness of 5,500 ft. (See L. LaForge, Ga. Geol. Surv. Bull. 35, 1919, pp. 43–45; also C. Butts, Ala. Geol. Surv. Spec. Rept. No. 14, 1926, p. 64.)

Named for fact it forms Weisner Mtn. Cherokee Co., Ala.

Weiss sand.

A subsurface sand, probably in Yegua fm. (Eocene), of Pettus area, Bee Co., SE. Tex.

Weitchpec schists.

Age (?): Northwestern California (Humboldt County).

O. H. Hershey, 1904 (Am. Geol., vol. 33, p. 357). The *Weitchpec schists* resemble the most highly metamorphosed Calaveras schists.

O. H. Hershey, 1906 (Am. Jour. Sci., 4th, vol. 21, p. 63). In approaching W. border of the belt the strata are bent up, and presently there appears under them a fm. made up of white sericite and green chloritic schists that are evidently sheared rhyolites and andesites. In a very short distance another fault brings down the Bragdon slates. This may be repeated several times in 20 mi., but far the larger part of area is Bragdon. The shearing becomes more pronounced toward W. until traces of bedding planes are virtually destroyed. I now consider *Weitchpec schists*, formerly classed as pre-Bragdon, as a portion of this series. Indeed, the apparent ancient schists of Redwood Mtn in Korbel-Hoopa trail are probably Bragdon, although undoubted pre-Dev. schists occur in South Fork Mtn.

Probably refers to schist exposed at or near Weitchpec, Humboldt Co.

Wekusko group.

Pre-Cambrian: Manitoba.

F. J. Alcock, 1920 (Canada Geol. Surv. Mem. 119, p. 16).

Wekwemikongsing beds.

Upper Ordovician: Ontario (Manitoulin Island).

A. F. Foerste, 1912 (Ohio Nat., vol. 13, p. 44). *Wekwemikongsing beds*.—A series of strata overlying Sheguindah beds (of Eden age) and underlying Waynesville beds or Lower Richmond. Contain fauna of Lorraine age. Total thickness may be 100 ft. in Cape Smyth area. Well exposed for about 2 mi. along shore btw. Wekwemikongsing and the Richmond Clay Cliffs on E. side of Cape Smyth.

Welch formation. (In Pottsville group.)

Pennsylvanian: Southern West Virginia and southwestern Virginia.

M. R. Campbell, 1897 (U. S. G. S. Tazewell folio, No. 44). *Welch fm*.—Ss. and sh. with many workable coal seams. Thickness 700 ft. Overlies Pocahontas [No. 3] coal (top bed of Pocahontas fm.) and underlies Raleigh ss. Named for exposures at Welch, McDowell Co., W. Va.

Welch sandstone. (In Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and R. M. Gawthrop, 1915 (W. Va. Geol. Surv. Rept. Wyoming and McDowell Counties, p. 198). *Welch ss*.—Massive to current-bedded, medium-grained to coarse, grayish white to light gray, 0 to 70 ft. thick. Lies 5 to 40 ft. below Sewell ("Davy") coal and 0 to 5 ft. above Welch coal. Exposed at Welch, McDowell Co.

Welch chert. (Buried.)

Pennsylvanian (early): Central Kansas.

R. C. Moore, 1926 (A. A. P. G. Bull., vol. 10, No. 3, pp. 208–211). *Welch chert*.—Mostly white chert, ranging in thickness to nearly 200 ft., encountered in well logs in Marion, McPherson, Reno, Rice, Ellsworth, and probably adjoining counties of central Kans. A part of the chert is much weathered, rotten, and deeply stained by iron oxide. The red material associated with the chert occurs below it, above it, or intermingled with it and is mostly a very deeply oxidized ferruginous clayey material, but part of it is a typical geest. The chert is evidently a secondary deposit. If evidences of clastic character of the [chert] deposit are substantiated it may be desirable to use the designation "*Welch chert gravel*." The deposit is underlain by over 200 ft. of fine-grained light bluish-gray clay sh., the middle part of which has yielded Penn. fossils and which probably corresponds to some part of Cherokee sh. The chert and at least the upper part of underlying sh. are definitely assigned to Penn. The overlying beds may belong to Marmaton fm. Named for fact it was producing horizon of Welch well, in sec. 35, T. 20 S., R. 6 W., Rice Co.

Welden limestone.

Mississippian: Central southern Oklahoma (Arbuckle Mountains).

C. L. Cooper, 1931 (Okla. Geol. Surv. Bull. 55, map of Arbuckle Mtns), shows: (1) In SW. part of mtns, Sycamore ls. overlain by Caney sh. and underlain by Woodford fm.; (2) in SE. part of mtns, Caney sh. resting on Woodford fm.; and (3) in NE. part of mtns, *Welden ls*. overlain by Caney sh. and underlain by Woodford fm. In latter area Welden Creek cuts across his *Welden ls*. [According to G. H. Girty (personal communication) the faunas of typical Sycamore ls. and Cooper's

Welden ls. differ. The bull. cited above is devoted to strat. and physical characteristics of Simpson group, and the text does not mention *Welden ls.*]

R. H. Dott, 1934 (A. A. P. G. Bull., vol. 18, No. 5, table on p. 579), showed the Miss. of Hunton arch area divided into (descending) Lower Caney, *Welden*, and Woodford; and on map on p. 583 of his paper, which is "after Geo. D. Morgan," appears *Welden ls.* (*Sycamore*).

C. L. Cooper, 1936 (letter dated June 30). Definition of *Welden ls.* has never been published. Am at present working on conodont fauna of this fm.

D. L. Hyatt, 1936 (A. A. P. G. Bull., vol. 20, No. 7), showed (p. 954) the following downward succession of fms. in Fitts oil pool, Pontotoc Co., Okla.: Penn. Caney, Miss. Caney, Mayes, Welden, and Woodford. On p. 958 he treated Mayes and Welden as part of "Miss. Caney," and stated that the Welden consists of 5 to 10 ft. of grayish white, finely crystalline ls.

Weldon series.

Carboniferous: New Brunswick.

W. J. Wright, 1922 (Canada Geol. Surv. Mem. 129, pp. 7, 15).

Weldon formation.

Mississippian: New Brunswick.

G. W. H. Norman, 1932 (Canada Geol. Surv. Econ. Geol. ser., No. 9, p. 170).

†Wellborn sandstone.

Eocene (upper): Eastern Texas.

W. Kennedy, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 39, 45). Gray sss. and gray sands, 65 to 90 ft. thick, forming top part of Eocene in Brazos Co. and tentatively denominated *Wellborn beds*. Underlie Navasota beds and overlie Yegua or lignitic div. of Claiborne.

For many years regarded same as Fayette ss., but F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 685, 686), states that it is basal part of McElroy memb. of Tex. Surv. (the middle memb. of Fayette ss. as Tex. Surv. now divides that fm.).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1298, 1302, 1305, etc.). *Wellborn sands* are middle memb. of McElroy fm., and are underlain by 250 to 300 ft. of Wooley's Bluff clays and overlain by Manning beds.

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17, and pp. 23–32). *Wellborn fm.* [expanded] conformably underlies Manning fm., conformably overlies Caddell marl, and is here divided into 3 mappable units (descending): (1) Carlos ss. memb., 5 to 22 ft.; (2) middle Wellborn, 10 to 120 ft.; and (3) Bedias ss. memb., 0 to 30 ft. The Carlos ss. of this rept. is approx.=the Wellborn of Miss Ellisor's 1933 paper. It is apparent from Kennedy's description that the Wellborn fm. must include Carlos ss. and Bedias ss. [See also Renick 1936 entry under *Wooley's Bluff clays*.]

Named for Wellborn, Brazos Co.

Weller horizon.

Weller sandstone.

Tertiary (Miocene ?): Northwestern Colorado (Moffat County).

O. A. Peterson, 1928 (Mem. Carnegie Mus., vol. 11, No. 2, pp. 90–94). Browns Park fm. of Douglas Mtn, Moffat Co., is divisible into (1) an upper part, consisting of soft, almost chalklike sands and sss. cemented with lime and sometimes intercalated with slightly argill. bands; and (2) a lower part, here named *Weller horizon*, consisting of hard *Weller ss.*, 6 to 15 ft. thick, underlain by very soft ss. which weathers into sandy ridges. Total thickness of Weller horizon 736± ft. It is exposed at northern flanks of Douglas Mtn, on Weller ranch, near Gray Stone P. O. The Weller ss. is a hard bed which forms tablelands.

Wellersburg limestone. (In Conemaugh formation.)

Pennsylvanian: Western Maryland and southern Pennsylvania.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pp. 65, 114, pl. 6). *Wellersburg ls.*—A ls. occurring locally beneath Wellersburg coal horizon in Castleman and Georges Creek Basins, Md. Overlies Barton ss. [Wellersburg coal was named for occurrence at Wellersburg, Pa.] [On p. 114 he shows 7 ft. of *Wellersburg ls. and fire clay* underlying Wellersburg coal and resting on Barton ss. and sh.]

Wellersburg clay. (In Conemaugh formation.)

Name applied to clay underlying Wellersburg coal in western Pa.

Wellesley formation.

Mississippian: Eastern Alaska.

A. H. Brooks, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 470–472, 479, 483). *Wellesley fm.*—Upper part almost entirely blue clay sl., locally altered to phyllite; several hundred ft. thick. Lower part coarse massive cgl. interlarded with a few beds of blue clay sl.; thickness 1,000 to 1,500 ft. Schuchert identifies the fossils as Dev. or Carbf. [Map shows it composes Wellesley Mtn. btw. Tanana and White Rivers.]

A. H. Brooks, 1911 (U. S. G. S. P. P. 70, p. 82). *Wellesley fm.* occurs in series of isolated hills through broad alluvial flat that separates central part of White River Basin from Chisana or east fork of Tanana River. It may have thickness of 1,000 to 2,000 ft. at type loc. Rests uncon. on Birch Creek schist.

This fm. is now classified as early Miss.

Wellington formation. (In Sumner group.)

Permian: Central and southern Kansas and northern Oklahoma.

F. W. Cragin, 1885 (Washburn Coll. Lab. Nat. Hist. Bull., vol. 1, No. 3, pp. 85–86; and Kansas City Rev., vol. 8, pp. 678–682), in a description of glacial deposits, casually alluded to *Wellington shales*, the age of which was undet., as no fossils were found.

F. W. Cragin, 1896 (Colo. Coll. Studies, vol. 6, pp. 3, 16). *Wellington shales.*—Bluish-gray clay shales, 250 to 450 ft. thick, including beds of impure ls. and calc. shales, with occasional beds of gyp. and dol. Top fm. of Big Blue series and Sumner div. Overlies Geuda salt measures and underlies, probably uncon., Harper sss., basal fm. of Cimarron series.

C. S. Prosser, 1897 (Kans. Univ. Geol. Surv. vol. 2). [See under †*Marion fm.*]

L. C. Wooster, 1905 (The Carboniferous rock system of eastern Kans.), included the salt measures in Wellington and made Abilene cgl. top memb. of Marion, as did J. W. Beede, 1909; R. C. Moore and W. P. Haynes, 1917; L. C. Snider, 1920 (Oil and gas in Mid-Continent fields); and C. N. Gould, 1925, 1927; but R. C. Moore, 1920, stated that Abilene cgl. is Tert. He included the salt measures in Wellington, however, and gave thickness of latter fm. as 500 to 799 ft. (See under †*Marion fm.*)

Subsequent repts treated Pearl sh. as top memb. of Marion fm. and included the salt beds in overlying Wellington fm.

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, in cooperation with U. S. Geol. Survey), redefined *Wellington fm.* to include all beds below "Red Beds" and above Herington ls., and "Marion fm." was abandoned. Thickness 680 to 1,140 ft., of which only 80 ft. is exposed in Cowley Co., Kans. This is present approved definition of U. S. Geol. Survey. Includes beds formerly called "Pearl sh. memb." (now discarded by U. S. Geol. Survey).

The Tert. age of Abilene cgl. is now considered as established.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), divided the Perm. beds above Herington ls. into (descending): (1) Wellington sh. [greatly restricted], 62± ft. thick; (2) Donegal ls., 15 ft. thick (new); and (3) Pearl sh. [revived], 30± ft. thick.

See Kans.-Nebr. Perm. chart compiled by M. G. Wilmarth, 1936.

Top fm. of Sumner group.

Named for exposures at Wellington, Sumner Co., Kans.

†Wellington marble.

Popular term for marble quarried from beds in Sumner group (Perm.) of Sumner Co., Kans., that are older than Wellington fm., of Sumner group.

†Well Rock.

Pennsylvanian: Eastern Kansas.

G. C. Swallow and F. Hawn, 1865 (Kans. Geol. Surv. Rept. on Miami Co., p. 10). *Well Rock.*—Fossiliferous lss., 15 to 20 ft. thick, forming bed No. 20 of geol. section of Miami Co. Whitish-gray soft mag. ls. in upper part; bluish-gray and drab hard, compact, or crystalline ls. in middle; and usually bluish-gray cherty subcrystalline ls., weathering brown and parting into small angular masses, in lower part.

Not a definite geologic unit, but confused with several units, and not a geographic name.

†Well Rock series.

Pennsylvanian: Eastern Kansas.

G. C. Swallow, 1866 (Kans. Geol. Surv. Prel. Rept., pp. 21-22). *Well Rock series.*—Series of lss. and shales, 238½ ft. thick, including beds Nos. 167 to 177, inclusive, of geol. section of eastern Kans. Includes the Well Rock (bed No. 169). Underlies Spring Rock series and overlies Marais des Cygnes coal series.

Not a definite geologic unit, but confused with several units, and not a geographic name.

†Wells limestone.

Middle Ordovician (Lowville): North-central Tennessee.

A. F. Foerste, 1903 (Jour. Geol., vol. 11, pp. 557, 705). *Wells ls.*, belonging to upper part of the Stones River; exposed in central part of Wells Creek Basin; identified by Safford as Knox dol. The Black River absent in Tenn. River Valley. [On p. 705 is given a list of "Wells (Upper Stones River) fossils" collected 1¼ mi. SW. of Cumberland City.]

The fossils listed by Foerste are now considered by E. O. Ulrich to be of Lowville age, and the fm. to be same as Carters ls.

Named for Wells Creek Basin, Stewart and Houston Counties.

†Wells chert.

Lower Ordovician (Beekmantown): North-central Tennessee (Stewart and Houston Counties).

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 671, pl. 27). *Wells chert.*—In Wells Creek Basin, in NW. part of middle Tenn. [Stewart and Houston Counties], the low domelike elevation at center of the small but sharply defined uplift is formed by a highly cherty mag. ls. of Canadian [Beekmantown] age but undet. thickness. The prevailing type of the chert, which strews the surface and with a deep residual clay covers the light-gray fine-grained mag. ls. from which it is derived, is porous—even spongy—rather soft and sandy under the hammer and of red or brown color. With these occur harder, nearly white blocks. This cherty mag. ls. is overlain—not, as one might naturally suppose, by some Stones River ls.—but by Lowville ls. Contact concealed. The Lowville has hitherto been mistaken for Stones River, but the fossils are Lowville. As a distinct name for this cherty zone of Canadian rocks in Miss. Valley is desirable, especially in Tenn., the name *Wells chert* is here proposed.

Conflicts with Foerste's prior use of *Wells ls.* for a younger fm., which is now known as *Carters ls.* The Wells chert of Ulrich appears to be the same as the *Wells Creek* of R. G. Lusk, a name used by Lusk in a table of Lower Ord. rocks overlying Knox dol. in Wells Creek Basin, but not further defined. (See A. A. P. G. Bull., vol. 11, No. 9, p. 908, 1927.) Lusk probably introduced the name because of prior use of *Wells* in Tenn. and because of the later but established usage of the name *Wells* for a Carbf. fm. in Idaho and Utah.

Wells formation.

Pennsylvanian: Northeastern Utah, eastern Idaho, and southwestern Wyoming.

R. W. Richards and G. R. Mansfield, 1912 (Jour. Geol., vol. 20, pp. 683, 684, 689, 693). *Wells fm.*—The Phosphoria fm. is normally underlain by 2,400 ft. of sandy lss.,

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

calc. sss., and qtzites of somewhat variable character. These beds are here grouped in a fm. whose name is derived from Wells Canyon, in T. 10 S., R. 45 E., Bannock Co., Idaho, on N. side of which a detailed section [p. 690] was measured. The strat. interval is probably same as represented by Morgan, Weber, and lower part of Park City fm. of NE. Utah. In Idaho, however, these rocks show such variable lithologic features that it has been found impracticable to apply successfully the names *Weber* and *Morgan* over a major part of area (Bannock overthrust area of NE. Utah and SE. Idaho). Faunas also do not justify correlation. In detailed section given it is possible to subdivide Wells fm. into 3 parts: (1) An upper calc. ss. or siliceous ls. 0 to 75 ft. thick; (2) a middle sandy series, consisting of 1,700 to 1,800 ft. of nonfossiliferous sandy ls. with occasional thin beds of qtzite and sss., weathering white, red, or yellow; and (3) a lower sandy and cherty ls. series 750± ft. thick. The lower two divisions, however, do not correspond to Weber and Morgan fms. in Weber Canyon, Utah. Where upper ls. is absent the Phosphoria is uncon. on Wells fm. [Fossils listed.] In SE. Idaho Wells fm. rests conformably on ls. of upper Miss. age, but in Utah Blackwelder has observed uncon. at this horizon.

Wellsburg sandstone member (of Chemung formation).

Upper Devonian: Central and west-central New York.

H. S. Williams, 1906 (Sci., n. s., vol. 24, pp. 365–372) and 1907 (Am. Ass. Adv. Sci. Proc., vol. 56, pp. 265–267). Chemung fm. of Ithaca section divided into (descending): Fall Creek cgl. lentil, 0 to 10 ft. (interpreted to be=the cgl. of that name in Bradford and Tioga Counties, Pa.); *Wellsburg ss. memb.*, 600 to 650 ft.; and Cayuta sh. memb., 600 ft. Wellsburg memb. is characterized by Ashland *Leptostrophia* zone at top, and named for outcrop at Wellsburg [Chemung Co.].

H. S. Williams, 1909 (U. S. G. S. Watkins Glen-Catatonk folio, No. 169). *Wellsburg ss. memb.*—Thin-bedded ss. and drab shales, the ss. predominating. Flaggy ss. at top with 2 cgl. lentils and thin ls. Thickness 600 to 700 ft. Underlies Catskill fm. and overlies Cayuta sh. memb. [Wellsburg ss. memb. of this folio constituted a redefinition, because it included at top the 10 ft. of beds previously called *Fall Creek cgl. lentil*. The *Leptostrophia* zone is therefore stated in the folio to occur *near*, instead of *at*, top of the Wellsburg.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 86). *Wellsburg memb. of Chemung* contains in upper part several layers of cgl., the highest of which is supposed to represent Fall Creek cgl., which outcrops farther S., in Pa.

According to H. S. Williams, 1913 (U. S. G. S. P. P. 79), the Wellsburg memb. extends from Watkins Glen quad. eastward into Chenango Valley.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Wellsburg ss.* of Steuben Co. includes equivalents of Laona ss., Westfield sh., Shumla ss., Northeast sh., and (?) Volusia sh., all of Chautauqua Co.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10). *Wellsburg ss.* included in Chemung.

Wells Creek limestone.

Lower Ordovician (Beekmantown): North-central Tennessee (Stewart and Houston Counties).

R. G. Lusk, 1927 (A. A. P. G. Bull., vol. 11, No. 9, p. 908). [See last paragraph under †*Wells chert*.]

Welsh stray sand.

Drillers' term for a Miss. sand in SE. Ohio (Monroe Co.) that is correlated with Buena Vista ss. by W. Stout et al. (Geol. of nat. gas, A. A. P. G., 1935, p. 904).

Wenas basalt.

Miocene (early): Central Washington (Ellensburg region).

G. O. Smith, 1903 (U. S. G. S. P. P. 19 and U. S. G. S. Ellensburg folio, No. 86). *Wenas basalt.*—Lava flows interbedded in lower part of Ellensburg fm. (Mio.), which overlies Yakima basalt (also Mio.). Thickness 20 to 200 ft. Of only local importance. Type loc., valley of Wenas Creek.

Wendell Grade basalt.

Pleistocene: Southern Idaho (Gooding County).

H. T. Stearns, 1932 (Correlation chart of Idaho compiled by M. G. Wilmarth, dated Sept. 1, 1932) and 1936 (Jour. Geol., vol. 44, No. 4, p. 434). *Wendell Grade* *basalt.*—Black aphanitic pahoehoe basalt containing fresh green olivine phenocrysts and nearly bare of loess. Thickness 25± ft. Of Pleist. age, and younger than Minidoka basalt. Named for Wendell Grade in road in Gooding Co., NW. of town of Wendell. Three small branches of this flow cascaded over rim of Hagerman Valley, but elswhere it is conformable to the older basalts of the plains.

Weno clay member (of Denison formation).

Lower Cretaceous (Comanche series): Northeastern Texas and central southern Oklahoma.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 121, 247, 269–280). *Weno fm.*—Very ferruginous brownish clay marls and marly clays, with some impure ls. Thickness 92 ft. Included in Weno subgroup of Denison beds. Underlies Pawpaw fm. [The "Quarry ls.," a massive aren. ls., blue exteriorly but oxidizing yellow, quarried at East Denison, is both included in and excluded from this fm. in rept cited.] Overlies *Gryphaea washitaensis* aggl., in top of Denton subgroup of Denison beds.

The U. S. Geol. Survey treats †Quarry ls. as basal bed of Pawpaw sandy memb. of Denison fm. (See L. W. Stephenson, U. S. G. S. P. P. 120H, 1918.)

Named for Weno, Grayson Co., Tex.

†Weno subgroup.

Lower Cretaceous (Comanche series): Northeastern Texas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, pp. 121, 247, 269–280). *Weno subgroup.*—Middle subgroup of Denison beds. Divided into (descending) Pawpaw fm., Quarry ls. [on some pages included in Weno fm.], and Weno fm. Underlies Main Street ls. and overlies Denton subgroup, the top of which consists of *Gryphaea washitaensis* aggl.

Named for Weno, Grayson Co.

Wenonah sand. (Of Matawan group.)

Upper Cretaceous: New Jersey.

G. N. Knapp, as reported by R. D. Salisbury, 1899 (N. J. Geol. Surv. Ann. Rept. State Geol. 1898, pp. 35, 36). *Wenonah bed.*—Sand overlying Marshalltown bed and forming top div. of Clay Marl series [Matawan group].

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv. vol. 6, p. 154). *Wenonah sand.*—Reddish-brown or black sand, with thin seams of black or chocolate-colored clay. Thickness 50 to 60 ft. Overlies Marshalltown clay marl and underlies Navesink marl [original usage of Navesink, which included Mount Laurel sand of present nomenclature].

Named for occurrence at Wenonah, Gloucester Co.

Weskan shale member (of Pierre shale).

Upper Cretaceous: Northwestern Kansas (Wallace County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7). *Weskan sh. memb. of Pierre sh.*—*Upper 80 ft.* consists of gray clayey sh. with few thin beds of bentonite; large tough ls. concretions; rusty cone-in-cone lenses, and thin streaks of concretionary limonite. *Lower 90 ft.* consists of gray clayey sh. with comparatively abundant beds of bentonite; large ls. concretions common; here and there thin streaks of purple-brown limonite. Underlies Lake Creek sh. memb. of Pierre sh. and overlies Sharon Springs sh., basal memb. of the Pierre. Type loc. 5 mi. N. of town of Weskan, Wallace Co. Type loc. of *Upper Weskan* is on a small creek N. of Swisegood ranch, in SE¼ sec. 2, T. 13 S., R. 42 W., and best exposure of *Lower Weskan* is on S. side of Goose Creek, in SW¼ sec. 4, T. 13 S., R. 40 W.

Weskeag quartzite member (of Rockland formation).

Cambrian or Ordovician: Central southern Maine (Knox County).

E. S. Bastin, 1908 (U. S. G. S. Rockland folio, No. 158, pp. 3–4). *Weskeag qtzite memb.*—Qtzite which differs from Battie qtzite in total absence of conglomeratic forms and in being for most part thin-bedded. Prevailing color is yellowish gray on freshly fractured surfaces and buff brown on weathered surfaces. Locally somewhat shaly beds are present, but sheared phases were not observed. Thicknecs 250 to 300 ft. Basal memb. of Rockland fm. Named for development on Weskeag River, Knox Co.

West Baden. (In Chester group.)

Mississippian: Indiana, Illinois, Kentucky.

E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, p. 514, footnote). *West Baden* suggested to Professor Weller in 1920 for lower Chester, including all rocks btw. top of Beech Creek ls. above and base of Paoli ls. (restricted) below, but Weller preferred to use *lower Chester*.

Probably named for village of West Baden, Orange Co., Ind.

West Bath slate.

Name applied (without description) by M. Billings in Feb. 1933 (Am. Jour. Sci., 5th, vol. 25, No. 146, p. 149) to the pre-Sil. fm. immediately underlying his Fitch fm. in Littleton and Moosilauke quads., Ammonoosuc River region, NW. N. H. In Dec. 1934 (Am. Jour. Sci., 5th, vol. 28, pp. 412+) he called this sl. *Partridge sl.* Village of West Bath is in Woodsville quad., N. H.

Westboro quartzite.

Pre-Cambrian: Eastern Massachusetts and northern Rhode Island.

B. K. Emerson and J. H. Perry, 1903 (Geol. of Worcester, with map). *Westboro qtzite.*—Light-colored, nearly white fine-grained sugary qtzite. Overlies Northbridge gneiss. Named for town of Westboro, Worcester Co., Mass.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 24–25, 27, 30–31, and map). *Westboro qtzite.*—A shoreward bed of sugary qtzite, in places actinolitic or biotitic. Is same as "Grafton" qtzite and has priority, so "Grafton" is abandoned. Overlies Northbridge gneiss and underlies Marlboro fm.

See also L. LaForge, 1932 (U. S. G. S. Bull. 839).

West Branch shale.

Pennsylvanian: Southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 74, 82, 89, 111, 113). *West Branch sh.*—Greenish-blue argill. massive and crumbly sh.; dark near top; calc. bladed material above middle, and calc. lensing material near base. Thickness 26± ft. Top bed of Admire sh. memb. of Wabaunsee fm. Overlies Falls City ls. and underlies Americus ls. Named for exposures in West Branch Twp, Pawnee Co.

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification chart of Penn. rocks of Nebr. and Kans.), divided Admire sh. into (descending) Oaks sh., Houchen Creek ls., Stine sh., Five Point ls., West Branch sh., Falls City ls., Hawxby sh., Aspinwall ls., and Towle sh. Whether this is a restriction of West Branch sh. is unknown. The Stine sh. and Houchen Creek ls. were named by Condra in 1927 publication cited above, where they were defined as belonging to lower part of Elmdale sh., which overlies Americus ls.; but their 1932 chart includes them in Admire sh., which underlies Americus ls. R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), transferred all beds above Brownville ls. to Perm. (See Kans-Nebr. chart compiled by M. G. Wilmarth, 1936.)

West Branch morainic system.

Pleistocene (Wisconsin stage): Northern Mich. Shown on moraine map (pl. 32) of U. S. G. S. Mon. 53. Named for West Branch, Ogemaw Co.

Westbrook granite.

Pre-Carboniferous (?): Southwestern Maine.

F. J. Katz, 1917 (U. S. G. S. P. P. 108, p. 175). *Westbrook granite.*—Gneissoid granite, of medium-gray color and fine, even texture; contains conspicuous crystals of biotite. Presumably pre-Carbf. Intrudes Berwick gneiss. Named for exposures in Westbrook Twp, Cumberland Co.

On 1933 geol. map of Maine, by A. Keith, the rocks of Westbrook Twp are mapped as pre-Camb.

West Brook member.

Upper Devonian: Central New York (Onondaga County).

G. A. Cooper and J. S. Williams, 1935 (Geol. Soc. Am. Bull., vol. 46, pp. 790–813). *West Brook memb.*—Top memb. of Tully fm. In Tully region it consists of 10± ft. of dark-gray shaly and nodular lss.; near Sherburne it is 28 ft. 2 in. thick, and is chiefly dark-gray sandy and calc. sh. with 2 thin lss. (1 and 4 ft. thick); near Laurens it is 54 ft. 6 in. thick and is almost wholly sandy sh. and ss.; near Perrytown it is 67 ft. thick and consists of sh. and ss.; near New Berlin it is 97 ft. thick and consists of sh. and ss. Upper half of memb. is characterized by *Lopholasma;* lower half contains many Hamilton sp., especially *Elytha fimbriata.* Overlain by Geneseo sh. Btw. Canandaigua Lake and Unadilla Valley it rests on Apulia memb. of the Tully; in Butternut, Otego, and Susquehanna Valleys and at Schenevus it rests on Laurens memb. of the Tully. Type loc. is on West Brook, 3 mi. S. of Sherburne.

Westchester gneisses and granites.

Pre-Cambrian: Southeastern New York and northern New Jersey.

F. J. H. Merrill, 1901 (Geol. map of N. Y.). *Westchester (gneisses including granites).* [Mapped across SE. N. Y. and northern N. J. Apparently named for Westchester Co., N. Y., of which it forms a large part. Probably same in part as the paragneiss parts of Fordham gneiss.]

West Chicago moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. See M. M. Leighton, 1932 (16th Int. Geol. Cong. Guidebook 26, pp. 47, 50, pl. 2).

West Dummerston granite.

Devonian: Southeastern Vermont (Windham County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of eastern Vt., but without definition. Quarried at village of West Dummerston, Dummerston Twp, Brattleboro quad., Windham Co.

West Elk breccia.

Tertiary (Miocene?): Western central Colorado (Anthracite-Crested Butte region).

W. Cross, 1894 (U. S. G. S. Anthracite-Crested Butte folio, No. 9). *West Elk breccia.*—Coarse volcanic breccia alternating with finer ash and tuff. Lower part of what is mapped as West Elk breccia may possibly be more properly considered a sedimentary fm., but observations made do not permit a distinction btw. such material and the breccia. Forms West Elk Mtns and extends S. to Gunnison River. Is overlain by rhyolitic lavas near Gunnison.

West End rhyolite.

Tertiary: Central Nevada (Tonopah district).

J. E. Spurr, 1911 (Min. and Sci. Press, vol. 102, pp. 560–561; also Rept. on geol. of property of Montana-Tonopah Min. Co., Tonopah, Nev., published privately; also Econ. Geol., vol. 10, pp. 713–769, 1915). *West End rhyolite.*—A new fm. not exposed at time of original investigation [U. S. G. S. P. P. 42, 1905]. Does not outcrop at surface in surveyed or mapped dist., and was originally mistaken for Tonopah rhyolite-dacite, but is now known to be of distinctly greater age than the Tonopah. Intrudes Mizpah trachyte proper. Thickness 0 to 450 ft.

T. B. Nolan, 1930 (Univ. Nev. Bull., vol. 24, No. 4, p. 19). *West End rhyolite* is intrusive, and not a series of flows, as believed by J. A. Burgess (Econ. Geol., vol. 4, p. 692, 1909), who called it the "upper rhyolite." Is best exposed in Tonopah Extension and West End mines, where it is a westward-dipping mass separating Tonopah fm. and Mizpah trachyte. Max. thickness appears to be at least 600 ft. Intrudes Tonopah fm., Mizpah trachyte, and Extension breccia and is uncon. overlain by Fraction breccia.

Westerly granite.

Late Carboniferous or post-Carboniferous: Southeastern Connecticut and southwestern Rhode Island.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 136, 152, 154). *Westerly granite.*—Finely crystalline gray rock, which shows minor variations in color and texture but which is petrographically the same. This is Westerly gray granite of the trade. Is quarried at Westerly, R. I. Where typically exposed is massive, with no indication of gneissoid structure, but is cross-jointed and broken into blocks. Intrudes Sterling granite gneiss and the pegmatites that cut the Sterling granite gneiss and is youngest fm. in SE. Conn. Sterling granite gneiss is Westerly red granite of the trade. J. F. Kemp has described petrography of both types in Bull. Geol. Soc. Am., vol. 10, pp. 367–370, 1899.

†Western sandstone.

Pre-Cambrian (Keweenawan): Northeastern Wisconsin and Apostle Islands.

R. D. Irving, 1883 (U. S. G. S. Mon. 5, pp. 153, 154, 365, 366). The *Western ss.* occurs on Apostle Islands and adjoining coast of Bayfield Co., Wis. It has not been traced to any point where its relation to any of Mississippi Valley fossiliferous fms. can with certainty be made out, although the appearances in NW. Wis. and NE. Minn. are decidedly in favor of its being the downward continuation of Mississippi Valley Camb. or Potsdam ss., 1,000 ft. thick, and at a lower horizon than any met with in Mississippi Valley.

Replaced by *Bayfield group*. For many years was believed to be same as Camb. †Eastern ss. (Jacobsville ss.).

Westernport sandstone. (In Allegheny formation.)

Pennsylvanian: Western Maryland and adjacent parts of West Virginia.

I. C. White, 1882 (The Virginias, vol. 3, pp. 141–143). *Westernport ss.*, the massive coarse yellowish-gray rock which is usually found 290 to 300 ft. above Pittsburg coal [not Pittsburgh coal], and which caps summit of Westernport Hill, near Westernport, Md.

C. K. Swartz, W. A. Price, and H. Bassler, 1919 (Geol. Soc. Am. Bull., vol. 30, p. 572). *Westernport ss.* underlies fire clay beneath Piney Mtn coal and overlies Middle Kittanning (Luke) coal.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pls. 6, 7, pp. 47–48). *Westernport ss.*— Massive ss., gray, coarse-grained and cross-bedded at many places; contains interbedded lenses of sh. Rests on Luke (Middle Kittanning) coal, and underlies fire clay beneath Piney Mtn coal. Forms bold cliffs along the Potomac W. of Westernport, Allegany Co., Md., where it is 40 ft. thick.

Western Valley gravel.

A term applied by J. M. Safford (Am. Jour. Sci., 2d, vol. 37, pp. 360–362, 1864) to beds of gravel bordering the valley of Tennessee River in western Tenn., which, according to W. H. Monroe (personal communication) are in part Tuscaloosa fm. and in part high-level terrace deposits of Tennessee River, of Plio. (?) and Pleistocene age.

Westerville limestone member (of Kansas City formation).

Pennsylvanian: Southwestern Iowa, northeastern Kansas, and northwestern Missouri.

H. F. Bain, 1898 (Am. Jour. Sci., 4th, vol. 5, pp. 437–439). *Westerville ls.*— Fossiliferous ashy-gray fine-grained thin-bedded ls., 10 ft. thick, occurring "some little distance" above DeKalb ls. Included in Bethany ls., although probably it more properly belongs with next higher div. of Missourian series.

For further explanation, see *DeKalb ls.*

For several years Westerville ls. was regarded as probably same as Cement City ls. bed in Chanute sh. memb. of Kansas City fm. of Mo. R. C. Moore and G. E. Condra (Oct. 1932 revised classification chart of Penn. rocks of Kans. and Nebr.) showed it as separated from overlying Cement City ls. by Quivira sh. See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936. Named for exposures at Westerville, Decatur Co., Iowa.

Westfield serpentine.

Ordovician: Western Massachusetts (Hampden County).

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 92), applied name *Westfield serpentine* to an outcrop of serpentine in W. edge of Westfield.

Westfield phase (of Otis limestone).

Middle Devonian: Central eastern Iowa.

W. H. Norton, 1921 (Iowa Geol. Surv. vol. 27, p. 377). *Westfield phase of Otis ls.*—A fourth distinct type of Otis ls., a basal cgl. resting on the Sil. At Westfield Bridge at Fayette [Fayette Co.] it consists of about 8 ft. of mag. ls. or dol. in heavy beds distinguished by aren. bands with rounded grains of fine quartz sand and angular bits of white chert. The same aren. bed is seen in Bremer Co., SE. of Waverly. These beds have essential relations of a basal cgl. In both counties they are succeeded by nonmag. lss. of Cedar Valley phase of the Otis.

Westfield shale.

Upper Devonian: Western New York (Chautauqua County).

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). [*Westfield sh.* applied in table to beds of Chemung age overlying Laona ss. and underlying Shumla ss. in Chautauqua Co.]

G. H. Chadwick, 1924 (N. Y. State Mus. Bull. 251, p. 151). For the beds btw. Laona [below] and Shumla sss. the name *Westfield sh.* may be used. Lithologically indistinguishable from Gowanda beds, they contain, like those at W., a persistent Portage cephalopod element in their fauna, yielding eastward wholly to Chemung brachiopods. East of Cattaraugus these beds appear to maintain their identity as far as Elton, beyond where they are gradually merged in [lower part of] Wellsburg [ss.] memb. Thickness 120 ft. on Lake Erie, 160 ft. at Laona, and perhaps 200 ft. near Perrysburg. [Probably named for exposures at or near Westfield, Chautauqua Co.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369), included all of above-mentioned beds in the Chemung, but G. H. Chadwick (1933, etc.) transferred them all to his Canadaway group.

Westfield lime.

Drillers' name for oil-bearing beds in Spergen (Salem) ls. or in Osage group of the Miss. of Clark Co., Ill. (See Ill. Geol. Surv. Bull. 54, index.)

West Fork formation.

Upper Devonian or Mississippian: Northern Alaska (Wiseman-Chandalar region).

F. C. Schrader, 1900 (U. S. G. S. 21st Ann. Rept., pt. 2, p. 475). *West Fork series.*—Fine-grained dark-gray qtzite, dark flint, calc. black sh., and impure ls. Cut by dikes. May be Paleozoic. So far as known it crosses Chandalar River Valley in belt 15± mi. wide from below Granite Creek to above West Fork [of Chandalar River], and probably has much wider distribution. Seems to overlie Lake qtzite schists on NW. and granite on SE.

These rocks are now considered to be either Upper Dev. or Miss.

West Franklin limestone.

Pennsylvanian: Southwestern Indiana.

J. Collett, 1884 (Ind. Dept. Geol. and Nat. Hist. 13th Ann. Rept., pp. 61–62). *West Franklin ls.*—Fossiliferous calc. sh. and black ls., 2 to 25 ft. thick, in Coal Measures of Posey Co. Overlain by either thin-bedded ls. or thin-bedded schistose ss., and underlain by argill. sh.

R. E. Esarey, 1927 (A. A. P. G. Bull., vol. 11, No. 6, pp. 601–610). *Somerville or West Franklin ls.*

R. R. Shrock and C. A. Malott, 1929 (A. A. P. G. Bull., vol. 13, pp. 1301–1314). *West Franklin fm.*—Consists of (descending): (1) Dense gray crystalline ls. about 3 ft. thick, rarely brecciated; (2) sh., 25 ft. max.; (3) hard blue to gray brecciated ls., 5± ft. Consistently occurs 280 to 315 ft. above coal V. Overlain by 0 to 30 ft. of sh. and ss. which uncon. underlies Merom ss. Is same as Somerville ls. and has priority. Is of post-Allegheny age.

Named for exposures at West Franklin, Posey Co.

West Haven moraine.

Pleistocene (Wisconsin stage): Central Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for West Haven, Shiawassee Co.

Westheimer member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 15). *Westheimer memb.* of Hoxbar fm. lies 800 ft. above base of the Hoxbar. Includes a 10-foot pinto ls. cgl. of variegated pebbles of chert, sh., and ls. in a ls. matrix, together with a calc. ss. or sandy ls. About 600 ft. above Westheimer memb. occurs Crinerville ls. memb.

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 42). *Westheimer memb.* consists at top of a pinto ls. cgl. 10 ft. thick, and at base of 10 ft. of calc. ss. or sandy ls., the two being separated by a few ft. of beds. Lies 400 to 500 ft. below Crinerville memb. and 800± ft. above Union Dairy memb. of Hoxbar fm. Well exposed on property of Westheimer & Daube, in NW¼SE¼ sec. 7, T. 6 S., R. 2 E., and about 200 yds E. of asphalt prospect belonging to that firm.

C. W. Tomlinson (1934) stated that recent detailed mapping showed this ls. is same as Confederate ls., and he discarded Westheimer. (See 1934 entry under *Confederate ls. memb.*)

West Hill formation.

Upper Devonian: West-central New York.

J. M. Clarke, 1903 (N. Y. State Mus. Hdb. 19, p. 23). *Westhill flags*, a subdivision of Naples beds in Ontario Co. and in Genesee Valley and Lake Erie sections.

J. M. Clarke and D. D. Luther, 1903 (N. Y. State Mus. Bull. 69, map). *West Hill sands* overlie Grimes ss. and underlie Dunkirk black shales.

J. M. Clarke, 1904 (N. Y. State Mus. Mem. 6, pp. 199–204). *Westhill sss.*—Heavy-bedded sands, flags, and few shales. Thickness 600 ft. in Naples section, where they overlie Grimes ss. and underlie Highpoint ss. Belong to Portage. Fossils scarce but chiefly indicative of Ithaca fauna or possibly earliest stages of Chemung fauna. Included in Gardeau of Genesee River section, which contains no Ithaca fossils but a Naples fauna.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63). *West Hill flags and sh.*—Light bluish-gray sss. or flags 2 to 12 in. thick, separated by beds of dark-blue, olive, or black sh. Thickness 550 ft. in Canandaigua and Naples quads. Sharply distinguished from underlying Grimes ss. by thinner bedding and bluish color. Fauna is continuation of Grimes brachiopod fauna, with some interesting additions, but none specially distinctive of Chemung, and therefore considered as belonging to Ithaca invasion. Underlie Highpoint ss. *Named for West Hill, Ontario Co.*

D. D. Luther, 1910 (N. Y. State Mus. Bull. 137). *West Hill flags and shales* of Auburn and Genoa quads. contain species belonging to both Naples and Ithaca faunas.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 77). *West Hill flags and sh.* in part=Gardeau of Genesee Valley, but different faunally in that the West Hill is characterized by Ithaca fauna, while Gardeau contains Naples fauna. The fm. is recognized as far E. as Schuyler Co., where it contains species of both Ithaca and Naples faunas. Assigned to Portage.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Westhill sh.* of Steuben Co. overlies Grimes ss. and underlies Highpoint ss. (=Nunda ss.). Is=Gardeau sh. of Cattaraugus and Allegany Counties. The Dunkirk sh. is much younger than Westhill sh.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *West Hill flags* underlie High Point ss. and overlie Grimes ss. All included in Portage group.

The U. S. Geol. Survey uses *West Hill fm.* for this unit, which is overlain by Nunda ss. and underlain by Grimes ss. (See U. S. G. S. Bull. 899 A, on Steuben and Yates Counties, N. Y., by W. H. Bradley and J. F. Pepper, in course of publication.)

West Index andesitic series.

Tertiary (Eocene or Miocene): Central Washington (Snohomish County).

C. E. Weaver, 1912 (Wash. Geol. Surv. Bull. 7, pp. 34–50). *West Index andesitic series.*—Intercalated layers of fine-grained andesitic breccias, cgls., and badly altered lavas; gray, often with greenish tint. Thickness 2,500 to 3,000 ft. Uncon. underlies Howard arkose fm. No fossils. May be Eo. or of same age as Howard arkose fm. (Mio. ?). Named for Mount West Index.

West Jefferson sandstone.

Middle Devonian: Central Ohio.

E. Orton, 1888 (Ohio Geol. Surv. vol. 6, pp. 4, 21). *West Jefferson ss.*—Sharp sand, few ft. thick, underlain by and interstratified with Lower Corniferous or Columbus ls.

Named for West Jefferson, Madison Co.

Westkettle quartz diorite.

Jurassic (?): British Columbia.

L. Reinecke, 1915 (Canada Geol. Surv. Mem. 79, pp. 41, 46).

West Ledge formation.

Pre-Cambrian: Southwestern South Dakota (Lawrence County).

J. O. Hosted and L. B. Wright, 1923 (Eng. and Min. Jour.-Press, vol. 115, pp. 793–799, 836–843, with maps). *West Ledge fm.*—Gray-green siliceous, chloritic, dolomitic ls., grading into impure calc. phyllite. Contains some cummingtonite and much white quartz. Usually weathers red from iron oxides. Thickness 100 ft. Underlies Northwestern fm. and overlies Ellison fm. Believed to be of Keewatin age.

Derivation of name not stated, but occurs in Lead dist., Lawrence Co.

West Mead limestone member.

Mississippian: Northwestern Pennsylvania.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, p. 132), proposed *West Mead ls. memb.* to replace so-called *Lower Meadville ls.* of early repts on NW. Pa. Named for West Mead Twp, Crawford Co., where the ls. is especially well developed in gullies, runs, and ravines. [This is middle part of Sharpsville ss. memb. of previous repts.]

West Minesota conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and p. 21). We next [above West Minesota trap] find a belt of cgl. 150 ft. wide, known as *West Minesota cgl.*

Named for occurrence on property of West Minesota Mining Co., in Ontonagon Co.

West Minesota trap.

Pre-Cambrian (Keweenawan): Northern Michigan (Ontonagon County).

S. H. Broughton, 1863 (Remarks on the mining interest and details of the geology of Ontonagon County, pam. of 24 pp. and map, Phila., 1863; map and p. 21). After this [the copper vein overlying †Oneida cgl.] succeeds alternately belts of compact and highly amygdaloidal traps 2,160 ft. in width. Lithology peculiar. Carry copper. Have been thoroughly explored and some of them worked by West Minesota Mining Co. Overlain by West Minesota cgl.

Weston limestone.

Pennsylvanian: Northwestern Missouri.

J. A. Gallaher, 1898 (Mo. Bur. Geol. and Mines Bien. Rept., p. 52). *Weston ls.*—Massive argill. ls., with abundant *Fusulina cylindrica*, resting on coal No. 3 near Weston.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, pp. 139, 140). Weston ls. of Gallaher abandoned. Not properly defined. Evidently refers to Iatan ls.

Named for exposures at Weston, Platte Co.

Weston shale. (In Douglas group, Kansas.)

Weston shale member (of Douglas formation, in Missouri).

Pennsylvanian: Southwestern Iowa, northwestern Missouri, southeastern Nebraska, and eastern Kansas.

C. R. Keyes, 1899 (Am. Geol., vol. 23, p. 306). *Weston sh.*—Basal memb. of Lawrence shales in Mo. and eastern Kans. Underlies Iatan ls. memb. of Lawrence and overlies Plattsburg (Garnett) ls. [Lawrence sh. as used above is a broader unit than Lawrence sh. of generally accepted usage. See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.]

H. Hinds and F. C. Greene, 1915 (Mo. Bur. Geol. and Mines vol. 13). *Weston sh. memb.*—Basal memb. of Douglas fm.; underlies Iatan ls. memb. and overlies Stanton ls. memb. of Lansing fm. [This definition was followed for many years.]

In 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. chart) R. C. Moore transferred Weston sh., Iatan ls., and basal part of overlying Lawrence sh. to Lansing fm., divided the rest of Lawrence sh. into 3 units (to which he restricted *Douglas group*), and transferred Oread ls. to overlying Shawnee group. (See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.) In 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook) Moore restricted Lansing group to beds below Weston sh., and assigned Weston sh., Iatan ls., and Hardesty sh. (a new name applied to basal part of Lawrence sh. of previous usage) to his Pedee group (new name). This classification was followed by N. D. Newell, 1935 (Kans. Geol. Soc. Bull. 21, pp. 17, 81). Newell stated that in some areas Iatan ls. and Hardesty sh. of Moore are absent and Weston is uncon. overlain by Stranger fm. The U. S. Geol. Survey has not yet had occasion to consider, for its publications, these recent innovations.

Named for Weston, Platte Co., Mo.

Weston sandstone. (In Monongahela formation.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1916 (W. Va. Geol. Surv. Rept. Lewis and Gilmer Counties, p. 124). *Weston ss.*—Along Town Run, at SE. edge of village of Weston, Lewis Co., it consists at top of shaly sand layers 10 ft. thick; in middle of 7 ft. of sh.; at base greenish-gray and harder sand layer 10 ft. thick. Overlies Redstone ls. and lies 5 ft. below Redstone coal.

Weston shale. (In Monongahela formation.)

Pennsylvanian: Northern West Virginia.

D. B. Reger, 1916 (W. Va. Geol. Surv. Rept. Lewis and Gilmer Counties, p. 128). *Weston sh.*—Gray sh., 10 ft. thick, used for brickmaking. Underlies Redstone ls. and overlies Pittsburgh coal. Exposed in vicinity of Weston, Lewis Co.

Westphalia limestone.

Pennsylvanian: Eastern Kansas.

R. C. Moore and N. D. Newell, 1936 (Kans. Geol. Surv. Bull. 22, pp. 145, 146, 150). *Westphalia ls. memb. (of Stranger fm.).*—Thin ls. containing fusulinids. Underlies Vinland sh. [restricted] and appears to lie just above horizon of Sibley coal, which, however, is not present at Westphalia type loc. Was included in Vinland sh. as first defined. In NW. part of Anderson Co. is overlapped by channel filling of Ireland ss., and in S. part of Franklin Co. is cut out by this ss. Named for village in W. part of Anderson Co. Typical outcrops are in roadside exposures along N. part of sec. 12, T. 21 S., R. 17 E., and at NE. cor. sec. 20, T. 21 S., R. 18 E. Not definitely recognized in outcrops N. of T. 19 S.

West Point formation. (In Chaleur series.)

Silurian (Niagaran): Quebec (Gaspe Peninsula).

C. Schuchert and J. D. Dart, 1926 (Canada Geol. Surv. Bull. 44, p. 51).

S. A. Northrop, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 1, p. 271). Faunas of Bouleaux, West Point, and Indian Point fms. of middle Sil. Chaleur series are of Lockport and Guelph age.

West Point member.

Mississippian: Western Kentucky (Hardin County).

A. H. Sutton, 1931 (Ky. Geol. Surv. ser. 6, vol. 37, p. 281). Some 50 or 60 ft. of cherty and argill. ls. are included in lower part of Warsaw ls. of Hardin Co., Ky. These beds contain some fossils found at other localities only in the Keokuk, together with typical Warsaw forms. Because it seems more reasonable to consider the Keokuk species as having carried over in an area where there was no break in sedimentation, and to take the introduction of the Warsaw forms as marking beginning of Warsaw time, it is proposed to designate these beds *West Point memb.* and include them in the Warsaw. For a more detailed discussion of these doubtful beds reader is referred to work of C. Butts in his repts on Miss. of Ky. Above these doubtful beds lies main body of Warsaw fm., which consists of gray to bluish ls. of typical Warsaw (Harrodsburg) character, together with some shaly and siliceous beds. [Derivation of name not stated, but there is a village called West Point in Hardin Co., Ky.]

West Point shale. (In Admire shale.)

Pennsylvanian: Kansas.

R. C. Moore, Sept. 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. correlation chart). Misprint for *West Branch sh.*

West Princeton sand.

A subsurface sand in Brazil fm. (Penn.) of Ind.

West Prospect basalt.

Age(?): Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 21, No. 8, pp. 214–376, map), applied following names to volcanic rocks in Lassen Nat. Park, arranged in following downward order on map: *West Prospect basalt; Crescent Crater dacites; Manzanita dacites; Prospect Peak basalts; Raker Peak pyroxene andesites; Brokeoff andesites; Eastern basalts; Twin Lakes andesites; Juniper and Flatiron andesites; Willow Lake basalts.* (The latter 5 units are described in the text; the others are not.)

West Range limestone.

Upper Devonian: Eastern Nevada (Pioche district).

L. G. Westgate and A. Knopf, 1927 (Am. Inst. Min. and Met. Engrs. Trans., No. 1647, p. 7). *West Range ls.*—Several hundred ft. of thin- and thick-bedded lss., certain layers of which are nodular and weather yellow. At several levels abundant fossils [of Upper Dev. age]. Composes, with underlying Silverhorn ls., the whole of West Range, which lies W. of Bristol Range.

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171, pp. 7, 16, map, etc.). *West Range ls.*—Blue-gray medium- and heavy-bedded fine-grained lss., in places nodular, commonly weathering yellow. Thickness 500± ft. Conformably underlies Bristol Pass ls. (Miss.) and conformably overlies Silverhorn dol. (Middle Dev.).

West River shale. (In Genesee group.)

Upper Devonian: Western and west-central New York.

J. M. Clarke and D. D. Luther, 1904 (N. Y. State Mus. Bull. 63, p. 28). *West River sh.*—Fine blue-black or dark-gray shales with thin bands of black slaty sh. at intervals of 2 to 6 ft. Are lighter and less bituminous than underlying Genesee sh. [restricted]. Fauna is return of Genesee sh. [restricted] fauna with a few additional species. Named for exposures in West River Valley, Yates Co. Overlies Genundewa ls. and underlies Standish flags and shales. Included in Genesee beds or group [broad sense]. Previously called "upper Genesee sh." [In N. Y. State Mus. Bull. 101, 1906, Luther gave thickness of West River sh. in Penn Yan and Hammondsport quads. as 100 to 110 ft.; and in N. Y. State Mus. Bull. 99, 1906, he gave thickness in Buffalo quad. as 12 ft. In N. Y. State Mus. Bull. 137, 1910, he applied *West River sh.* to all beds in Auburn and Genoa quads. btw. Genundewa ls. and Cashaqua sh.]

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 73). *West River sh.* is recognized from Cayuga Lake to Erie Co. In region of Seneca and Cayuga Lakes and farther E. it embraces all strata btw. Genundewa ls. and Cashaqua sh. Included in Genesee.

See further explanation under *Genesee sh.*

†West Roxbury slate.

Carboniferous or Devonian: Eastern Massachusetts (Boston region).

W. W. Dodge, 1881 and 1882 (Boston Soc. Nat. Hist. Proc., vol. 21, pp. 208–210), called the "slates on each side of the tract near West Roxbury station" the *West Roxbury sl.*

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), and L. LaForge, 1932 (U. S. G. S. Bull. 839), mapped the slates of West Roxbury as *Cambridge sl.*, a name which has priority and is better established.

West Rutland marble.

Lower Ordovician (Chazy): Southwestern Vermont (Rutland County).

E. J. Foyles, 1929 (16th Rept. Vt. State Geol., pp. 281–288). *West Rutland marble belt* is thought to be in large part of Chazy age because it contains obscure Chazy fossils. [*West Rutland ls.* had long been in use as a quarry term.]

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 398). *West Rutland marble.*—Best known from its use as ornamental stone, West Rutland [Castleton quad.] having long been the principal center of the marble industry. There is considerable variation in the beds of marble, and different quarries make a specialty of particular beds. A long line of quarries, old and new, lies along E. side of the marble belt, and there are a few quarries on W. side of belt. Prevailing colors are white, more or less banded with dark blue, mottled blue, and light gray; a few beds have a pale-green banding, and in the quarries on W. side of the belt mottled cream-colored marbles are produced. In the 2 northerly areas of the fm. btw. Brandon and West Rutland the synclines in which fm. lies are shallower than that at West Rutland and only lower part of fm. appears. In these areas the marbles are in the main dark blue, and there is a thin memb. of blue-banded lss. at base. This memb. also appears in West Rutland area but is thinner and poorly exposed. The lower lss. contain a brachiopod fauna and many crinoid stems; the upper marbles, particularly the bluish or blue-banded ones, have many large Maclureas that have always been considered to be of Chazy age. Several small areas of the marble (containing fossils) occur along E. side of Taconic Range, coming in and out against the Taconic overthrust. The marble rests uncon. on Ira sl., of Beekmantown age.

West Spring Creek formation.

Middle Ordovician: Central southern Oklahoma (Arbuckle and Wichita Mountains).

In ms. chart dated April 1928 (but not published by him) E. O. Ulrich divided Simpson fm. of Taff into (descending): (1) *West Spring Creek fm.*, *Criner memb.* (of Trenton and Black River age); uncon. on (2) Bromide fm.; and (3) Oil Creek fm., the latter having great uncon. at base. At Dec. 1928 meeting of Geol. Soc. of Am., in N. Y., Ulrich exhibited a ms. chart (which he did not publish) in which he divided Simpson fm. into (descending) *Bromide*, *Criner*, *Tulip Creek*, McLish, Falls, Nebo, and *Joins Ranch*, as reported by Dr. C. N. Gould. In Feb. 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 73) Ulrich divided Simpson fm. into (descending): *Bromide* (of Trenton and Black River age) uncon. on *Criner; Tulip Creek*, Falls, McLish, *Oil Creek*, and *Joins*. Ulrich's 1928 list of names as reported by Gould was published by C. E. Decker in Dec. 1930 (A. A. P. G. Bull., vol. 14, No. 12, p. 1495).

C. E. Decker, 1933 (Tulsa Geol. Soc. Digest, pp. 55–57). Simpson group of Arbuckle and Wichita Mtns divided into (descending) Bromide fm., Tulip Creek fm., McLish fm., Oil Creek fm., Joins fm., *West Spring Creek fm.*, Alden ls. (Ceratopia bed), and Cool Creek ls.

Above are only recorded uses of *West Spring Creek fm.*

Named for West Spring Creek, in SW. corner of Murray Co., 4 or 5 mi. SE. of Pooleville.

West Sutton slate.

Cambrian (Lower): Southern Quebec.

T. H. Clark, 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 225–226), listed the following fms. beneath Cheshire qtzite in southern Quebec: West Sutton sl., 40 ft.; White Brook dol., 40 ft.; Pinnacle graywacke, 400 ft.; and Call Mill sl., 25 ft.

West Union limestone.

Silurian (Niagaran): Southwestern Ohio.

E. Orton, 1871 (Ohio Geol. Surv. Rept. Prog. 1870, pp. 271, 274, 301, and fig. 1, opp. p. 310). *West Union* or *Lower Cliff*.—Yellowish impure mag. lss., rather massive, 45 to 89 ft. thick, in Highland and Adams Counties. Overlies Niagara shales and underlies Springfield stone or *Blue Cliff*. All included in Niagara group. Contains Niagara fossils.

A. F. Foerste, 1900 (Ind. Dept. Geol. and Nat. Res. 24th Ann. Rept.). *West Union cliff rock* cannot be distinguished N. or W. of Greene Co., Ohio. Seems to replace ls. at top of Osgood in Ind.

C. S. Prosser, 1903 (Jour. Geol., vol. 11, pp. 519–546), J. A. Bownocker, 1915 (Ohio Geol. Surv., 4th ser., Bull. 18), and W. Stout, 1916 (Ohio Geol. Surv., 4th ser., Bull. 20), applied *Osgood beds* to beds underlying *West Union ls.* in Ohio.

C. S. Prosser, 1915 (Outlines of field trips in geol. in central Ohio), applied *Alger sh.* to beds underlying *West Union ls.* and overlying Brassfield ls. in Ohio.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, pl. 3). *West Union ls.* is=Osgood ls. of Ind.

A. F. Foerste, 1917 (Ohio Jour. Sci., vol. 17, No. 6), applied *West Union fm.* to beds underlying Cedarville ls. and overlying Crab Orchard sh. in Highland and Adams Counties, Ohio, and divided it into two faunal horizons, called Lilley memb. (above) and Bisher memb. (below). In 1919 (Ohio Jour. Sci., vol. 19, pp. 367–375) he gave thickness of his Lilley memb. as 20 to 30 ft. and thickness of his Bisher memb. as 45 ft., and stated that Lilley memb. corresponds to Upper or Blue Cliff of Orton, and Bisher memb. to Lower or West Union Cliff of Orton. In 1923 (Denison Univ. Bull., Sci. Lab. Jour., vol. 20, pp. 41–49) Foerste applied *Euphemia dol.* to the beds underlying Springfield dol. and overlying "so-called Laurel ls." from Wilmington, Clinton Co., Ohio, northward, and stated that the beds called Euphemia dol. are those included by Prof. Orton in his West Union bed, when using that name for tier of counties here named; also that *Lilley fm.* includes that part of section erroneously identified many years ago by Orton as *Springfield stone*, but that Springfield dol. is younger than the Lilley; also that his Bisher fm. corresponds approx. to West Union or Lower Cliff of Orton, and that this name would have been retained if Prof. Orton ever had described any section from West Union area, or had designated at Hillsboro the same boundaries btw. West Union and Springfield beds as those adopted later btw. Bisher and Lilley fms. Also that the Bisher is of upper Clinton age, and overlies Alger clay sh.

Named for exposures at West Union, Adams Co.

Westville shale.

Pennsylvanian: Southeastern Massachusetts.

J. B. Woodworth, 1899 (U. S. G. S. Mon. 33, p. 134). [*Westville shales and Seekonk sss.* are shown in table on p. 134 as top div. of Rhode Island Coal Measures and as underlying Seekonk cgl. and overlying Tenmile River beds, but they are not described by name in the text.]

Westville formation.

Carboniferous: Nova Scotia.

H. M. Ami, 1900 (Canadian Rec. Sci., vol. 8, pp. 162–163).

Westwater gneisses and schists.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 39, 281). *Westwater gneisses and schists.*—Schists and gneisses composing earliest known pre-Camb. rocks in Colo. Of pre-Archeozoic or Azoic age. Exposed in bed of Grand River at Utah-Colo. line. [Derivation of name not stated.]

Westwater Canyon sandstone member (of Morrison formation).

Upper Jurassic: Southeastern Utah (San Juan country).

H. E. Gregory (U. S. G. S. P. P. 188, in press). A ss. that appears to lie in position of Salt Wash ss. memb. of Lupton stands as cliffs and forms base of many canyon walls. Along the San Juan N. and NW. of Bluff, btw. Brushy Basin and middle Cottonwood Wash, and at other places where the overlying variegated shales have been removed, this ss. appears as mesas, ridges, and the tops of broad platforms. Is tentatively here named *Westwater Canyon ss. memb.*, because its exact equivalency to typical Salt Wash ss. has not been satisfactorily established. Is essentially a series of white sss. (composed of rounded medium to coarse grains of quartz cemented by calcium carbonate and arranged in lenticular, irregular beds 1 to 30 ft. thick) interbedded with red earthy soft fine-grained sandy shales or mudstones; also a few thin short lenses of gray ls. cgl. Underlies Brushy Basin sh. memb. and overlies, with local uncon., Recapture sh. memb. Thickness 222 to 295 ft. Named for exposures in canyon of Westwater Creek, San Juan Co.

Wetmore conglomerate member.

Devonian or Carboniferous: Northwestern Pennsylvania and southwestern New York.

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 61, 111–112). *Wetmore cgl. memb. or lens.*—Lower cgl. of Knapp formational suite. Is less persistent of the two Knapp cgls. Found only, so far as known, in McKean, northern Forest, northern Elk, and eastern Warren Counties, Pa., and in typical Knapp area, in vicinity of Knapp Creek, N. Y. Is a flat-pebble rock, varying in thickness, possibly suggestive of a broad depression filling. Is 20± ft. thick at Ludlow and about 15 ft. at East Kane. Underlies East Kane sh. memb. and overlies Kushequa sh. memb. Replaces Ludlow cgl. of writer's 1933 paper. Named for exposures along face of the hills btw. Wetmore and Ludlow, McKean Co., Pa.

Wetumka shale.

Pennsylvanian: Central, central eastern, and central southern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Wetumka sh.*—Clay shales, 120 ft. thick, with thin shaly ss. layers near center. Overlies Calvin ss. and underlies Wewoka fm.

Named for exposures at or near Wetumka, Hughes Co.

Weverton sandstone.

Lower Cambrian: Virginia, West Virginia, Maryland, and southeastern Pennsylvania.

A. Keith, 1893 (as reported by G. H. Williams and W. B. Clark, in Maryland, its resources, industries, and institutions, chap. 3, p. 68. The fm. was described, but not named, by Keith in Am. Geol., vol. 10, p. 365, 1892). *Weaverton ss.*—Gray massive ss., often coarse and feldspathic. Thickness 1,000 to 1,200 ft. Underlies Harper's Ferry shales [Harpers sh.] and overlies Loudon shales [Loudoun fm.].

Named for exposures at Weverton [correct spelling], Washington Co., Md.

Wewe slate.

Pre-Cambrian (lower Huronian): Northwestern Michigan (Marquette district).

C. R. Van Hise and W. S. Bayley, 1895 (U. S. G. S. 15th Ann. Rept., pp. 530+). *Wewe sl.*—Chiefly sl., but contains some graywackes, cgl., mica sl., and in places mica schists. Thickness 500 ft. Rests conformably on Kona dol. Underlies Ajibik qtzite, usually conformably but in one place uncon. Typical development on Wewe Hills, W. of Goose Lake. [Later repts give thickness 0 to 1,050 ft.]

A. C. Lane, 1907 (Mich. State Bd. Geol. Surv. Rept. 1906, p. 500), used *Wewe or Goose Lake slates*, and elsewhere in same publication described the fm. as *Wewe sl.*, "the slates of Goose Lake, *Wewe* being Chippewa name for *Goose*."

Wewoka formation.

Pennsylvanian: Central, central southern, and central eastern Oklahoma.

J. A. Taff, 1901 (U. S. G. S. Coalgate folio, No. 74). *Wewoka fm.*—Massive brown friable ss., with interstratified soft blue clay sh. and thin ls. lentil in lower part. Thickness 700 ft. Underlies Holdenville sh. and overlies Wetumka sh.

Named for Wewoka Creek, Seminole and Hughes Counties, which crosses the fm.

Weymouth formation.

Lower Cambrian: Eastern Massachusetts.

L. LaForge, 1909 (Sci., n. s., vol. 29, pp. 945–946). *Weymouth fm.*—Name proposed for the fossiliferous beds of Lower Camb. age. Older than Braintree sl., which is Middle Camb.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, p. 37 and map). *Weymouth fm.*—At Weymouth, where exposed N. and E. of Mill Cove, it consists of reddish, brownish and greenish cherty sl. with greenish epidotic and calc. lenses and nodules and thin beds of white ls. At Nahant the few ft. of exposed beds are cherty greenish sl. and gray lydite with a few layers of white ls. Lower Camb. fossils.

See also L. LaForge, 1932 (U. S. G. S. Bull. 839).

†Weyquosque series.

Pleistocene: Southeastern Massachusetts.

N. S. Shaler, 1888 (U. S. G. S. 7th Ann. Rept., pp. 303-363 and maps). *Weyquosque series.*—Gray and blue clays and whitish sands, 1,500 to 2,000 ft. thick. Appears to overlie (uncon.) Vineyard series; underlies glacial deposits. Believed to have been deposited during first stages of glacial period, but may belong to an age btw. that of Vineyard series (Tert.) and the glacial epoch. Well exposed in W. part of Chilmark or Weyquosque Cliffs, Marthas Vineyard. [See also Shaler, 1890 (Geol. Soc. Am. Bull., vol. 1, pp. 443-452) and 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 959-974).]

J. B. Woodworth, 1896 (U. S. G. S. 17th Ann. Rept., pt. 1, pp. 975-988) and 1897 (Geol. Soc. Am. Bull., vol. 8, pp. 197-212). The *Weyquosque series of Shaler* (1888) is in this rept divided into Tisbury beds above and Sankaty beds below.

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). Shaler's *"Weyquosque series"* extended from top of Dukes gravel bed below to top of Manhasset fm. above.

Weyquosque formation.

Pleistocene: Southeastern Massachusetts (Marthas Vineyard) and Rhode Island (Block Island).

J. B. Woodworth and E. Wigglesworth, 1934 (Harvard Coll. Mus. Comp. Zool. Mem., vol. 52). *Weyquosque fm.*—Name *Weyquosque* restricted to 0 to 50 ft. of glacial gravels and sand forming basal bed of Shaler's "Weyquosque series" (which extended from top of Dukes gravel bed below to top of Manhasset fm. above). As restricted is older than Mannetto fm. and younger than Dukes boulder bed. Correlated with Nebraskan stage of Pleist. Present on Marthas Vineyard and Block Island. Named for exposures at E. end of Nashaquitsa Cliffs, on S. shore of Marthas Vineyard, "at a locality known to inhabitants from earliest days as Weyquosque."

Whalen group.

Pre-Cambrian: Southeastern Wyoming (Hartville uplift).

W. S. T. Smith and N. H. Darton, 1903 (U. S. G. S. Hartville folio, No. 91). *Whalen group.*—Qtzite, schist, siliceous ls., and gneiss, of Algonkian age. Oldest fm. in quad. Uncon. underlies Guernsey fm. (Miss.). Is intruded by granites of Algonkian(?) age. Typical occurrence along walls of Whalen Canyon.

Wharncliffe sandstone. (In middle of Pottsville group.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, p. 222). *Wharncliffe (Dotson?) ss.*—Massive current-bedded medium-grained pebbly grayish-white ss. Thickness 75 to 130 ft. Lowest surface rock in these counties. Lies 5 to 10 ft. below Gilbert coal [Lower Douglas coal?]. *Is top memb. of Middle Pottsville or New River series.* "Seems=Dotson ss. of Campbell." Named for town in Mingo Co.

Whately bed.

Name applied by B. K. Emerson (U. S. G. S. Mon. 29, 1898, pp. 190, 193) to a band of amphibolite that crops out beneath the sands of the valley in Whately, Old Hampshire Co., Mass., and runs SW. across Whately and into Williamsburg.

Wheaton River volcanics.

Tertiary: Yukon Territory.

D. D. Cairnes, 1910 (Canada Geol. Surv. Summ. Rept. 1909, p. 51).

Wheeler formation.

Middle Cambrian: Western Utah (House Range).

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804, pp. 9, 10). *Wheeler fm.*—Alternating bands of thin shaly ls. and calc. sh., 570 ft. thick. Underlies Marjum fm. and overlies Swasey fm. Type loc. is center of Wheeler Amphitheater, SE. of Antelope Springs.

Wheeler sand.

A subsurface sand, of Penn. age, in Okla., that has been correlated with the whole and with the lower part of Oswego lime. Named for Wheeler farm, pool, and dome, Carter Co.

Wheeler lime.

A subsurface ls., of Penn. age, in central northern Okla. that is believed to correspond to Pawnee ls.

Wheeling group.

Pennsylvanian: Appalachian Basin.

J. J. Stevenson, 1907 (Geol. Soc. Am. Bull., vol. 18, p. 178). [See quotation under *Athens group*.]

Whepley shale.

Miocene (middle): Southern California (Kettleman Hills).

H. V. Dodd and E. J. Kaplow, 1933 (Calif. Oil Fields, Calif. Dept. Nat. Res., Div. Oil and Gas, vol. 18, No. 4, pp. 12, 14, pls. 1, 2). *Whepley sh.*, 0 to 40± ft. thick, lies at base of fifth oil and gas zone in North Dome of Kettleman Hills. Formerly considered by some geologists to be top of Kreyenhagen sh., but now generally conceded to be either Temblor or Vaqueros, and underlying 650± ft. of strata (mostly sand, with increasing amount of sh. near base) are also believed to be either Temblor [middle Mio.] or Vaqueros [lower Mio.]. The Whepley is found in only 2 areas. Lies at 2,935± ft. depth. To NW. of 41-3P area it is absent; to SE. the wells have not been drilled deep enough to encounter it. Underlies Felix siltstone and overlies "Mollusk-boring sand."

Named for occurrence in wells on Whepley lease.

Whetstone Branch shale.

Upper Devonian: Northeastern Mississippi (Tishomingo County).

W. C. Morse, 1928 (Jour. Geol., vol. 36, pp. 31–43). *Whetstone Branch sh.*—Largely black sh., but contains some sandy sh. and a few thin sss. At a number of places is represented by a rather prominent ss. layer with a conglomeratic base resting uncon. on older fms., but at other places typical black sh. underlies and overlies the ss. Contains Dev. fossils. Belongs to lower and greater part of Chattanooga sh. of type loc. Uncon. underlies Carmack ls. and uncon. overlies Island Hill fm. Named for picturesque tributary of Tenn. River.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23), gave many details of this fm. Thickness 0 to 31½ ft. Type loc. is mid portion of Whetstone Branch, which enters Tenn. River about 3½ mi. above Tenn. State line and mouth of Yellow Creek.

Whetstone Gulf formation.

Upper Ordovician: Northern New York (Black River Valley) and southern Canada.

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258). The term "Frankfort" could not very well be applied to the whole of the lower Lorraine shales. Therefore the lower Lorraine shales should receive a separate name (*Whetstone Gulf sh.*). The Frankfort, being of the same age as the lower portion of the lower Lorraine sh. and merging into it, could be incorporated into the Lorraine, as the New York Survey has done from its beginning, but not as its characteristic development but only as a local shore facies of the lower Whetstone Gulf horizons. (Page 147.) For the lower Lorraine shales we have selected the name "*Whetstone Gulf beds*," from the fine exposure of the lower Lorraine shales in the picturesque Whetstone Gulf near Martinsburgh in Lewis Co., N. Y. Here also the contact with both the *underlying* Atwater Creek and *overlying* Pulaski beds is shown. (Page 148.) [In some parts of this rept the name *Whetstone Gulf* is applied to the beds *between* Atwater Creek sh. and Pulaski sh.; in other parts of rept the Atwater Creek is included in the Whetstone Gulf. The beds btw. Atwater Creek and Pulaski shales are also divided into two faunal zones, called *Moose Creek beds* (above) and *Wood Creek beds* (below).]

Whetstone Run sand.

Drillers' name for a sand of late Upper Dev. (Catskill) age in W. Va. Lies at or near same horizon as Gordon sand.

Whirlpool sandstone member (of Albion sandstone).

Silurian (early): Western New York and Ontario.

A. W. Grabau, 1909 (Jour. Geol., vol. 17, p. 238). *Whirlpool ss.*—White quartzose ss., 25 ft. thick, forming basal bed of *true or Upper Medina* [i. e. Medina restricted, later named *Albion ss.*]. Overlain by red sss. and green and gray sss. and sh. and underlain by Queenston sh., of Richmond age.

In 1912 (N. Y. State Mus. Hdb. 19) C. A. Hartnagel included Queenston sh. in Medina, and treated Whirlpool ss. as an overlying part of Medina.

In 1913 (12th Int. Geol. Cong., Canada, pp. 26, 27, 30, 36, 49) E. O. Ulrich and J. M. Clarke replaced "Upper Medina" with *Albion ss.* (a name suggested by Clarke); and A. W. Grabau (Geol. Soc. Am. Bull., vol. 24, pp. 431, 460) applied *Whirlpool qtzite* to basal 25 ft. of that fm., to which, however, he applied *Medina* in a restricted sense. He described *Whirlpool qtzite* as hard white quartz ss., and stated that it occurred at Niagara and for some distance E. and W., but not as far E. as Rochester. In U. S. G. S. Niagara Falls folio (No. 190, 1913) the form of the name was changed to *Whirlpool ss. memb.*, and the beds were described as consisting of 20 ft. of coarse white ss., forming basal memb. of Albion ss. and resting on Queenston sh. In Canada Geol. Surv. Guidebook 4, 1913, W. A. Parks proposed that *Whirlpool ss. of Grabau* (consisting, at Hamilton, Ont., of 10 ft. of gray ss.) be treated as basal memb. of Schuchert's Cataract fm. [a name introduced by Schuchert in Geol. Soc. Am. Bull., vol. 24, p. 107, 1913], "which represents an invasion from N. and W. at commencement of Sil. time" [but which, according to Schuchert, 1913, corresponds to lower 50 ft. of the 135 ft. of Albion ss. at Niagara Falls]. Parks also restricted Medina to the beds above Cataract fm., or to uppermost part (60–70 ft. according to F. B. Taylor on pp. 22–24 of same volume) of beds formerly included in the Medina. The type loc. of Cataract fm. is a town in interior of Ontario, where it is also exposed at the cataract of Credit River. In 1914 (Geol. Soc. Am. Bull., vol. 25, pp. 277–320) Schuchert treated *Whirlpool ss. memb.* as basal bed of his Cataract fm. (and of Sil. system), and described it as consisting of 0 to 22 ft. of coarse cross-bedded white, red, or mottled ss., extending from Lockport, N. Y., to near Collingwood, Ont. He also stated that the white sss. at base of Medina E. of Lockport are not of same age as Whirlpool ss. The calc. beds overlying the Whirlpool ss. he designated *Manitoulin ls. memb.*, a name introduced by M. Y. Williams in 1913. E. M. Kindle, 1914 (Sci., n. s., vol. 39, pp. 915–918), endorsed Grabau's restriction of *Medina* and treated Whirlpool ss. as basal bed of that fm. M. Y. Williams, 1919 (Canada Geol. Surv. Mem. 111), treated Whirlpool ss. as basal memb. of *Medina-Cataract fm.*, as did A. F. Foerste, 1924 (Canada Dept. Mines Geol. Surv. Mem. 138), who stated that Whirlpool ss. extends from Niagara River to vicinity of Duntroon, about 8 mi. S. of Collingwood, and that it has not been traced as far E. as Rochester, N. Y. In 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21) E. R. Cumings proposed that Albion ss. be restricted to beds btw. Whirlpool ss. and Thorold ss., and that Whirlpool be treated as basal fm. of *Medinan series.*

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 317), treated Whirlpool ss. as basal bed of Albion ss., as did H. L. Alling and J. E. Hoffmeister, 1932 (16th Int. Geol. Cong. Guidebook 4). This is the definition still followed by U. S. Geol. Survey.

Named for occurrence at the Whirlpool of Niagara River.

†White limestone.

Oligocene and Eocene: Alabama.

A descriptive term applied, in a titular sense, in early repts to the white ls. in vicinity of St. Stephens, Ala., later called "St. Stephens ls.," but now known to be divisible into Vicksburg group (Olig.) and Jackson fm. (upper Eo.).

†White limestone.

Lower Ordovician (Beekmantown): Leadville district, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept. pp. 215-230), 1883 (U. S. G. S. Leadville Atlas), and 1886 (U. S. G. S. Mon. 12). [A color term applied in a titular sense to 160 ft. of light-gray to dark-gray dolomitic ls., with shaly layers, overlying the Camb. (Sawatch) qtzite and underlying Parting qtzite.]

Same as Manitou ls.

White porphyry.

Eocene: Leadville district, Colorado.

S. F. Emmons, 1882 (U. S. G. S. 2d Ann. Rept., pp. 215-230), 1883 (U. S. G. S. Leadville Atlas), 1886 (U. S. G. S. Mon. 12, p. 76), and 1927 (U. S. G. S. P. P. 148) used *White porphyry* in a titular sense. This is a color term applied to a "white or granular compact, homogeneous-looking rock, composed of quartz, feldspar, and muscovite," and of earlier age than the Gray porphyry group of Leadville dist. Is also called "White or Leadville porphyry." Petrographic description, by W. Cross, on p. 324 of Mon. 12. For convenience of mining public this descriptive term is still used in a titular sense in the Leadville dist.

White Sands.

A geographic descriptive term applied to part of the Tularosa quad., N. Mex., the surface of which is composed of granular gyp. and other white deposits of loose sand, mostly silica.

Whitean series.

A name employed by C. R. Keyes instead of *White River group.*

White Beach sandrock.

Miocene (lower): Central Florida.

W. H. Dall, 1892 (U. S. G. S. Bull. 84, pp. 114, 337). *White Beach sand rock.*—A yellowish ls., much water-worn and covered in places with a thin layer of recent sandrock. It contains distorted molds of many species which cannot be recognized, but in some places these molds have become filled with a pseudomorph in lime of the original shell. About half of species collected have been studied sufficiently to show their near equivalence to *Orthaulax* bed of Tampa and Chipola marl bed of Alum Bluff. It is certainly to be included in Tampa group, and may possibly be a little younger than either *Orthaulax* bed ["so-called silex bed" of Tampa ls.] or Chipola marl.

Named for exposures at a locality known in 1892 as "White Beach," at northern and western extreme of Little Sarasota Bay, S. of Tampa Bay, on W. coast of Fla.

White Bluff marl.

Eocene (upper): Jefferson County, southeastern Arkansas.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 343 and table opp. p. 334). *White Bluff marl.*—White Bluff, Jefferson Co., Ark. See Harris, Ann. Rept. Geol. Surv. Ark. for 1892, vol. 2, 1894, p. 87. [In chart opp. p. 334 Dall placed

"White Bluff marl" at top of Claibornian and above "Claiborne sand." In Harris' rept cited in above quotation Harris gave following section of rocks present at White Bluff, but did not use *White Bluff marl.*]

Soil
Sand and clay } 10 ft.
Gravel

Thin-banded light-gray clay, alternating with sand, 10 ft.

Green marly clay, with fossils, underlain by light- and dark-colored marls, highly fossiliferous, 60 ft.

The fossils found in above section (some of which are figured on pl. 9, accompanying this rept) belong to Eocene Tertiary.]

The beds referred to belong to Jackson fm., to which they were assigned by Harris.

White Brook dolomite.

Cambrian (Lower): Southern Quebec.

See under *West Sutton sl.*

Whitecap schist series.

Devonian, Carboniferous: British Columbia.

C. W. Drysdale, 1916 (Canada Geol. Surv. Summ. Rept. 1915, p. 79).

White Caps limestone member (of Gold Hill formation).

Cambrian? (Upper Cambrian?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *White Caps ls. memb.*—Pure blue-gray crystalline ls., 30± ft. thick. Lies at about middle of Gold Hill fm. and nearly 200 ft. above Morning Glory ls. memb. Is the bed that contains the ore deposit at White Caps mine.

White Church zone.

A name applied by H. S. Williams (Jour. Geol., vol. 15, p. 97) to a zone of *Tropidoleptus* assigned to Chemung fm. of Ithaca region, N. Y.

†White Cliff limestone.

Upper Jurassic: Southwestern to northeastern Utah and northwestern Colorado.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 51, 152). A bed of ls. has been found at base of Flaming Gorge group wherever it has been studied, varying in thickness from 10 to 250 ft. In southern Utah it caps an extensive escarpment known as the White Cliffs, and we have called it the *White Cliff ls.* In vicinity of Flaming Gorge [NE. Utah] it also forms basal part of Flaming Gorge group and rests on White Cliff ss. The ls. is bluish buff, compact, sometimes shaly, and interstratified with orange shales and thin beds of gyp.

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed White Cliff ls. of Powell=Twin Creek ls. of SW. Wyo.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 40). White Cliff ls. of Powell is=Curtis fm., which is=Twin Creek ls.

†White Cliff sandstone.

†White Cliff group.

Jurassic (?): Southwestern to northeastern Utah and northwestern Colorado.

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 51, 52, 151). *White Cliff group.*—Massive, obliquely laminated ss., often of beautiful white or golden color, sometimes red; in a few places rather heavily bedded sss. are found. Of lighter color than Vermilion Cliff group. Thickness 0 to 1,100 ft. Underlies Flaming Gorge group and overlies Vermilion Cliff group. Type loc., escarpment known as White Cliffs, in southern Utah, in Paria, Kanab, and Rio Virgen region [Kane Co.].

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 33), showed that the ss. of the White Cliffs of Kane Co., southern Utah, is Navajo ss. (Jurassic?); and (chart opp. p. 40) showed that the White Cliff ss. of Powell in eastern Uinta Mtns region, NE. Utah, is=(descending) Entrada ss. (Upper Jurassic), Carmel fm. (Upper Jurassic), and upper part of Navajo ss. (Jurassic?).

†White Cliffs chalk.

Upper Cretaceous (Gulf series): Southwestern Arkansas and northwestern Louisiana.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 72, 87–88, 188). *White Cliffs chalk.*—Purest-white chalk at bluffs of Little River, sec. 35, T. 11 S., R. 29 W. Thickness 135 to 150 ft. Underlies Brownstown marl [not Brownstown but Marlbrook marl] and overlies White Cliffs subchalk.

Preoccupied. Replaced by *Annona chalk*. Represents upper part of Annona chalk, and is all of Annona present at White Cliffs, according to 1925 and 1926 studies of L. W. Stephenson and C. H. Dane. Overlies Ozan fm. (See C. H. Dane, U. S. G. S. Press Bull. 8823, Sept. 10, 1926; L. W. Stephenson, A. A. P. G. Bull., vol. 11, No. 1, Jan. 1927; and C. H. Dane, Ark. Geol. Surv. Bull. 1, 1929.)

Named for exposures at White Cliffs of Little River, Little River Co., Ark.

†White Cliffs subchalk.

Upper Cretaceous (Gulf series): Southwestern Arkansas.

R. T. Hill, 1888 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 2, pp. 7, 88–89, 188). *White Cliffs subchalk.*—Highly fossiliferous impure chalk, composed of glauconite and aren. grains cemented by calc. matrix. Basal 60 ft. of White Cliffs of Little River. Lowest Upper Cret. horizon seen in Ark. Underlies White Cliffs chalk.

Included in Annona chalk.

White Cloud shale. (In Scranton shale.)

Pennsylvanian: Eastern Kansas and southeastern Nebraska.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 40, 41, 58). *White Cloud sh.* is here named from exposures W. of White Cloud, Kans., where it is 100± ft. thick. It underlies Rulo ls. and overlies Howard ls. The salmon-colored ls. in White Cloud sh., about 26 ft. below overlying Rulo ls., is here called *Happy Hollow ls.*, from exposures in bluffs at mouth of Happy Hollow Creek, located below mouth of Big Nemaha River. [On p. 40 a thickness of 1 ft. 9 in. is given for Happy Hollow ls.]

G. E. Condra, 1930 (Nebr. Geol. Surv. Bull. 3, p. 53). The Nebr. Geol. Survey now restricts *White Cloud sh.* to that part of Scranton sh. below Happy Hollow ls., and applies *Cedar Vale sh.* to beds above Happy Hollow ls. and below Rulo ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), dropped Scranton sh. and treated White Cloud as a fm. in his Wabaunsee group redefined.

White Cone series.

Tertiary or Pleistocene: Northeastern Arizona.

See 1932 entry under *Bidahochi fm.*

Whiteface anorthosite.

Pre-Cambrian: Northern New York (Essex County).

J. F. Kemp, 1898 (N. Y. State Mus. 52d Ann. Rept., vol. 1, pp. 51–63). *Whiteface type of anorthosite* forms summit of Mount Whiteface and southern portion of mtn. Contains large amounts of hornblende and pyroxene, together with milky-white feldspar. Assigned to pre-Camb. (?).

H. P. Cushing, 1899 (N. Y. State Geol. 18th Ann. Rept.). Kemp's *Whiteface type of anorthosite* is assigned to pre-Camb.

W. J. Miller, 1919 (N. Y. State Mus. Bull. 213, 214, p. 33). *Whiteface anorthosite* mapped. Is a more or less well-defined border development of the pre-Camb. anorthosite series and is finer-grained and of lighter color than Marcy anorthosite.

J. F. Kemp, 1921 (N. Y. State Mus. Bull. 229, 230, p. 33 and map). *Whiteface type of anorthosite* is characterized by white plagioclase. Assigned to pre-Camb. Algoman intrusives.

W. J. Miller, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 400–462). Around the borders of the great body of anorthosite, and in some places a number of miles within it, there is generally a notable increase in femic minerals, causing the rocks to be anorthosite-gabbro or even gabbro. Almost invariably medium-grained and therefore notably finer-grained than typical Marcy anorthosite, though at some places a few scattering labradorite individuals occur. A foliated structure is generally well developed. Although they are more or less variable in general appearance and composition, I here propose that these border phases of the anorthoclase be classed as *Whiteface anorthoclase*, a name given by Prof. Kemp to a type of anorthoclase which occurs abundantly on Mount Whiteface. The typical Marcy anorthosite is not so gabbroid, is very coarse-grained, light to dark bluish gray, and generally not well foliated. Both Whiteface and Marcy types are certainly differentiation phases of same cooling magma, the Whiteface doubtless representing a chilled border portion. The two types grade into each other. Intrusive into Grenville rocks.

G. H. Chadwick, 1930 (Geol. Soc. Am. Bull., vol. 41, p. 82). [See under *Adirondack anorthosyte*.]

Whitehall moraine.

Pleistocene (Wisconsin stage): Western Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Belongs to Port Huron morainic system. Named for Whitehall, Muskegon Co.

Whitehead granite.

Pre-Cambrian: Southwestern Colorado.

W. Cross and E. Howe, 1905 (U. S. G. S. Needle Mtns folio, No. 131). *Whitehead granite*.—Reddish pink biotite granite. Intrudes Archean schists but does not intrude the Algonkian rocks, and is therefore assumed to be older than Algonkian. Named for occurrence about mouth of Whitehead Gulch, this quad.

Was assigned to Algonkian by E. S. Larsen in U. S. G. S. Bull. 843, 1933. The terms "Algonkian system" and "Archean system" were discarded by U. S. Geol. Survey in 1934. For 1935 Colo. geol. map this fm. was included in Front Range granite group and assigned to pre-Camb.

Whitehead formation.

Upper Ordovician: Quebec (Percé).

C. Schuchert, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 161–170). *Whitehead or Cape Blanc fm.*—Younger than Cape Canon fm., which is probably a part of the younger series. Is 2,000 or more ft. thick and of Upper Ord. age.

Whitehorse sandstone.

Permian: Northwestern, southwestern, and central southern Oklahoma, and central southern Kansas.

C. N. Gould, 1905 (U. S. G. S. W. S. P. 148, p. 55). *Whitehorse ss. memb. of Woodward fm.*—[Introduced to replace preoccupied name "Red Bluff ss." Quotes Cragin's definition of "Red Bluff."] Extends from vicinity of Whitehorse Springs, Woods Co., Okla., SW. across the Cimarron to high divides beyond. Overlies Dog Creek sh. and underlies Day Creek dol.

R. W. Sawyer, 1924 (A. A. P. G. Bull., vol. 8, No. 3), proposed restricting *Whitehorse ss.* to upper part of the Whitehorse, and named lower part *Marlow fm.* This usage did not prevail, and in 1929 Sawyer named his restricted Whitehorse ss. the *Rush Springs memb. of Whitehorse*, and called the lower part the *Marlow memb.*

N. Evans, 1931 (A. A. P. G. Bull., vol. 15, No. 4), stated that Day Creek dol. overlies (instead of underlies) Cloud Chief gyp., and treated the Cloud Chief as a memb. of the Whitehorse. [These proposed innovations are still under investigation.]

Is middle fm. of Woodward group of Okla. In Kans. is in Cimarron group. The name has also been used by Tex. Geol. Surv. in Tex.

†White Iron granite.

Pre-Cambrian (Laurentian): Northeastern Minnesota (Vermilion district).

A. Winchell, 1888 (Minn. Geol. Nat. Hist. Surv. 16th Ann. Rept.). *White Iron granite* (Laurentian) occupies all shores of White Iron Lake except those of northern extremity, and is continuous with Saganaga granite.

†White Medina.

Name applied in some early repts to Albion ss. of N. Y. and to Tuscarora qtzite of Pa., Md., etc.

†White Mesa sandstone.

Jurassic (?): Northeastern Arizona.

H. F. Lunt, 1904 (Am. Inst. Min. Engrs. Trans., vol. 34, pp. 989–990). *White Mesa ss.*—White ss. which gives the name of "White Mesa" to that locality. Shows all phases of cross-bedding in great complexity. Prevailing color white or gray, but occasionally is red. Composed of well-worn grains of quartz sand, from which most of cementing material has been leached out, leaving it soft and friable; possibly the cement was ferruginous. Thickness 200 to 250 ft.

According to H. E. Gregory (U. S. G. S. P. P. 93, p. 141, 1917) the ss. described by Lunt is Navajo ss.

White Mountain series.

Pre-Cambrian (?) and later: Northern New Hampshire (White Mountains region).

C. H. Hitchcock, 1869 (1st Rept. on geol. and min. N. H.), in a rept on Ammonoosuc gold field, applied the term *gneissic or White Mtn series* to rocks older than those he termed *Quebec group*.

C. H. Hitchcock, 1870 (2d Rept. on geol. and min. N. H., map and pp. 31–32). *White Mtn or gneissic series.*—In our last rept this term was used to indicate the general mass of gneissic and granitic rocks of the State. It occupies four-fifths of State. Includes normal gneiss, ferruginous gneiss, granitic gneiss, feldspathic mica schist, andalusite gneiss, chiastolite slates, granite, sienite, porphyritic granite, qtzites, lss., and soapstones. Little doubt remains as to pre-Sil. age of this entire series. [On 1932 geol. map of U. S. most of rocks here mapped as *White Mtn series* are mapped as *pre-Camb.*, but Billings now questions any pre-Camb. in N. H.]

C. H. Hitchcock, 1871 (Geol. Surv. N. H. Rept. 1870). *White Mtn series.*—Gneissic rocks—various imperfect gneisses, verging into mica schists, a few beds of genuine gneiss, granitic gneiss, andalusite gneiss—and granite, both bedded and in veins. Has a great development in middle and southern parts of State, perhaps embracing everything not included in Exeter, Merrimack, and Coos groups. It uncon. underlies Coos group. It is not certain whether it is=Laurentian of Canada or Camb. of Great Britain as restricted by Govt. Survey.

C. H. Hitchcock, 1872 (Geol. Surv. N. H. Rept. for 1871). *White Mtn or andalusite gneiss* occupies great part of White Mtn area E. of Saco.

C. H. Hitchcock, 1874 (Geol. N. H., pt. 1, btw. pp. 508 and 545), called the rocks *Montalban or White Mtn series*.

C. H. Hitchcock, 1877 (Geol. N. H., pt. 2), changed *White Mtn series* to *Montalban group*, and included in it Franconia breccia, fibrolite schists with gigantic granite veins, ferruginous schists, Concord granite, and gneisses and feldspathic mica schists. In the 1878 Atlas of N. H. he did not use either *White Mtn series* or *Montalban group*, but in 1884 he used *Montalban* in different parts of N. H.

C. H. Hitchcock, 1884 (Am. Mus. Nat. Hist. Bull., vol. 1, No. 5, pp. 178–179, pls. 16 and 17). *Montalban* typical loc., as shown by the name, lies within our territory. It is same as my "White Mtn series," adopted as a matter of convenience. A different use of equiv. term *Montalban* was proposed by T. S. Hunt in 1871. It was applied to a somewhat similar series of schists overlying the Huronian and expressly stated to include Coos group and calciferous mica schists of our repts. In our belief he has included under this designation rocks of different age, one a system below the Huronian and the other a system above Huronian. We invariably employ the term in its original significance of pre-Huronian and post- or upper Laurentian, including the schists holding the coarse granite veins carrying merchantable mica.

C. H. Hitchcock in 1896 (Jour. Geol.) continued to use *Montalban* instead of *White Mtn series*, as did M. Billings (1928).

This term seems to be no longer used. On 1932 geol. map of U. S. the rocks of the White Mtns are mapped as pre-Camb. over large areas, but other large areas are mapped as Carbf. and Sil. intrusives. M. Billings (Sci., Jan. 19, 1934, pp. 55–56) now, however, doubts presence of any pre-Camb. rocks in N. H. See his *White Mtn magma series*, which he assigned to late Dev. or late Carbf.

White Mountain magma series.

Late Devonian or late Carboniferous: Central and northern New Hampshire.

M. Billings, 1934 (Sci., Jan. 19, vol. 79, No. 2038, pp. 55–56). [See under *Highland Croft magma series.*]

M. P. Billings and C. R. Williams, 1935 (Geology of Franconia quad., N. H., pp. 11, 21, map). *White Mtn magma series* includes a group of volcanic and intrusive igneous rocks with definite mineralogical peculiarities. Distinctly younger than New Hampshire magma series and abundant in Franconia, Crawford Notch, North Conway, Mount Chocorua, Percy, and Mount Washington quads., as well as Red Hill, Ossipee Mtns, and Belknap Mtns. Includes both intrusive and extrusive phases, the latter being called *Moat volcanics.* In Franconia quad. it includes, besides Moat volcanics, diorite, quartz diorite, syenite, Mount Lafayette granite porphyry, Mount Garfield porphyritic quartz syenite, and Mount Osceola and Conway granites, named in ascending order of age. Age is late Dev. or late Carbf.

M. Billings, 1935 (letter dated July 19). "There is no one type loc. for *White Mtn magma series.* It refers to a group of comagmatic igneous rocks that are exposed all over central and northern N. H. If there must be a type loc. it would be the North Conway quad."

M. P. Billings, 1935 (Geology of Littleton and Moosilauke quads., N. H., p. 28 and Moosilauke map). In Littleton and Moosilauke quads. the Landaff granite and certain dikes and sills are related to White Mtn magma series. [For fms. included see N. H. correlation chart.]

D. Modell, 1936 (Geol. Soc. Am. Bull., vol. 47, pp. 1895–1931). The chronology of *White Mtn magma series* in Belknap Mtns, N. H., is as follows (ascending): Moat volcanics, Gilford gabbro, Endicott diorite, Ames monzodiorite, Gilmanton monzodiorite, Belknap syenite, Sawyer quartz syenite, Lake quartz syenite, Albany quartz syenite, Conway granite, and Rowes vent-aggl.

Whitemud formation.

Upper Cretaceous: Saskatchewan.

N. B. Davis, 1918 (Canada Dept. Mines, Mines Branch, Rept. clay resources southern Saskatchewan, p. 9). Assigned to Eo. Included in Fort Union beds.

All subsequent repts, by several other authors, assign this fm. to Cret.

Whiteoak sandstone.

A name applied by E. O. Ulrich (12th Int. Geol. Cong., Canada, 1913, advance copy, pp. 16, 48, and chart, =pp. 614, 651, and chart of Compte rendu, 1914) to the ss. which he called *Whiteoak Mtn ss.* in description of map 7, on p. 666 of latter publication. On p. 614 he stated Whiteoak ss. of Tenn. corresponds to lower part of upper Medina of N. Y. On p. 651 he stated: "The post-Richmond hiatus in Ohio represents *White-oak ss.* (400 ft. thick) plus a part or all of the smaller hiatus which separates this ss. from underlying Sequatchie fm. (=Queenston of N. Y., Juniata of Pa., and Richmond of Ind. and Ohio)." His chart placed *Whiteoak ss.* opp. Albion of N. Y. and Tuscarora ss. of Pa.

White Oak sand.

Drillers' name for a sand, of Lower Ord. age, that outcrops on White Oak Creek, Estill Co., Ky

White Oak Mountain sandstone.

Silurian: Southeastern Tennessee and northwestern Georgia.

N. Sayler, 1866 (Geol. map of Tenn.). *Clinch and White Oak Mtn ss. and sh.*; 800 to 1,000 ft.; of Medina age. Underlies Dyestone and overlies Nashville group.

J. M. Safford, 1869 (Geol. Tenn., pp. 151, 161, 299–302). *White Oak Mtn ss.*—Variegated sss. with some sh. Thickness 500 ft. in Tenn.; at least 600 ft. in gap at Ringgold, Ga. The sss. are mostly fine-grained, thin- and even-bedded, sometimes thick-bedded, fossiliferous, generally reddish brown but also greenish gray, buff, and other colors; some layers highly ferruginous. Shales are reddish brown, pale green, and other colors, alternating in beds of various thicknesses with the sss. Not observed either E. or W. of belt including White Oak and its spurs. Underlies Dyestone group, and overlies Clinch Mtn ss. Included in Niagara group.

Included in Rockwood fm. of C. W. Hayes, in U. S. G. S. Ringgold folio, No. 2, 1894. Probably corresponds to Rockwood ss. memb. of Rockwood fm. of Ringgold folio, a name that has been discarded.

See also *Whiteoak ss.*

Named for White Oak Mtn, James and Bradley Counties, Tenn.

White Pine shale.

Mississippian (lower and middle): Northern Nevada and eastern California (Inyo County).

A. Hague, 1883 (U. S. G. S. 3d Ann. Rept., pp. 253, 266–267). *White Pine sh.*—Black argill. shales, more or less aren., with intercalations of red and reddish-brown friable ss., changing rapidly with locality. Plant impressions. Thickness 2,000 ft. Conformably overlies Nevada ls. and is overlain by Diamond Peak qtzite. Named for exposures in White Pine mining dist. [now known as Hamilton], White Pine Co., Nev.

This fm., with a thickness of 1,000 ft., has been identified by E. Kirk (U. S. G. S. P. P. 110, 1918) in Inyo Range of eastern Calif.

White Prairie d'Ane clay.

See under *Prairie d'Ane clay.*

White Ranch limestone. (In Graham formation.)

Pennsylvanian: Central Texas (McCulloch County).

F. M. Bullard and R. H. Cuyler, 1936 (Tex. Univ. Bull. 3501, pp. 197, 222). Varying from 35 to 45 ft. above base of Bluff Creek sh. memb. of Graham fm. is a persistent and distinctive impure reddish-brown ferruginous ls. 2 to 3½ ft. thick, that proved to be quite persistent and valuable in both geol. and structural mapping. It is here designated *White Ranch ls.*, after the White ranch, on which it is typically exposed along W. side of Bluff Creek. It is separated from overlying Bunger ls. memb. of Graham fm. by a sh. bed, 15 to 20 ft. thick, of same general character as sh. bed underlying White Ranch ls. [to which they, in detailed section on p. 222, restrict the name *Bluff Creek sh.*, but on other pages they designate the sh. separating Bunger ls. from the younger Gunsight ls. as *Upper Bluff Creek sh.*, and the sh. underlying White Ranch ls. as *Lower Bluff Creek sh.*]

White Raven quartz monzonite.

Eocene: Central northern Colorado (Boulder County).

P. G. Worcester, 1921 (Colo. Geol. Surv. Bull. 21, pp. 33–34). There are 22 dikes of this rock (*White Raven quartz monzonite porphyry*) in Ward region, nearly all of them btw. Sunset and Sunnyside and northward, in a belt less than 2 mi. wide, to Ward. Named for White Raven mine.

White Ridge limestone member.

Middle Devonian: Northwestern Montana.

C. F. Deiss, 1933 (Mont. Bur. Mines and Geol. Mem. 6, pp. 42 and passim). *White Ridge ls. memb.*—Basal memb. of Jefferson ls. Rests uncon. on Devils Glen dol. (Camb.) and underlies Glenn Creek sh. memb. of Jefferson ls. Thickest (150 ft.) on Gordon Mtn; thinnest (50 ft.) on Spotted Mtn. Has no one distinguishing characteristic, but varies considerably in composition at different places, being buff shaly aren. ls. on Pentagon Mtn, Monitor Mtn, and Wall Creek-Juliet Creek Ridge; changing until it is massive white-gray sandy siliceous ls. on Nannie Basin Ridge, Gordon Mtn, and Spotted Bear Mtn. Named for White Ridge. Forms lower part of slope above saddle on S. side of peak forming W. end of White Ridge, in S½ sec. 16, T. 22 N., R. 11 W. On White Ridge it is 63 ft. thick and consists of 39 ft. of massive brown thin-bedded argill. fine-grained ls. that weathers to shaly light gray-buff fragments; underlain by 24 ft. of thin-bedded steel-gray calc. ss. that weathers drab, gray-buff.

White Rim sandstone member (of Cutler formation).

Permian: Southeastern Utah.

A. A. Baker and J. B. Reeside, Jr., 1929 (A. A. P. G. Bull., vol. 13, No. 11, pp. 1444 and 1445, also 1423, 1425, 1436, 1446). *White Rim ss. memb. of Cutler fm.*—White ss., 0 to 100± ft. thick, at top of Cutler fm. in Moab region and adjacent areas of SE. Utah. Exposed in escarpment, btw. Green and Colorado Rivers, known as the White Rim. In earlier repts called De Chelly (?) ss.

White River group (also **White River formation**).

Oligocene (upper, middle, and lower): Wyoming, North Dakota, South Dakota, eastern Montana, Nebraska, northeastern Colorado.

F. B. Meek and F. V. Hayden, 1858 (Phila. Acad. Nat. Sci. Proc. 1857, vol. 9, pp. 119, 133). *White River* (Mio.) deposits in places crown summits of hills on E. side of the Missouri near mouth of White River. The *Titanotherium* bed of White River Basin is oldest memb. We have no evidence that any Tert. deposits now known in Nebr. are older than Mio.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc., vol. 13, pp. 433, 434). *White River group.*—White and light-drab clays with some ss. beds and local layers of ls. Thickness 1,000+ ft. Fossils contain no brackish-water or marine forms. Occurs on Bad Lands of White River, on Niobrara, and across the country to the Platte. Overlies Fort Union group on North Platte River above Fort Laramie. [No Fort Union fm. is now recognized in vicinity of Fort Laramie, Goshen Co., Wyo. To E. of Fort Laramie the White River group rests on Lance fm., but to NW., in parts of Converse and Niobrara Counties, Wyo., the Fort Union fm. underlies the White River.] Underlies Loup Fork beds (Plio.).

F. B. Meek, 1876 (U. S. Geol. and Geog. Surv. Terr. Mon. 9, pp. lxi–lxiv). *White River group.*—Most interesting fm. because of great numbers and fine state of preservation of mammalian and chelonian remains. No marine or brackish-water remains have been found in it. It is evidently an extensive fresh-water lacustrine deposit. Spreads out over extensive space S. of Black Hills in Nebr. and extends into Colo., NW. corner of Kans., narrowing rapidly southward after passing into those States. Overlies Fort Union group uncon. and underlies Plio. lake deposit on Loup River and at other places in Nebr., the latter filling depressions in White River group.

In many areas is treated as a *group*, divided into Brule clay (above) and Chadron ss. (below). Where not divided is called *White River fm.*

†White River limestone.

Lower Ordovician: Southwestern Missouri.

A. Winslow, 1894 (Mo. Geol. Surv. vol. 6, pp. 331, 338–340). *White River ls.*—Mag. lss. and interbedded sss., 375 or more ft. thick, comprising all of Ozark series in SW. Mo. Overlain uncon. by Lower Carbf.

The 1926 geol. map of Mo. shows that the rocks along White River in southern Mo. consist of Jefferson City, Cotter, and Powell.

Named for White River, SW. Mo.

†White River limestone.

A name applied in some early Ind. repts to Spergen ls. (Mississippian), which has been quarried on White River and sold under trade name of "White River stone."

Whiterock quartzite.

Cambrian or pre-Cambrian: Nova Scotia.

E. R. Faribault, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 336).

White Rock moraine.

Pleistocene (Wisconsin stage): Northeastern Illinois. See M. M. Leighton, 1932 (16th Int. Geol. Cong. Guidebook 26, p. 48, pl. 2).

Whiterock Bluff shale member (of Santa Margarita formation).

Miocene (upper): Southern California (Cuyama Valley).

W. A. English, 1916 (U. S. G. S. Bull. 621, pp. 191–215). *Whiterock Bluff sh. memb.*—Middle memb. of Santa Margarita fm. Conformably overlies Redrock

Canyon ss. memb. of Santa Margarita fm. and is uncon. overlain by Morales memb. of Santa Margarita. Near Whiterock Bluff, on N. side of Cuyama Valley, it consists of not less than 1,500 ft. of white "chalky" diatomaceous sh., which rests (uncon., it is believed) on Monterey group. On S. side of Cuyama Valley it consists of interbedded white clay sh., diatomaceous sh., and ss., and apparently grades into underlying ss. and sh. beds mapped as *Maricopa sh.*, the line of separation being drawn at lowest horizon at which Santa Margarita echinoderms occur. Three zones of white ss. and two zones of sh. are present, aggregating 2,000 to 2,500 ft., of which about one third is sh.

White Sage formation.

Tertiary (Eocene?): Western Utah (Gold Hill district).

T. B. Nolan, 1935 (U. S. G. S. P. P. 177). *White Sage fm.*—Fresh-water, rather impure, very fine-grained lss., generally brownish, with basal cgl., 1 to 50 ft. thick, containing pebbles of Penn. and Perm. rocks. Is everywhere uncon. overlain by lava or recent gravels. Occurs only in NW. part of Gold Hill quad. Rests on Triassic, Perm., and Penn. rocks. Few fossils; of probable Eo. age. May correspond to Wasatch or Green River fm. to E., both of which are said by Reeside to contain identical lss. Named for White Sage Flat (Gold Hill quad.), which is just W. of most southerly outcrops of the fm.

Whites Bend limestone.

Silurian (Niagaran): Western Tennessee.

A. F. Foerste, 1901 (Geol. Soc. Am. Bull., vol. 12, pp. 397, 402). *Whites Bend ls.*—Overlies South Tunnel bed (Osgood shaly clay) and underlies Newsom (Waldron) shaly clay in Tenn. Same as Laurel ls. of Ind. Included in Clifton ls. and also in Centerville ls. Thickness 0 to 24½ ft.

Named for Whites Bend, Davidson Co.

Whitesburg limestone. (In Blount group.)

Lower Ordovician (Chazy): Northeastern Tennessee and western Virginia.

E. O. Ulrich, 1924 (Tenn. Dept. Ed., Div. Geol., Bull. 28, p. 34, and Bull. 31, p. 16). [*Whitesburg ls.* shown in table as 50 to 600 ft. thick, underlying Athens sh., and uncon. overlying Lenoir ls. in Athens trough of Tenn., and as younger than Holston marble. Type loc. not stated.]

E. O. Ulrich, 1930 (U. S. Nat. Mus. Proc., vol. 76, art. 21, p. 2). The term *Whitesburg ls.* has been used by me for many years and is now formally proposed for the dark crystalline ls. that at many places in Appalachian Valley S. of Staunton, Va., underlies the dark calc. Athens sh. or ls. At most places it rests on Lenoir ls., but at Lexington and in the belt that runs along W. base of Walker Mtn just E. of Bland, Va., the Holston marble lies btw. the Whitesburg and the Lenoir. Type loc. is at and particularly 2 mi. SE. of Whitesburg [Hamblen Co.], Tenn., and 1½ mi. SW. of Bulls Gap, Tenn. At latter place it is 500± ft. thick and rests on Lenoir. NW. of Whitesburg the fm. pinches out completely in 2 mi. Its fauna (distinctive) aggregates about 100 sp.

Whiteside granite.

Late Carboniferous (?): Northwestern South Carolina and western North Carolina.

A. Keith, 1907 (U. S. G. S. Pisgah folio, No. 147, p. 4). *Whiteside granite.*—Composed mainly of orthoclase and plagioclase feldspar, quartz, muscovite, and biotite, enumerated in order of importance. Mostly of fine or medium grain. One variety is marked by a decided flow banding. Intrusive into all rocks in which it comes in contact except Triassic diabase.

Named for development in cliffs of Whiteside Mtn, Jackson Co., N. C., in Cowee quad.

White Spot sandstone.

Lower Cambrian: Southeastern Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, pp. 165, 166). *White Spot ss.*, at Reading. Same as Chiques ss. At the White Spot on mtn behind Reading it has been famous since early settlement of Great Valley.

Whitetail conglomerate.

Tertiary: Central Arizona (Globe region).

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Whitetail fm.*—Fluviatile deposit, usually composed of rather angular fragments of diabase and ls. Older than Gila cgl. and younger than Globe ls.

Named for exposures in Whitetail Gulch and Whitetail Spring, Globe quad.

†White Wall sandstone.

Jurassic (?): Southeastern Utah (San Juan County).

B. S. Butler, 1920 (U. S. G. S. P. P. 111, p. 619). In Abajo (Blue) Mtns, San Juan Co., Utah, M. R. Thorpe has described (unpublished ms.) the *White Wall ss.*, 300 to 400 ft. thick, as underlying McElmo fm. and overlying 75 to 100 ft. of shales and sss. which separate it from Vermilion Cliff ss.

A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, chart opp. p. 36), show this ss. to be Navajo ss.

Whitewater formation. (In Richmond group.)

Upper Ordovician: Southeastern Indiana and southwestern Ohio.

J. M. Nickles, 1903 (Am. Geol., vol. 32, pp. 208, 218). *Whitewater or Homotrypa wortheni beds.*—Thin-bedded ls. and sh., usually brownish or yellowish but at some localities bluish, presenting roughish concretionary, nodular appearance. Thickness 45 to 50 ft. Underlain by Liberty or *Strophomena planumbona* beds and overlain by Madison [Saluda] fm., all included in Richmond group.

Some more recent repts describe *Saluda* as a wedge in lower part of Whitewater fm. (see *Saluda ls.*), and define *Whitewater* as resting on Liberty fm., but most geologists, including U. S. Geol. Survey, still treat the Saluda deposits as a distinct fm.

J. J. Wolford, 1930 (Ohio Jour. Sci., vol. 30, No. 5, p. 304). Base of Turkey Track ls. layer has been designated by Dr. Geo. M. Austin as plane of division btw. Whitewater and Liberty fms. in SW. Ohio.

Named for Whitewater River, at Richmond, Ind.

Whitewater series.

Pre-Cambrian (Huronian): Ontario.

W. H. Collins, 1913 (12th Int. Geol. Cong., Canada, advance copy, pp. 5, 7).

Whitewater Creek rhyolite.

Tertiary: Mogollon district, New Mexico.

H. G. Ferguson, 1927 (U. S. G. S. Bull. 787). Light purple; breaks with platy fracture. Several flows and beds of white tuff mark periods of explosive activity. Thickness 700± ft. Oldest fm. in dist.

Named for exposures in steep canyons along lower reaches of Whitewater and Mineral Creeks, Mogollon dist.

Whitewood limestone.

Upper Ordovician (pre-Richmond): Western South Dakota and northeastern Wyoming.

N. H. Darton, 1904 (Geol. Soc. Am. Bull., vol. 15, p. 383). *Whitewood ls.*—Massive buff ls., 0 to 80 ft. thick, of Ord. age, underlying Englewood ls. and overlying Deadwood fm. in Black Hills uplift.

Named for exposures in Whitewood Canyon, below Deadwood, S. Dak. See 1936 entry under *Deadwood fm.*, for suggested redefinition.

Whitian series.

A term used by C. [R.] Keyes instead of *White River group* of other geologists.

Whiting sand.

A subsurface sand, of Penn. age, in central northern Okla., which is correlated with Cleveland sand and with part of Nowata sh.

Whitingham schist.

Upper Cambrian (?): Southeastern Vermont (Windham County).

Geo. D. Hubbard, 1924 (14th Rept. Vt. State Geol., pp. 276–278 and map). *Whitingham schist.*—Quartz-biotite schist with calcite; nearly half the rock is quartz in small even grains, and nearly half is even-grained biotite. Calcite occurs in crystals in many parts of the rock. Is believed to be of sed. origin. Thickness 40 to more than 100 ft. Immediately overlies Sherman marble, with gradation from the marble to the schist through several ft. of rock. Underlies Heartwellville schist, into which it passes through a transition zone 5 to 20 ft. thick. Assigned to Ord. through correlation of associated fms. with those of Mass.

Named for exposures in Whitingham Twp. Windham Co.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned this fm. to Upper Camb., but without discussion.

Whitlash sands.

Three sands called *Whitlash* have been recognized in Blackleaf sandy memb. of Colorado sh. in Whitlash dome, central northern Mont., as follows: (1) *First Whitlash sand* (10 to 40 ft. thick), lying 430 ft. below top of the Blackleaf; (2) *Second Whitlash sand* (5 to 40 ft. thick), lying 220± ft. lower; and (3) *Third Whitlash sand* (0 to 35 ft. thick), lying 100± ft. lower.

Whitmores Ferry amphibolite.

Name applied by B. K. Emerson (U. S. G. S. Mon. 29, 1898, pp. 190, 194) to a bed of dark amphibolite that crops out in midst of Triassic shales at Whitmores Ferry, in North Sunderland, Old Hampshire Co., Mass.

Whitney sand.

A subsurface sand, of Perm. age and 10 ft. thick, in central northern Okla. In Garber pool, Garfield Co., it is reported to lie at 800 ft. depth, the Kisner sand at 700 ft., and the Hoy sand at 1,100 ft.

Whitsett limestone lentils (in Myrtle formation).

Lower Cretaceous: Southwestern Oregon (Roseburg quadrangle).

J. S. Diller, 1898 (U. S. G. S. Roseburg folio, No. 49). *Whitsett ls. lentils.*—Variegated gray and red foraminiferal ls. and marble interbedded in Myrtle fm. One of lentils, 60 ft. thick, occurs near J. H. Whitsett's, secs. 14 and 15, T. 28 S., R. 5 W.

†Whitsett beds.

Oligocene (?) and Eocene: Southwestern Texas coastal plain.

E. T. Dumble, 1924 (A. A. P. G. Bull., vol. 8, pp. 424–436). *Whitsett beds.*—Greenish-gray and yellow waxy or carbonaceous clays and sandy clays, with some of chocolate color, interbedded with yellow, gray, pink, and brown sands; beds of volcanic ash occur. The fm. is characterized by opalized wood and chalcedony; aragonite is common; dark septarial concretions occur throughout. Uncon. underlie Frio group and uncon. overlie and overlap true Fayette ss., but were included in Fayette ss. as defined by writer. [These beds were included in Frio clay as mapped by A. Deussen in U. S. G. S. P. P. 126.]

Exposed S. of town of Whitsett, Live Oak Co., southern Tex., but town is built on Fayette ss.

This name was in 1929 discarded by U. S. Geol. Survey for its publications, the upper part having been included in Frio clay as mapped by Deussen in U. S. G. S. P. P. 126, and the lower part being the upper part of Fayette ss. (See J. Gardner and A. C. Trowbridge, A. A. P. G. Bull., vol. 15, 1931, No. 4, p. 470.)

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 680, 685, 686–687, 694, 695, 696). *Whitsett memb.*—Upper memb. of Fayette fm. (Jackson Eocene). Definitely limited at base by top of McElroy or Lipan memb. of Fayette and overlain by

Frio or Catahoula fms. [He restricted McElroy memb. to eastern Tex. and Lipan memb. to central and southern Tex.]

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, pp. 1310+). *Whitsett fm.*—Upper third of Jackson group. Includes all beds from top of Manning beds of McElroy fm. to base of Frio; therefore it includes Lipan beds and overlying Whitsett beds of Dumble. Unfortunately Dumble did not give type loc. for his Whitsett beds. The section he described in 1902, in bluff 90 ft. high on E. bank of Atascosa River, near Whitsett's house in sec. 48, Reiffert & Forbese 109-acre tract of Juan Houligan survey, is included within Whitsett fm. (in Dubose zone) as is here used, and is selected by writer for type loc. of Whitsett fm. The fm. varies in lithologic character across the State, and can be divided on the surface into lithologic as well as paleontologic zones. In SW. Tex. these zones have been named (descending): Olmos sand, Fashing clays, Calliham sand, Dubose sands and sh., Stone's Switch sand, Falls City sh., and Dilworth sand. In E. Tex. the zones below Calliham sand have been named *Glendale beds, Mitchell's Ferry beds,* and *Dilworth sand.* Jackson group of southern Tex. is here divided into (descending) Whitsett fm., McElroy fm., and Cadell fm., which are=Fayette fm. of U. S. Geol. Survey.

A. Deussen, 1934. [See Deussen 1934 entry under *Fayette ss.*]

A. Deussen and E. W. K. Andrau, 1936. [See 1936 entry under *Fayette ss.*]

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17 and pp. 43–55), restricted *Whitsett fm.* to beds above his expanded Manning fm. and below Catahoula ss., and defined it as consisting of 75 to 132 ft. of cross-bedded sand and ss. interbedded with some tuffaceous sh. and containing opalized logs and fossil leaves. In Brazos Co. contains fine sandy tuff beds. Is mostly nonmarine but contains a few marine lentils in Fayette and Gonzales Counties. His restricted Whitsett fm. is placed 0 to 25 ft. above his Yuma ss., which he states may possibly be same as Dilworth sand of Ellisor, but which he places 25 to 40 ft. above the Dilworth. Ellisor treated Dilworth sand as basal memb. of Whitsett.

A. C. Ellisor, 1936 (Gulf coast oil fields, A. A. P. G., pp. 475, 487), continued to apply *Whitsett fm.* to all beds from base of Dilworth sand up to base of the Vicksburg, and divided it into (descending) Olmos sand, Fashing clays, Calliham sand, Dubose sands and clays, Stone's Switch sand, Falls City shales, and Dilworth sand.

Whittlesey.

Name applied to a glacial lake, of Pleist. age, in Great Lakes region. (See U. S. G. S. Mon. 53, 1915, p. 469.)

Whitwell shale. (In Lee group.)

Pennsylvanian (lower Pottsville): Central Tennessee.

C. Butts and W. A. Nelson, 1925 (Tenn. Geol. Surv. Bull. 33D, pl. 4 and p. 7). *Whitwell sh.*—Dark-colored sh., partly clayey and partly sandy, containing some thin ss. layers, and two, possibly three, coal beds, including Sewanee coal at base. Thickness 75 to 100 ft. Overlies Sewanee cgl. Underlies Bonair ss. Named for Whitwell mines near Whitwell, Marion Co., where the main Sewanee coal has long been mined.

W. A. Nelson (Tenn. Geol. Surv. Bull. 33A, pp. 48, 49, 1925) gave thickness of 50 to 175 ft., and on p. 25 of Bull. 33C a thickness of 0 to 70 ft. in Herbert Domain.

†Whyte formation.

Lower Cambrian: Alberta.

C. D. Walcott, 1908 (Canadian Alpine Jour., vol. 1, pp. 240–242). Lower Camb. of Mount Stephen divided into *Whyte fm.* (above) and St. Piran fm. (below). The Whyte fm. consists of (descending): (1) Thin-bedded bluish-black and gray fossiliferous ls., 3 ft.; (2) gray siliceous sh. with interbedded gray fossiliferous ls. in layers 5 in. to 2 ft. thick in upper part, 108 ft.; (3) thin-bedded compact, hard dark bluish-gray ls. with a little interbedded gray siliceous sh. and a few beds of coarser gray ls., 6 to 10 in. thick, 52 ft.; (4) brownish-gray qtzitic ss. in layers 2 to 4 in. thick, 32 ft.; (5) gray siliceous sh., 102 ft.; (6) bluish-black and gray ls., 18 ft. [Fossils from all members listed.] Underlies Cathedral fm. (Middle Camb.). [Derivation of name not indicated.]

C. D. Walcott, 1908 (Smithsonian Misc. Coll., vol. 53, No. 1804), applied *Mount Whyte fm.* to the Lower Camb. fm. underlying Cathedral fm. in Alberta and B. C., which is the name in current use.

Wichita formation (also **Wichita group**).

Permian (early): Northern and central Texas and western Oklahoma.

E. T. Dumble and W. F. Cummins, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. lxix and 188). *Wichita beds.*—Fossiliferous red, gray, and variegated massive and shaly sss. and sandy shales, red and bluish clays, and a peculiar cgl., the sss. and sandy shales often containing large oval concretions, the sss. often ripple-marked and in places cross-bedded. Underlie Clear Fork beds and overlie Coleman-Albany series of the Coal Measures. [Misinterpretation. See below.]

W. F. Cummins, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 361, 373, 400–402). Permian of NW. Tex. divided into (descending) Double Mtn beds, Clear Fork beds, and *Wichita beds*. The Wichita consists of sss., clay beds, and a peculiar cgl. There are no lss. from top to bottom. The sss. are of various colors; the clays are red and bluish. Iron concretions occur in the red clays. The cgl. is composed of clay, or clay ironstone, in a ferruginous matrix. The Wichita beds do not extend S. of Brazos River. They are heaviest along Big Wichita River, where they attain thickness of 2,000± ft. [In table on p. 361 the Wichita is shown as resting on "Albany beds," and the "Albany" is excluded from Perm. In table on p. 373 the Wichita of northern field (1,800 ft. thick) is shown as contemp. with "Albany beds" of central field (1,180 ft. thick), and the "Albany" is included in Perm.] "The Albany beds not occurring N. of Brazos River, the Wichita beds rest directly upon and are conformable with Cisco beds."

W. F. Cummins, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, btw. pp. 222–232), stated that Wichita "may be a different phase of the Albany."

E. T. Dumble, 1897 (Tex. Acad. Sci. Trans., vol. 2, pp. 93–98). "Wichita and Albany are simply different facies of the same beds," and they rest on Cisco fm. [This is present generally accepted opinion, and "Albany" has been discarded by U. S. Geol. Survey. In Okla. the Wichita rests on Pontotoc group.]

Some geologists include Arroyo fm. of Beede and Waite in Clear Fork group, but Beede, Waite, and Wrather include it in Wichita group. The U. S. Geol. Survey includes it in Clear Fork group. E. H. Sellards, 1933 (Univ. Tex. Bull. 3232) transferred Putnam and Moran fms. from Cisco group (Penn.) to overlying Wichita group, and this transfer has been adopted by U. S. Geol. Survey.

Named for Wichita River and Wichita Co., Tex.

†Wichita conglomerate. (In Clear Fork formation.)

Permian: Central northern Texas.

E. C. Case, 1907 (Am. Mus. Nat. Hist. Bull. 23, pp. 662–664). *Wichita cgl.*—Hard pebbly cgl., 6 in. to 1 ft. thick, nonfossiliferous, varying in color from dark to light but through most of its extent is of deep purplish-red color. Underlies massive ss., in places 100 ft. thick, of red and brilliant shades of orange, yellow, and blue colors. Overlies 20 to 30 ft. of gray and red clay filled with concretions. Included near top of Clear Fork div. of Big Wichita River region.

Named for Big Wichita River, near Seymour-Vernon road, Baylor Co.

Wichitan series.

A provincial series term applied by C. [R.] Keyes to late Carbf. rocks of Tex. region that correspond to his Oklahoman series. (See Pan-Am. Geol., vol. 49, pp. 130, 133, 1928.) In 1932 (Pan-Am. Geol., vol. 57, p. 355) he showed *Wichitan* as younger than his Oklahoman, and as covering Wichita fm. only.

Wickcliff sandstone. (In Chester group.)

Mississippian: Southern Indiana and western central Kentucky.

C. A. Malott, 1925 (Ind. Acad. Sci. Proc., vol. 34, pp. 108–132). *Wickcliff ss.*—A ss., ranging in thickness from a few ft. to max. of 35 or 40 ft., that occurs in the shales above Tar Springs ss. and below Siberia ls. in Perry and Crawford Counties, Ind., also at Buffalo Wallow, Breckinridge Co., Ky. It is usually bedded and very hard or qtzitic where its thickness is but a few ft.; where its thickness exceeds 10 or 15 ft. it is usually quite massive and often laminated or cross-bedded. Well developed along Middle Fork of Anderson Creek above Bristow to Doolittle, in Perry Co · also along Anderson Creek northward from mouth of

Sigler Creek and N. of Southern Railway and S. of Patoka River. Probably does not extend beyond Patoka River. Top lies about 35 ft. below Siberia ls., and base is separated from underlying Tar Springs ss. by sh., usually 50 to 60 ft. thick but varying in thickness from 20 to over 100 ft. Belongs to upper Chester.

Named for good exposures in ravines about Wickcliff, Crawford Co., Ind.

†Wicker formation.

Pliocene: Florida.

H. F. Osborn, 1907 (Am. Mus. Nat Hist. Bull., vol. 23, pl. opp. p. 249). [Evidently a misprint for Archer fm., because on p. 251 author uses *Archer fm.* for Plio. of Fla. Latter name is now replaced by *Alachua fm.*, the older term.]

Wickett oolitic zone.

A subsurface oil-producing zone in upper part of Trinity group (of Comanche age) of Bellevue dist., Bossier Parish, La., and Pine Island dist., Caddo Parish, La. Lies higher than Dillon oolitic zone.

Wicomico formation. (Of Columbia group.)

Pleistocene: Atlantic Coastal Plain from Delaware to Florida.

G. B. Shattuck, 1901 (Johns Hopkins Univ. Circ., vol. 20, No. 152, pp. 73–75). *Wicomico fm.*—What has just been said regarding the materials which enter into underlying Sunderland fm. applies equally well to those comprising Wicomico terrace, except that it possesses perhaps a larger proportion of sand and loam derived from its subterrane. In southern Md. the base of Wicomico terrace lies at about 40 or 50 ft., and the top, where it borders its ancient sea cliff, at about 90 ft. Wicomico River, in St. Marys and Charles Counties, suggested the name for this fm. Separated from underlying Sunderland fm. and from overlying Talbot fm. by erosion uncon. Is middle fm. of Columbia group.

G. B. Shattuck, 1902 (Md. Geol. Surv. Cecil Co. Rept., pp. 171+). *Wicomico fm.*—Clays, loam, sands, and gravels, 0 to 70± ft. thick. Terrace and off-shore deposits. Older than Talbot fm., which extends from tide to 30 or 40 ft., and younger than Sunderland fm. Occupies entire surface of Eastern Shore of Md. above 35 or 40 ft., and is developed as a terrace, usually a mile or more wide. Its limits are btw. 90 and 100 ft. and 30 and 40 ft.

C. W. Cooke, 1931 (Wash. Acad. Sci. Jour., vol. 21, Dec. 19), restricted Talbot fm. to deposits on 40-foot level (Talbot terrace), restricted *Wicomico fm.* to deposits on 100-foot level (Wicomico terrace), and recognized as a distinct fm. the deposits on 70-foot level (Penholoway terrace). The deposits on 70-foot level were not then given a distinct fm. name, but are now known as *Penholoway fm.* They have heretofore been included in Wicomico fm. to N. and in †Chowan fm. to S. These rstricted definitions have been adopted by U. S. Geol. Survey.

The terrace fms. of the Columbia group (including the Wicomico) now recognized by Cooke from Del. to southern Ga. and probably into Fla., are enumerated herein under *Columbia group.*

Widder beds.

Devonian: Ontario.

C. R. Stauffer, 1915 (Canada Geol. Surv. Mem. 34, p. 10).

Wier sand.

See *Weir sand*, the correct spelling of this subsurface sand.

Wigdon sand.

A subsurface sand, of Penn. age, in Henryetta dist., central eastern Okla., lying lower than so-called Calvin sand and higher than Oswego lime.

Wigwam formation.

Pre-Cambrian: Southern British Columbia and northwestern Montana (Galton Range).

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines, Mem. 38, maps 2, 3, 4). *Wigwam fm.*—Thin- to thick-bedded red ss. and metargillite. [Wigwam River is on map 2, and the fm. appears to be exposed on it.]

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 103, 178). Chiefly red or brownish-red sss. and metargillite, 1,200 ft. thick. Conformably underlies Siyeh fm. and overlies MacDonald fm. Named for river.

Wilbarger Creek bed. (In Strawn formation.)

Pennsylvanian: Central Texas.

N. F. Drake, 1893 (Tex. Geol. Surv. 4th Ann. Rept., pt. 1, pp. 374, 384). *Wilbarger Creek bed.*—Ss., 75 to 200 ft. thick, in places very massive. Memb. of Strawn div. Underlies Comanche Creek bed and overlies Buffalo Creek bed.

Named for Wilbarger Creek, San Saba Co.

Wilberns formation.

Upper Cambrian: Central Texas.

S. Paige, 1911 (U. S. G. S. Bull. 450, p. 23). *Wilberns fm.*—Lss. and shales, the shales occupying approx. upper third of fm., 170 to 220 ft. thick. Overlies Cap Mtn fm. and underlies Ellenburger ls. without any detected uncon.

S. Paige, 1912 (U. S. G. S. Llano-Burnet folio, No. 183). [Same definition as above. For faunal subdivisions of Wilberns fm. and Ellenburger ls. and for inconstant bdy btw. the two fms. as mapped, see C. L. Dake and J. Bridge, Geol. Soc. Am. Bull., vol. 43, pp. 725–748, 1932.]

Named for Wilberns Glen, Llano Co.

†Wilbraham gneiss.

Late Carboniferous or post-Carboniferous: Southern central Massachusetts.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, p. 116), stated that Glastonbury granite gneiss of Conn. extends into Mass. and is = *Wilbraham gneiss of Emerson.* B. K. Emerson stated (letter dated Oct. 1, 1914) he never published *Wilbraham.* Gregory is of opinion he took the name from Emerson's notebooks. Emerson (U. S. G. S. Bull. 597, 1917) mapped the extension of Glastonbury granite gneiss in Mass., across Wilbraham Twp, as *Monson granodiorite.*

Wilbur tuff lentils.

Eocene: Southwestern Oregon (Roseburg quadrangle).

J. S. Diller, 1898 (U. S. G. S. Roseburg folio, No. 49). *Wilbur tuff lentils.*—Chiefly volcanic material with some calc., siliceous, and organic sediments, interstratified with Umpqua fm. Of small thickness and extent. Occurs in patches. Been traced from 2 mi. W. of Wilbur to Calapooya, a distance of 13± mi.

R. Arnold and H. Hannibal, 1913 (Am. Phil. Soc. Proc., vol. 52). *Wilbur tuff* is a lithologic phase of the Arago.

Wilbur limestone member (of Salina formation).

Silurian: Eastern New York.

J. M. Clarke, 1903 (N. Y. State Mus. Bull. 69, pp. 855–867). *Wilbur ls.* is not = typical or Schoharie Co. Cobleskill, but its fauna carries a much stronger impress of Niagaran age. We are compelled, for purposes of correlation E. and W., to designate this bed by a distinctive term and shall call it *Wilbur ls.* Underlies waterlimes of considerable thickness [in Hdb. 19, 1903, Clarke called these *Salina waterlime*], and overlies soft gray Salina shales. [On a later page of Bull. 69 C. A. Hartnagel gave thickness of *Wilbur ls.* as 8 ft., and stated that it has also been erroneously called "Coralline ls." In that bull. it was described as dark argill. ls.]

C. A. Hartnagel, 1905 (N. Y. State Mus. Bull. 80, pp. 342–357). *Wilbur ls.*, fossiliferous band of shaly ls., underlying Rosendale cement and overlying Binnewater qtzites, all of which are included in *Salina beds.*

In 1913 (Md. Geol. Surv. Lower Dev. vol.) C. K. Swartz, C. Schuchert, and C. S. Prosser classified *Wilbur ls.* as Lower Dev.; but present N. Y. State Geol. Survey includes it in Salina (Sil.). (See W. Goldring, N. Y. State Mus. Hdb. 10, p. 343.)

Named for exposures at Wilbur, Ulster Co.

See also under *Bertie ls. memb.*

Wilbur zone.

A petroliferous zone, about 200 ft. thick, lying 1,000 ft. below top of Fernando group in Long Beach field, Los Angeles Basin, Calif.

Wilburton group.

Pennsylvanian: Kansas and Oklahoma.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). Des Moines series is divided into 2 uncon. groups, Okmulgee group (above) and *Wilburton group* (below). Latter includes McAlester fm., Hartshorne ss., and Atoka fm. and equiv. rocks in Kans., Mo., and Nebr. [Derivation of name not stated. Not used in 1932 or later classifications of R. C. Moore up to and including Kans. Geol. Surv. Bull. 22, Aug. 31, 1936.]

Wilcox group.

Eocene (lower): Gulf Coastal Plain from Georgia to southern Texas, inclusive, also southeastern Missouri, western Tennessee and Kentucky, and southwestern Illinois.

The term *Wilcox*, as the geographic name to replace the nongeographic term "Lignitic" in its typical region (Ala. and Miss.), was formally adopted by U. S. Geol. Survey March 23, 1905, in connection with repts then in preparation on geology and underground water resources of Miss. (under supervision of E. C. Eckel) and Ala. (by E. A. Smith). This name was selected after correspondence (by E. C. Eckel) with the State Geologist of Ala. (E. A. Smith), and type loc. was specifically stated in the records to be Wilcox Co., Ala., "which affords good exposures of the entire 'Lignitic' section." At the time the name *Wilcox* was adopted the Survey also had in course of preparation (by A. C. Veatch) a rept (U. S. G. S. P. P. 46) on geology and underground water resources of La. and northern Ark., and it was decided that if the author of that rept was unwilling to correlate the †Lignitic of that area with the typical †Lignitic of Ala., the name *Sabine* would be acceptable W. of Miss. River. On April 2, 1906, the mss. for U. S. G. S. W. S. P. 159 (underground water resources of Miss., by A. F. Crider and L. C. Johnson) and U. S. G. S. Bull. 283 (Geology and mineral resources of Miss., by A. F. Crider) were sent to the Govt. Ptg Office. The geol. map in both repts is by E. C. Eckel and A. F. Crider. The bulletin contains an introduction by Eckel and the W. S. P. states that the work was under the supervision of Eckel and M. L. Fuller.

The W. S. P. was completed and delivered Aug. 20, 1906, and the Bull. was delivered Sept. 25, 1906. E. A. Smith's rept was published by Ala. Geol. Surv. in 1907.

A. F. Crider and L. C. Johnson, 1906 (U. S. G. S. W. S. P. 159, pp. 5, 9). *Wilcox fm.*—called Lignitic by Hilgard, but that is not a locality name. Has also been called LaGrange, but LaGrange of Safford included present Lafayette and portions of the Cret. and has been discarded. The name Wilcox was first given in some unpublished work by E. A. Smith, State Geologist of Ala., for reason that typical strata of former Lignitic of Hilgard are exposed at Wilcox, Ala. [This is a misapprehension, because the U. S. G. S. records distinctly state that the fm. was named for Wilcox Co.] The name has been adopted by U. S. Geol. Survey to include the complex mass of sands, clays, lignites, marls, etc., btw. Porters Creek clays below and Tallahatta buhrstone (of Claiborne group) above. Thickness (est. from width of outcrop) 750 to 800 ft. [The records of U. S. Geol. Survey do not contain any reference to a town of Wilcox, Ala., but specifically state that the type loc. is Wilcox Co. The 1918 and 1931 Rand McNally atlases, however, show a small town of that name in Conecuh Co. (S. of Wilcox Co.), about 1 mi. NE. of Gregville, but it is on Citronelle fm. (Plio.) of 1926 Ala. geol. map.]

A. F. Crider, 1906 (U. S. G. S. Bull. 283, pp. 7, 25–28). *Wilcox fm.*—Originally named *Lignitic* by Hilgard and termed *Lagrange* by Safford. A recent decision of the committee on nomenclature of the United States Geological Survey has substituted the name *Wilcox*, which is that of a locality in Alabama where the fm. is typically exposed. [Defined by Crider as underlying Tallahatta buhrstone of Claiborne group and overlying Porters Creek clay (of Midway group).]

Since its introduction the name *Wilcox* has been the generally accepted designation for the deposits overlying the Midway and underlying the Claiborne in the Gulf Coastal Plain, and has been used in more than 100 repts.

H. V. Howe, 1933 (A. A. P. G. Bull., vol. 17, No. 6, pp. 617–621), proposed the revival of *Sabine group* and the abandonment of *Wilcox group*.

A. F. Crider, 1933 (A. A. P. G. Bull., vol. 17, pp. 654–655). Dr. Howe has pointed out two objections to use of *Wilcox*. These are (1) lack of priority, and (2) better type loc. of Sabine. In Wilcox Co., Ala., the present type loc. for what has been called "Lignitic" by Hilgard and Smith, the entire Wilcox group as then known is exposed. Veatch recognized the type section in Ala. as being all that could be wished for and admitted the Sabine section occupies same relative position as Ala. section. The faunal assemblage of the Lignitic was well known, and he added nothing new to this phase of the fm., and there was nothing new added to the near-shore deposits. All that Veatch ever claimed for the name *Sabine* was that it was same as the old term *Lignitic*. My description of type section of the Wilcox may not have been as clear and complete as it should have been, but it was not the fault of the type loc. It does not seem justifiable, at this late date, to change the name of Wilcox to Sabine because of better type loc. of latter. Recent drill cores, far down the dip from the outcrop of the Wilcox, show that only a small part of the Wilcox is exposed at surface from Ala. to Tex. Approx. 1,700 ft. of Wilcox has been recognized in a well in southern Ala. and in wells drilled far down the dip of Sabine uplift, while Veatch places thickness of fm. at his type loc. as only 900 ft. New beds come in down the dip from the outcrop, so that the Wilcox, far down the dip, differs more from what it is at Veatch's type loc. than the original Lignitic in Ala. differs from Veatch's type loc. of the Sabine in La. In all of the literature since 1906 the type loc. of the Wilcox has been referred to Wilcox Co., Ala. There has been no confusion in minds of geologic writers on this point. If the question of substitution of name *Sabine* for *Wilcox* is to be considered at this late date, after the name Wilcox has been in general use in the literature of all the States where the fm. is exposed at the surface, in U. S. G. S. publications and in foreign publications, let it be on priority alone and not because of better type loc. of Sabine.

In Ala., Miss., western Tenn., western Ky., and southern Ill. the Wilcox deposits are now treated as a group. In Ala. they are divided into (descending) Hatchetigbee, Bashi, Tuscahoma, Nanafalia, and Ackerman fms. The 1926 geol. map of Ala. shows that the Hatchetigbee, Bashi, Tuscahoma, and Nanafalia fms. are all present in Wilcox Co. The Ackerman fm. of Miss. has been identified by C. W. Cooke as extending a short distance into Ala. In Miss. the Wilcox is divided into (descending) Hatchetigbee (to E. and contemp. Grenada to N.), Bashi, Holly Springs, and Ackerman fms. In SW. Tex. the deposits formerly assigned to the Wilcox have been divided into (descending) Bigford, Carrizo, and Indio fms., but the Bigford and Carrizo are now generally assigned to Claiborne group. In western Tenn. and Ky. the Wilcox group is represented by Grenada fm. and Holly Springs sand. The Wilcox contains deposits of both marine and nonmarine origin. The following thicknesses of Wilcox group have been given: Ala., 609 ft.; Miss., 1,435 ft.; western Tenn., 600± ft.; La., 1,000 ft.; Tex., 950 to 3,000 ft. (in wells). The name *Wilcox group* is the well-established name of this geol. unit, having been used in more than 100 repts on the Coastal Plain States, while *Sabine* has been used in only 9 repts (the last in 1920), and in 1920 the name was adopted by the Canadians for a Camb. fm. of B. C.

See also under †*Sabine fm.*

Named for extensive development in Wilcox Co., Ala. See 1926 geol. map of Ala.

Wilcox sand.

A term that has been variously applied to subsurface Ord. sands in Okla. said by some geologists to lie in approx. position of Tyner fm. and by other geologists to lie in upper part of Simpson fm. In U. S. G. S. Tahlequah folio (No. 122) the sand was included in upper part of typical Tyner fm. as mapped. It was named for H. F. Wilcox, who drilled the first well to it in a pool about 6 mi. W. of Beggs, in NW. part of Okmulgee Co. The Wilcox pool was named for the sand. The terms "First Wilcox sand" and "Second Wilcox sand" have also been applied to sands in approx. this strat. position. It was originally called "deep sand."

Wildcat series.

Pliocene: Northern California (Humboldt County, along the coast to Eureka).

A. C. Lawson, 1894 (Calif. Univ. Pub., Dept. Geol. Bull., vol. 1, pp. 255–263). *Wildcat series.*—Evenly bedded yellow and brown clays, silty clay shales, sandy clays, argill. sands, compact yellow sss., and pebbly cgls., 4,000 ft. thick. Contain Plio. fossils and are correlated with Merced fm. The region occupied by the terrane is commonly known to the people of Humboldt Co. as the "Wild-cat Country." Occupies large part of Humboldt Co. to N. of Bear River Ridge and E. of Humboldt Bay, and is also doubtless extensively developed in coastal region N. of Eureka.

†Wild Cat coquinite.

Upper Devonian or Miss.: Northwestern Pennsylvania (McKean County).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). Oswayo sh. memb. of Riceville fm. [restricted], Dev., includes *Wild Cat coquinite.* [All.]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, p. 61), replaced his *Wild Cat coquinite* with *Roystone coquinite memb.*, which he excluded from Oswayo sh. memb. On p. 97 he stated that *Roystone coquinite zone* is well shown on Wild Cat Creek at Ludlow, McKean Co., Pa. Assigned to Dev.

The U. S. Geol. Survey classifies Oswayo fm. as Dev. or Carbf.

Wild Cat Mountain conglomerate.

Pennsylvanian: Southeastern Kentucky.

C. J. Norwood, 1877 (Ky. Geol. Surv., 2d ser., vol. 2, pt. 6, btw. pp. 201 and 243). *Wild Cat Mountain cgl.*—Soft, disintegrating pink, drab, and light-colored conglomerated ss., 20 to 120+ ft. thick. Forms top of Wild Cat Mtn and extends to hills around London, which it covers.

Wildhorse limestone. (In Nelagoney formation.)

Pennsylvanian: Central northern Oklahoma (Osage County).

F. C. Greene, 1918 (A. A. P. G. Bull., vol. 2, pp. 121–122). *Wild Horse ls.*—Most conspicuous outcrop is in W. half of T. 22 N., R. 10 E., and it forms a good marker in well logs around Hominy, where it is 5 to 40 ft. thick. North of T. 23 N. it is either very thin or absent, although its position is indicated by a massive ss. which is believed to be that exposed at Quapaw. In many places the base of this sand is extremely coarse, containing pebbles up to ¼ in. diam. The section above Quapaw ss. contains no well-marked beds for about 200 ft. Assigned to Penn. Lies about 220 ft. below Rock Creek ls. and from 80 to 125 ft. above Bull Creek ls. in eastern Osage Co. [Type loc. not stated.]

H. T. Beckwith, 1928 (Okla. Geol. Surv. Bull. 40T, p. 24). *Wildhorse ls. (lentil) memb.*—Yellowish to light-gray very fossiliferous ls., sandy and rather soft where thin, but a hard, nearly pure ls. in its thickest part. Thickness 1 ft. or less at N. end of its outcrop to 20 ft. in thickest part. Most of following data obtained from R. H. Wood (personal communication): Its most northerly outcrop is in the shales btw. top of Bigheart ss. and base of Fourmile sss. in sec. 27, T. 23 N., R. 10 E., where it occurs as a thin yellowish sandy ls. Thickens rapidly to S. to 20 ft. in cliff-like escarpments on each side of Hominy Creek Valley in NW. part of T. 22 N., R. 10 E. To S., in T. 21 N., R. 10 E., it thins, becomes very sandy locally, and finally disappears or merges with overlying sss. Near N. end of its outcrop it lies 30 to 50 ft. below top of overlying shales. To S., as it thickens, the overlying shales gradually pinch out, and in T. 22 N., R. 10 E., the overlying sss. lie close to or directly upon the ls. Included in Nelagoney fm. It is possible it lies at nearly same horizon as Labadie ls.

Wildhorse sandstone.

Permian: Central southern Oklahoma (Garvin and Carter Counties).

E. R. Brockway and H. J. Owens, 1923 (Univ. Okla. Bull., n. s., No. 271, pp. 95-96). The *Wildhorse ss.* makes a ridge on N. side of and parallel with Wildhorse Creek in R. 1 W. [Garvin Co.]. West of that the ss. curves around the mtns to SW., with one irregularity, namely, a large nose is folded in it extending westward toward town of Tatums [Carter Co.]. Assigned to Perm.

Wildhorse formation.

Pleistocene: Southeastern Oregon.

W. D. Smith, 1926 (Oreg. Univ. Commonwealth Rev., vol. 8, pp. 207-214). *Wildhorse fm.*—Glacial morainal material, consisting of gravel and sand of varying thickness. Occurs at altitudes above 8,000 ft. Typically exposed in Kieger and Wildhorse Canyons, Harney Co.

Wildie sandstone member (of Warsaw formation).

Mississippian: Southeastern Kentucky.

C. Butts, 1922 (Ky. Geol. Surv., ser. 6, vol. 7, pp. 89, 102). *Wildie ss. memb.*—Thick-bedded, very uniformly fine-grained bluish ss. of medium hardness. Known to trade as "Rockcastle freestone." Thickness 0 to 6 ft. Rests on 15 in. of highly glauconitic sh. with black nodules. Is overlain by a few ft. of sh. and ss., above which lies 20 ft. of thick-bedded yellow ls. Lies near base of Warsaw fm. Extends for about 16, possibly 20, mi. in NE.-SW. direction. Best developed and extensively quarried in vicinity of Wildie, Rockcastle Co.

Wildrose formation.

Lower Paleozoic (?): Southeastern California (Inyo County).

F. MacMurphy, 1930. [See under *Telescope group*. Derivation of name not stated.]

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July-Oct. 1932, pp. 329-356). *Wildrose fm.*—Largely cgl. qtzite with widely scattered elongated pebbles, up to 4 in. diam., of qtzite, granite, and granite gneiss in a dark-gray to black matrix of round to angular quartz grains, completely cemented by complex metamorphic aggregates; also finely banded brown to gray biotite schist and some crystalline ls. Thickness 500± ft. Conformably overlies Mountain Girl cgl.-qtzite and conformably underlies Sentinel dol.—all included in Telescope group (lower Paleozoic?), of S. part of Panamint Range. [Derivation of name not stated, but it is mapped near Wildrose Canyon.]

Wildwood limestone.

Permian: Northern California (Trinity County).

J. P. Smith, 1910 (Jour. Geol., vol. 18, chart opp. p. 217 and p. 218). *Wildwood ls.*—Limestones of Trinity Co. with Guadalupian fauna, *Stacheoceras*, etc. Assigned to Perm.

Named for Wildwood (Landis' ranch), on Hay Fork.

Wiles limestone member (of Graford formation).

Pennsylvanian: Central northern Texas (Brazos River region).

C. E. Dobbin, 1922 (U. S. G. S. Bull. 736C, p. 60). *Wiles ls. memb. of Graford fm.*—Massive dark-gray ls., 8 to 10 ft. thick. Lies 136 ft. above Palo Pinto ls. Named for exposure near Wiles, Stephens Co.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 48). Graford fm. of Palo Pinto Co. is divided into (descending): (1) Merriman ls.; (2) Wolf Mtn sh. [new name]; (3) *Wiles ls.*, consisting of 3 to 8 ft. of gray (blue when freshly broken) hard ls.; and (4) Posideon sh., 50± ft., which rests on Palo Pinto fm.

Wiley cyclical formation.

A name applied by H. R. Wanless (Ill. Geol. Surv. Bull. 60, 1931, pp. 179-193) to a portion of upper part of Pottsville fm. (Penn.) of central western Ill., based upon the rhythmic-cycle theory of sedimentation. Derivation of name not stated.

Wiley dolomite.

A name casually applied by C. [R.] Keyes (Pan-Am. Geol., vol. 59, No. 2, 1933, p. 136) to dol. of Wiley Mtns, E. of Van Horn, Tex., which he stated replaces the Delaware Mtn sss. of Richardson. According to P. B. King (personal communication April 1937) this fm. is Hueco ls. (Perm.).

†Wiley's Landing bed.

Miocene (lower): Southwestern Georgia and northern Florida.

A. F. Foerste, 1894 (Am. Jour. Sci., 3d, vol. 48, pp. 50–51). *Wiley's Landing bed.*—Peculiar white ls., about 20 ft. thick, resembling upper Vicksburg; brecciated toward base. Position and lithology seem to be upper Vicksburg, but fossils seem to have Chattahoochee facies. Included in Chattahoochee series, as basal bed.

According to C. W. Cooke (personal communication) this bed is part of Tampa ls. (†Chattahoochee fm.). At Wiley's Landing it is underlain by Flint River ls., which contains corals and other fossils.

Named for exposures at Wiley's Landing, on Flint River, in Decatur Co., Ga.

Wilgus clay.

A name applied to the shaly clay, 1 ft. thick, underlying Wilgus coal in Conemaugh fm., Ohio.

Wilhite slate.

Lower Cambrian: Eastern Tennessee and western North Carolina.

C. D. Walcott, 1894 (Geol. Soc. Am. Bull., vol. 5, pp. 196–198). Named *Wilhite sl.* by A. Keith. Rarely exceeds 700 ft. in thickness. Is capped by siliceous Citico cgl. of Keith. Within Wilhite sl., especially in upper 200 ft., numerous beds of ls. occur. Usually a ls. cgl. is found in same section, above the bedded ls. Exceptional to find a bedded ls. above the cgls. in the Wilhite slates, but large boulders of ls. were observed above main cgl. bed in Wilhite slates on Wilhite Creek, Tenn.

Defined by Keith in U. S. G. S. Knoxville folio (No. 16, 1895) and Loudon folio (No. 25, 1896). In Knoxville quad. it consists of ls. cgls. and sandy ls. in upper part and bluish-black argill. and calc. sl. in lower part; reaches a thickness of 1,000 ft.; underlies Citico cgl.; and is oldest fm. in area.

Is considered=lower part of Hiwassee sl.

Named for exposures on Wilhite Creek, Sevier Co., Tenn.

Wilkeson [coal] series.

Eocene: Western central Washington (Puget Sound region).

B. Willis, 1886 (U. S. 10th Census, vol. 15, pls. 81, 84). [See under *Evans Creek coal series.* This appears to correspond, in a general way at least, to Wilkeson fm. of Willis, 1898.]

Wilkeson formation. (In Puget group.)

Eocene: Western Washington (Puget Sound region).

B. Willis, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 400–436). *Wilkeson fm.* (also *Wilkeson sss.*).—Massive sss., with some sh. beds and a few coal beds, which lie at base of Pittsburg fm. and indeed form part of it. Separated from Pittsburg or South Prairie fm. [later renamed by him *Burnett fm.*] because of essentially distinctive characteristics and importance as key rock. Thickness 1,000 ft. Typical occurrence upon the eastern dip, either in quarries along South Prairie Creek immediately E. of Burnett or in bluffs ¼ mi. E. of Wilkeson, Pierce Co., on N. side of valley. Overlies Carbonado fm.

B. Willis and G. O. Smith, 1899 (U. S. G. S. Tacoma folio, No. 54). *Wilkeson fm.* (*Wilkeson ss.* on map).—Massive sss., some sh., few coals. Thickness 1,024 ft. Lies at base of Burnett fm. and indeed forms part of it. Includes Burnett coal at base.

Willamette group.

Miocene: Northwestern Oregon.

T. Condon, 1902 (The two islands). The following 3 groups represent the sea beaches in their relation to each other in the order of their occurrence: (1) *Rogue River group* (Cret.), named for Rogue River Valley [SW. Oreg.]; (2) *Umpqua group* (Eocene), named for association with Umpqua Valley [SW. Oreg.]; (3) *Willamette group* (Miocene), named for Willamette region [NW. Oreg.].

Willamettian stage.

Pleistocene: Central northern Oregon.

E. T. Hodge, 1930 (Monthly Weather Rev., vol. 58, pp. 405-411). *Williamettian* [Willamettian] *stage* (*Pleistocene*).—An epoch of aggradation and comparably small precipitation in Oreg., separating Jeffersonian epoch of glaciation from Cascadian epoch of glaciation. Possibly correlates with Puyallup interglacial epoch of Wash. Willamette Valley at Portland was aggraded to 300 ft. above present river level. Along the valley near Portland are important terraces.

Willard shale. (In Wabaunsee group.)

Pennsylvanian: Eastern Kansas, southeastern Nebraska, northwestern Missouri, and southwestern Iowa.

J. W. Beede, 1898 (Kans. Acad. Sci. Trans., vol. 15, p. 31). *Willard sh.*—Sh., 55 ft. thick, included in Upper Coal Measures of Shawnee Co., Kans. [From statement on p. 28 appears to underlie Chocolate ls. of Swallow and to overlie Elmont ls.]

J. W. Beede, 1902 (Kans. Univ. Sci. Bull., vol. 1, pp. 163-181). *Willard shales*, 55 to 85 ft. thick, overlie Barclay ls. (=Burlingame ls. and=Wyckoff ls.) and underlie Chocolate ls., 7 to 10 ft. thick.

E. Haworth, 1908 (Univ. Geol. Surv. Kans., vol. 9), defined *Willard sh.* as underlying Emporia ls. and overlying Burlingame ls., and that definition was followed for many years.

G. E. Condra, 1927 (Nebr. Geol. Surv. Bull. 1, 2d ser., pp. 61, 62, 71, 78, 90, 226). Kans. Geol. Surv. applies *Willard sh.* to beds below Emporia ls. and above Burlingame ls. The Willard sh. and so-called Emporia ls. have been difficult to work out. The beds called by these names in Kans. need redefining in order to establish a basis for correlation in Nebr. [p. 61]. The top of Willard sh. as defined by Beede in 1898 is at base of what is now known to be Tarkio ls. and the base at top of our div. 3 of Nebr. section of Nemaha beds or to Emporia ls. as that name should be defined if used. The Elmont ls. is one [the upper] bed of the unit which Kirk may have meant to call Emporia ls. [pp. 66, 71]. As here defined *Willard sh. memb. of Wabaunsee fm.* underlies Tarkio ls. memb. and overlies Emporia ls. memb. Its thickness is 30 ft. or more in Nebr., Iowa, and Mo., and 50 to 60 ft. in Kans. It consists of bluish and reddish argill. sh. with some calc. material and sand. Named for exposures S. of Willard [Shawnee Co., Kans.].

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3, p. 96). Willard sh. underlies Tarkio ls. and overlies *Emporia ls.* The Willard sh. of Haworth, Hinds, and Greene underlies Emporia ls., overlies Burlingame ls., and is replaced by *Humphrey sh.*

R. C. Moore and G. E. Condra, 1932 (Oct. 1932 revised classification of Perm. and Penn. rocks of Kans. and Nebr.), followed above 1932 classification, as did Condra, 1935 (Nebr. Geol. Surv. Paper No. 8), and R. C. Moore, 1936.

The U. S. Geol. Survey has not yet had occasion to consider, for its publications, the modified definition of Willard sh.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Williams Brook coquinite member.

Upper Devonian: Central New York (Ithaca region).

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 202). *Williams Brook coquinite memb.*, 15 to 25 ft. thick, characterized by *Spirifer mesistrialis* fauna. Underlies Marathon ss. memb. and overlies Cascadilla sh. memb., all included in Ithaca facies subgroup of Ithaca-Enfield group of fms. in Ithaca region.

Williamsburg granodiorite.

Late Carboniferous or post-Carboniferous: Central Massachusetts.

B. K. Emerson, 1898 (U. S. G. S. Holyoke folio, No. 50; also U. S. G. S. Mon. 29, pl. 34). *Williamsburg granite.*—Coarse muscovite-biotite granite with veins of pegmatite and albitic granite. [In text heading misspelled *Williamstown.*]

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 253–254). *Williamsburg granodiorite*, named for its development at Williamsburg, Mass., extends S. from Goshen into Conn., forming E. rim of Berkshire Hills.

†Williamsburg marl.

†Williamsburg pseudobuhr.

Eocene (lower): Eastern South Carolina (Williamsburg County).

E. Sloan, 1908 (S. C. Geol. Surv., ser. 4, Bull. 2, pp. 449, 451, 452). *Williamsburg Pseudo-Buhr.*—Consists of a heavy mantle of red and yellow sands mixed with glauconite and enclosing a hard silicified ledge about 2 ft. thick, in which casts of *Ostrea arrosis* and *Venericardia planicosta* occur. Included in Upper Black Mingo. Overlies Rhems sh. and underlies Lang Syne beds. Named for exposures in Williamsburg Co. near Rhems, but more extensively as a mantle covering ridge btw. Black River and Santee River, notably on scarp of swamp SW. of Gourdin Station and on crest of ridge 3 mi. N. of Salters.

C. W. Cooke, 1936 (U. S. G. S. Bull. 867). Above beds are part of Black Mingo fm. and name is abandoned. Deposits of kind described by Sloan as Williamsburg pseudobuhr make up greater part of Black Mingo fm., and are interbedded with dark clay, sh., or fuller's earth resembling †Rhems sh.

Williamsburg sand.

Drillers' name for a sand in Pottsville group of Whitley Co., SE. Ky.

Williams Canyon limestone.

Devonian (?): Eastern Colorado (El Paso County).

A. E. Brainerd, H. L. Baldwin, Jr., and I. A. Keyte, 1933 (A. A. P. G. Bull., vol. 17, No. 4, pp. 381–396). *Williams Canyon ls.*—About 30 ft. of thin-bedded lss. and calc. shales occur in section along Front Range uncon. below Madison ls. (Miss.) and uncon. above Ord. beds (Manitou, Harding, or Fremont). Typically exposed near Cave of Winds, in Williams Canyon at Manitou. Excellent exposures in Manitou Park, at Perry Park, in Canyon City embayment, and at Beulah, on E. slope of Wet Mtns. Consists of thin white to gray lss. 2 to 6 in. thick, with partings of gray calc. sh. and occasional thin sss. Occurs in all sections measured except btw. Manitou Springs and Oil Creek section. Max. thickness (65 ft.) at Missouri Gulch, in Manitou Park. W. Cross (U. S. G. S. Pikes Peak folio, No. 7) applied *Millsap ls.* to 30 ft. of thin-bedded dolomitic ls. with a few thin ss. layers exposed btw. Oil and Millsap Creeks, NE. of Canyon City; chert nodules in upper part carry fossils identified as Carbf. This series is believed by writers to be=the thin-bedded section in Williams Canyon and the chert nodules derived from erosion of overlying Madison and deposited in the basal Penn., which in this area overlies the thin-bedded lss. The name *Millsap* might be applied to the thin-bedded section at Beulah were it not preoccupied in Tex. Careful search revealed no fossils, either macro or micro, but writers are inclined to believe the Williams Canyon ls. is=the Parting and of Dev. age. [The application in this rept. of *Madison ls.* (Miss.) to 100 ft. of light-gray, very dense, massive ls., containing much brecciated material but practically without bedding, separating their Williams Canyon ls. from the overlying Fountain fm., is explained as follows:] "The massive lss. below the Pennsylvanian Fountain fm. NW. of Beulah, at Manitou Springs, and in Manitou Park and some distance northward have been recognized as true Miss. and essentially equiv. to the Madison of Wyo. and Mont. Although this is largely a lithologic correlation, a number of Miss. fossils have been found at Beulah and in Manitou Park, and a crinoid (*Actinocrinus marcoui* Collignon) of Kinderhook age was found by Marcou in the ls. in Williams Canyon." "The Madison is the equiv. of Leadville ls. of the west slope and is essentially equiv. to the Madison of Wyo., Idaho, and Mont."

Williams Fork formation. (In Mesaverde group.)

Upper Cretaceous: Northwestern Colorado.

Named by E. T. Hancock, but publication of his rept. was delayed, so that name first appeared in U. S. G. S. Press Memo. 16037, Oct. 1, 1923, on map of Hamilton and Seeping Spring Gulch domes and vicinity, Moffat Co., Colo.; and it was also used by J. D. Sears (but credited to Hancock) in U. S. G. S. Bull. 751, 1924, p. 290.

E. T. Hancock, 1925 (U. S. G. S. Bull. 757). *Williams Fork fm.*—Alternating beds of ss., sandy sh., and coal through nearly its entire thickness of 1,600 ft. Includes Twentymile ss. memb. about 900 ft. above base. Is upper fm. of Mesaverde group in Axial and Monument Butte quads. Rests conformably on Iles fm., lower fm. of Mesaverde group. Is conformably overlain by Lewis sh. Exposed on Williams Fork Mtn and along Williams Fork near its junction with Yampa River.

Williams Island limestone.

Devonian: Ontario.

E. M. Kindle, 1924 (Canada Geol. Surv. Summ. Rept. 1923, pt. C_1, p. 34).

Williamson shale member (of Clinton formation).

Silurian: Central and western New York.

J. M. Clarke, 1906 (N. Y. State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12). [See under *Irondequoit ls.*]

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114, pp. 5–35). *Williamson sh.*—Not of so uniform green color as older Sodus sh., and has interbedded a number of purple bands and 2 or 3 bands of pearly ls. Thickness in Rochester and Ontario Beach quads. 24 ft. Included in Clinton fm. Overlain by Irondequoit ls. and underlain by Wolcott ls.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368), stated that at both Williamson, Wayne Co. (type loc. of Williamson sh.) and at Wolcott (type loc. of Wolcott ls.) true Williamson sh. rests on true Wolcott ls., but that at Rochester true Wolcott ls. is absent and *Williamson sh.* was applied by Hartnagel to all beds btw. Irondequoit ls. and Reynales ls., a much older ls. than Wolcott. He restricted *Williamson* to upper or graptolite-bearing part (6 ft. thick) of what Hartnagel called *Williamson sh.* at Rochester, and identified lower part (18 ft.) of Hartnagel's Williamson sh. at Rochester as true Sodus sh., Hartnagel's Sodus being the much older Maplewood sh. At Brewerton [Onondaga Co.] the Williamson sh. is overlain by Brewerton sh., which is=lower part of Irondequoit ls. Chadwick gave thicknesses of his true Williamson sh. as 33–105 ft.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 191, 347), and W. Goldring, 1931 (N. Y. State Mus. Hdb. 10). [See under *Phoenix or Schroeppel sh.*]

Williamson sandstone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen and D. B. Reger, 1914 (W. Va. Geol. Surv. Rept. Logan and Mingo Counties, pp. 84, 165). *Williamson ss.*—Massive, medium-grained, dull gray, micaceous. Thickness 5 to 25 ft. Lies 1 to 5 ft. below Dingess coal and 1 to 30 ft. above Dingess ls. Exposed on Williamson Creek at Williamson, Mingo Co.

†Williamsport sandstone.

Mississippian: Central western Indiana (Warren County).

A. Winchell, 1870 (Am. Phil. Soc. Proc., vol. 11, pp. 414–415), and S. S. Gorby, 1886 (Ind. Dept. Geol. and Nat. Hist. 15th Ann. Rept., p. 86). [No definition except that *Williamsport gritstone* is of Kinderhook age.]

According to E. R. Cumings, 1922 (Hdb. Ind. Geol., pt. 4, Sep. Pub. 21, pp. 489–490), this is same as Riverside ss. and an unnecessary name. Apparently named for Williamsport, Warren Co., according to S. S. Gorby (Ind. Dept. Geol. and Nat. Hist. 15th Ann. Rept., 1886, p. 86), who calls it *Williamsport ss.*

Williamsport sandstone.

Silurian: Mineral and Grant Counties, West Virginia.

D. B. Reger, 1924 (W. Va. Geol. Surv. Rept. Mineral and Grant Counties, pp. 395–398). *Williamsport ss.*—Hard, compact greenish-brown or reddish-brown ss., massive, fine-grained. Marine fossils. Thickness 5 to 50 ft. Included in Bloomsburg red sh. In places (due to erosion of overlying beds of the Bloomsburg) it lies just below Rondout waterlime; in other places it rests on Niagara ls. In rare instances it is the only Bloomsburg stratum present in the section. Is the only ss. present in Bloomsburg sh. of this region. Named for exposure on a short branch of Patterson Creek, 0.6 mi. E. of Williamsport, Grant Co., at a point where a short private road turns NE. from main Williamsport-Moorefield highway.

W. F. Prouty, R. C. Tucker, P. H. Price, 1927 (W. Va. Geol. Surv. Rept. Hampshire and Hardy Counties, p. 258). For most of Hardy Co. the Bloomsburg is of one type, a brownish-red ss., but for some of western outcrops there is a shaly upper portion. Where the shaly portion is conspicuous, in Grant Co., Mr. Reger has called the ss. portion the *Williamsport ss.*

Williamstown granite.

A misprint (in heading on p. 6 of U. S. G. S. Holyoke, Mass., folio, No. 50, 1898, and on p. 433 of U. S. G. S. Bull 191) for the granite mapped in Holyoke folio as *Williamsburg granite* (Carbf.).

Williamstown granite.

Devonian: Northeastern Vermont (Orange County).

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), listed this name in Dev. of "central Vt.," but without definition. Probably named for Williamstown Twp, or village within that twp, NW. part of Orange Co.

Williamsville waterlime and shale.

Silurian (Cayugan): Western New York.

G. H. Chadwick, 1919 (as reported by M. Y. Williams, Canada Geol. Surv. Mem. 111, pp. 85, 93). "Chadwick (Bull. Geol. Soc. Am., No. 1, vol. 28, p. 173) has divided the upper part of the Cayugan group in western N. Y. as follows: [See 1917 entry under *Bertie ls. memb.*] In the criticism [unpublished?] of this memoir, however, Chadwick has omitted the term *Buffalo* and used in its place 'Williamsville'." (p. 85). On p. 93 Williams stated: "Prof. G. H. Chadwick disagrees with the above conclusions and offers the following alternative correlation. His table (for western N. Y.) is as follows:" * * * Akron dol., *Williamsville waterlime and sh.*, Scajaquada limy sh., Falkirk dol., and ?Oatka dol.

Probably named for exposures at Williamsville, Erie Co.

See also under *Akron dol.*

Williamsville clay.

Tertiary: Trinidad.

V. C. Illing, 1928 (Geol. Soc. London Quart. Jour., vol. 84, p. 17).

Willimantic gneiss.

Probably Carboniferous or post-Carboniferous: Eastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 115, 140, 141, 142). *Willimantic gneiss.*—Alternating light and dark bands. In general coarse-grained, often times even porphyritic in structure, usually considerably crumpled and folded. The dark variety has a relatively small amount of feldspar and quartz with a large amount of biotite and some hornblende. The light stock is granitic and contains quartz, feldspar, and biotite in proportions of normal granite. The gneiss extends about 4 mi. in all directions from city of Willimantic. It is merely a more injected phase of Hebron gneiss, which forms an irregular band almost completely encircling the Willimantic gneiss, into which it grades.

H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7, p. 36 and map). *Willimantic gneiss* is of igneous origin and Hebron gneiss is believed to be sedimentary.

Willis sand.

Tertiary? (Pliocene?): Southeastern Texas and southern Louisiana.

J. Doering, 1935 (A. A. P. G. Bull., vol. 19, No. 5, pp. 655, 656, 660). *Willis fm.*—Proposed by writer for the fm. of sand and gravelly sand occurring at or near base of post-Fleming group in SE. Tex. and S. La. Called "unnamed Pliocene sand" and "Upper Citronelle sand" by Plummer, in Univ. Tex. Bull. 3232, 1933, pp. 530 and 749-763. Is in general red sand, coarse and gravelly in part, and slightly indurated. Exposed in a dissected hilly belt 15 to 20 mi. wide, paralleling and just S. of Fleming belt of outcrop. Rests uncon. on clay beds which are in part Fleming and which may be in part Goliad. Highly probable the Willis is younger than Goliad sand, but upper memb. of Goliad (the Labahia) may be=lowest memb. of the Willis, the *Willis gravel*. Is overlapped uncon. by Lissie fm. and locally by the [later] Beaumont and Recent. Divided into 3 members (all of which are present in both SE. Tex. and SW. and SE. La.), named (descending): (1) *Hockley Mound sand memb.*, 20–25 ft.; (2) *Willis ferruginous sand memb.* 30 to 60 ft.; and (3) *Willis gravelly sand memb.*, 30 to 40 ft. Named for town of Willis, 10 mi. N. of Conroe, Montgomery Co., Tex., which is located on top of N. end of a ridge held up by the fm. No fossils. Is late Plio. or early Pleist. Tentatively correlated with upper part of Citronelle fm.

Willis sand.

A subsurface sand of Chester (upper Miss.) age in Ind. that has been correlated with Elwren ss. of Malott.

†Willis ferruginous sand member.

†Willis gravelly sand member.

See under *Willis sand* of Tex., of which they are members. The U. S. Geol. Survey does not apply the name of a fm. to its members.

Williston limestone.

Upper Cambrian: Northwestern Vermont (Chittenden County).

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 117+). *Williston ls.*—Light- or dark-blue ls. and marbleized ls., interbedded with some layers of shaly blue ls. and a very little calc. sh. and with scattered beds of dolomitic ls., usually dark blue or gray. Beds are fine-grained. Fossils very scarce. Thickness probably 500 ft. No precise contacts btw. this ls. and underlying Shelburne marble, but differences are marked and change is probably abrupt. In towns of Williston and St. George the ls. is overlain by a fine black phyllite, which appears to be conformable, but its age relation to the Williston is unknown.

A. Keith, 1932 (Wash. Acad. Sci. Jour., vol. 22, pp. 360, 377). Fossils collected from Williston ls. in Williston and South Burlington are pronounced by C. Schuchert to be Upper Camb. The fm. is named for its exposures in W. part of Williston Twp about 5 mi. SE. of Burlington. In Burlington region it overlies Highgate sl. (Upper Camb.); in Brandon-Rutland region it rests on Shelburne marble, a much older fm. [here assigned to Lower Camb., but now believed to be Middle Camb.], from which it is separated by a hiatus.

†Willow limestone.

An abbreviation of †Willow River ls. of Wooster (Lower Ord., upper Miss. Valley) employed by C. R. Keyes.

Willow limestone.

Lower Ordovician: Eastern Nevada (Ely region).

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 53) and 1924 (Pan-Am. Geol., vol. 41, p. 78). *Willow lss.*, 100 ft. thick, uncon. underlie Eureka sss. and overlie Cherry shales. [His 1924 definition states that these lss. are uppermost memb. of *Mid* Ordovicic section.] Named for exposures on E. flank of Egan Range along Willow Creek.

Upper part of Pogonip ls.

Willowbunch member (of Ravenscrag formation).

Eocene (early): Saskatchewan.

F. H. McLearn, 1930 (Canada Geol. Surv. Summ. Rept. 1929, pt. B, p. 58).

In later repts McLearn assigned this fm. to "Paleocene," which is included in Eocene by American geologists.

Willow Creek formation.

Upper Cretaceous: Northwestern Montana and southwestern Alberta.

G. M. Dawson, 1883 (Canada Geol. Surv. Rept. 1880–82, pp. 3B–6B). In Belly River region, E. of belt of disturbed rocks, a series of reddish and purplish clays with gray and yellow sss., which may be named provisionally *Willow Creek series*, appears to be very persistent in Laramie of this region. Overlies, conformably, St. Mary River beds and conformably underlies sss. and shales of Porcupine Hills. [Mentions fossils obtained from the fm. on Old Man River, a few mi. below mouth of Willow Creek, SW. Alberta.]

E. Stebinger, 1916 (U. S. G. S. Bull. 621, pp. 124–128). *Willow Creek fm.*—Variegated clay and soft ss., chiefly maroon to chocolate brown, with subordinate gray, yellow, and greenish-gray beds; the clay in many places contains thin lenticular beds of purplish-gray ls. Thickness 720+ ft. in northern Teton Co., Mont. Top not seen. Mainly continental. Overlies St. Mary River fm. and underlies glacial drift. Is lithologically identical with underlying St. Mary River fm. except that Willow Creek rocks are characterized by dominantly red color instead of light-grayish tints of coal-bearing St. Mary River fm. It is not coal-bearing in Teton Co. Change to St. Mary River fm. occurs in transition zone 50 ft. thick, in which red beds alternate with gray and white beds. To N., in Alberta, the red color disappears and the strata at same position are coal-bearing.

†Willow Creek beds.

Upper Cretaceous: Eastern Colorado (Denver Basin).

G. H. Eldridge, 1888 (Colo. Sci. Soc. Proc., vol. 3, pt. 1, pp. 86–112). *Willow Creek beds.*—Consist of 600 to 1,200 ft. of gray argill. or aren. shales with lenticular masses of hard quartzose ss. and an occasional ironstone, underlain by 200 ft. of cgl. or gritty ss., which may become bulk of fm., as in type locality, or may thin to merest edge, as in northern limit along Platte River near Brighton. This fm. contains pebbles from every fm. that lies beneath it in Denver field, as well as from others far beyond, especially the Carbf. Uncon. overlies Laramie fm. and uncon. underlies Denver beds, described by Cross. Contains dinosaur remains. Named for Willow Creek, in S. part of field, 1 to 3 mi. SE. of mouth of Platte Canyon, where it has its greatest and most typical development. [In footnote on p. 97 Eldridge withdrew "Willow Creek beds," because of preoccupation in Canada, and substituted *Arapahoe*.]

Willow Creek rhyolite. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). The thick series of flows of fluidal felsitic rhyolites characteristically exposed above Creede in the canyons of both forks of Willow Creek is here named *Willow Creek rhyolite*. Thickness 0–2,000+ ft. Is a fm. in Alboroto group, of Potosi volcanic series. Uncon. underlies Campbell Mtn rhyolite and uncon. overlies Outlet Tunnel quartz latite. It is possible latter fm. represents a lens btw. flows of Willow Creek rhyolite, but this is not believed probable.

Willow Lake basalts.

Age(?): Northern California (Lassen National Park).

H. Williams, 1932 (Calif. Univ. Pub., Bull. Dept. Geol. Sci., vol. 21, No. 8, pp. 214–376, map). *Willow Lake basalts.*—Blue-black vesicular pyroxene basalt flows, including a small outcrop of coarse basaltic aggl. on N. slope of Kelly Mtn. Earliest volcanic activity in the park. Exposed around margins of Willow Lake and thence over the divide into Warner Valley.

Willow Point limestone. (In Palo Pinto formation.)

Pennsylvanian: Central northern Texas (Wise and Jack Counties).

J. M. Armstrong, 1929 (Tex. Bur. Econ. Geol., geol. map of Jack Co.). *Willow Point ls.*, in lower part of *Graford fm.*, lies 40± ft. above Bridgeport coal.

J. M. Armstrong and G. Scott, 1930 (Tex. Bur. Econ. Geol., geol. map of Wise Co.). *Willow Point ls.*, 15± ft. thick, lies 105± ft. below Rock Hill ls. and 40± ft. above Bridgeport coal, all included in Graford fm.

E. H. Sellards, 1931 (Sept. 1931 News Letter from Bur. Econ. Geol. Univ. Tex.). [See 1931 entry under *Boone Creek memb.*] Included in Palo Pinto fm.

G. Scott and J. M. Armstrong, 1932 (Tex. Univ. Bull. 3224, p. 27). *Willow Point ls.* included in Palo Pinto fm. Is about 4 ft. thick. Consists almost entirely of broken fragments of crinoid stems and many other reworked fossils. When fresh it is light to dark gray, hard, and crystalline but weathers easily to yellowish color and breaks down into a "rotten" ls. Named for Willow Point, SW. part of Wise Co. Also well exposed at Bridgeport and other places in W. part of Wise Co. Was originally called *Bridgeport ls.* by Böse, but since he had already spoken of the coal in connection with Bridgeport it is thought best to retain that name for the coal. It lies 32 to 55 ft. above Bridgeport coal.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 105). *Willow Point ls.*, in Palo Pinto fm., replaces *Bridgeport ls.* (preoccupied).

†Willow River limestone.

Lower Ordovician (Beekmantown): Central western Wisconsin.

L. C. Wooster, 1882 (Geol. Wis., vol. 4, pp. 106, 123–129). [See 1882 entry under *New Richmond ss.*]

Later work proved these beds to be same as Shakopee dol., by which name they have been universally designated in Wis., Minn., Iowa, and Ill. repts for 50± years.

E. H. Powers, 1935 (Geol. Soc. Am. Proc. 1934, p. 102). "The revised and redefined term *Willow River* is preferred to the controversial term *Shakopee* for upper dol. memb." [of Prairie du Chien "fm."].

According to 1935 Rept. Ann. Field Conf. Kans. Geol. Soc., the Wis., Minn., Iowa, and Ill. Geol. Surveys continue to use *Shakopee*, as does U. S. Geol. Survey.

See also under *Shakopee dol.*

Named for exposures on Willow River, St. Croix Co.

Willow Spring granite.

Mesozoic (?): Central Arizona.

F. L. Ransome, 1903 (U. S. G. S. P. P. 12). *Willow Spring granite.*—Gray fine-grained granite; exact petrological relationship in doubt. Intrudes Pinal schist. Exposed in Willow Spring Gulch, Globe quad.

F. L. Ransome, 1919 (U. S. G. S. P. P. 115), assigned this fm. to "Mesozoic (?), probably early Mesozoic."

Wills Creek shale. (In Cayuga group.)

Silurian: Western Maryland to central Pennsylvania and western Virginia.

P. R. Uhler, 1905 (Md. Acad. Sci. Trans., vol. 2, pp. 20–25). *Wills Creek fm.*—Yellowish shales (black when fresh), argill. and calc., with a few thin layers of dark-purple ss. and 2 ft. of coarse dark-purple unfossiliferous ss. at base. Underlies Lower Helderberg and overlies Water Lime. Thickness 150± ft. Appears to constitute an unrecorded fm. Named for creek next to which it is conspicuously exposed [at Cumberland, Md.]. Might be regarded as the upper memb. of the Water Lime were it not for the difference in the fauna.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pp. 522, 541, pl. 28). *Wills Creek fm.*—Overlies Bloomsburg ss. and underlies Tonoloway ls. in Pa. and Md. Is middle fm. of Cayugan series.

G. W. Stose, 1912 (U. S. G. S. Pawpaw-Hancock folio, No. 179). *Wills Creek sh.*—Chiefly greenish sh., with some sss. (greenish) and lss., and, at base, Bloomsburg red ss. memb., 52–80 ft. thick. Thickness of fm. 445 ft. Underlies Tonoloway ls. and overlies McKenzie fm.

C. K. and F. M. Swartz, 1931 (Geol. Soc. Am. Bull., vol. 42, No. 4, pp. 622–660), treated *Bloomsburg red beds* as a distinct fm., underlying Wills Creek fm. and overlying McKenzie fm.; and on pp. 651–660 they extended the name into SE. N. Y. as far as Otisville, Orange Co. On p. 657 they state: It is manifest the Bloomsburg is a lithological phase—not a geological age. It accumulated on the continental margin to E. while different marine deposits were formed to W. On p. 660 they show Bloomsburg red beds to NE. to be the time equivalent of lower part of Tonoloway ls., Wills Creek sh., and upper part of McKenzie, its basal bed to S. (called Rabble Run red bed) interfingering with middle part of McKenzie, while a higher heavy bed of the Bloomsburg wedges in btw. the McKenzie and the Wills Creek. This higher bed, however, they show as representing an early part of the Bloomsburg to east.

G. W. Stose and C. Butts, 1932 (16th Int. Geol. Cong. Guidebooks of Appalachian region). *Wills Creek sh.* restricted to beds above Bloomsburg sh. [This is present approved definition.]

Wills Point formation. (In Midway group.)

Eocene: Eastern Texas Coastal Plain.

R. A. F. Penrose, Jr., 1890 (Tex. Geol. Surv. 1st Ann. Rept., pp. xlii, 17, 19). *Basal or Wills Point clays.*—Great beds of stiff stratified clays of various colors interbedded with sand and containing some ls. concretions. Thickness 250 to 300 ft. Underlie Timber Belt or Sabine River beds and uncon. overlie Upper Cret.

In 1896 G. D. Harris (Bulls. Am. Pal., vol. 1, No. 4, p. 155) applied *Wills Point clays and sand* to upper part only of Wills Point clay of Penrose. The Penrose definition, however, was generally adopted, and btw. 1890 and 1907 *Wills Point clay* was name applied to basal Eo. deposits of Tex. Coastal Plain, which are now generally agreed are same as the Midway of E. part of Gulf Coastal Plain, and are called by latter name.

H. J. Plummer, 1933 (Univ. Tex. Bull. 3201—issued in Feb. 1933, according to footnote on p. 51, p. 54, footnote). In forthcoming Univ. Tex. Bull. 3232 the "upper Midway" will be called *Wills Point fm.* of Midway group, and a new name will be applied to "basal Midway."

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, p. 555). In 1927 the work of Mrs. [H. J.] Plummer on the Foraminifera and that of Miss [Julia] Gardner on the large fossils demonstrated that the Midway is composed of two easily mappable units containing distinctly different faunas. The U. S. Geol. Survey on prel. ed. of geol. map of Tex. published in 1932, proposed to restrict Penrose's name and to apply it to upper div. only of the Midway. Wills Point fm. as now defined includes all strata below Wilcox group and above Tehuacana ls. lentil [of Kincaid fm., p. 532] or its equiv. horizon. Its base is drawn at base of the upper glauconite, which appears to be uncon. on underlying beds. [See Plummer, 1933, under *Kincaid fm.*]

Named for Wills Point, Van Zandt Co.

†Wilmington beds.

Eocene (upper) and Miocene (lower): Southeastern coast of North Carolina.

W. H. Dall, 1898 (U. S. G. S. 18th Ann. Rept., pt. 2, p. 344 and chart opp. p. 334). *Wilmington beds.*—See Clark, U. S. G. S. Bull. 83, 1891, pp 48–50; also note under E22. [The note under E22 is:] This [the Shark River beds of N. J.], like the Eocene of N. C., is regarded by Harris as newer than that of Md. and Va., which has been included under name Pamunkey by Darton. [Assigned to Clairbornian in table opp. p. 334.]

On pp. 48–50 of U. S. G. S. Bull. 83 W. B. Clark described the Eocene deposits of N. C. but did not apply a geographic name to them. In region described by Clark the deposits are now divided into Castle Hayne marl (of upper Eocene, Jackson, age) above and Trent marl (lower Mio.) below, both of which were evidently included in "Wilmington beds."

Apparently named for exposures at Wilmington, N. C.

Wilmington group.

Late Pleistocene: Southern California.

R. T. Hill, 1929 (Sci., n. s., vol. 69, pp. 379–380). *Wilmington group.*—Has hitherto included Lower San Pedro, Upper San Pedro, and [Los] Cerritos stages of Arnold, or their equivalents. Contains Pleist. marine invertebrate fossils. Structural and physiographic evidence proves these beds are older than the Pleist. invertebrate-bearing beds of La Brea pits, but both belong to Later Pleist. stage, and not to Earlier Pleist. [Derivation of name not stated.]

Wilmington limestone.

Upper Ordovician (Richmond): Northeastern Illinois.

See under *Aux Sable ls.*

Wilmore sandstone member (of Conemaugh formation).

Pennsylvanian: Western Pennsylvania (Cambria County).

C. Butts, 1905 (U. S. G. S. Ebensburg folio, No. 133). *Wilmore ss.*—Varies from thin-bedded and micaceous to thick-bedded and coarse. Thickness 20 to 30 ft.

Is a memb. in upper part of Conemaugh fm. Its base is about 60 ft. above Summerhill ss. or 520 ft. above Upper Freeport coal. Exposed at top of first railroad cut W. of Wilmore, also on hillside W. of Wilmore [Cambria Co.], about 3 mi. SW. of Wilmore, and at other places.

†Wilmore limestone.

Middle Ordovician (Trenton): Central Kentucky.

J. M. Nickles, 1905 (Ky. Geol. Surv. Bull. 5, p. 15), used *Wilmore*, in table only, without any description or thickness, for fm. in Lexington group underlying Paris and overlying Logana.

According to A. F. Foerste (Ky. Geol. Surv. Bull. 7, 1906) the †*Wilmore* is 125 ft. thick. According to E. O. Ulrich (Geol. Soc. Am. Bull., vol. 22, pp. 416–417, 1911) it underlies Bigby ls. and overlies Hermitage. According to A. F. Foerste (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, pp. 389, 429–430, 1913) it is 70 ft. thick, consists of lss., frequently argill. and usually interbedded with thin clay layers, and is underlain by Logana and overlain by Bigby.

The name "Wilmore" being preoccupied, A. M. Miller replaced it with *Jessamine ls.*

Named for exposures at Wilmore, Jessamine Co.

Wilmot.

Name applied to a subsurface sand in Cisco group (Penn.) of Archer Co., Tex., lying from 160 to 200 ft. above Gose sand and probably not far above Breckenridge ls. memb. of Thrifty fm.

Wilson formation.

Pennsylvanian: Southeastern Kansas and northeastern Oklahoma.

F. C. Schrader and E. Haworth, 1905 (U. S. G. S. Bull. 260, p. 447). *Wilson fm.*—Lss. and shales, 280 ft. thick, underlying Buxton fm. and overlying Drum fm. in SE. Kans. Includes Piqua ls., Vilas sh., Iola-Allen ls., and Chanute sh.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 124). †*Wilson fm.* of Schrader and Haworth included strata from base of Chanute sh. to top of Stanton ls., and is abandoned.

Named for Wilson Co., Kans.

Wilson sand.

A subsurface sand, 0 to 30± ft. thick, in Carbondale fm. of Centralia region, SW. Ill., in SW. part of Marion Co., lying 1,110± ft. below Herrin coal.

Wilson sand.

A subsurface gas sand in lower part (Hiawatha memb. of Nightingale) of Wasatch fm. of Vermilion Creek gas area, on Wyo.-Colo. State line in Sweetwater Co., SW. Wyo., and Moffat Co., NW. Colo. Lies higher than Newberger sand. (See W. T. Nightingale, A. A. P. G. Bull., June 1935.)

Wilson sand.

A subsurface sand in central southern Okla., which is reported to occur at base of Perm.

Wilson diorite.

See *Mount Wilson quartz diorite.*

Wilson Ranch beds.

Pliocene: Western California (Sonoma County).

V. C. Osmont, 1904 (Calif. Univ. Pub., Dept. Geol. Bull. vol. 4, p. 74). *Wilson Ranch beds.*—West of Santa Rosa Valley, sss. and small proportion of shales and fine volcanic cgl., with marine fauna. East of Santa Rosa Valley, sss., shales, and a large proportion of coarse volcanic cgl.; no fossils; coarseness of gravel and close bedding indicating fluviatile origin. Believed to be older than St. Helena rhyolite and younger than Sonoma tuff.

Probably named for exposures on a ranch in Sonoma Co.

†Wilton formation.

Pre-Cambrian (?): Southwestern Connecticut (Fairfield County).

J. G. Percival, 1842 (Conn. Geol. Surv. Repts., pp. 51–53, 63, and map). *Wilton fm.* (*No. 4 of Eastern Primary system*).—Chiefly dark subporphyritic, more rarely porphyritic rock similar to that of Greenwich fm., and like that generally more or less subhornblendic. Includes subordinate beds of white granitic rock. Covers considerable part of Wilton.

Included in Danbury granodiorite gneiss as mapped by H. E. Gregory and H. H. Robinson, 1907 (Conn. Geol. and Nat. Hist. Surv. Bull. 7).

Wilton's Run.

P. Frazer, Jr. (2d Pa. Geol. Surv. Rept. C., p. 82, 1876) applied *Wilton's Run ls. belt* to a belt of ls., 500 to 1,000± ft. thick, in vicinity of Wilton's Run, near Wrightsville, York Co., Pa.

Wimer beds.

Miocene (upper), Pliocene, or Pleistocene: Northwestern California (Del Norte County).

J. S. Diller, 1902 (U. S. G. S. Bull. 196, pp. 32–35, 47). Neocene marine deposits occur on edge of plateau at elev. of about 2,200 ft., along old Wymer stage road, in sec. 20, about 13 mi. NE. of Crescent City. North of old Harvey place, where Thomas Haley now lives, a thin coating of the soft iron-stained, slightly indurated shaly sands is exposed on banks of road for several miles, and has furnished numerous imperfect casts of mollusks as well as impressions of leaves. A short distance farther E., in an excavation made by Mr. Williamson near his barn, in sec. 22, a very fine soft gray sandy clay, very slightly indurated, is rich in shells. The deposits of the two localities just mentioned will be called for distinctness *Wymer beds*. They are very thin, resting on schists, peridotite, ss., and other rocks. [Fossils described.] Flora said by F. H. Knowlton to be upper Mio. W. H. Dall says fauna is not characteristic but not older than Tert. If on further study the Wymer beds should turn out to be Plio. or Pleist. the age of the Klamath peneplain would be correspondingly reduced.

According to J. H. Maxson (letter dated Jan. 5, 1933) this name should be spelled *Wimer*, as it is derived from the man who built the stage road on which the fm. is exposed.

Winchell member (of Graford formation).

Pennsylvanian: Central northern Texas (Colorado River to Brazos River).

C. O. Nickell (rept completed and soon to be published by Tex. Geol. Survey). *Winchell memb. of Graford fm.*—The group of thin lss. separated by thick sh. beds and thin sss. in the Winchell area, Brown Co., which to W. develop into a conspicuous ls. bed, as recorded in well logs drilled in central Coleman Co. This group of lss. includes "Clear Creek ls." of Drake and of Plummer and Moore, plus the ls.-bearing part (55 ft. thick) of overlying Placid sh. memb. of Brad fm. of Plummer and Moore. The lowest ls. of the memb. is the ls. that caps the escarpment W. of Winchell, and the top bed of the memb. is the ls. that forms the broad bench about 1 mi. NW. of Winchell on which U. S. G. S. benchmark is set at elev. 1,417. Thickness of memb. ¾ mi. N. of Winchell is 72 ft., but the beds thicken to W. Is top memb. of Graford fm. as here redefined.

Winchester limestone.

Upper and Middle Ordovician: Central Kentucky.

M. R. Campbell, 1898 (U. S. G. S. Richmond folio, No. 46). *Winchester ls.*—Thin-bedded crystalline blue ls. with bands of calc. sh., 200 to 230 ft. thick. Overlain by Garrard ss. and underlain by Flanagan chert.

A. M. Miller, 1905 (Ky. Geol. Surv. Bull. 2, pp. 8–23). *Winchester substage* [restricted].—Blue and gray knotty ls. with some sh. Thickness 40 ft. Underlies 200 ft. of blue sh. and thin lss. forming lower part of Eden stage [and named Million sh. by Nickles in 1905]. Overlies Flanagan chert phase of Lexington group.

The approved definition of Winchester ls. is for beds underlying Eden group and overlying Flanagan ls.

Named for Winchester, Clark Co.

Windegokan series.

Pre-Cambrian: Ontario (east of Lake Nipigon).

T. L. Tanton, 1926 (Canada Geol. Surv. Summ. Rept. 1924, pt. C, p. 4).

E. S. Moore, 1929 (Geol. Soc. Am. Bull., vol. 40, p. 553). Highly folded cgl. found E. of Lake Nipigon, Ont.

Windfall sand.

A subsurface sand of Upper Dev. age in Bradford dist., NW. Pa. (See under *Lewis Run sand.*)

Windigokan.

See *Windegokan.*

Windom shale.

Middle Devonian: Western New York (Lake Erie region).

A. W. Grabau, 1917 (Geol. Soc. Am. Bull., vol. 28, p. 946). In western N. Y. the Tichenor ls. is not seen, and Moscow and Ludlowville shales are together reduced to thickness of 17 ft. at Eighteen Mile Creek. For this 17-foot fm., which has commonly but erroneously been called Moscow sh., I propose *Windom sh.*, from exposures near village of Windom, Erie Co. In western N. Y. the Tully is scarcely represented, although there is a very persistent calc. bed, 4 in. thick and only a few in. below top of Windom sh. at Eighteen Mile Creek and on Lake Erie shore, which may indicate Tully type of sedimentation. The Windom is succeeded at Eighteen Mile Creek by an in. or two of Genesee sh. In western Ont. the beds equiv. to Moscow and Ludlowville shales thicken to 150 ft. In northern Ohio they have been eroded away.

G. A. Cooper, 1930 (Am. Jour. Sci., 5th, vol. 19, p. 232). *Windom memb. of Moscow fm.*—Grabau used this name for the soft gray sh. on Smokes Creek at Windom [Erie Co.] extending from Tichenor ls. (his Morse Creek ls.) upward to the "Pyrite." Traced eastward this sh. comes to overlie the beds here named *Kashong memb. of Moscow fm.*, and greatly increases in thickness, from 17 ft. on Eighteenmile Creek to 50 ft. at type section, 52 ft. in Genesee Valley, 120 ft. in Portland Point Ravine, Cayuga Lake, 165 ft. in Bucktail Ravine at Spafford Valley, and 265 ft. in Unadilla Valley at New Berlin.

Windom member.

Lower Cretaceous (Comanche series): Central Kansas.

W. H. Twenhofel, 1924 (Kans. Geol. Surv. Bull. 9, pp. 31–32). *Windom memb.*—Thin marine lss. near base of Belvidere fm. Two 6-in. layers of gray shell ls. separated by gray sh. The ls. consists almost wholly of shells. Fossils identical with those of Kiowa sh. Thickness 3 ft. Underlies Marquette memb. and overlies Natural Corral memb. All included in Belvidere fm.

Named for extensive occurrence NE. of village of Windom, McPherson Co.

Wind River formation.

Eocene (lower): Western Wyoming (Wind River Basin).

F. V. Hayden, 1862 (Am. Phil. Soc. Trans., n. s., vol. 12, pp. 125–127). *Wind River Valley deposits.*—Throughout Wind River Valley is series of beds, 1,500 to 2,000 ft. thick, which seems to be intermediate in character btw. the true lignite beds of the Tert. and the White River Tert. deposits. From divide btw. the North Platte and the Wind River they occupy greater portion of Wind River Valley. Differ from the other deposits in great predominance of aren. sediments and in absence of vegetable remains, but they contain fragments of turtles and numerous fresh-water and land shells. Rest on the true lignite beds with slight discordance.

F. V. Hayden, 1862 (Am. Jour. Sci., 2d, vol. 33, pp. 310–311). We have already expressed view, in a previous paper, that *Wind River group* is intermediate in age btw. lignite Tert. and White River beds. There is no strict uncon. btw. the lignite beds and Wind River group, but latter incline in same direction, only at a much smaller angle.

F. B. Meek and F. V. Hayden, 1862 (Phila. Acad. Nat. Sci. Proc. 1861, vol. 13, pp. 433, 434, 447). *Wind River group.*—Light-gray and ash-colored sss. with more or less argill. layers. Thickness 1,500 to 2,000 ft. Fossils listed. No marine or brackish-water fossils. Found in Wind River Valley and W. of Wind River Mtns.

Considered older than White River group and younger than Fort Union or Great Lignite group, but not seen in contact with any other Tert.

F. V. Hayden, 1867 (U. S. Geol. Geog. Surv. Terr. 1st Ann. Rept., pp. 162–177 of Rept. of Comr. Gen. Land Office). *Wind River deposits* consist of 1,500 to 2,000 ft. of light-gray and ash-colored sss. with more or less argill. layers. Occur in Wind River Valley, also W. of Wind River Mtns. Fossils listed. Underlie White River group and overlie Fort Union or great lignite deposits.

F. V. Hayden, 1869 (U. S. Geol. Geog. Surv. Terr. 3d Ann. Rept., pp. 89–92). *Wind River deposits* are limited, so far as we now know, to Wind River Valley.

O. St. John, 1883 (U. S. Geol. Geog. Surv. Terr. of Wyo. and Idaho for 1878, pt. 1, pp. 228–269). *Wind River fm.* of Wind River Range contains *Viviparus paludinaiformis*, which elsewhere characterizes Wasatch Tert. horizons. Hence the variegated deposits to which Dr. Hayden gave name *Wind River group*, recognizing their probable Mio. age, are either emphasized variegated upper Wasatch strata or a much later and actually nonconformable memb. of Tert. series peculiar to region N. of Gros Ventre Mtns and E. of Wind River Range.

W. D. Matthew, 1900 (Am. Mus. Nat. Hist. Bull., vol. 12, pp. 20–21). All sediments of Wind River Basin, Wyo., are later than Wasatch and earlier than Bridger. The Wind River fm. (*Bathyopsis* zone) is 800 ft. thick; the Wasatch fm. (*Coryphodon* zone) of Bighorn Basin, Wyo., is 2,000 ft. thick.

W. B. Scott, 1907 (Textbook geol., pp. 731–732). Wind River fauna is a development of the Wasatch, apparently without admixture of foreign elements by immigration.

H. F. Osborn, 1907 (Am. Mus. Nat. Hist. Bull., vol. 23, art. 11, fig. 1, p. 242) and 1909 (U. S. G. S. Bull. 361, pp. 23, 43–48), showed lower 500 ft. (*Lambdotherium* beds) of Wind River fm. = upper part of Wasatch fm., and upper 800 ft. (*Eotitanops* beds) of Wind River to be of post-Wasatch but pre-Bridger age, and reported *Coryphodon* from both upper and lower parts of Wind River fm.

W. J. Sinclair and W. Granger, 1911 (Am. Mus. Nat. Hist. Bull., vol. 30, pp. 87+), divided the Tert. of Wind River Basin into:

Oligocene, 210–528. Eocene: Uinta fm., 90–260	[Probably = White River of early repts.]
Discon. (?). so-called Bridger fm., 20–325 ft. No fossils. Conformable. Wind River group: Lost Cabin fm. (*Lambdotherium* zone). Conformable. Lysite fm., 350+ ft. Wasatch fm. absent.	[Apparently = Wind River of previous repts.]

W. D. Matthew, 1924 (Geol. Soc. Am. Bull., vol. 35, pp. 749–750), divided Wasatch fm. of Bighorn Basin as follows (descending):

Lost Cabin, Lysite } = Wind River group.
Gray Bull.
Sand Coulee.

H. F. Osborn, 1929 (U. S. G. S. Mon. 55), divided *Wind River fm.* of Wind River Basin into (1) Wind River B ("Lost Cabin"), 450 ft., containing *Eotitanops* and *Lambdotherium*; and (2) Wind River A ("Lysite"), 350 ft., consisting of *Heptodon* zone (300 ft. thick) underlain by nonfossiliferous clays with gyp.; and he showed Wind River fm. = upper two faunal zones of Wasatch fm. This is present approved definition of U. S. Geol. Survey.

Wind River Valley deposits.

See 1st entry under *Wind River fm.*

Windrock sandstone.

Pennsylvanian: Northeastern Tennessee (Morgan County).

L. C. Glenn, 1925 (Tenn. Geol. Surv. Bull. 33B, pp. 327–328). [Shows, in cross-country sections from Windrock to American Knob, *Windrock ss.*, a ss. or grit at top of Anderson fm. On American Knob the top of this ss. is 18 ft. below summit; it is 40 ft. thick, and contains occasional gritty quartz pebbles of size of wheat grains.]

Windrow formation.

Cretaceous or Tertiary: Southwestern Wisconsin (Monroe County, Sparta and Tomah quadrangles).

F. T. Thwaites and W. H. Twenhofel, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 133; see also vol. 32, pp. 293–311, 1921). *Windrow fm.*—Widely scattered patches of quartz and chert gravels, with associated limonite deposits, which occur on tops of high elevations throughout the driftless area of upper Miss. Valley and adjacent glaciated area to W. and S. The chert pebbles contain fossils, the youngest of which are certainly Sil. The fm. was river-deposited at a time far antedating the Pleist. and not necessarily connected with peneplanation, but no definite age can be assigned to it.

Named for exposure on top of Windrow Bluff, near Tomah.

Windsor group.

Mississippian: New Brunswick and Nova Scotia.

H. M. Ami, 1900 (Can. Rec. Sci., vol. 8, p. 160). *Windsor fm.*, Carbf.

C. Schuchert and C. O. Dunbar, 1933 (Textbook geol., pt. 2, p. 227). *Windsor group* corresponds to Mauch Chunk sh. (of Chester age) of Appalachian region.

Windy Arm series.

Age (?): Yukon Territory.

D. D. Cairnes, 1908 (Canada Dept. Mines, Geol. Surv. Branch, Pub. 982, pp. 23, 29).

Windy Gap limestone member (of Greene formation).

Permian: Southwestern Pennsylvania and northern West Virginia.

I. C. White, 1891 (U. S. G. S. Bull. 65, pp. 24, 30). *Windy Gap ls.*, 4 to 5 ft. thick, lies 25 to 30 ft. above Windy Gap coal in Greene Co., Pa. Included in Dunkard Creek series [Dunkard group].

Named for Windy Gap, a divide separating Laurel Run branch of Fish Creek from waters of Wheeling Creek, in Springfield Twp, Greene Co., Pa.

Windy Gulch rhyolite breccia. (In Potosi volcanic series.)

Miocene: Southwestern Colorado (Creede district).

W. H. Emmons and E. S. Larsen, 1923 (U. S. G. S. Bull. 718). A rhyolite breccia, made up of light-colored rhyolite, in part an ordinary tuff, in part a normal flow rock, but chiefly a breccia, probably a flow breccia, in lower part of Piedra group of Potosi volcanic series. Underlies the tridymite latite of Piedra group in drainage basin of Windy Gulch and to W. Characterized by porous character and abundant fragments of pumice. Thickness 100 to 200+ ft.

Windy Point granite.

Pre-Cambrian: Eastern Colorado (Pikes Peak region).

G. I. Finlay, 1916 (U. S. G. S. Colorado Springs folio, No. 203). *Windy Point granite.*—Holocrystalline and fine-grained. Forms summit of Pikes Peak. Appears to have been intruded into Pikes Peak granite. Does not extend into Colorado Springs quad.

Winfield limestone. (In Chase group.)

Permian: Eastern Kansas, southeastern Nebraska, and central northern Oklahoma.

C. S. Prosser, 1897 (Kans. Univ. Geol. Surv. vol. 2, pp. 64–66). *Winfield concretionary ls.*—Ls., 13 ft. thick, heretofore called Marion concretionary ls. Top memb. of Chase fm.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 715). *Winfield fm.*—Massive concretionary ls. [Winfield concretionary ls. of previous repts] at top; yellowish shales in middle; and cherty ls. [†Marion flint] at base. Thickness 25 ft. Overlies Doyle shales and underlies Marion fm. [This expanded definition of Winfield ls. was followed by Kans. Geol. Survey and U. S. Geol. Survey until 1929.]

N. W. Bass, 1929 (Kans. Geol. Surv. Bull. 12, p. 87, in cooperation with U. S. Geol. Survey), applied *Winfield ls.* to 10 or 11 ft. of massive ls. in Cowley Co., Kans., which "probably corresponds to the 'massive concretionary ls.' of Prosser, which he described as occurring at the top of his Winfield fm. The lower part of his Winfield fm. may then correspond to upper part of Doyle sh. as herein described, the basal cherty ls. ('Marion flint') being absent in southern Kans."

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser.), divided *Winfield fm.* into 3 members (descending)—Cresswell ls. ("concretionary ls." of early repts), Grant sh., and Stovall ls.—with a combined thickness of 26 ft., apparently following Prosser's definition. They also divided underlying *Doyle fm.* into 3 named members, aggregating 66 ft. in thickness.

R. C. Moore, 1936 (Kans. Geol. Soc. 10th Ann. Field Conf. Guidebook, p. 12), treated Luta ls. as top memb. of Winfield ls. and treated Condra's members of Doyle sh. as fms., dropping *Doyle*.

These recent reports (which apparently follow Prosser's 1902 definitions of *Winfield* and *Doyle*) have not yet been considered by U. S. Geol. Survey for its publications.

Named for exposures around Winfield, Cowley Co., Kans.

†Winfield formation.

See under *Winfield ls.*

†Winfield dolomite.

Lower Ordovician: Central eastern Missouri and southwestern Illinois.

C. R. Keyes, 1898 (Iowa Acad. Sci. Proc., vol. 5, pp. 59, 60). *Winfield dol.*—Deep buff, somewhat earthy mag. ls., rather heavily bedded and containing some sandy material; apparently unfossiliferous. Thickness 40 ft. Oldest bed exposed along the Mississippi btw. Missouri River and northern Iowa. Underlies Cap au Gres [St. Peter] ss. in Lincoln Co., Mo., and across the river in Ill.

Now classified by Mo. Geol. Surv. as same as Cotter dol.

Named for Winfield, Lincoln Co., Mo.

Wing conglomerate.

Lower Ordovician (Beekmantown): Northwestern Vermont (Champlain Valley).

H. M. Seely, 1906 (5th Rept. Vt. State Geol., pp. 174–187). *Wing cgl.* is the "cgl. bed" of Rev. A. Wing. Belongs to Beekmantown, but exact horizon uncertain. Believed to lie near top of Div. D.

Wingate sandstone. (In Glen Canyon group.)

Jurassic (?): Western New Mexico, northeastern Arizona, southeastern Utah, and southwestern and western Colorado.

C. E. Dutton, 1885 (U. S. G. S. 6th Ann. Rept., pl. 16, p. 136). *Wingate sss.*—Bright-red sss., 450 ft. thick. Underlie Zuni sss. in Zuni Plateau, N. Mex., and are separated from underlying Shinarump cgl. by 1,450 to 1,550 ft. of red sh. and sandy sh. [later named *Chinle fm.*].

H. E. Gregory, 1917 (U. S. G. S. P. P. 93), gave detailed description of Wingate ss. in Navajo country, and applied *Todilto fm.* to the beds separating it from the younger Navajo ss., and *Chinle fm.* to the underlying beds.

Subsequent work showed that the Todilto at its type loc. in NW. N. Mex. is basal memb. of Morrison fm., but that in SE. Utah and parts of SW. Colo. the Morrison is separated from the Wingate ss. by several intervening fms., in descending order Summerville, Curtis, Entrada, Carmel, Navajo, and Kayenta. (See A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., U. S. G. S. P. P. 183, 1936.)

Winifrede sandstones. (In Kanawha formation.)

Pennsylvanian: West Virginia.

I. C. White, 1908 (W. Va. Geol. Surv. vol. 2A, pp. 271, 430). *Upper Winifrede ss.*—Massive yellowish-gray ss., coarse in upper half but close and fine-grained below; 50 to 80 ft. thick. Lies 10 to 20 ft. below Coalburg coal and rests on Winifrede coal. *Lower Winifrede ss.*—Grayish-white hard, often massive ss., 20 to 40 ft. thick. Rests uncon. on Chilton ss. and lies 5 to 15 ft. below Winifrede coal. [Probably named for occurrence at Winifrede, Kanawha Co.]

POLITECHNIKA GDAŃSKA ZAKŁAD GEOLOGII

Winifrede limestone. (In Kanawha formation.)

Pennsylvanian: Southern West Virginia.

R. V. Hennen, 1914 (W. Va. Geol. Surv. Rept. Kanawha Co., pp. xxvi, 641). *Winifrede ls.*—Impure ls., ½ to 1 ft. thick, containing fossil shells. Overlies Upper Chilton ss. and is separated from overlying Chilton A coal by 5 to 19 ft. of fire clay and sh. The weathered ls., not in place, was found 1 mi. S. of Winifrede, on Fields Creek, North Hollow, 100 yds. E. of mouth of South Hollow, Kanawha Co.

Winkler Ford limestone member (of Grape Creek formation).

Permian: Central Texas (Concho County).

W. Kramer, 1934 (A. A. P. G. Bull., vol. 18, No. 12, p. 1581). A 1-ft. bed of dark-gray ls. lying 670 ft. above Coleman Junction ls. makes a ledge btw. Millersview and Concho River. This bed might be called *Winkler Ford memb.*, for it crops out (0.1 mi. S. of NW. corner Elizabeth Aurand survey No. 1861) on road 1.2 mi. SE. of that crossing on Concho River.

Winnebago shale.

Pennsylvanian: Southeastern Nebraska and northeastern Kansas.

See under *South Fork ls.*

Winneshiek limestone.

Lower Ordovician: Iowa.

C. [R.] Keyes, 1934 (Pan-Am. Geol., vol. 61, No. 3, p. 240). The Willow [River] beds at type loc. may possibly therefore represent only not more than ¼ of southern section, the rest being removed through planation before the Peter [St. Peter] ss. was laid down. In its max. development in Iowa, some such term as *Winneshiek dol.* would be really more appropriate.

†Winnfield limestone.

Upper Cretaceous (?): Northwestern Louisiana.

G. D. Harris and A. C. Veatch, 1899 (La. Geol. Surv. pt. 5, Rept. for 1899, pp. 56–59). *Winnfield ls.*—Highly crystalline ls., full of cracks, pockets, and joints, shows whitish and bluish bands of various shades. No fossils found, but included in Ripley stage of Upper Cret.

Named for Winnfield, Winn Co., where it is quarried.

According to M. I. Goldman (personal communication, Dec. 1936) the rock to which this name was applied is a calcite cap rock.

Winnipeg sandstone.

Ordovician: Manitoba.

D. B. Dowling, 1896 (Ottawa Field Nat. Club Trans. 1895–96, vol. 11, pp. 67–68).

Winnipeg limestone.

Ordovician: Ontario.

A. C. Lawson, 1912 (Canada Geol. Surv. Summ. Rept. 1911, p. 243).

Winnipegosan formation.

Winnipegosis formation.

Devonian: Manitoba.

J. B. Tyrrell, 1893 (Canada Geol. Surv., n. s., vol. 5, pt. 1, pp. 144E–199E). Winnipegosan fm., Dev., Manitoba.

R. C. Wallace, 1915 (Canada Geol. Surv. Summ. Rept. 1914, p. 77). [Both spellings are used in this rept., which states that the beds are exposed at Graves Point, Lake Winnipegosis.]

Winnipeg River granite.

Pre-Cambrian: Ontario.

E. M. J. Burwash, 1923 (Ont. Dept. Mines 32d Ann. Rept., pt. 2, p. 7).

†Winnipesaukee gneiss.

See under *Lake Winnipesaukee gneiss.*

[library stamp]

Winoka gravel.

Pliocene: Southwestern Missouri.

Emma J. Park, Mabel Hays, and E. M. Shepard, 1904 (Bradley Geol. Field Sta. Drury Coll. Bull. 1, pt. 1, pp. 14, 19, 41). *Winoka gravel.*—Scattered deposits of orange-brown to grayish-yellow river gravel, 50 ft. thick, occurring for most part on hilltops and hillsides far above present stream beds. Rests on Upper Burlington ls. except in one area, where it rests on Chouteau ls. Assigned to Tert. [Later rept by E. M. Shepard assigned this gravel to Plio. and stated it is same as so-called "Lafayette."]

Named for exposures at Winoka, Greene or Christian Co.

Winona conglomerate.

Pre-Cambrian (Keweenawan): Northern Michigan.

A. C. Lane, 1911 (Mich. Geol. and Biol. Surv. Pub. 6, geol. ser. 4, pp. 547, 563, 566, 576, 982, fig. 42). *Winona cgl.* is same as Marvine's cgl. No. 8.

Is generally regarded as same as Bohemia cgl., top fm. of Bohemian Range group.

Named for occurrence in Winona mine, Houghton Co.

Winona amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Probably same as Isle Royale amygdaloid. The mineralized part is the Winona lode. Named for occurrence in Winona mine, Houghton Co. Belongs to Central Mine group.

Winona flow.

Includes Winona amygdaloid and underlying trap.

Winona sand member (of Lisbon formation).

Eocene (middle): Mississippi.

E. N. Lowe, 1919 (Miss. Geol. Surv. Bull. 14, p. 73). *Winona sand.*—In NW. Miss. consists of approx. 350 ft. of highly glauconitic marine sands and clayey sands, locally abundantly fossiliferous. In eastern Miss. the materials change to white and yellowish coarse sand, frequently cross-bedded and nonfossiliferous. Near Meridian only 75 to 100 ft. thick. Especially well developed around Winona, Vaiden, and eastward in adjacent counties. Included in Tallahatta fm., as basal memb. Conformably underlies Basic claystone.

C. W. Cooke, 1925 (U. S. G. S. P. P. 140). *Winona sand memb.* redefined so as to include typical Winona sand of Montgomery Co. and typical "Enterprise marl" of Clarke Co., but to exclude the sands at base of Tallahatta fm. in Lauderdale Co., Miss., which were formerly erroneously supposed to be same as the much younger sand at Winona. Is basal memb. of Lisbon fm. in Miss.

Named for development at Winona, Montgomery Co.

Winooski marble.

Lower Cambrian: Northwestern Vermont (Chittenden County).

E. Hitchcock, 1861 (Rept. Geol. Vt., vol. 1), designated the basal 40 ft. of his Red Sandrock series as *Winooski marble*, "not to multiply local designations, but to designate a peculiar variety of the Red Sandrock series, using the name by which it is known in economic geol." Subsequent repts on geol. of Vt. frequently contained references to *Winooski marble*.

G. H. Perkins, 1885 (Am. Nat., vol. 19, pp. 128-136), in a description of Swanton, Vt., described the *Winooski or Wakefield marble* as consisting of 370 ft. of white and red dol. with sandy layers, some strata mottled rose red and white and a few brick red or Indian red, and as containing fossils.

A. Keith, 1923 (Am. Jour. Sci., 5th, vol. 5, p. 108). *Winooski marble.*—Outcrops in nearly continuous belts from Snake Mtn to Canada. The name is a very old one, given for fine exposures along Winooski River in Burlington, where marble was first quarried from the fm. and is still obtained from other quarries near Swanton. The fm. is mainly dol., of prevailing red or pink mottled color; interbedded with these colored beds are considerable layers of light-gray dol. A few of gray beds are rather coarsely crystalline, but most of the dolomites, both gray and colored, are very dense and have marked conchoidal fracture. The characteristic feature of the dol. is a very marked wavy, lumpy surface for the individual layers. At base the dol. is interbedded with qtzite layers for 50 ft., forming transition into underlying Monkton qtzite. Just below top of the Winooski there is a marked horizon, 9 ft. thick, of red, buff, and purple qtzite layers interbedded with pink and buff mottled fine-grained dol. In the pink dol. just above this qtzite there are a few inches of edgewise cgl. containing thin, flat dol. pebbles. The qtzite layers at this horizon form broad, flat surfaces like those of Monkton qtzite, which they strongly resemble, and also show ripple marks, mud cracks, and annelid trails. These beds and the underlying mottled pink or purple dolomites aggregating 85 ft. are well exposed at Winooski Falls in Burlington. There is abrupt change above topmost qtzite of the fm. to the massive gray beds of overlying Mallett dol. Thickness of fm. 100± on E. side of Snake Mtn to 400 ft. about 12 mi. N. of Burlington.

†Winslow formation.

Pennsylvanian: Northwestern Arkansas and northeastern Oklahoma.

G. I. Adams, 1904 (U. S. G. S. P. P. 24, p. 29). *Winslow fm.*—The rocks in northern Ark. which have usually been called *Millstone grit.* Base of fm. at most localities characterized by presence of quartz pebbles. Attains great thickness in Boston Mtns. Upper limit not definitely determined. Contains much more ss. than underlying Morrow fm., and the beds are often massive and exposed in heavy ledges which give rise to escarpments. No persistent ls. beds so far as known. The sss. have not yielded fossils, although they undoubtedly contain fossils in some places.

G. I. Adams and E. O. Ulrich, 1905 (U. S. G. S. Fayetteville, Ark., folio, No. 119) gave thickness of *Winslow fm.* in that quad. as 100+ ft., and stated that it appeared to be uncon. on underlying Morrow fm. and that its top was eroded.

J. A. Taff, 1905 (U. S. G. S. Tahlequah, Okla., folio, No. 122), mapped *Winslow fm.* in eastern Okla., where he applied the name to 1,100 ft. of strata uncon. overlying Morrow fm. and composing the youngest fm. in that area. In 1906 (U. S. G. S. Muscogee, Okla., folio, No. 132) Taff mapped as *Winslow fm.* 800 to 1,000 ft. of strata underlying what he mapped as Boggy fm. and uncon. overlying Morrow fm. In latter folio he stated that his Winslow fm. was = Atoka, Hartshorne, and McAlester fms. of other areas in Okla.

A. H. Purdue, 1907 (U. S. G. S. Winslow, Ark., folio, No. 154), mapped *Winslow fm.* in its type area, gave its thickness as 2,300± ft., stated that it rested conformably on the Morrow, and that it was overlain by alluvium.

The strata included in Winslow fm. are of late Pottsville and early Allegheny age. That it is a blanket term covering rocks susceptible of subdivision into several fms. has long been recognized by J. A. Taff, C. Croneis (Ark. Geol. Surv. Bull. 3, 1930), and other geologists. According to field work of B. Parks and T. A. Hendricks, all of it that is present in Fayetteville quad. is now known to belong to Atoka fm. In Winslow quad. it included Atoka fm., Hartshorne ss., and lower part of McAlester fm.; and as used in some other areas it included, in addition, upper part of McAlester fm., the overlying Savanna ss., and at least the lower part of Boggy sh. This blanket name has therefore been discarded. (See references under *Akins sh. memb.*)

Named for exposures at and around Winslow, Ark.

Winslow shale.

Lower Triassic: Northeastern Arizona.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 250, 339). Name *Winslow shales* is given to 3d sh. bed of Ward's Moenkopian series, exposed in Rio Chiquito Colorado Valley, at mouth of Rio Puerco, Navajo and Coconino Counties, Ariz. Thickness 200 ft.

Derivation of name not stated. Mouth of Rio Puerco is in Navajo Co., near Holbrook, a considerable distance E. of Winslow.

Winston dolomite.

Silurian (pre-Niagaran): Northeastern Iowa and northwestern Illinois.

T. E. Savage, 1914 (Am. Jour. Sci., 4th, vol. 38, pp. 34–37). *Winston ls.*—Yellow earthy fine-grained dol., in rather thin even layers, 22 ft. thick, with 6 in. of conspicuously laminated bluish calc. and shaly ss. at base. Uncon. overlies Maquoketa sh. and underlies Waucoma ls. Represents about same period of deposition as Edgewood fm. but thought to belong to a northern province. Lower fm. of Alexandrian series.

T. E. Savage, 1926 (Geol. Soc. Am. Bull., vol. 37, pp. 526+), discarded his *Winston ls.*, being satisfied it is same as Edgewood ls., which has priority. (See 1926 entry under *Waucoma ls.*)

Named for Winston, Jo Daviess Co., Ill.

Winters clay. (In Allegheny formation.)

Name applied to plastic clay, 3 ft. 7 in. thick, underlying Winters coal in Vinton Co., Ohio. (See W. Stout, Ohio Geol. Surv., 4th ser., Bull. 31, 1927.)

Winterset limestone. (In Kansas City group, Kansas.)

Winterset limestone member (of Kansas City formation, Missouri).

Pennsylvanian: Western Iowa and Missouri, eastern Kansas, and southeastern Nebraska.

J. L. Tilton, 1897 (Iowa Acad. Sci. Proc., vol. 4, pp. 48–54). *Winterset ls.*—Alternating lss. and shales, with some ss., representing Missourian stage in Madison Co., Iowa. Thickness about 30 ft.

J. L. Tilton and H. F. Bain, 1897 (Iowa Geol. Surv. vol. 7, pp. 517–519). *Winterset ls.*, 12 ft. thick, is separated from overlying *Fusulina* [DeKalb] ls. by a sh. bed and from underlying Earlham [Bethany Falls] ls. by 8 ft. of sh. [Galesburg sh. memb.].

For many years the generally accepted definition of Winterset ls. was a memb. of Kansas City fm. underlying Cherryvale sh. memb. and overlying Galesburg sh. memb.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 91, 97), stated that *Winterset ls.* of his present revised classification of rocks of Kans. is "the same as previously recognized in Kans. and Mo.;" it is top memb. of Dennis ls. as here defined; the sh. underlying it is younger than Galesburg sh. and is here named Stark sh.; the Stark sh. is separated from true Galesburg sh. by a ls. here named *Canville ls.*

See under *Dennis ls.*

Named for exposures at Winterset, Madison Co., Iowa

Winthrop sandstone.

Cretaceous: Central northern Washington.

I. C. Russell, 1900 (U. S. G. S. 20th Ann. Rept., pt. 2, pp. 100–137). *Winthrop ss.*—Nearly white massive arkose ss. and light-gray sandy shales. Thickness 2,000+ ft. Fossil leaves (Cret.). Finely exposed on N. border of Methow Valley, 5± mi. NW. of Winthrop, Okanogan Co.

Winzeler shale.

Pennsylvanian: Eastern Kansas, southwestern Iowa, and southeastern Nebraska.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 94, 96). [See under *Bachelor Creek ls.* On p. 20 *Winzeler sh.* is described as consisting of 5 ft. of light-bluish sandy sh.; on p. 21 it is described as 3.15 ft. of yellowish-gray clayey calc. sh.]

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 208). *Winzeler sh.* overlies Church ls. and underlies Utopia ls. It is 3 to 8 ft. thick, bluish gray or yellowish and clayey to calc. Marine fauna in lower part. Is recognizable from Nebr. and Iowa to Okla., but locally, where Utopia ls. disappears, the beds immediately overlying Church ls. are classed as White Cloud sh. Type loc., Winzeler farm, sec. 4, T. 26 S., R. 11 E., Greenwood Co., Kans.

Wirtemburg limestone.
Wirtemburg sandstone.
See *Wurtemburg*.

Wisconsin stage of glaciation, also **Wisconsin drift** (Pleistocene).

Wisconsin stage is name applied to last stage of glaciation, which has usually been divided into two substages, called *early Wisconsin* and *late Wisconsin*. Three substages (early, middle, and late Wisconsin) are, however, now recognized by Leverett (Moraines and shore lines of Lake Superior Region, U. S. G. S. P. P. 154A, 1929). The name was proposed by T. C. Chamberlin (Great ice age, by James Geikie, 3d ed., pp. 754–775, 1894) in the form *East Wisconsin stage of glaciation* for the time, and *East Wisconsin fm.* for the deposits, because of their development in eastern Wis. In 1895 (Jour. Geol., vol. 3, pp. 270–277) Chamberlin, upon the suggestion of Upham, shortened the name to *Wisconsin*. In 1931 (Jour. Geol., vol. 39, pp. 51–53) M. M. Leighton proposed to "reclassify the Iowan and Wisconsin drifts" by including in the Wisconsin the Peorian loess and the underlying Iowan drift. He also introduced *Hudsonian substage* for the late Wisconsin drift, *Quebecan substage* for the early and middle Wisconsin drift, and applied the new name *Manitoban substage* to the Iowan drift. (See under †*Manitoban substage*.) In 1933, however (Sci., vol. 77, p. 168), he withdrew his proposed names Hudsonian, Quebecan, and Manitoban, and proposed the following subdivisions of his Wisconsin (or fourth) glacial "age": Mankato (late Wisconsin), Cary (middle Wisconsin), Tazewell (early Wisconsin), and *Iowan* (oldest Wisconsin). F. Leverett, 1933 (Sci., vol. 77, p. 560), objected to introduction of Mankato, Cary, and Tazewell. (See under *Mankato substage*.) In 1931 (Geol. Soc. Am. Bull., vol. 42, pt. 1, pp. 449+) G. F. Kay introduced *Eldoran epoch* to include Wisconsin, Peorian, and Iowan. In 1933 (Geol. Soc. Am. Bull., vol. 44, pp. 669–673, August 31) Kay and Leighton proposed the following classification for Mississippi Valley:

- Pleistocene or Glacial period (system):
  - Eldoran epoch (series): [Redefined to include Recent.]
    - Recent age (stage).
    - Wisconsin age (stage):
      - Mankato substage (Late Wisconsin).
      - Cary substage (Middle Wisconsin).
      - Tazewell substage (Early Wisconsin).
      - Iowan substage.
  - Centralian epoch (series):
    - Sangamon age (stage).
    - Illinoian age (stage).
  - Ottumwan epoch (series):
    - Yarmouth age (stage).
    - Kansan age (stage).
  - Grandian epoch (series):
    - Aftonian age (stage).
    - Nebraskan age (stage).

Regarding Peorian they stated: The name *Peorian* will continue to be used in Iowa for the widespread loess which lies on the Iowan drift and around its border and beneath the Mankato (Late Wisconsin) drift; and in Ill. for the widespread loess which lies above the Late Sangamon loess outside of Tazewell drift. Within the border of Tazewell drift the *loess* which immediately underlies it may be called *Iowan*, as originally proposed, and the loess which overlies it the *Tazewell* loess. These two loesses are indistinguishable outside of the Tazewell drift border and compose the Peorian loess.

†Wisconsin Valley slates.

Pre-Cambrian (Huronian): Central northern Wisconsin (upper part of Wisconsin River).

C. R. Van Hise, 1892 (U. S. G. S. Bull. 86, pl. 3, map), and R. D. Irving, 1892 (U. S. G. S. Mon. 19, pl. 1, map). *Wisconsin Valley slates* mapped along upper part of Wisconsin River and assigned to Huronian.

The U. S. Geol. Survey does not now use this name, but uses *slates of Wisconsin Valley*, in a geographic sense.

Wiscoy shale (also **Wiscoy sandstone**).

Upper Devonian: Western and west-central New York.

J. M. Clarke, 1899 (N. Y. State Mus. 16th Ann. Rept., pp. 31–41). *Wiscoy beds*.—Shales and sands overlying Portage [Nunda] sss. in Genesee River section. Contain normal Portage or Naples fauna.

D. D. Luther, 1902 (N. Y. State Mus. Bull. 52, p. 619). *Wiscoy shales*.—Mainly soft sh., bluish and argill., or olive and sandy, with, occasionally, thin black layers, a few flags or thin sss., and calc. concretions. Thickness 150 ft. Top fm. of Portage or Nunda group. Overlain by band of flags and thin sss. that form "Long Beards riffs" [Long Beards Riffs ss.] and contain fossils of Chemung group in Genesee River section. Underlain by Portage [Nunda] sss.

J. M. Clarke and D. D. Luther, 1904. See 1904 item under *Prattsburg*.

J. M. Clarke and D. D. Luther, 1905 (N. Y. State Mus. Bull. 81). *Wiscoy sh.* can be traced W. to Lake Erie, showing little change in lithologic character and fauna, but eastward the fauna is more aren., and S. of Dansville, 25 mi. E. of Wiscoy, the fm. is mainly laminated ss. crowded with brachiopods. So conspicuous is its development from Dansville eastward, and so profuse and striking its development of *Chemung* brachiopod fauna, that on map of Naples quad. it was deemed advisable to apply to it the term *Prattsburg ss. and sh.*, inasmuch as there has been this fundamental change in nature of fauna.

Later repts by Luther give thickness of 170 to 190 ft. in Wyoming and Erie Counties.

See Luther, 1906, under *Prattsburg*.

C. A. Hartnagel, 1912 (N. Y. State Mus. Hdb. 19, p. 79). *Wiscoy sh. and sands*.—Top div. of Portage beds in western and west-central N. Y. Named from exposure at falls of Wiscoy Creek, Allegany Co.

G. H. Chadwick, 1923 (Geol. Soc. Am. Bull., vol. 34, p. 69). *Wiscoy sh.* is overlain by Canaseraga ss. in Allegany Co. and by equiv. Dunkirk sh. (including Long Beard Riffs ss. in lower part) in Cattaraugus Co. Is of Portage age.

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, p. 369). *Wiscoy sh.* underlies Dunkirk sh. (of Chemung group) and overlies Nunda ss. Is top fm. of Portage group.

G. H. Chadwick, 1933 (Pan-Am. Geol., vol. 60, pp. 193, etc.). *Wiscoy sh.* is = Hanover sh. (above) and Pipe Creek sh. (below). Included in Nunda [Portage] group.

In Steuben and adjacent counties of south-central N. Y. the Wiscoy is ss. and is called *Wiscoy ss.* To W. it is sh. and is called *Wiscoy sh.*

Wise formation. (In Pottsville group.)

Pennsylvanian: Southeastern Kentucky and southwestern Virginia.

M. R. Campbell, 1893 (U. S. G. S. Bull. 111, pp. 28, 34). *Wise fm.*—Shales and sss., with clays and coal beds, 1,270 ft. thick, in upper part of Coal Measures of Bigstone Gap coal field of Va. and Ky. Underlain by Gladeville ss. and overlain by Harlan ss.

Belongs to upper part of Pottsville group.

Named for Wise Co., Va.

Wiser sand.

A subsurface sand, of Penn. age and 0 to 60 ft. thick, in central northern Okla., which is correlated with a part of Oologah ls. In Wiser pool.

Osage Co., the producing sands are called Wayside (at 750 ft. depth), Bartlesville (at 1,475 ft. depth), and Burgess (at 1,700 ft. depth).

Wissakickon schist.

Wissahickon formation.

Pre-Cambrian (Glenarm series): Southeastern Pennsylvania, northern Maryland, and across Virginia.

F. Bascom, 1902 (Md. Geol. Surv. Cecil Co. Rept., pp. 104-108). *Wissahickon mica gneiss.*—The gneisses of Phila. belt of crystallines (Chestnut Hill, Manayunk, and Philadelphia schist and gneisses) are divisible into a mica gneiss of sed. origin and several presumably intrusive igneous bodies—peridotites and pyroxenites, largely represented now by serpentines, gabbro, and norite, and two granite gneisses. The fm. into which these igneous rocks have been intruded is a mica gneiss, provisionally named *Wissahickon gneiss*, from creek along banks of which it is finely exposed.

F. Bascom, 1904 (U. S. G. S. W. S. P. 106). *Wissahickon mica gneiss and mica schist (Hudson).*—A crystalline bedded fm., which outcrops in a NE.-SW. belt. The mica gneiss extends from Delaware River to Chestnut Hill. Toward N. the fm. becomes a mica schist, which forms the south Chester Valley hills and immediately overlies Chester Valley ls.

F. Bascom, 1909 (U. S. G. S. Phila. folio, No. 162), introduced *Octoraro schist* to replace Wissahickon mica schist, which was stated to be younger than Wissahickon mica gneiss, to overlie Shenandoah ls., and to be of Ord. age, while Wissahickon mica gneiss was assigned to pre-Camb.

A. I. Jonas and E. B. Knopf, 1921 (Wash. Acad. Sci. Jour., vol. 11, p. 447). An upper memb. of Wissahickon fm. that is less highly anamorphosed than the Wissahickon itself has been separated and named by the writers the *Peters Creek schist.*

E. B. Knopf and A. I. Jonas, 1923 (Am. Jour. Sci., 5th, vol. 5, pp. 40-62). *Wissahickon fm.* (as now restricted) consists of two contemp. facies, one here called the oligoclase-mica schist facies and the other here called the albite-chlorite schist facies. Overlying the oligoclase-mica schist and grading into it through a phyllitic zone is fm. named by writers *Peters Creek schist.* It is a series of chloritic and sericitic qtzites interbedded with chlorite-muscovite schist and grading toward top into mildly anamorphosed quartzose and conglomeratic sediments. It comprises part of what was originally mapped as *Wissahickon gneiss* and part of *Octoraro schist.* The *Peters Creek schist* grades upward into Cardiff cgl. The Wissahickon fm. rests on Cockeysville marble. All included in Glenarm series.

A. I. Jonas, 1928 (Va. Geol. Surv. prel. ed. of geol. map of Va.), mapped *Wissahickon schist* entirely across Va., to N. C. line.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, p. 34). Work by writers in Md. and Pa., along Susquehanna River section, shows that the pre-Camb. Wissahickon gneiss N. of Phoenix anticline in Md., where the fm. is oligoclase-biotite schist, dips under a synclinal fold of Peters Creek schist and reappears from under N. limb of the syncline in a different mineralogic facies, the albite-chlorite schist. It was thus shown that "Octoraro schist" is not a strat. unit and that the fms. which made up the old "Octoraro schist" are part of a conformable sequence of pre-Camb. rocks of Glenarm series.

In southern Pa., on Susquehanna River, the Peters Creek schist is 2,000 ft. thick and the Wissahickon restricted is estimated to be 8,000 to 10,000 ft. thick. The fm. was formerly classified by U. S. Geol. Survey as of Algonkian age, but that term having been discarded as a time term the fm. is now classified as *pre-Camb.*

Witnet formation.

Tertiary (pre-Miocene): Southern California (northeastern part of Kern County).

J. P. Buwalda, 1934 (Pan-Am. Geol., vol. 61, No. 4, p. 310). *Witnet fm.*—Many hundred ft. of arkosic cgl. and coarse ss., overturned and overthrust by pre-Cretacic crystalline rocks from the SE. Is pre-Mio. Tert. Occurs NE. of Monolith [NE. part of Kern Co.]. At type section, along N. side of lower Oil Canyon, overlain with strong angular uncon. by Kinnick fm. (Lower Mio.). [Derivation of name not stated.]

Wittenberg shale.

Middle Devonian: Southeastern Missouri.

C. Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, p. 253). *Wittenberg terrane.*—Shales, 30 ft. thick, uncon. underlying Callaway ls. and uncon. overlying Grand Tower ls.

Probably named for Wittenberg, Perry Co.

Wittenberg conglomerate.

Upper Devonian: Southeastern New York (Ulster County?).

See Feb. 1935 entry (G. H. Chadwick) under *Slide Mtn cgl.*

Wizard Wells limestone. (In Graford formation.)

Pennsylvanian: Central northern Texas (Wise County).

J. M. Armstrong and G. Scott, 1930 (Tex. Bur. Econ. Geol. map of Wise Co.). *Wizard Wells ls.* is top part of Graford fm. Overlies Rock Hill ls.

E. H. Sellards, 1933 (Tex. Univ. Bull. 3232, p. 105). *Wizard Wells ls.* is same as Devils Den ls. and is discarded.

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, p. 24), showed *Wizard Wells ls.* of Wise Co. as much older than Clear Creek ls., as somewhat older than Merriman ls., as=basal part of Brad fm. of Colorado River Valley, and as, in part of its area, extending downward to a thickness, locally, of 370 ft., with its base slightly higher than Rock Hill ls.

Woburn formation.

Pre-Cambrian: Eastern Massachusetts (Boston quadrangle).

L. LaForge, 1932 (U. S. G. S. Bull. 839). *Woburn fm.*—A complex of felsic igneous rocks, probably chiefly volcanic, and interbedded siliceous sediments. Most of the igneous rocks are highly siliceous and well laminated and have frequently been taken for and mapped as qtzite, for which reason the fm. has often been confused with Westboro qtzite. Rhyolite and dacite are predominating rock types, although there are some sparsely porphyritic varieties that are probably andesitic. Seems to overlie Marlboro fm. and to be youngest of supposed pre-Camb. fms. of Boston region. Thickness uncertain, but average is probably about 500 ft. Named for good exposures in SW. part of Woburn.

Wolcott limestone member (of Clinton formation).

Silurian: Central and western New York and Ontario.

J. M. Clarke, 1906 (N. Y. State Mus. 2d Rept. Dir. Sci. Div., 1905, p. 12). [See under *Irondequoit ls.*]

C. A. Hartnagel, 1907 (N. Y. State Mus. Bull. 114, pp. 5–35). *Wolcott ls.*, 14 ft thick in Rochester and Ontario Beach quads., has appearance of crystalline ls. Included in Clinton fm. Underlies Williamson sh. and overlies Furnaceville ore. Named for Wolcott, Wayne Co. [In Niagara quad. is 6–10+ ft. thick.]

G. H. Chadwick, 1908 (Sci., n. s., vol. 28, pp. 346–348). Furnaceville ore bed lies *in* and not *below* Wolcott ls. [See under *Furnaceville iron ore.*] The true *Pentamerus* ls. of Wolcott Furnace must inherit the name *Wolcott ls.*

C. Schuchert, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 314), identified 8 ft. 8 in. of *Wolcott ls.* at Hamilton, also at other places in Ont., underlying Irondequoit ls.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368), showed *true Wolcott ls.* absent at Rochester, where the much older Reynales ls. was mistaken for the Wolcott by Hartnagel. See further explanation under *Williamson sh.*, 1918 entry.

E. O. Ulrich, 1923 (Md. Geol. Surv. Sil. vol., pp. 191, 347, etc.), placed *Wolcott ls.* uncon. below Williamson sh. and above Sodus sh., which is position assigned to it by W. Goldring, 1931 (N. Y. State Mus. Hdb. 10).

Wolcott Furnace iron ore.

Silurian: Central New York.

G. H. Chadwick, 1918 (Geol. Soc. Am. Bull., vol. 29, pp. 327–368). Ore bed that crops out at old Wolcott Furnace on Wolcott Creek, 1 mi. N. of Wolcott village [Wayne Co.]. Is of limited extent even in wells. Lies btw. true Williamson sh. above and true Wolcott ls. below. [Is a memb. of Clinton fm.]

W. Goldring, 1931 (N. Y. State Mus. Hdb. 10, pp. 317, 326), stated that *Wolcott Furnace ore bed* occurs at base of Williamson sh.

Wolf porphyry.

Post-Cretaceous: Central northern Montana (Fort Benton quadrangle).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Wolf porphyry.*—Typical granite porphyry, white to pinkish when fresh, weathering greenish or rust-colored. Forms intrusive mass of Wolf Butte, the peak S. of it, and Mixes Baldy, E. of Barker. Differs from Barker porphyry.

Wolf formation.

Pre-Cambrian: Southern British Columbia and northeastern Washington.

R. A. Daly, 1912 (Canada Geol. Surv., Dept. Mines Mem. 38, map 7, 117° to 117°30'). *Wolf fm.*—Massive gray grit and arkose in very thick beds; subordinate ss.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 150, 178, 194). *Wolf fm.*—Siliceous heavy-bedded grits, sss., and fine-grained cgls. 2,900 ft. thick. Exposed from Mount Ripple N. to headwaters of Wolf Creek, in Selkirk Mtns, B. C., N. of 49th par. Underlies Dewdney fm. conformably and overlies Monk fm. conformably. All belong to Summit series.

Wolf Butte type (of granite porphyry).

A term used by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, p. 498, 1900) for an area of intrusive granite porphyry on Wolf Butte and peak to S., in Little Belt Mtns of central southern Mont. On preceding pp. of above rept W. H. Weed used name *Wolf porphyry.*

Wolfcamp formation.

Permian: Western Texas (Marathon region).

J. A. Udden, 1917 (Univ. Tex. Bull. 1753, p. 41, pl. 3). *Wolfcamp fm.*—Mostly sh., varying from almost black to gray and greenish gray. Interbedded are several layers of ls. which are cemented shell breccias, in places conglomeratic. There are also layers of calc. ss. At Wolfcamp is 92 percent sh., 6 percent ls., and 2 percent calc. cgl. Thickness 500 ft. at Wolfcamp, which is greatest known thickness in Glass Mtns. Uncon. underlies Hess fm. and overlies Gaptank fm., with uncon., E. Böse and J. W. Beede believe. Fossils from basal part [listed; include *Uddenites minor*] indicate, in Böse's opinion, considerable time interval btw. Gaptank and Wolfcamp. Named for Wolfcamp, the site of an old dwelling place just S. of the two buttes located 6½ mi. E. and 2 mi. N. of E. end of Leonard Mtn, and now marked by an old open well 100± ft. deep.

J. A. Udden, 1917 (Univ. Tex. Bull. 1762, p. 16, footnote). *Wolfcamp fm.* was named by Böse, Baker, and Udden. Includes *Uddenites* zone.

E. Böse, 1917 (Univ. Tex. Bull. 1762, pp. 15–22), included *Uddenites* zone in Wolfcamp fm.

In subsequent repts the *Uddenites* zone has been included in Wolfcamp fm. by some writers and in Gaptank fm. by other writers. See under *Gaptank fm.*

C. Schuchert, 1927 (Am. Jour. Sci., 5th, vol. 14, pp. 383–400). Wolfcamp fm. does not have a basal cgl. at type loc., where it is 475 ft. thick, but to SW., where it overlaps upon much-folded fms., its thickness attains 600 ft., of which 400 ft. are cgls. Writer believes *Uddenites* zone belongs to Wolfcamp, but Keyte, Blanchard, and Baldwin believe it belongs to Gaptank. Absent in Del Norte Mtns but present throughout Glass Mtns.

E. H. Sellards, 1933 (Univ. Tex. Bull. 3232, p. 148). *Uddenites* and overlying ls. members are in this rept. included in Gaptank fm. (Penn.) instead of in Wolfcamp fm. (Perm.).

P. B. King, 1934 (Geol. Soc. Am. Bull., vol. 45, pp. 697–798), tentatively drew base of Wolfcamp fm. at top of *Uddenites* zone, and treated the overlying gray ls. as basal bed of Wolfcamp fm. He believed the uncon. reported at top of the gray ls. is debatable.

Wolf Creek conglomerate lentil (of Cattaraugus formation).

Devonian or Carboniferous: Southwestern New York.

C. S. Prosser, 1892 (Rochester Acad. Sci. Proc., vol. 2, pp. 54–57, 64, 93–95). *Wolf Creek cgl.*—Flat-pebble cgl. overlain by 300 ft. of Upper Dev. beds, which separate it from Little Genesee cgl. (believed=Olean cgl.), and underlain by 1,150+ ft. of Chemung rocks along Genesee River.

J. M. Clarke, 1902 (N. Y. State Mus. Bull. 52, pp. 524–528). *Wolf Creek cgl.* underlies Cattaraugus beds, overlies beds containing common Chemung species, and contains certain well-defined aspect of Carbonic life, while leading features of Chemung fauna abruptly disappear with its incoming.

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, pp. 967–989). *Wolf Creek cgl. lentil* (basal bed of Cattaraugus beds) varies in thickness from few in. to 20 ft. Assigned to Dev. [On pp. 696–699 of same bull. J. M. Clarke assigned Cattaraugus beds to Carbf.]

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203), says Wolf Creek cgl. is same as Panama cgl. and LeBoeuf cgl. and older than Salamanca cgl. This is also the correlation of N. Y. State Survey. (See W. Goldring, 1931, N. Y. State Mus. Hdb. 10, p. 425.)

Whether Cattaraugus fm. is late Dev. or early Carbf. is still a debated question.

Named for occurrence on Wolf Creek, W. of West Clarksville, Allegany Co.

Wolf Creek dolomite.

Ordovician: Southern Oklahoma (Arbuckle and Wichita Mountains).

C. E. Decker, 1933 (Tulsa Geol. Soc. Digest, pp. 55–57). [See this entry under *Arbuckle group*.]

Wolf Creek sand.

A subsurface sand in NW. part of Washington Co., SE. Ohio. Seems to be only a local development of Morgantown ss. memb. of Conemaugh fm. (W. Stout et al., Geol. of nat. gas, A. A. P. G., 1935, p. 900.)

Wolfe City sand member (of Taylor marl).

Upper Cretaceous: Northeastern Texas.

L. W. Stephenson, 1918 (U. S. G. S. P. P. 120H, p. 155). *Wolfe City sand memb. of Taylor marl.*—Fine calc. gray sand or sandy marl with a few round, oval, or irregular concretions of calc. ss. Near middle a more or less persistent layer of highly fossiliferous calc. ss. of varying thickness. Some beds of calc. clay occur in upper part of the memb. Thickness 75 to 100 ft. Wolfe City, Hunt Co., is situated on the sand, but only small, poor exposures were seen within town limits. Lies in upper part of Taylor marl, and underlies Pecan Gap chalk memb. of the Taylor. [The Pecan Gap was later made a memb. of Annona chalk. (See C. H. Dane and L. W. Stephenson, A. A. P. G. Bull., vol. 12, No. 1, 1928. See also 1929 entry under *Pecan Gap tongue*.)]

Wolff porphyry.

A misprint in U. S. G. S. Bull. 191, p. 433, for porphyry mapped and described as *Wolf porphyry* in U. S. G. S. Fort Benton folio, No. 55.

Wolf Lake schist.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Gogebic County).

R. C. Allen and L. P. Barrett, 1915 (Mich. Geol. and Biol. Surv. Pub. 18, geol. ser. 15, pp. 131–139). *Wolf Lake schists.*—Green schist or amphibolite, uniformly dark green to black, approaching sl. in appearance, and mica schist. The conclusion that the Paint sl. and mica schist of Wolf Lake area are same fm. is almost inescapable.

Wolf Lake granite.

Pre-Cambrian (upper Huronian): Northwestern Michigan (Gogebic County).

R. C. Allen and L. P. Barrett, 1915 (Mich. Geol. and Biol. Surv. Pub. 18, geol. ser. 15, pp. 131–139). *Wolf Lake granite.*—Mainly white, pink, and gray, with typical granitic, pegmatitic, and porphyritic textures. Intrudes Paint sl.

Named for occurrence in vicinity of Wolf Lake, Gogebic Co.

Wolf Mountain shale member. (In Graford formation.)

Pennsylvanian: Central northern Texas (Palo Pinto County).

F. B. Plummer and J. Hornberger, Jr., 1936 (Univ. Tex. Bull. 3534, pp. 48–55, map). *Wolf Mtn sh.*—A memb. in upper part of Graford fm. in Palo Pinto Co., underlying

Merriman ls. memb. of the Graford and overlying Wiles ls. memb. Consists of bluish-gray soft fossiliferous sh. containing numerous hard small brown limonitic concretions and a few lentils or layers of ss. Typically exposed below the capping Merriman ls. in slopes of Wolf Mtn, 4 mi. W.-NW. of Palo Pinto.

Wolfpen tonalite.

Devonian (?): Eastern central Massachusetts.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 170–171 and map). *Wolfpen tonalite.*—A belt of tonalite or quartz diorite which extends from Sudbury Reservoir southwestward across northern part of Southboro and Westboro and is seemingly a SW. extension of the mass of Dedham granodiorite that extends from Lincoln to Southboro. Well exposed in Wolfpen Hill, in Southboro.

Wolf Ridge sandstone member (of Pottsville formation).

Pennsylvanian: North-central Alabama.

C. Butts, 1927 (U. S. G. S. Bessemer-Vandiver folio, No. 221). *Wolf Ridge ss. memb.*—Hard qtzitic ss., 50 to 100 ft. thick, in Pottsville fm. of Cahaba and Coosa fields. Lies about 1,200 ft. above Pine ss. memb. and about 800 ft. below Straight Ridge cgl. memb. Named for fact that it forms Wolf Ridge.

Wolf River limestone.

Pennsylvanian: Northwestern Missouri, eastern Kansas, southwestern Iowa, and southeastern Nebraska.

G. E. Condra and E. C. Reed, June 1937 (Nebr. Geol. Surv. Bull. 11, 2d ser., pp. 7, 12, 16, 20, 24, 26, 30, 33, 51–52, figs. 1, 2). *Wolf River ls.* is a new name here applied to lower memb. of Topeka ls. fm. Where typically developed consists of a thin-bedded, very fossiliferous upper zone, a middle heavy-bedded massive brownish middle zone, and a thin blocky bed at base separated from the middle zone by a few inches of sh. To N. the ls. is a single bed. Thickness 4 ft. 9 in. NE. of Topeka, 5½ ft. near Iowa Point and Curzen Station, 1 ft. 4 in. N. of Thurman, 1 ft. 2 in. at Jones Point, less than 2 ft. at Weeping Water, 1 ft. 3 in. NE. of Greenfield. Type loc. at mouth of Wolf River, Doniphan Co., Kans. Writers feel they are justified in introducing this new name notwithstanding Moore's use of "Dashner ls." [See further explanation under *Dashner ls.*]

Wolfville sandstone.

Triassic: New Brunswick and Nova Scotia.

S. Powers, 1915 (Geol. Soc. Am. Bull., vol. 26, p. 93).

Wolsey shale.

Middle Cambrian: Central northern Montana (Fort Benton quadrangle), central western Montana (Helena-Big Belt Mountain region), and central southern Montana (Little Belt Mountains quadrangle and to southeast).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). *Wolsey sh.*—Purple and green micaceous shales holding small ls. nodules containing fossils. Thickness 125 ft. Rests on Flathead ss. and underlies Meagher ls., all included in Barker fm.

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Wolsey sh.*—Micaceous sh. containing small ls. concretions near base and interbedded calc. shales higher up. Overlies Flathead qtzite and underlies Meagher ls., all included in Barker fm.

W. H. Weed, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 285). *Wolsey sh.*—Dark-gray or greenish, often micaceous sh., carrying oval concretions of ls., a few in. thick and seldom over 6 in. long, containing Middle Camb. fossils. Average thickness 150 ft. Well exposed at old dam on Sheep Creek near Wolsey, also in Keegan Butte and on hill S. of it, which rises above the open and nearly level surface of Belt Park.

Wolverine sandstone.

Pre-Cambrian (Keweenawan): Northern Michigan.

L. L. Hubbard, 1898 (Mich. Geol. Surv. vol. 6, pt. 2, pp. 77, 81, 93). *Wolverine ss.*—According to Capt. Hodgson this bed is an altered cgl., chiefly of dark-colored ss., 40 ft. wide, with 2 ft. of fluccan on footwall. It may correspond to Marvine's cgl. No. 9 exposed (?) near Portage Lake. It may at other points be an amygdaloid cgl. Underlies Wolverine ophite [a bed of ophite forming footwall of Kearsarge amygdaloid in Wolverine and Kearsarge mines].

Belongs to Central Mine group. Is older than Kearsarge amygdaloid and younger than Old Colony amygdaloid.

Named for outcrops near Wolverine mine, Houghton Co.

Wolverine amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Local name for Kearsarge amygdaloid in Wolverine mine.

Womack gneiss.

Pre-Cambrian: Eastern Colorado (Pikes Peak quadrangle).

L. C. Graton, 1906 (U. S. G. S. P. P. 54). *Womack gneiss.*—Rather dark brownish gray, medium-grained, of fairly uniform texture; abundance of red feldspar and deep-brown mica; not much quartz. No evidence that it is related to Pikes Peak granite. Is certainly older than Cripple Creek granite. Probably derived from a third distinct granite, which is thought to be older than either of the others. Named for Womack Hill, at E. edge of town of Cripple Creek. Underlies most of town.

Womble shale (in Arkansas).

Womble schistose sandstone (in Oklahoma).

Lower and Middle Ordovician: Southwestern Arkansas and southern Oklahoma.

H. D. Miser, 1917 (U. S. G. S. Bull. 660, p. 67). *Womble sh.*—Black graphitic sh. with thin beds of ss. near base and beds of ls. near top. The sh. near base is composed of black and green layers that split at an angle with the bedding and thus show ribboned cleavage surfaces. Thickness 1,000 ft. Underlies Bigfork chert and overlies Blakely ss. Named for town of Womble, Ark. [now called Norman], part of which is on the base of this sh. The Womble forms upper part of "Ouachita sh." of previous repts.

H. D. Miser and A. H. Purdue, 1923 (U. S. G. S. Hot Springs folio, No. 215). *Womble sh.* includes "Stringtown sh." and upper part of "Ouachita sh." of previous repts on Ark. geology.

The Womble sh. of Ark. has yielded Beekmantown, Chazy, and Black River fossils. The Womble sh. of Okla. has yielded Chazy and Black River fossils, but no fossils in lower part. The fm. is at present classified as of Lower Ord. (Beekmantown and Chazy) and Middle Ord. (Black River) age. The name is now employed by U. S. Geol. Survey to replace "Stringtown sh." of both Ark. and southern Okla.

Type section of Womble sh. is at Crystal Mtn, Ark., according to H. D. Miser, March 1937.

Wompats limestone.

Permian: Northern Arizona (Grand Canyon region).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 339). *Wompats ls.*—Highly fossiliferous white subcrystalline lss. immediately underlying surface of Kaibab Plateau. Thickness 225 ft. Younger than Havasupai sss. Included in Aubreyan series. Named for Wompats Spring, NE. of great Shinumo Amphitheater, Grand Canyon, Ariz.

May apply to upper part only or to all of Kaibab ls. Is probably upper part of Kaibab, according to N. H. Darton (personal communication).

Wonah quartzite.

Ordovician: British Columbia.

C. D. Walcott, 1924 (Smithsonian Misc. Coll., vol. 75, pp. 14, 32, 49). [In this rept. and in a 1928 rept. Walcott assigned this fm. to Sil. Several other repts, by others, assign it to Ord.]

Wonder rhyolite.

Tertiary: Central western Nevada (Wonder, Churchill County).

J. A. Burgess, 1917 (Econ. Geol., vol. 12, No. 7, pp. 589–593). *Wonder rhyolite.*—Oldest Tert. eruptive in dist. Is a basic type of rhyolite that might well be called a quartz latite, but it has so commonly been known as Wonder rhyolite that it seems better not to change this name. Contains the ore-bearing veins of Wonder dist., which are quarried in Nevada Wonder mine.

Wood shale.

Triassic(?): Southeastern Idaho.

G. R. Mansfield, 1915 (Wash. Acad. Sci. Jour., vol. 5, p. 492) and 1916 (vol. 6, p. 41). *Wood sh.*, 220 to 250 ft. thick, is memb. of Nugget ss. in Fort Hall Ind. Res., underlying the main ss. memb. of the Nugget and overlying Deadman ls.

G. R. Mansfield, 1916 (Wash. Acad. Sci. Jour., vol. 6, pp. 32, 41). *Wood sh. memb.*—Bright-red sh. that weathers to red soil. Thickness 200 to 250 ft. Memb. of Nugget ss. in Fort Hall Ind. Res. Underlies main ss. memb. of Nugget and overlies Deadman ls. memb. Named for Wood Creek, T. 3 S., R. 38 E., Boise meridian, in NE. part of reservation, which cuts across entire Nugget fm.

G. R. Mansfield, 1920 (U. S. G. S. Bull. 713, pp. 29, 52), treated Wood sh., Deadman ls., Higham grit, and "main ss. memb." of above-cited rept as distinct fms., and restricted Nugget ss. to the "main ss. memb." of his previous repts. This is the present generally accepted definition of Wood sh.

Woodbine sand (also **Woodbine clay**).

Upper Cretaceous (Gulf series): Texas, central southern and southeastern Oklahoma, western Louisiana, and southwestern Arkansas.

R. T. Hill, 1901 (U. S. G. S. 21st Ann. Rept., pt. 7, p. 293). *Woodbine fm.*—Ferruginous argill. sands, in places unconsolidated, accompanied by laminated, usually sandy clays, in some places bituminous. Thickness 45 to 600 ft. Divided into (descending): (1) Sands and clays [now known to belong to Eagle Ford clay]; (2) Lewisville beds; and (3) Dexter sands, including Basal clay of Taff. Underlies Eagle Ford fm. and uncon. overlies Washita div. Replaces Timber Creek group and Lower Cross Timbers fm. Basal fm. of Upper Cret. of Tex.

Named for exposures at Woodbine, Cooke Co., Tex., but best exposures are at Denison, Tex., in southern half of city.

Woodbridge fire clay.

Economic term for a bed of clay, 50 to 80 ft. thick, in lower part of Raritan fm. in NE. N. J. Lies 15 to 35 ft. higher than Raritan fire-clay bed. See G. H. Cook and J. C. Smock, 1877 (N. J. Geol. Surv. map of clay dist. of Middlesex Co.), and G. H. Cook, 1878 (N. J. Geol. Surv. Rept. on clays, p. 34). Is worked S. of Woodbridge.

Woodburn phosphatic memb. (of Flanagan limestone).

Middle Ordovician: North-central Kentucky.

A. M. Miller, 1913 (Ky. Geol. Surv., 4th ser., vol. 1, pt. 1, p. 326). *Woodburn bed.*—Thin-bedded granular phosphatic ls., 30 to 40 ft. thick, constituting remainder of Flanagan memb. (of Lexington ls.) above Brannon bed.

Adopted by U. S. Geol. Survey as *Woodburn phosphatic memb. of Flanagan ls.*

Named for celebrated Alexander estate in Woodford Co.

†Woodbury formation.

Upper Cretaceous: Northwestern Iowa.

C. A. White, 1870 (Iowa Geol. Surv. vol. 1, pp. 26, 291–293). *Woodbury sss. and shales.*—Alternating sss. and shales, the latter sometimes sandy and sometimes clayey, with more or less calc. material intermixed. Max. thickness 150± ft. Overlies Nishnabotany ss. and underlies Cret. *Inoceramus* beds. Not observed outside of Woodbury Co.

Corresponds to lower part of Benton sh. and name not in use since 1893.

Named for Woodbury Co.

Woodbury clay. (In Matawan group.)

Upper Cretaceous: New Jersey.

G. N. Knapp, as reported by R. D. Salisbury, 1899 (N. J. Geol. Surv. Ann. Rept. State Geol. 1898, p. 35). *Woodbury bed.*—Dove-colored clay underlying Columbus bed [Englishtown sand] and overlying Merchantville bed. All included in Clay Marl series [Matawan group].

H. B. Kümmel and G. N. Knapp, 1904 (N. J. Geol. Surv, vol. 6, p. 157). *Woodbury clay.*—Thick black clay which weathers to dove or light chocolate color. Thickness 55± ft. Underlies Columbus sand and overlies Merchantville clay.

Named for exposures in railway cut at Woodbury, Gloucester Co.

Woodbury granite.

Devonian: Northeastern Vermont (Washington County).

See under *Knox Mtn granite.* Quarried in Woodbury Twp, Washington Co.

C. H. Richardson, 1908 (6th Rept. Vt. State Geol.). *Woodbury granite,* Dev., intrudes Waits River ls.

E. J. Foyles and C. H. Richardson, 1929 (16th Rept. Vt. State Geol., table opp. p. 288), assigned *Woodbury granite* to Dev.

Wood Canyon formation.

Lower Cambrian: Southeastern Nevada.

T. B. Nolan, 1928 (Am. Jour. Sci., 5th, vol. 17, pp. 461–472). *Wood Canyon fm.*—Thin-bedded qtzitic sss., sandy shales, and, near top, a few ls. beds. Cross-bedding, ripple marks, and sun cracks common. Thickness 2,100 ft. Lower Camb. fossils about 150 ft. below top. Grades into underlying Stirling qtzite and is uncon. overlain by Bright Angel sh. Named for exposures in Wood Canyon, about 4 mi. S. of Crystal Springs, on W. side of Spring Mtns, Clark Co.

Woodchopper volcanics.

Middle Devonian: Northeastern Alaska (Eagle-Circle district).

J. B. Mertie, Jr., 1930 (U. S. G. S. Bull. 816, pp. 75–80, map). *Woodchopper volcanics.*—Basaltic greenstone interbedded with minor amounts of ls., sl., and chert. Complexly folded and faulted. Thickness 7,700± ft. Contains late Middle Dev. fossils (17 collections). Exposed on Woodchopper Creek at and below Woodchopper.

Woodcock sandstone.

Devonian or Carboniferous: Northwestern Pennsylvania (Erie County).

G. H. Chadwick, 1925 (Geol. Soc. Am. Bull., vol. 36, pp. 457–464). Dr. [I. C.] White's "Venango group" consisted of five members, which, to avoid confusion with Venango oil sands, we propose to name as follows (descending): Upper ss. = *Woodcock ss.*; Upper sh. = Saegerstown sh.; Middle ss. = Millers ss.; Lower sh. = Amity sh.; and Lower or Le Boeuf ss. of White. The Woodcock ss. is highly fossiliferous and underlies Riceville sh., where present, and Cleveland sh. where Riceville is absent. [Outcrops mentioned.] Included in Bradfordian and also treated as next to top memb. of Chagrin fm. [which U. S. Geol. Survey classifies as Upper Dev.].

See under *Venango group* for Chadwick's correlations with I. C. White's units.

K. E. Caster, 1933 (Geol. Soc. Am. Bull., vol. 44, No. 1, p. 203). *Woodcock ss. memb.* (*Venango 1st oil,* (?) *Tuna cgl.*).—Top memb. of Cattaraugus fm. in NW. Pa. Overlies Saegerstown sh. memb. and underlies Riceville fm., restricted. [The U. S. Geol. Survey classifies Cattaraugus fm. as *Dev. or Carbf.*]

K. E. Caster, 1934 (Bulls. Am. Pal., vol. 21, No. 71, table opp. p. 61, pp. 92–94), assigned this ss. to Dev., stated that it was named for exposures along Woodcock Creek, Woodcock Twp, Crawford Co., and that it is probably younger than Tuna, Killbuck, and Hosmer Run cgls.

Wood Creek beds.

Upper Ordovician: Northern New York (Black River Valley).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 90–95, 137, 141, 149, 154). *Wood Creek beds* (zone of *Cryptolithus bellulus* and *Bollia pulchra.* Fauna best exhibited along Wood Creek, btw. Lee's Center and Stokes, 7 mi. NW. of Rome, Oneida Co., and in Lorraine Gulf. Underlie Moose Creek beds and overlie Atwater Creek sh.; all of lower Lorraine age. Included in Whetstone Gulf fm.

Woodford chert.

Devonian (?): Central southern and southeastern Oklahoma (Ouachita Mountains).

J. A. Taff, 1902 (U. S. G. S. Atoka folio, No. 79). *Woodford chert.*—Thin-bedded chert and fissile black sh., 500 to 700 ft. thick. Underlies Caney sh. and overlies Hunton ls.

Named for exposures about 1/4 mi. N. of Woodford, Carter Co.

In 1911 C. A. Reeds introduced *Bois d'Arc ls.* for top div. of Hunton ls. of previous repts on southern Okla., the type loc. being in Pontotoc Co. The Bois d'Arc ls. is now classified as of Oriskany and Becraft (?) age. (Type loc. of Hunton fm. is in SW. part of Coal Co.)

In 1927 E. O. Ulrich introduced *Brushy Creek chert* for beds uncon. underlying Woodford chert and overlying Bois d'Arc ls. in Arbuckle Mtns. He stated these beds were included in top of Hunton fm. of Taff. (Type loc. of Brushy Creek is in Pittsburg Co.)

In 1934 H. D. Miser introduced *Pinetop chert* (of Onondaga age) to replace the preoccupied name "Brushy Creek chert," in Ti Valley-Choctaw belt of Ouachita Mtns, Okla. Type loc. of Pinetop chert is in Pittsburg Co. Miser stated that in his opinion Woodford chert is=middle and upper members of Arkansas novaculite of Ark. and northern McCurtain Co., Okla., and that he regards it as of Dev. age, but that E. O. Ulrich, C. L. Cooper, and others regard it as Miss. The U. S. Geol. Survey at present classifies the Woodford as Dev. (?).

†Woodford gneiss.

Pre-Cambrian: Southwestern Vermont (Bennington County).

F. A. Burt, 1929 (16th Rept. Vt. State Geol., pp. 68–69). The pre-Camb. gneisses of Bennington area, commonly called *Stamford gneiss*, lie uncon. below Vermont fm. and form core of Green Mtn Range. Six of these pre-Camb. gneisses have been found by writer in kaolin area. One of these is Stamford gneiss of literature of region. Another is probably the white gneiss of parts of adjoining Berkshire Co., Mass. Identity of the two has not been proved, but structure and lithology suggest their oneness. This probable white gneiss, together with the 4 as yet undescribed and little-studied gneisses, will, for brevity, be called collectively *Woodford gneisses*. Uncon. underlie Vermont fm. (Lower Camb.).

F. A. Burt, 1931 (17th Rept. Vt. State Geol., pp. 115–135). *Woodford gneisses* is a group term for several pre-Camb. gneisses underlying Vermont fm. which have not yet been differentiated or worked out as to their relations.

L. M. Prindle and E. B. Knopf, 1932 (Am. Jour. Sci., 5th, vol. 24, pp. 264–269), adopted *Mount Holly gneiss* for Taconic quad., within which lies type loc. of Woodford gneiss (preoccupied), and *Woodford gneiss* was accordingly abandoned by U. S. Geol. Survey.

Apparently named for Woodford village or Woodford Twp, Bennington quad.

Woodhouse clay. (In Ogallala formation.)

Miocene or Pliocene: Western Kansas (Wallace County).

M. K. Elias, 1931 (Univ. Kans. Bull., vol. 32, No. 7, Kans. Geol. Surv. Bull. 18, pp. 155+). *Woodhouse clays*.—Bentonitic clays, highly plastic, of bright colors. Are a local lateral change in lithology of lower half of Ogallala fm. in Wallace Co. The prel. examination by H. T. Martin of vertebrates from these clays showed decisively they are not Olig. but may belong to either Mio. or Lower Plio., or to age of Ogallala fm. of Wallace Co. It appears probable the Woodhouse clays correspond, at least in their upper part, to the Ogallala of Wallace Co., which in turn appears to correspond to type Ogallala (about 200 ft. thick) in Nebr. The lower portion of Woodhouse clays, in which the bones of type loc., 1 mi. W. of Woodhouse ranch, were collected, may be somewhat older than the strictly Ogallala beds and may possibly belong to Upper Mio. It is possible the Tert. clays in the counties E. and NE. of Wallace also belong in part to slightly earlier time than typical Ogallala beds of Wallace Co., which are undoubtedly Lower Plio. The clays are exposed 1 mi. W., also SW., of Guy Woodhouse ranch, in right tributary canyon on Goose Creek.

Woodhurst limestone member (of Madison limestone).

Mississippian (lower): Central northern Montana (Fort Benton quadrangle and to west) and central southern Montana (Little Belt Mountains quadrangle).

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Woodhurst ls.*—Well-bedded light-colored lss. separated by very thin argill. layers, the lss. often carrying much dark chert. The Woodhurst ls. is well jointed and often forms masonry-like exposures of cliffs with balcony ledges and retreating benches. On weathering breaks into small angular fragments. Underlies Castle ls. memb. and overlies Paine sh., which consists of thin-bedded shaly lss., commonly of gray color. [Derivation of name not stated, but Madison ls. is mapped over broad area at and surrounding Woodhurst Mtn. NE. corner of this quad.]

Woodland trachyte.

Age (?): Northeastern Maine (Aroostook County).

H. E. Gregory, 1900 (U. S. G. S. Bull. 165, pp. 109, 110, 164). *Woodland trachyte* forms low hills along a branch of Caribou Stream, in Woodland Twp, Aroostook Co.

On 1933 geol. map of Maine, by A. Keith, the trachytes of NE. Maine are assigned to Dev.

Woodman formation.

Mississippian (upper): Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Woodman fm.*—Lower part is dominantly calc. ss. and upper part sandy ls. The ss. is 200± ft. thick, generally purplish or reddish brown, fine-grained, and contains small amount of calcite as cement. Thin lenses of ls. and sh. are interbedded with the ss. Greater part of upper div. is dark-gray to almost black sandy ls. that weathers to light brown to pinkish. Nodules of dark-gray to black chert are abundant, many of them a ft. in diam. Interbedded with the lss. are calc. sss. A few beds of relatively pure ls. are also present. Thickness 1,500± ft. Contains upper Miss. fossils. Overlies Madison ls. and underlies Ochre Mtn ls. Named for fact it underlies Woodman Peak, on S. end of Dutch Mtn, Gold Hill region.

See also U. S. G. S. P. P. 177, 1934.

Woodmansie phase (of Bridgeton formation).

Pleistocene: New Jersey.

See 1917 entry under *Bridgeton fm.*

Probably named for occurrence at or near Woodmansie, Burlington Co.

Woodmont shale member (of Jennings formation).

Upper Devonian: Northern West Virginia, western Maryland, and southern Pennsylvania.

C. K. Swartz et al., 1913 (Md. Geol. Surv. Lower Dev. vol., p. 26, and Middle and Upper Dev. vol., pp. 411, 412). *Woodmont sh. memb.*—Middle memb. of Jennings fm. Consists of greenish argill. and aren. shales alternating with thin sss. of similar color, all of which weather yellowish green. Upper 1,000 to 1,100 ft. contain Ithaca fauna. Lower 500 to 1,300 ft. contain Naples fauna. Underlies Parkhead ss. memb. and overlies Genesee black sh. memb.

Named for exposures at Woodmont station on B. & O. R. R., Morgan Co., W. Va.

Wood Mountain gravels.

Miocene (middle or upper): Saskatchewan, Canada.

C. M. Sternberg, 1930 (Roy. Soc. Canada Trans., vol. 24, sec. 4, p. 29). Vertebrates considered by G. G. Simpson to be middle or upper Mio.

Woodpecker limestone.

Devonian: Eureka district, Nevada.

C. [R.] Keyes, 1923 (Pan-Am. Geol., vol. 40, p. 52) and 1924 (Pan-Am. Geol., vol. 41, p. 79). *Woodpecker lss.*, 1,200 ft. thick, underlie Combs ls. and overlie Atrypa ls. Included in Nevadan series [Nevada ls.]. Especially characterized by remains of sponges and chaetetid corals. Name derived from Woodpecker Peak, Eureka dist.

Wood River formation.

Pennsylvanian: Southern central Idaho.

W. Lindgren, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, pl. 8, pp. 89–90, 193–195). *Wood River fm.*—A series of qtzites, fine cgls., large masses of black slates and calc. shales, and a small amount of heavy-bedded gray lss. Unusually barren of fossils, but those that have been found are of Carbf. age, probably upper Carbf.

The fm. is usually thrown into sharp folds, so that the stratigraphy is difficult to decipher, and rocks older or more recent than Carbf. may have been included in this div. The Carbf. is certainly very largely represented and seems to have attained a thickness rarely found in other parts of the West. In places overlain by masses of the great post-Carbf. granite intrusive mass of Idaho. In places is overlain by Neocene Columbia River lava. Thickness several thousand ft.

L. G. Westgate and C. P. Ross, 1930 (U. S. G. S. Bull. 814, pp. 10, 29+). *Wood River fm.* restricted to rocks of Penn. age, which consist chiefly of calc. and qtzitic beds, but also contain cgl., sh., and dol. Nearly everywhere the basal memb. is a massive brownish qtzitic cgl. 300 to 800 ft. thick. Thickness of fm. 8,000± ft. The lower part of Wood River fm. of Lindgren is here named *Milligen fm.* It is of Miss. and possibly Dev. age.

Woods Bluff marl. (In Bashi formation.)

Eocene (lower): Southwestern Alabama.

A. Heilprin, 1882 (Phila. Acad. Nat. Sci. Proc. 1881, p. 157). [Refers to 25 ft. of highly fossiliferous marl comprising No. 2 of Tuomey's section on Bashi Creek, Clarke Co., as *Wood's Bluff marl bed.*]

E. A. Smith, 1883 (Ala. Geol. Surv. Prog. Rept. 1881–82, pp. 257, 321). *Wood's Bluff marl.*—Greensand shell marl with an indurated bed, usually near top, but sometimes near middle. Thickness 10–15 ft. Exposed at Wood's Bluff, on Tombigbee River, and at Johnson's Landing, below Bell's Landing, on Alabama River. Overlain by 25–30 ft. of laminated clays and clayey marls, and separated from the older Bell's Landing marl by 50–80 ft. of lignitic clays and sands. Included in Lagrange or Lignitic (pp. 236–237).

E. A. Smith, 1887 (U. S. G. S. Bull. 43, pp. 39, 43–46, 69). *Wood's Bluff or Bashi marl.*—Marl, with marine fossils and much greensand, 15–30 ft. thick, forming top memb. of Wood's Bluff or Bashi series. Overlain by purplish-brown sandy clays forming basal part of Hatchetigbee series.

As defined is top memb. of Bashi (†Woods Bluff) fm.

Named for exposures at Woods Bluff, on Tombigbee River, in NW. part of Clarke Co.

†Woods Bluff group.

†Woods Bluff series.

Eocene (lower): Southern Alabama and southeastern Mississippi.

A. Heilprin, 1882 (Phila. Acad. Nat. Sci. Proc. 1881, pp. 158–159). [See quotation under *†Eo-lignitic.*]

E. A. Smith and L. C. Johnson, 1887 (U. S. G. S. Bull. 43, pp. 43–47). *Wood's Bluff or Bashi series.*—Consists of (descending): (1) Wood's Bluff or Bashi marl, 15 to 30 ft. thick; (2) 25 ft. of gray sandy clays containing toward base 4 or 5 thin seams of lignite; (3) 35 to 40 ft. of yellowish cross-bedded sands; and (4) lignite bed 2 ft. thick. Underlies Hatchetigbee series and overlies Bell's Landing series.

Abandoned for *Bashi fm.*, the monomial alternative name.

Named for exposures at Woods Bluff, on Tombigbee River, in NW. part of Clarke Co., Ala.

Woods Hollow shale.

Middle Ordovician (Trenton): Southwestern Texas (Brewster County).

P. B. King, 1931 (A. A. P. G. Bull., vol. 15, No. 9, pp. 1066, 1071–1072). *Woods Hollow sh.*—Lower part consists of flaggy, thinly laminated gray or yellowish sandy ls. or limy ss., with some sh. partings. It grades up into greenish clay sh. with a few interbedded flaggy ls. layers. Some sandy beds are rill-marked on bedding surfaces, and some of lower flaggy layers contain graptolites. There are 5 or 6 nodular beds of coarsely granular and conglomeratic ls., weathering yellowish, crowded with comminuted remains of bryozoans, trilobites, brachiopods, and crinoids. Thickness at type loc. 470 ft. Named for exposures in Woods Hollow Mtns, btw. Woods Hollow and Little Woods Hollow, in an anticlinal valley on former Louis Granger ranch. Contains fossils of Trenton age. Underlies (uncon.?) Maravillas chert and overlies Fort Peña fm.

Woodside shale.

Lower Triassic: Northeastern Utah, southwestern Wyoming, and southeastern Idaho.

J. M. Boutwell, 1907 (Jour. Geol., vol. 15, pp. 439–458). *Woodside sh.*—A lithologic unit composed, from bottom to top, without significant exception, of fine-grained thinly bedded dark-red sh. Bears ripple marks, mud cracks, and raindrop imprints. Thickness, 1,180 ft. in Park City dist., Utah, where it underlies Thaynes ls. and overlies Park City fm. Named for Woodside Gulch, Park City dist., the best exposure being at head of this gulch, on slope that overlooks the Silver King plant from W.

Woods Run limestone. (In Conemaugh formation.)

Pennsylvanian: Western Pennsylvania and western Maryland.

P. E. Raymond, 1910 (Carnegie Mus. Annals, vol. 7, p. 147). *Woods Run ls.*—Marine ls., fossiliferous, lying lower in section than Ames ls. and higher in section than Pine Creek [Cambridge] ls.

P. E. Raymond, 1911 (Pa. Topog. and Geol. Surv. Comm. Rept. 1908–10, pp. 88–89). *Woods Run ls.*—A previously unnoticed marine ls. to which writer called attention [but did not name] in Sci., n. s., vol. 29, p. 941, 1909. Named for Woods Run, within city of Allegheny, Pa. [The description of this (unnamed) ls. in Sci., vol. 29, states that it lies about 50 ft. below Ames ls. on Brighton Run, just W. of Woods Run, Allegheny, Pa.; that it is about 3 in. thick; and that it consists of hard clayey ls. with most of lime leached out at outcrop.]

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6, pl. 7), showed Woods Run ls. and fauna resting on Bakerstown coal at Pittsburgh, Pa., and as occurring in interval btw. Buffalo and Saltsburg sss. at Latrobe, Pa.

M. E. Johnson, 1929 (Topog. and Geol. Atlas Pa., No. 27, Pittsburgh quad.). [On p. 31 *Woods Run ls.* is shown as underlying Bakerstown coal and as same as Cambridge ls., while Pine Creek ls. is placed at a lower (p. 70 says 45 to 55 ft.) horizon. On p. 53 *Woods Run ls.* is placed about 15 ft. *above* Saltsburg ss. On pp. 66–67 is statement that *Woods Run ls.* occurs in 1 or 2 thin beds, from 80 to 119 ft. below Ames ls. and 35 to 55 ft. above Pine Creek ls., and that it includes Woods Run coal just below the upper ls. bed; also that it is 0 to 10 ft. thick in Pittsburgh quad.]

Woods Run shale. (In Conemaugh formation.)

Pennsylvanian: Western Maryland.

C. K. Swartz, 1922 (Md. Geol. Surv. vol. 11, pl. 6). *Woods Run sh.*—Rests on Lower Bakerstown (Thomas) coal in Lower Youghiogheny Valley, Md., also at Somerset, Pa., and in Castleman Basin and Georges Creek Basin, Md. Thickness 25 to 30 ft.

Woodstock conglomerate.

Carboniferous: New Brunswick.

H. Y. Hind, 1865 (Geol. of New Brunswick, p. 67).

Woodstock granite.

Carboniferous(?): Northern Maryland.

G. H. Williams and N. H. Darton, 1892 (U. S. G. S. map of Baltimore and vicinity, to accompany "Guide to Baltimore," prepared for Baltimore meeting Am. Inst. Min. Engrs., Feb. 1892). *Woodstock granite*, including eruptive granite and gneiss. Quarried at Woodstock and other places.

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799). *Woodstock granite* is possibly Paleozoic.

E. B. Knopf and A. I. Jonas, 1929 (Md. Geol. Surv. Baltimore Co. Rept., pp. 104, 131). *Woodstock granite* assigned to epi-Paleozoic(?).

In 1932 A. I. Jonas expressed opinion that this granite is Carbf., and U. S. Geol. Surv. adopted *Carbf.* (?) for its age. (See 16th Int. Geol. Cong. Guidebook 30, sheet 1.)

Woodstock greensand marl member (of Nanjemoy formation).

Eocene: Eastern Maryland and Virginia.

W. B. Clark, 1895 (Johns Hopkins Univ. Circ., vol. 15, No. 121, p. 3). The upper beds of Eocene of middle Atlantic slope may be designated *Woodstock stage*, and lower beds may be designated *Aquia Creek stage*. Fossils of Woodstock stage are closely related to "Claiborne" types, and those of Aquia Creek stage are decidedly "Lignitic."

W. B. Clark, 1896 (U. S. G. S. Bull. 141, pp. 54, 57; Am. Jour. Sci., 4th, vol. 1, pp. 369–370). *Woodstock stage or fauna*.—Fossiliferous greensand, 40 ft. thick, forming top div. of Pamunkey fm. Separated from underlying Aquia Creek stage or fauna of Pamunkey fm. by 117 ft. of greensands and argill. sands

W. B. Clark and G. C. Martin, 1901 (Md. Geol. Surv. Eocene vol., p. 58). *Woodstock memb. or substage*.—Characterized by fine homogeneous greensands and greensand marls, less argill. than Potapaco memb. Upper part consists of 80 ft. of greensand with *Ostrea sellaeformis* and other fossils; lower part consists of 40 ft. of greensand with few fossils, chiefly *Venericardia potapacoensis*. Is top memb. of Nanjemoy fm. Overlies Potapaco or lower memb. of Nanjemoy fm. Named for Woodstock, an old estate a short distance above Mathias Point of Va. bank of the Potomac [in King George Co., Va.].

W. B. Clark and B. L. Miller, 1912 (Va. Geol. Surv. Bull. 4, p. 104). *Woodstock greensand marl memb.*—Top memb. of Nanjemoy fm. Overlies Potapaco clay memb.

Woodstock stage.

See under *Woodstock greensand marl memb.*

Woodstock quartz schist.

Carboniferous: Northeastern Connecticut.

H. E. Gregory, 1906 (Conn. Geol. and Nat. Hist. Surv. Bull. 6, pp. 114, 128, and map). *Woodstock quartz schist*.—Varies from almost pure qtzite to mica schist with abundant quartz grains. Extends through E. part of Woodstock Twp and S. through Pomfret. Few outcrops. Of sed. origin.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the continuation of Woodstock in Mass. as *Paxton quartz schist*, of Carbf. age. *Paxton* has priority.

Woodstock schist.

Ordovician: Southeastern Vermont (Windsor County).

C. H. Richardson, 1927 (15th Rept. Vt. State Geol., pp. 127–158), in rept on Barnard, Pomfret, and Woodstock Twps, Vt., which lie short distance to SW. of Vershire Twp, stated: *Woodstock schist* may be considered by some geologists to be Vershire schist of earlier repts, but Vershire schist overlies Waits River ls., and Woodstock schist apparently underlies Waits River ls. If this interpretation is true, then Vershire schist and Woodstock schist represent two different fms., and a new name is needed, hence *Woodstock schist* is here introduced, from outcrops in Woodstock. It is represented by 2 beds intercalated in Waits River ls., which are very quartzose, micaceous, and grade into a micaceous qtzite.

Woodville sandstone.

Pennsylvanian (of Conemaugh age): Southern Michigan.

A. Winchell, 1861 (Mich. Geol. Surv. 1st Ann. Rept. Prog., pp. 126, 138, 153, 158). *Woodville ss.*—Pale-buff to nearly white friable, rather coarse quartzose ss., stained to variable extent with oxyd of iron. Varies greatly in hardness. Thickness 0 to 92 ft. Overlies dark bituminous shales of Coal Measures [Saginaw fm.] and is uncon. overlain by Quat. drift. Exposed at Woodville, Jackson Co., where it is 30 to 45 ft. thick. Near Lyons, Ionia Co., it is striped and mottled with red or even uniformly brick-red color. Is not easily distinguished from Parma ss.

A. C. Lane, 1895 (Mich. Geol. Surv. vol. 5, pt. 2). *Woodville ss.* is 304+ ft. thick. Overlies Jackson coal group [Saginaw fm.].

A. C. Lane, 1899 (U. S. G. S. W. S. P. 30). Top fm. of Carbf. in Mich. is a red ss. which Winchell called *Woodville ss.*, which appears to be uncon. on Jackson coal measures.

A. C. Lane, 1909 (Mich. Geol. Surv. Rept. 1908). *Woodville ss.* consists of 0 to 110 ft. of light-reddish ss. and sandy sh. Uncon. overlies Saginaw fm.

R. A. Smith, 1914 (Mich. Geol. and Biol. Surv. Pub. 14, pp. 22–32). *Woodville ss.* consists of 0 to 79 ft. of buff-colored ss., largely removed by erosion. Wells at Maple Rapids, St. Johns, Ionia, and Gladwin indicate presence of a reddish ss. that may be same as buff-colored Woodville ss.

R. C. Allen, R. A. Smith, and L. P. Barrett, 1916 (Mich. Geol. Surv. Geol. map of Mich.). *Woodville ss.* consists of 0 to 100 ft. of light-reddish ss. and sandy sh.; erosion remnants at top of Coal Measures.

W. A. Kelly and E. L. Beutner, 1930 (Mich. Acad. Sci., Arts, and Lett., vol. 14, pp. 471–474). *Ionia ss.*, youngest fm. of Penn. in Mich. Undoubted examples of this ss. are found in abandoned quarries near Grand River btw. Lyons and Ionia. Overlies Saginaw fm.

R. B. Newcombe, 1931 (letter dated Mar. 21). The name "Woodville," which was originally applied by Prof. Winchell to a ss. memb. at old Woodville mine, Jackson Co., Mich., was defined as uppermost ss. in Penn. of Mich. We have later learned that the locality near Ionia where a pink russet-color ss. occurs, is possibly the uppermost ss. memb. of Penn. However, a typical red-bed facies containing plastic shales and gyp. occurs above this ss. in central part of State farther to N. It is still a matter of conjecture whether these "red beds" are equiv. in age to the Woodville or are younger, and in my new strat. column it is proposed that the whole series be given the name "Red Beds," because of lack of any faunal evidence for exact strat. position of the beds. Prof. Wm. Kelly, of Mich. State College, who has been conducting the detailed studies of the paleontologic work for Miss. and Penn. rocks in Mich., maintains that *Ionia* is much more appropriate for this upper pink ss. memb. than the old Woodville, which actually refers to an entirely different bed. For this reason *Ionia* may be adopted for our new time scale.

R. B. Newcombe, 1933 (Mich. Geol. Surv. Pub. 38), in his classification of rocks of Mich. Basin, used *Woodville (Ionia)*, but on p. 61 he stated: The name of Woodville applying to a ss. which at its type loc. is only a lenticular restricted bed, probably should be dropped. A better name for the apparently persistent basal pink or russet-colored ss. of "Red Beds" section would be *Ionia ss.*, suggested by Lane in 1909. [On p. 22 he shows *Woodville (Ionia)* as overlain by sh., sandy sh., gyp., red, pink, gray, the thickness of which is given in fig. 6 as 50 to 120± ft.]

Woodward group.

Permian: Southwestern Oklahoma and Panhandle of Texas (?).

C. N. Gould, 1902 (Okla. Geol. Surv. 2d Bien. Rept., pp. 42, 49). *Woodward div.*—Chiefly shales, sss., and dolomites, 300 [500] ft. thick, distinguished from divisions above and below by prominence of dolomites and absence of gypsums. Includes all rocks btw. the two conspicuous gyp. horizons, the Blaine and Greer divisions. In general divided into three members [now fms.] (descending), Day Creek dol., Red Bluff [Whitehorse] sss., and Dog Creek shales.

The "Greer fm." as originally defined applied to Cloud Chief gyp. of present nomenclature, but as mapped it included Blaine and Cloud Chief (†Cyril) gypsums. The present definition of Woodward group is for rocks overlying Blaine gyp., underlying Cloud Chief gyp., and divided into (descending) Day Creek dol., Whitehorse ss., and Dog Creek sh. The name has been used in Tex., but E. H. Sellards, 1933 (Univ. Tex. Bull. 3232), omits it from the Tex. classification.

Named for Woodward Co., Okla.

Wooley's Bluff clays.

Eocene (Jackson): Eastern Texas and western Louisiana (Sabine Parish).

A. C. Ellisor, 1933 (A. A. P. G. Bull., vol. 17, No. 11, p. 1303, etc.). The bluff on Caney Creek back of old Wooley home in Sabine Parish, La., sec. 4, T. 3 N., R. 12 W., is here designated Wooley's Bluff. In this bluff is exposed 5± ft. of highly fossiliferous sandy glauconitic marly blue clays that weather yellowish brown, and 10 or more ft. of light chocolate-brown clays. These are the *Wooley's Bluff clays*. Total thickness 250 to 300 ft. Not well exposed but seen in San Augustine, Angelina, and Sabine Counties. Basal zone of McElroy fm. To W. of Angelina Co. these clays disappear on surface, and the overlying Wellborn sss. rest uncon. on Caddell fm. As weathered surface is identical with that of Caddell fm. it is difficult to differentiate the two units in field. Fossils listed.

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, p. 24). In writer's opinion the Wooley's Bluff beds of Ellisor represent a marine facies within Wellborn fm., and the name Wellborn is applicable to them. The Wooley's Bluff fauna was not found W. of Neches River, but there is no field evidence to support the uncon. reported by Miss Ellisor btw. the Wellborn and the Caddell fm.

†Woonsocket conglomerate.

Carboniferous: Northeastern Rhode Island.

G. R. Mansfield, 1906 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 49, geol. ser. vol. 8, p. 100). *Woonsocket cgl.* occupies a rather limited area [around Woonsocket, R. I.] and is characterized by such a high degree of metamorphism that its composition is often not clearly distinguishable.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the cgl. of Woonsocket region as *Bellingham cgl.*, and "Woonsocket cgl." has been discarded.

†Woonsocket Basin series.

Carboniferous: Northeastern Rhode Island.

A. C. Hawkins, 1918 (Am. Jour. Sci., 4th, vol. 46, pp. 437–472, and map). *Woonsocket Basin series.*—Sh., ss., and cgl. of Carbf. age. The "Bellingham series" of Warren and Powers.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), mapped the deposits of Woonsocket Basin as *Bellingham cgl.*

Wooton coal group.

Local name for a group of coal beds in Raton fm. in Elmoro-Spanish Peaks region, Colo. Exposed a short distance above Wooton's station, on old Santa Fe Trail, and on line of Atchison, Topeka & Santa Fe Railway. See U. S. G. S. Elmoro folio, No. 58, 1899.

Worcester phyllite.

Pennsylvanian: Eastern central Massachusetts, central southern New Hampshire, and northern Connecticut.

B. K. Emerson, 1889 (Geol. Soc. Am. Bull., vol. 1, p. 560), mentioned, but did not define, *Worcester argillite.*

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 17). *Worcester argillite (phyllite)* overlies Harvard cgl. in Worcester Co., Mass.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597, pp. 60–72, 77, 225). In its least-changed or typical phase the *Worcester phyllite* ranges from soft black sl. or phyllite, partly carbonaceous and partly graphitic, to light greasy sericite schist. The prevailing rock is thinly fissile, lead gray, with corrugated satiny surface, generally splitting on original lamination. Laterally the typical Worcester phyllite grades into different types of schist. To W. it becomes the Brimfield schist. [See under *Brimfield schist.*] Includes Harvard cgl. lentil.

Is exposed at Worcester, Mass., and over broad area in N. part of Worcester Co., Mass.

†Worcester quartzite.

Carboniferous: Eastern central Massachusetts, central southern New Hampshire, and northern Connecticut.

B. K. Emerson, 1898 (U. S. G. S. Mon. 29, p. 17). *Worcester qtzite* underlies Harvard cgl. in Worcester Co., Mass.

B. K. Emerson, 1917 (U. S. G. S. Bull. 597), replaced "Worcester qtzite" with *Oakdale qtzite*, and retained Worcester for the phyllite.

Exposed at Worcester, Mass., and over a large area in N. part of Worcester Co., Mass.

†Worcester County gneiss.

E. Hitchcock, 1833 (Rept. geol., min., bot., and zool. of Mass., pp. 387–388). *Worcester County gneiss.*—The broad ranges of gneiss in central part of Mass. Porphyritic gneiss prevails extensively along W. margin of Worcester Co. gneiss range, in Northfield, Mass., and Winchester, N. H. Granitic gneiss abounds in various parts of deposit, but more in southern than in northern part of State. The range of Worcester County gneiss which extends northeasterly into Middlesex Co. possesses some peculiar characteristics and belongs to a different system of stratification from the gneiss W. of Worcester Valley. It contains numerous beds of ls., which are wanting in western ranges.

Includes 7 or 8 of the fms. differentiated by B. K. Emerson in U. S. G. S. Bull. 597, 1917.

Word formation.

Permian: Western Texas (Marathon region, Brewster County).

J. A. Udden, C. L. Baker, and E. Böse, 1916 (Univ. Tex. Bur. Econ. Geol. and Tech. Bull. 44, p. 52). *Word fm.*—Consists of (descending): (1) Thin- and thick-bedded gray and yellow to reddish ls., in part dolomitic, containing chert concretions and some interbedded ss., 380 ft.; (2) yellow ss., in part laminated, 120 ft.; (3) heavy-bedded gray ls. with chert concretions, 120 ft. Underlies Vidrio fm. and overlies Leonard fm.

J. A. Udden, 1927 (Geol. Soc. Am. Bull., vol. 38, p. 159). *Word fm.* is same [?] as Delaware Mtn fm., and name should be abandoned.

E. H. Sellards, 1933 (Tex. Univ. Bull. 3232, p. 151). *Word fm.* of Glass Mtns is Delaware Mtn fm. in part. [This is interpretation of P. B. King also. See Geol. Soc. Am. Bull., vol. 45, 1934.]

Named for Word's ranch, Glass Mtns, Hess Canyon quad.

Worland limestone.

Pennsylvanian: West-central Missouri.

F. C. Greene, 1933 (Mo. Bur. Geol. and Mines 57th Bien. Rept., pp. 14, 18, 37, App. 2, pl. 2). *Worland ls.*—In central Bates Co., at Worland, a zone of lss. and calc. shales appears in Bandera sh. memb. of Pleasanton fm. and persists to N., usually as two thin lss., here termed *upper and lower Worland ls.*, and an intervening sh. The upper ls. has been mistaken for Pawnee ls.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 58). The ls. beds in western Mo. that Greene has called lower and upper Worland may prove to be=already named beds in Kans., including Altamont ls., but Greene believes his *Worland ls.* is definitely below horizon of Altamont ls., and reconn. study by N. D. Newell indicates the so-called Worland ls. belongs to Pawnee ls.

World Beater porphyry.

Pre-Cambrian (?): Southeastern California (Inyo County).

F. M. Murphy, 1933 (Calif. State Div. Mines, Rept. 28 of State Min., July–Oct. 1932, p. 339 and map). *World Beater porphyry (porphyritic granite)*, of pre-Camb. (?) age. Forms quadrangular area of about 6 sq. mi., stretching from Pleasant Canyon to Happy Canyon, in S. part of Panamint Range. [Derivation of name not stated and not apparent from his map.]

Worm Creek quartzite member (of St. Charles limestone).

Upper Cambrian: Northeastern Utah and southeastern Idaho.

G. B. Richardson, 1913 (Am. Jour. Sci., 4th, vol. 36, pp. 407, 408). *Worm Creek qtzite.*—Massive gray qtzite, 300 ft. thick, forming basal memb. of St. Charles ls. in northern Utah and SE. Idaho.

Named for exposures on Worm Creek, Bear Lake Co., SE. Idaho.

Wormstones.

Upper Cambrian: Southwestern Wisconsin (Sparta and Tomah quadrangles).

W. H. Twenhofel and F. T. Thwaites, 1919 (Jour. Geol., vol. 27, p. 616). "*Wormstones.*"—Topmost beds of Dresbach ss. in Tomah-Sparta quads., SW. Wis., consisting of 1 to 10 ft. of ss., coarse- to medium-grained gray to brown beds, composed of firm ss., in which are large vertical worm holes ("wormstones") alternating with thinner beds of soft white ss. with limonite and siliceous concretions (nodular layers).

According to E. O. Ulrich, 1924 (Wis. Acad. Sci., Arts, and Lett. Trans., vol. 21, p. 93, footnote) this ss. "may be a part of Ironton ss. memb. of Franconia ss."

†Wortham aragonite lentil (in Wills Point formation).

Eocene (lower): Northeastern Texas (Brazos River region and northeastward).

F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 530, 535, 537, 538, 559). *Wortham aragonite lentil.*—Impure concretionary persistent stratum of ls., 6 to 10 in. thick; crystalline structure, in which many of the crystals are aragonite arranged in form of rosettes. Lies on top of Mexia memb. (lower memb. of Wills Point fm.). Been traced along outcrop from Brazos River NE. through Limestone, Freestone, Navarro, Henderson, Kaufman, Van Zandt, Hunt, and Hopkins Counties. Typical exposure is in town of Eureka, Navarro Co. It also occurs in R. R. cut just W. of station at Wills Point, Van Zandt Co., and in a stream valley 1 mi. E. of Wortham, Freestone Co.

The U. S. Geol. Survey includes this bed in Kerens memb. of Wills Point fm. but does not consider that a geographic name for it is necessary.

Worthington sandstone member (of Allegheny formation).

Pennsylvanian: Western Pennsylvania.

J. P. Lesley, 1880 (2d Pa. Geol. Surv. Rept. H_5, pp. xxi, 319). [See under *Kittanning ss. memb.* Lesley proposed *Pine Creek ss.*, also *Worthington ss.*, for a ss. lying in interval below Middle Kittanning coal and above Lower Kittanning coal, but sometimes occupying interval btw. Upper and Lower Kittanning coals.]

The U. S. Geol. Surv. uses *Worthington ss. memb.* for the ss. btw. Upper and Lower Kittanning coals, and has abandoned "Pine Creek ss." because of conflict with the name of a younger ls. in same region.

Worthville beds.

Upper Ordovician: Northern New York (Black River Valley).

R. Ruedemann, 1925 (N. Y. State Mus. Bull. 258, pp. 137, 141, 149, 154). *Worthville beds* (zone of *Pholidops subtruncata* and *Lyrodesma cincinnatiense*. Exposed along Sandy Creek about Worthville [Jefferson Co.]. Overlie Tremaines Bridge beds and underlie Sandy Creek beds; all included in Pulaski fm.

Wrangell lava.

Late Tertiary to Recent: Southeastern Alaska (Wrangell Mountains region).

W. C. Mendenhall, 1905 (U. S. G. S. P. P. 41, p. 54, map). *Wrangell lavas.*—A succession of lava flows and tuffs, 6,300 to 8,400± ft. thick, forming entire W. part of Wrangell group of mtns. Range in age from Tert. (nearly as old as Eo.) to present time.

Wreck Bay formation.

Pleistocene: British Columbia.

V. Dolmage, 1920 (Canada Geol. Surv. Summ. Rept. 1919, pt. B, p. 16).

Wreford limestone. (In Chase group.)

Permian: Eastern Kansas, central northern Oklahoma, and southeastern Nebraska.

R. Hay, 1893 (Kans. State Bd. Agr. 8th Bien. Rept., p. 104). *Wreford ls.*—Lss., 25 ft. thick, containing numerous flint nodules and separated by definite layers of flints. Form lower flint beds of Kans. section. Worked for lime at Wreford. Underlain and overlain by shales.

C. S. Prosser, 1902 (Jour. Geol., vol. 10, p. 713). *Wreford ls.*—Buff ls. and chert or flint. Thickness 35 to 50 ft. Cherty ls. at top, heavy ls. in middle, and cherty ls. at base. Is Strong flint of Prosser, 1895, and Wreford ls. of Hay. Basal fm. of Chase stage. Underlies Matfield shales and overlies Garrison fm.

Named for occurrence at Wreford, Geary Co., Kans., where it has been quarried and burned for lime.

Wright moraine.

Pleistocene (Wisconsin stage): Northeastern Minnesota.

F. Leverett, 1928 (U. S. G. S. P. P. 154). Named for Wright station, Carlton Co.

Wrightsville conglomerate.

Devonian or Carboniferous: Northwestern Pennsylvania (Warren County).

J. F. Carll, 1883 (2d Pa. Geol. Surv. Rept. I_4, pp. 180, 203–208, 230). *Wrightsville cgl.*—Massive flat-pebble cgl., yellowish, iron-seamed; sometimes contains numerous fossils. Thickness 15–25 ft. Lies 220–240 ft. below sub-Olean cgl. Forms several fine escarpments near Wrightsville, Warren Co. Is probably SW. continuation of Pope's Hollow cgl. of N. Y.

G. D. Harris, 1891 (Am. Geol., vol. 7, pp. 168, 172–178). *Wrightsville cgl.* is probably=Pope Hollow cgl.

L. C. Glenn, 1903 (N. Y. State Mus. Bull. 69, pp. 967–989). Name *Wrightsville cgl.* has been applied to Salamanca cgl. lentil of Cattaraugus beds in this region (Olean and Salamanca quads., N. Y.). [This is correlation accepted by N. Y. State Survey. (See W. Goldring, N. Y. State Mus. Hdb. 10, p. 425, 1931.)]

Wulff River formation.

Cambrian: Northwest Greenland.

C. Poulsen, 1927 (Meddelelser om Grønland, Bd. 70, pp. 239, 328). [Assigned to Camb. L. Koch, 1933, Bd. 73, Afd. 1, No. 2, p. 23, assigned it to Lower Camb.]

Wurtemburg limestone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania (Lawrence County).

J. P. Lesley, 1875 (2d Pa. Geol. Surv. Rept. J, pp. 93–100). *Wirtemburg lower ls.* (also *lower Wirtemburg ls.*).—Is 1 ft. thick at Wirtemburg (Lawrence Co.), and never exceeds 1½ ft. for 5 mi. above Wirtemburg along the creek. Always contains *Caulerpites marginatus.* Is separated from overlying Wirtemburg ss. by 15 ft. of soft sh. and is underlain by a thin coal, which rests on the Subcarbf., the "great cgl." (No. XII) being wholly absent. [His section at Wirtemburg describes 3 ft. of ls. above his Wirtemburg ss., which is evidently the reason he called this ls. *lower* Wirtemburg ls. His Wirtemburg ss. appears to be Homewood ss. memb. of later repts.]

I. C. White, 1878 (2d Pa. Geol. Surv. Rept. Q) and 1879 (2d Pa. Geol. Surv. Rept. Q_2). [See under *Mercer ls.*]

B. L. Miller, 1925 (Pa. Geol. Surv., 4th ser., Bull. M_7, pp. 280, 281, 332). Upper Mercer ls.=Mahoning ls.=*Upper Wurtemburg* ls.; Mercer ls.= Lower Mercer ls=*Lower Wurtemburg* ls. [Page 332.] "Another good exposure of Mercer ls. is to be seen just E. of Wurtemburg along Slippery Rock Creek, where it measures 12 to 14 inches." [Page 281.]

Wurtemburg sandstone. (In Pottsville formation.)

Pennsylvanian: Western Pennsylvania (Lawrence County).

J. P. Lesley, 1875 (2d Pa. Geol. Surv. Rept. J, pp. 93–94). *Wirtemburg ss.* thickens to 12 ft. ½ mi. above Smalley's Run and 23 ft. at mouth of Smalley's Run, where upper 17 ft. of it is gravel and lower 6 ft. sand. Near mouth of Conoquenessing, on Beaver River, it is from 60 to 75 ft. thick, and well developed into two gravel-sand fms. with a streak of coal between. It has always been recognized here as the genuine cgl. No. XII. At Wirtemburg [Lawrence Co.] the bottom of the ss. is 30 ft. above the water on both sides of the stream. Lies 180 ft. below Freeport ss. Is underlain by 15 ft. of soft grayish sh., which rests on *lower Wirtemburg ls.* [As defined appears to be Homewood ss. memb.]

Wyandot amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group and is probably=Winona amygdaloid. The mineralized part is the Wyandot lode. Named for occurrence in Wyandot mine, Houghton Co.

Wyandot flow.

Includes Wyandot amygdaloid and underlying trap.

Wyandot No. 8 amygdaloid.

Pre-Cambrian (Keweenawan): Northern Michigan.

Name locally in use many years. Used by B. S. Butler in U. S. G. S. P. P. 144, 1929. Belongs in Central Mine group. Occurs in interval btw. cgl. No. 6 above and Superior West amygdaloid below, and is eight amygdaloids back from Wyandot shaft, Houghton Co. The mineralized part is Wyandot No. 8 lode.

Wyandot No. 8 flow.

Includes Wyandot No. 8 amygdaloid and underlying trap.

Wyandotte group.

Pennsylvanian: Eastern Kansas.

R. C. Moore, 1931 (Kans. Geol. Soc. 5th Ann. Field Conf. Guidebook, correlation chart). *Wyandotte group*, new name, includes (descending) Lane sh., Iola ls., Chanute sh., Drum ls., Quivira sh., Dekalb ls., and Cherryvale sh.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, Aug. 28 to Sept. 3), discarded his Wyandotte group and applied *Kansas City group* to the fms. he previously had included in it. And, at same time and place, he used *Wyandotte ls.* for younger strata. (See *Wyandotte ls.*)

Wyandotte limestone.

Pennsylvanian: Eastern Kansas and northwestern Missouri.

R. C. Moore, 1932 (Kans. Geol. Soc. 6th Ann. Field Conf. Guidebook, pp. 85, 91, 92, 97). *Wyandotte ls.*—Basal fm. of Lansing group. Includes "Iola" ls. of Kansas City area (which is now named *Argentine*), a few ft. of overlying sh. (here called *Island Creek sh.*), and, at top, Farley ls. At base of the Argentine at some exposures are a very dark or black fissile sh. (*Quindaro*) and blue dense ls. (*Frisbie*). The Wyandotte includes a complete cycle except for the "lower" ls. and sh. It is very prominent in Wyandotte Co. and along Kansas River, but becomes thinner southward and disappears in Miami Co., Kans. Overlies Lane sh. and underlies Bonner Springs sh. [On p. 47 is a detailed section of Wyandotte ls. aggregating 59 ft.]

N. D. Newell, 1935 (Kans. Geol. Surv. Bull. 21, p. 59). Because no other name has been suggested for the ls. in interval btw. Iola and Plattsburg lss., I propose to apply to it the name *Wyandotte*, from county of that name in NE. Kans. The 5 subdivisions (Farley ls., Island Creek sh., Argentine ls., Quindaro sh., and Frisbie ls.) are recognizable throughout NE. Kans. N. of Miami Co. and far into NW. Mo.

R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22), stated that Newell is author of this name.

†Wyckoff limestone.

Pennsylvanian: Eastern Kansas.

E. Haworth and M. Z. Kirk, 1894 (Kans. Univ. Quart., vol. 2, p. 111). *Wyckoff ls.*—Ls. No. 9, 20 ft. thick, of section along Neosho River from Indian Territory to White City, Kans. Overlain and underlain by shales.

Preoccupied. Replaced by *Burlingame ls.*, according to R. C. Moore, 1936 (Kans. Geol. Surv. Bull. 22, p. 215).

Named for Wyckoff, Lyon Co.

Wycliffe glacial epoch (and drift).

Pleistocene: British Columbia.

S. J. Schofield, 1915 (Canada Geol. Surv. Mem. 76, p. 85).

Wykoff beds.

Upper Ordovician (Richmond): Southeastern Minnesota and northeastern Iowa.

C. W. Hall and F. W. Sardeson, 1892 (Geol. Soc. Am. Bull., vol. 3, pp. 349, 359, 366). *Wykoff beds.*—Rather heavy-bedded, very fossiliferous shaly lss., 20 to 70 ft. thick, overlying Maquoketa sh. and forming top div. of Cincinnati "group" in southern Minn. and northern Iowa. [In many subsequent repts this name was applied to beds overlying Maquoketa sh.]

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, pl. 28), showed that *Wykoff ls.* of Iowa and Minn. underlies Maquoketa sh. in places and is=Clermont sh. and older beds down to Dubuque dol.; in other places it underlies Clermont sh., and its upper part is=lower part of Maquoketa sh. of Mo.

C. L. Dake, 1921 (Mo. Univ. School of Mines and Met. Bull., Tech. ser., vol. 6, No. 1, p. 109). *Wykoff fm.* overlies Maquoketa sh. in Minn.

C. L. Dake, 1922 (Pan-Am. Geol., vol. 37, No. 4). Maquoketan shales are more limy to N., as represented by *Wykoff beds*, and more sandy to S., as indicated by Thebes ss.

Late reports of Minn. Geol. Surv. do not recognize any fm. in Minn. btw. Maquoketa sh. and the Dev. ls. They therefore include Wykoff beds of

Hall and Sardeson in Maquoketa sh. According to E. O. Ulrich (unpublished statement) they are a part of Maquoketa, and are so treated by U. S. Geol. Survey.

Named for exposures at Wykoff, Fillmore Co., Minn.

Wylie.

See under *Limpia*.

†Wyman sandstone.

Mississippian: Northern Arkansas and eastern Oklahoma.

F. W. Simonds, 1891 (Ark. Geol. Surv. Ann. Rept. 1888, vol. 4, pp. 26, 38–41). *Wyman ss.*—Rather soft ss., yellowish brown on weathered surface but much lighter-colored when freshly broken. Thickness 2 to 9 ft. At many localities in Washington Co., Ark., separates Boone chert and its accompanying ls. from Fayetteville sh. Frequently forms a layer, 2 to 3 ft. thick, interpolated just beneath uppermost layer of the ls. [evidently mistaken for the thin younger ls. of Chester age, which in places constitutes basal part of Fayetteville sh.] or btw. uppermost layer [of the Boone] and the black sh. above.

Same as Batesville ss. See explanation under *Fayetteville sh.*

Named for Wyman, Washington Co., Ark.

Wyman.

Name applied by C. [R.] Keyes to 300 ft. of shales in basal part of Kootenai fm. of Mont. Derivation of name unknown. (See Pan-Am. Geol., vol. 46, pp. 195–232, Oct. 1926.)

Wyman formation.

Pre-Cambrian: Central eastern California (Inyo Range).

J. H. Maxson, 1934 (Pan-Am. Geol., vol. 61, No. 4, p. 311). [See this entry under *Roberts fm.*]

J. H. Maxson, 1935 (Geol. Soc. Am. Proc. 1934, p. 314). *Wyman fm.*—Spotted schists and phyllites with a few interbedded dolomites. Thickness 3,700± ft. in Wyman Canyon, Inyo Range, Bishop quad. Uncon. underlies Reed fm. and overlies (uncon.?) Roberts fm. All of pre-Camb. age.

Wymer beds.

Tertiary: Northwestern California.

See *Wimer beds*.

Wymore shale. (In Chase group.)

Permian: Eastern Kansas and southeastern Nebraska.

G. E. Condra and J. E. Upp, 1931 (Nebr. Geol. Surv. Bull. 6, 2d ser., p. 37). *Wymore sh.*—Basal memb. of Matfield fm. Consists of olive to gray sh., some mudstone, and a zone of red sh. near middle. Thickness about 20 ft. or more in Nebr. and northern Kans., but only about 9 ft. in vicinity of Burden, Kans. Type loc. ravines W. side of creek 2½ mi. E. of S. side of Wymore, Gage Co., Nebr., in E½ sec. 27, T. 2 N., R. 4 E., about ¼ mi. N. of where highway crosses Burlington and Union Pacific Railroads. Underlies Kinney ls. and overlies Wreford ls.

See Kans.-Nebr. chart compiled by M. G. Wilmarth, 1936.

Wynona sandstone member (of Nelagoney formation).

Pennsylvanian: Central northern Oklahoma (Osage County).

C. F. Bowen, 1918 (U. S. G. S. Bull. 686D, pp. 17, 18). At top of section in T. 24 N., R. 10 E., Osage Reservation, Okla., is a ss., 15 to 20 ft. thick, named by K. C. Heald (Rept. on T. 24 N., R. 9 E., in preparation, to form part of Bull. 686) *Wynona ss.*, from exposures at and near town of Wynona, T. 24 N., R. 9 E. It lies 25 ft. above Fourmile ss.

K. C. Heald, 1918 (U. S. G. S. Bull. 686E, p. 28), showed (but did not define) *Wynona ss.*, 10 to 15 ft. thick in section of S. part of T. 25 N., R. 9 E., as lying 7 ft. below Oread ls. and separated from underlying Fourmile ss. by 30 to 40 ft. of shales containing 2 sss.

Wynona sandstone group or series.

Pennsylvanian: Central northern Oklahoma.

H. T. Beckwith, 1928 (Okla. Geol. Surv. Bull. 40T, pp. 22–24). *Wynona ss. (group) memb.* (also *Wynona ss. group or series*).—This name is given to a series of lenticular sss. in upper part of Nelagoney fm. The group as a whole extends from Arkansas River to Kans. line, but it cannot be traced continuously except by adjacent distinctive beds. The ss. beds have few distinguishing characteristics, and individual beds cannot be traced more than a few miles. They thin very rapidly, and as one lens pinches out another usually comes in a short distance below or above. The Bowman [Bowhan] and Jonesburg ss. is considered a part of this group. Thickness of entire group variable. In N. part of county, from base of Bowman [Bowhan] ss. up to base of Middle Oread ls. the thickness is 120± ft., of which over half is sh. In T. 26 N., R. 10 E., a thickness of 150 ft. has been measured, the greater part of which is sh. In vicinity of Wynona the Wynona ss., *including Fourmile ss. memb.*, has a thickness of 100 ft., most of which is ss. South in T. 22 N., R. 10 E., the ss. is split up into several lenses separated by sh. beds of variable thickness. In this locality the ss., from top of Wildhorse ls. to top of ss. lying under the gray to dark blue-gray shales below Elgin ss., has total thickness of 160 ft. or more. The Cochahee ss. memb. is = middle (?) bed of Fourmile ss.

Wyo division.

Upper Cambrian or Lower Ordovician: Central Texas.

T. B. Comstock and E. T. Dumble, 1890 (Tex. Geol. Surv. 1st Ann. Rept., pl. 3, pp. 295–306). *Wyo div.*—Chiefly brown-weathering dolomites or semicrystalline lss., of dark-reddish or purplish color, becoming sandy or granular above; beds rather thinly laminated. Thickness 60 to 80 ft. No fossils. Middle div. of Leon series. Overlies Beaver div. and underlies, apparently uncon., Hoover div.

Is a part of Ellenburger ls.

Named for "well-known cattle brand (YO) used in Blue Mtn region along course of James River in adjoining parts of Mason and Kimble Counties."

†Wyoming conglomerate.

Tertiary (Miocene ?): Southern Wyoming, northwestern Colorado, and northeastern Utah.

C. King, 1876 (U. S. Geol. Expl. 40th Par. Atlas, maps 1 and 2; separate sheets were issued in 1875, but atlas bears 1876 imprint). *Wyoming cgl. (Plio.)* mapped over scattered areas.

C. King, 1878 (U. S. Geol. Expl. 40th Par. vol. 1). *Wyoming cgl.*—Coarse semistratified gravels and cgls., 0 to 300 ft. thick. Distinctly overlies Niobrara Plio. Absolutely certain it antedates Glacial period. Is the cgl. of Bishop Mtn.

A. Hague, 1877 (U. S. Expl. 40th Par. vol. 2, btw. pp. 58 and 65). Isolated patches of coarse gravel and smooth boulders held together by ferruginous sands, in region of Big Thompson, eastern Colo., reach thickness of 200 ft. From close resemblance to beds E. of Laramie Hills and to others westward on *Wyoming Plains* they have been referred provisionally to Wyoming cgl., the latest Plio. beds of Rocky Mtns.

Now replaced by *Bishop cgl.*, the type loc. of which (Bishop Mtn) is more definite, and also because *Wyoming* has been applied to deposits of different ages, widely separated geographically and stratigraphically.

†Wyoming formation.

†Wyoming group.

Pennsylvanian, Permian, and Triassic (?): Eastern Colorado.

G. H. Eldridge, 1896 (U. S. G. S. Mon. 27, on Denver Basin). *Wyoming fm.*—Prominent series of brilliant red cgls., sss., and shales, with thin lss. and gypsums in upper part. Constitutes well-known Red Beds of Rocky Mtns region. Commonly referred to Trias. In Denver field they rest directly and uncon. on ancient crystalline rocks, although in many other localities there intervene thousands of Paleozoic measures—Perm. (?), Carbf., Sil., and Camb. Thickness 500 to 3,000 ft. In Denver Basin consists of an upper div. and a lower div. The upper div. consists of (descending): (1) Fine-grained ss., often massive, pink and brown, persistent, 15 to 25 ft.; (2) gray, yellow, green, pink, and lilac clays, gypsiferous and calc., especially 40 ft. below top, 125 to 175 ft.; (3) clays more aren. than those above, transitional in color from grays above to prevailingly brick reds below, 150 to 200 ft.; (4) sss. and shales alternating, brick red to pink, white dots, 50 ft.; (5) sss. and shales, 60 ft.; and (6) sandy and argill. shales, brick red, with narrow bands of white crystalline ls., 75 ft. The lower div. is divided into *"Creamy" ss.* at top and Red Beds below. The *"Creamy" ss.*, named for its color, is 200 to 400 ft. thick, and consists of quartzose ss., conglomeratic at base, with two sandy ls. bands in lower part and round ferruginous concretions near top. The Red Beds consist of 270 to 2,000 ft. of cgls., sss., and shales (chiefly cgls. and sss.), of red color, the basal 5 to 20 ft. nearly everywhere composed of coarse subangular fragments of adjacent granite, gneiss, or schists, usually loosely agglomerated, with small admixture of sand which in places shades to red aren. mud.

Is now divided into (descending) Lykins fm. ("Upper Wyoming" of Eldridge); Lyons ss. restricted; Ingleside fm.; and Fountain fm.; the latter 3 representing "Lower Wyoming" of Eldridge. The Lykins fm. is now considered to be of Triassic (?) and probably Perm. age; the Lyons ss. restricted of Perm. age; and the Ingleside and Fountain of Penn. age.

Named for widespread development in Wyo., but the application of the name in the literature has been restricted to eastern Colo.

Wyoming Valley limestone beds.

A name applied by C. A. Ashburner (2d Pa. Geol. Surv. Rept. 1885, pp. 437–450, map, 1886) to the lss. occurring in the post-Pottsville rocks of Wyoming Valley, Luzerne Co., NE. Pa. His table (p. 449) lists (descending): (1) *Mill Creek ls.*, 1 ft. thick, lying 138 ft. below top of Penn. section; (2) *Canal ls.*, 2 ft. thick, lying 25 ft. lower; (3) unnamed ls., 2 ft. thick, lying 134 ft. lower; and (4) *Hillman ls.*, 3 ft. thick, lying 156 ft. lower.

Yaak quartzite.

Pre-Cambrian: British Columbia (Idaho-Montana bdy) and northwestern Montana (Purcell Range).

R. A. Daly, 1905 (Canada Geol. Surv. Summ. Rept. 1904, pp. 96–100). *Yahk qtzite.*—White to gray indurated sss. bedded in thin to medium courses. Thickness 500+ ft.; top not seen. Conformably overlies Moyie argillite, in section along Int. Bdy from Port Hill, Idaho, to Gateway, Mont.

R. A. Daly, 1913 (Canada Dept. Int. Rept. Chief Ast. 1910, vol. 2, pp. 119–139). Moyie fm. includes at summit the *Yahk qtzite*, which it appears advisable to withdraw from list of Boundary fms. It crops out at only one place in whole belt. The upper 400 ft. of *Moyie fm. as redefined* are chiefly composed of whitish and gray qtzites with meta-argillitic intercalations.

Probably named for *Yaak* River (NW. Mont.-B. C.), the spelling adopted by U. S. Geog. Bd.

Yabucoa granite.

Age (?): Puerto Rico.

C. R. Fettke, 1924 (N. Y. Acad. Sci. Scientific survey of Porto Rico and Virgin Islands, vol. 2, pt. 2, p. 159).

Yahk quartzite.

See *Yaak qtzite.*

Yakataga formation.

Oligocene: Southeastern Alaska (Yakataga district, Controller Bay region).

N. L. Taliaferro, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 756+). *Yakataga fm.*—Series of sss., dark shales, and cgls., 5,000± ft. thick, conformably overlying Poul Creek fm. in Yakataga dist. The shales resemble those of Poul Creek fm. but are usually softer and less platy. The cgls. are often thick and heavy and, like those in underlying beds and many cgls. of Katalla dist., are in part of glacial origin. Although sss. and cgls. are much more abundant than in Poul Creek fm., sh. and sandy sh. form almost half of exposed section. Many sss. contain scattered grains of glauconite, and there are occasional beds, up to 40 ft. thick, largely made up of closely packed glauconite grains. First thick ss. above the shales of Poul Creek fm. is taken as base of the Yakataga. This ss. is well exposed on Two Mile Creek and eastward on ridge btw. White River Valley and the coast. The fm. is well exposed at Yakataga Reef and on N. and S. flanks of Yakataga anticline. The entire area of Yakataga dist. is underlain by Tert. sediments that appear to be wholly of upper Olig. age. A fairly large fauna was obtained from various parts of both Yakataga and Poul Creek fms. According to B. L. Clark both are of upper Olig. age, and=Blakely horizon of Wash. and San Ramon horizon of Calif.

B. L. Clark, 1932 (Geol. Soc. Am. Bull., vol. 43, No. 3, pp. 797–846). [See summary under *Poul Creek fm.*]

Yakima basalt.

Miocene: Central and southern Washington, northern Washington, and eastern Washington.

G. O. Smith, 1901 (U. S. G. S. W. S. P. 55). *Yakima basalt.*—Includes the great series of lavas poured out in Mio. time over the vast area btw. what is now the crest of Cascade Mtns on W. and mtns of Idaho on E., and btw. mtns of NE. Wash. on N. and Blue Mtns of Oreg. on S. In Snake River Canyon 3,000 ft. of lava is exposed and Russell counted 8 distinct lava sheets. Max. thickness there is estimated at 5,000+ ft. Ten or more separate flows can be counted in the 2,500+ ft. vertical section in canyon of Yakima River, and individual flows can be traced great distances. The names *Columbia lava* and *Columbia River lava* have been used by Prof. I. C. Russell in describing the extensive lava series of Columbia River Basin. Under those terms are included basalts of both Eo. and Mio. age, also hypersthene andesite of post-Tert. age. In detailed mapping of Yakima area, which is a part of Columbia River Basin, it has been found inadvisable to use this general fm. name, because the lavas of different ages must be separated. *Yakima basalt* is therefore used for that of Mio. period. In Yakima Co. the basalt is a black rock, compact and heavy, often brownish on weathered surface.

G. O. Smith, 1903 (U. S. G. S. P. P. 19). *Yakima basalt* is early or middle Mio. Rests uncon. on Manastash fm. in Wash.

See also under *Columbia River basalt.*

Yakima group.

Pliocene: Central northern Oregon.

T. Condon, 1902 (The two islands). *Yakima group*, Plio. [Not defined. Lake deposits?]

Yakinikak limestone.

Mississippian (upper): Northwestern Montana (Glacier National Park).

B. Willis, 1902 (Geol. Soc. Am. Bull., vol. 13, pp. 316, 324). *Yakinikak ls.*—Light-gray to dark gray-blue crystalline ls. speckled with black cleavage faces, or amorphous; sometimes oolitic; weathers rough. Thickness 0–100+ ft. Is without upper strat. limit but rests conformably on an unnamed Carbf. [?] qtzite, 25 ft. thick, which is uncon. on Algonkian strata. Contains numerous fossils, identified by Weller as of St. Louis horizon. Absence of earlier Miss. strata indicates unusual overlap. Type loc. on Yakinikak Creek, 4 mi. W. of North Fork of Flathead River. Is apparently down-faulted.

Yakoun volcanics.

Jurassic: British Columbia.

J. D. MacKenzie, 1914 (Canada Geol. Surv. Summ. Rept. 1913, p. 41).

Yakutat group.

Mesozoic(?): Southeastern Alaska (Yakutat Bay region).

I. C. Russell, 1891 (Nat. Geog. Mag., vol. 3, pp. 167–175). *Yakutat system.*—The gray and brown heavily bedded sss. and nearly black shales about Yakutat Bay and westward along foot of St. Elias Mtn to Icy Bay. Forms bold shore of Yakutat and Disenchantment Bays. Faulted and upheaved. Dips beneath St. Elias schist. Relations to Pinnacle system undet.

G. C. Martin, 1926 (U. S. G. S. Bull. 776, pp. 485–486). *Yakutat group* is of unknown thickness; its relation to adjoining rocks has not been satisfactorily determined, and it has yielded no fossils except the supposed worm tube *Terebellina palachei* Ulrich and a supposed irregular echinoid which Stanton believes to be post-Triassic.

Yale member (of Ironwood formation).

Pre-Cambrian (upper Huronian): Northwestern Michigan and northwestern Wisconsin (Gogebic district).

W. O. Hotchkiss, 1919 (Eng. and Min. Jour. vol. 108, pp. 501, 503). *Yale memb.*—Interbedded ferruginous cherts and even-bedded ferruginous slates, with slates predominating. At base a "flatwise" cgl., which may belong to underlying Plymouth ferruginous chert memb. Thickness of Yale memb. 65 to 370 ft. Conformably underlies Norrie ferruginous chert memb. and overlies (uncon.?) Plymouth ferruginous chert memb.; all members of Ironwood fm. Named for Yale mine, near Bessemer, Mich.

Yale moraine.

Pleistocene (Wisconsin stage): Southeastern Michigan. Shown on moraine map (pl. 32) in U. S. G. S. Mon. 53. Named for Yale, St. Clair Co.

Yallahs formation.

Cretaceous: Jamaica.

R. T. Hill, 1899 (Harvard Coll. Mus. Comp. Zool. Bull., vol. 34, p. 42).

†Yampa sandstone.

Pennsylvanian: Northeastern Utah (Uinta Mountains).

J. W. Powell, 1876 (Geology of eastern portion of Uinta Mtns, pp. 41, 55). The Upper Aubrey group consists of sss. and lss., the latter cherty. To N. there are 2 members of this group; the upper is cherty ls., 100 to 200 ft. thick, which we have called *Bellerophon ls.* The lower, the *Yampa ss.*, is very massive, rarely showing evidences of stratification; in some places obliquely laminated. [On p. 55 he says:] In Uinta Mtns we have a homogeneous gray ss. which we call *Yampa ss.*, from 1,000 to 1,200 ft. thick, capped by a bed which is believed to be equiv. to the one at top of Upper Aubrey at junction of Grand and Green and varies in thickness from 150 to 200 ft. [According to Powell's map the canyon of Yampa River, in NW. Colo. and NE. Utah, is cut in his "Upper Aubrey group," which also forms most of Yampa Plateau.]

A. R. Schultz, 1920 (U. S. G. S. Bull. 702, table opp. p. 24), showed Yampa ss. of Powell's Uinta Mtns section as exact equiv. of Weber qtzite, the more widely used name.

Yampa limestone lentil (of Bingham quartzite).

Pennsylvanian: Central northern Utah (Bingham district).

A. Keith, 1905 (U. S. G. S. P. P. 38, p. 43, map, sections). *Yampa ls. lentil of Bingham qtzite.*—White siliceous cherty marble; nodules and irregular masses of chert are frequently found in it. Thickness 0 to 400 ft. Possibly is same as Commercial ls. [In sections is shown as much younger than Highland Boy ls. Named for Yampa mine.]

Yampai sandstone.

Permian: Northwestern Arizona (Grand Wash Cliffs).

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, pp. 251, 339). *Yampai sss.* is proposed for the red friable sss. particularly distinguishing the middle section of Supaian series and outcropping in Yampai Cliffs, or southern extension of Grand Wash Cliffs, in western Ariz. Thickness 300 ft.

Yankee Fork rhyolite member (of Challis volcanics).

Tertiary (late Oligocene or early Miocene): Southern central Idaho (Casto region).

C. P. Ross, 1932 (Idaho correlation chart compiled by M. G. Wilmarth). *Yankee Fork rhyolite memb. of Challis volcanics.*—Varicolored flows and light-colored tuffs, 0 to 1,600± ft. thick. In places comprises top memb. of Challis volcanics, and in places is overlain by tuffaceous beds belonging to the Challis. Rests on Germer tuffaceous memb. of Challis. Type loc. head of Yankee Fork Creek, SE. corner of Casto quad.

C. P. Ross, 1934 (U. S. G. S. Bull. 854, on Casto quad.). *Yankee Fork rhyolite memb.*—Flows, in general brownish with more or less distinct violet tinge; some, especially where weathered, are light-colored; a few are almost black. Many of lower flows contain small subangular fragments of the light-colored rocks of Germer memb. In most places light-colored tuff such as characterizes the Germer is interbedded in the rhyolite, but in minor amount. Top is greatly eroded. Thickness 500 to 1,600± ft. Encircles head of Yankee Fork, Casto quad. No fossils found. Assigned to Tert. (Mio.?).

C. P. Ross, 1937 (U. S. G. S. Bull. 877, on Bayhorse region). In Casto quad. most of rhyolitic flows were grouped in *Yankee Fork rhyolite memb.* at top of Challis volcanics. In Bayhorse region the corresponding flows interbed with Germer tuffaceous memb. to greater extent than they do farther N. Is late Olig. or early Mio.

Yankeetown chert. (Of Chester group.)

Mississippian: Southwestern Illinois and eastern Missouri.

S. Weller, 1913 (Ill. Acad. Sci. Trans., vol. 6, pp. 120, 124). *Yankeetown fm.*—Light-buff or nearly white siliceous ls., 20 ft. thick, some beds slightly sandy, and locally the fm. is partly qtzitic. Rests, with probable uncon., on Renault fm. and is overlain by Paint Creek fm.

Named for Yankeetown School, SE. corner of Monroe Co., Ill. Typically developed in region adjacent to the school.

Yaque group.

Miocene: Dominican Republic.

C. W. Cooke, 1920 (Geol. Soc. Am. Bull., vol. 31, p. 219).

Yaquina formation.

Oligocene: Northwestern Oregon (Lincoln County).

Harrison & Eaton (firm), 1920 (Min. Res. Oreg., Oreg. Bur. Min. and Geol., vol. 3, No. 1). *Yaquina ss.* (also *Yaquina div.*).—Upper 1,300 ft. consists of micaceous blue-gray ss., heavy-bedded, very fine-grained and very fossiliferous. Lower 1,000 to 1,300 ft. consists of coarse-grained buff-colored ss. interbedded with carbonaceous sh.; some thin seams of soft coal in lower part. Underlies *Acila* sh. and overlies Toledo div.

H. G. Schenck, 1927 (Calif. Univ. Pub., Dept. Geol. Sci. Bull., vol. 16, No. 12). *Yaquina fm.* is middle Olig. Underlies, apparently uncon., Nye sh. It is believed no angular uncon. separates Yaquina and Toledo fms.

H. G. Schenck, 1928 (Univ. Calif. Pub., Dept. Geol. Sci. Bull., vol. 18, pp. 22–31). Thickness of *Yaquina fm.* is 4,000± ft., according to writer's interpretation. Type loc. is town of Yaquina. Fossils correlate with Eugene fm., Tunnel Point ss., Pittsburg Bluff ss.

Yarmouth stage of deglaciation (Pleistocene).

Yarmouth stage is name applied to the interglacial stage following the second or Kansan stage of glaciation and preceding the third or Illinoian stage of glaciation. The deposits include soil, gumbotil, vegetal, and other interglacial deposits. The name was proposed by F. Leverett (Jour. Geol., vol. 6, pp. 176, 238–243, 1898), deposits of this interglacial stage having been discovered in material thrown out of a well at Yarmouth, Des Moines Co., Iowa. The locality name is therefore objectionable, but there are many exposures of the deposits in SE. Iowa.

Yates sand.

A subsurface sand, of Perm. age and 50 to 60+ ft. thick, lying 400± ft. below eroded top of Perm. in Yates oil pool, Pecos Co., western Tex. Also known locally as *Smith sand*. Oil-bearing lss. lying at approx. horizon of this sand have been called *Yates lime* and *Yates ls.*

Yavapai schist.

Pre-Cambrian: Central Arizona (Bradshaw Mountains).

T. A. Jaggar, Jr., and C. Palache, 1905 (U. S. G. S. Bradshaw Mtns folio, No. 126). *Yavapai schist.*—Most abundant rock is an argill. phyllite varying to sl., mica schist, and chlorite schist, but the fm. as mapped locally includes gneisses, granulites, hornfels, and epidote and hornblende schists, also cgl. and ss. bands and lenses and zones of intense metamorphism. The variations of the normal schist are mapped separately. Greater part of fm. is clearly sedimentary. Is oldest fm. in area. Assigned to Algonkian, but Archean rocks may be present in area. Thickness 5,000 to 7,000 ft. Is=Vishnu schist of Grand Canyon and is same as "Arizonian" of Blake. Named for extensive development in Yavapai Co.

Yazoo clay member (of Jackson formation).

Eocene (upper): Mississippi and southwestern Alabama.

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, p. 79). *Yazoo clay marl.*—Drab or yellowish calc. clays showing heavy bedding and distinct jointing. Thickness 300 ft. Of marine origin. Most notable fossil *Zeuglodon*. Included in Jackson group. Underlies Moody's Branch green marls.

C. W. Cooke, 1918 (Wash. Acad. Sci. Jour., vol. 8, No. 7, pp. 186–198). *Yazoo clay memb. of Jackson fm.* overlies Moodys marl memb., which includes, at top, the bed called "Zeuglodon bed" in Ala.

Later work led Cooke to modify the definitions so as to include the *Zeuglodon*-bearing bed in Yazoo clay memb. (See A. A. P. G. Bull., vol. 17, No. 11, pp. 1387–1388, 1933.) These modified definitions are those now followed by U. S. Geol. Survey, which treats the Yazoo and Moodys as *members* of Jackson fm., instead of as fms. of Jackson group. The Yazoo clay is overlain by Vicksburg group. Cooke (1918) described the Yazoo as almost entirely calc., very plastic clay of various colors, but in most places blue or green when wet and gray when dry. He gave its thickness at Vicksburg as 600 ft., at Jackson as 200 ft., at Shubata as 70 ft. In western Ala. the lower part of Yazoo clay of Miss. is represented by Cocoa sand memb. of Jackson fm., and the name *Yazoo* is there restricted to the overlying clay beds. The Yazoo and Moodys have not been mapped separately.

Named for exposures in bluff of Yazoo River at Yazoo City, Miss.

†Yeager clay.

Tertiary (Oligocene?): Southern Texas.

Julia Gardner and A. C. Trowbridge, 1931 (A. A. P. G. Bull., vol. 15, No. 4, p. 470). *Yeager clay.*—Massive or obscurely bedded clays in pastel shades of green, gray, yellow, or pink, carrying little or no sand and ash, which because of rarity of outcrops and absence of organic remains have not received the attention they deserve. Deussen (1924) included them in Frio clay. Dumble (1924) probably included them in upper part of his "Whitsett beds," the lower part of which form upper part of Fayette ss. of present writers. Bailey (1926) in most sections assigned them to his Frio, which was not Frio of Dumble, 1894. Unfortunately, both Dumble's original description and the text map that accompanies it include only outcrops of the volcanic series, and for that reason the name Frio must, by accepted laws of nomenclature, be retained for that series. For the lithologic unit of dominantly nonvolcanic clays, persisting from northern Live Oak Co. to the border, and several hundred ft. in max. thickness, the name Yeager is proposed, from Yeager ranch, on Cotulla-San Diego road in NE. Webb Co. The clays are interruptedly exposed from about ¼ to ½ mi. E. of to 3½ mi. SE. of the ranch house, where they are succeeded by the dominantly volcanic Frio fm. Fossil wood is commonly associated with the Yeager, but no other organic remains, either macro- or microscopic, have been recovered from surface exposures or well cores. Age not established. Absence of any evidence of uncon. btw. Fayette and Yeager is suggestive of Jackson age, but this appearance of conformity may be due to nonresistant lithologic character of the two fms., rather than to continuous deposition, and the field and possibly organic evidence may later prove the Yeager to be of Olig. age.

Owing to delay in publication of repts in which this fm. was defined by its proposers, the name first appeared in U. S. G. S. Press Mem. 50678 (pp. 10, 13, Feb. 16, 1931), entitled "Survey of the underground waters of Tex.," wherein it is described as consisting of gray to grayish-violet clay; (?) to 125 ft. thick; overlying Fayette ss. and underlying Reynosa fm. Later (Sept. 1931) it was decided to drop the new name "Yeager" and to adopt instead the definition of *Frio clay* which restricts that name to the beds beneath Catahoula tuff (=†Corrigan fm.) and above Fayette ss.

Yegua formation. (In Claiborne group.)

Eocene (middle): Eastern and southern Texas, northwestern Louisiana, and western and southern Mississippi.

E. T. Dumble, 1892 (Brown coal and lignite of Tex., pp. 124, 148–154). *Yegua div.*—Chiefly sands, sandy clays, clays, and brown coal, overlying Cook's Mtn beds (marine) and underlying Fayette div. [restricted]. Is lower part of deposits heretofore classed as Fayette beds.

The rept cited above gives sections in E. part of Burleson Co., along Brazos River above mouth of Yegua Creek, which show thicknesses ranging from 32½ to 37 ft., while sections given along Colorado River show 90 to 116 ft. of Yegua strata. The fm. was also identified along Rio Grande, but no mention was made of Lee Co. Until 1918, therefore, the type loc. of Yegua fm. was supposed to be in E. part of Burleson Co. In 1918, however (Tex. Univ. Bull. 1869, pp. 102–106), Dumble stated that type loc. is near mouth of Elm Creek, on [West] Yegua River [Creek], in Lee Co., and that in type section the line btw. Cook Mtn and Yegua fms. is drawn at base of the massive selenite-bearing clays. The fact that the thick nonmarine deposit mapped and described in eastern Tex. as Yegua fm. is same as †Cockfield fm. (top fm. of Claiborne group of La.) has been known for many years, but the more recent intensive work of Julia Gardner showed that the deposit at Yegua type loc. is a thin marine bed belonging to the underlying Cook Mtn fm. In view of these facts it was believed that a single name should be applied to the deposits in both States, and *Cockfield* was thought to be the better name. *Yegua* was therefore for a time discarded in favor of *Cockfield*. But in 1933 it was decided by Tex. geologists and U. S. Geol. Survey to revive *Yegua fm.* for the dominantly nonmarine unit forming top fm. of Claiborne group, and to abandon Cockfield fm. The Yegua fm. as now defined underlies Fayette ss. (of Jackson age) and overlies Cook Mtn fm.

See F. B. Plummer, 1933 (Univ. Tex. Bull. 3232, pp. 666–677).

Yegua River conglomerate. (In Yegua formation.)

Eocene: Eastern Texas (central Brazos County).

L. C. Reed and O. M. Longnecker, Jr., 1929 (Univ. Tex. Bull. 2901, pp. 163–174). *Yegua River cgl.*—Composed of clay balls, some angular, up to ft. or so in diam., which have been derived from material similar to that in underlying Turkey Creek bed. Considerable sand, in lenses and masses, is present in the cgl. No flint, pebbles, or petrified wood observed. Thickness at least 40 ft. It has shape and trend of a river channel. It gouges both the Turkey and Upper Turkey Creek beds, and its contact with the former is quite clear at one outcrop. Is a lithologic div. of Yegua fm., but name is used for convenience only and is not intended as a fm. or memb. name. [Is mapped. Derivation of name not stated, and appears to be applied to a *river* cgl. in Yegua fm., without reference to its proximity to Yegua River.]

Yellian series.

A term proposed by C. [R.] Keyes (Pan-Am. Geol., vol. 49, p. 287, 1928, and vol. 57, p. 344, 1932) to replace his *Arkansan series* (Penn.), "which is preoccupied many years previously by Endlich for a Carbonic ss. in Colo." Named for Yell Co., Arkansas River Valley, western Ark. coal-field region.

Yellow Creek sandstone member (of Hance formation).

Pennsylvanian: Southeastern Kentucky and northeastern Tennessee.

G. H. Ashley and L. C. Glenn, 1906 (U. S. G. S. P. P. 49, pp. 31, 33, 38, 119). *Yellow Creek ss. memb.*—Massive cliff-making ss., 25 to 60 ft. thick, in Hance fm., lying 100 ft. above base of Hance.

Named for Yellow Creek, Bell Co., Ky.

†Yellow Creek beds.

Mississippian (early) and Devonian: Northeastern Mississippi (Tishomingo County).

E. N. Lowe, 1915 (Miss. Geol. Surv. Bull. 12, p. 51). *Yellow Creek beds.*—Dark-gray and blue shaly lss., shaly and cherty toward top. Thickness 450 ft. Contain fauna corresponding to that of New Scotland of N. Y. Named for exposures on Yellow Creek, a branch of Tenn. River in Tishomingo Co.

W. C. Morse, 1930 (Miss. Geol. Surv. Bull. 23, pp. 18, 71). Yellow Creek beds of Lowe included Carmack ls. (Miss.) and all underlying Dev. terranes, and was a most appropriate term had not this uppermost ls. later proved to be Miss. in age. [On pp. 30 and 31 he gives sections on Yellow Creek, which show (descending): Carmack ls., 53 ft.; Whetstone Branch fm. (Upper Dev.), 0–31½ ft.; Island Hill fm. (Lower Dev.), 3 ft.; and New Scotland ls. (Lower Dev.), 39 ft.]

Yellow Hill limestone.

Lower Ordovician (Beekmantown): Eastern Nevada (Pioche region).

L. G. Westgate and A. Knopf, 1932 (U. S. G. S. P. P. 171). *Yellow Hill ls.*—Medium-bedded gray lss., weathering light gray, in part conglomerate, passing up into fine-grained gray lss., in beds 2 or 3 inches to 1 ft. thick, which cap Yellow Hill (near center of Ely Springs Range) and are well exposed in its W. face. The lowest part of fm. is on E. slope of Yellow Hill. Cgl. layers are common in fm., which weathers to gray or yellowish slabs and debris. Thin-bedded layers alternate with thicker beds and give a fluted cliff face on weathering. Total calculated thickness 670 ft. Fossils [listed] are late Beekmantown, according to E. Kirk. Faults bound the fm., so that neither base nor summit is shown, and it is impossible to say whether this Ord. fm. is conformable on Upper Camb. Mendha ls.

Yellowjacket formation.

Pre-Cambrian (Belt series): Southern central Idaho (Casto region).

C. P. Ross, 1934 (U. S. G. S. Bull. 854). *Yellowjacket fm.*—Dark-gray to greenish argill. qtzite with some calc. beds and, rarely, lenses of ls. Thickness probably nearly 9,000 ft. Underlies Hoodoo qtzite. Named for exposures at town of Yellowjacket, Casto quad. Basal fm. of Belt series. A. L. Anderson suggests (Idaho Bur. Mines and Geol. Pam. 34, p. 10, June, 1930) the rocks here named *Yellowjacket fm.* and *Hoodoo qtzite* may correspond to lower and middle members of Prichard fm. as identified by him in Orofino region.

Yellow Leaf quartz schist.

Devonian (possibly post-Lower Devonian): Eastern Alabama.

C. Butts, 1926 (Ala. Geol. Surv. Spec. Rept. No. 14, map, pp. 57, 147–148). *Yellow Leaf quartz schist.*—An unknown thickness, but at least 500 ft., of thin-layered fine-grained siliceous rock, varying in composition and texture from argillite to fine-grained ss., the latter greatly predominating. As the rock has a well-developed schistose structure, resulting from deformative stresses to which region has been subjected, the lithologic designation quartz schist can appropriately be applied to it. Immediately overlies Jemison chert (Oriskany). No fossils, but believed to be of Oriskany or later Dev. age. Formerly included in Talladega sl., to a part of which it corresponds.

Named for exposures on headwaters of Yellow Leaf Creek, 1½ mi. E. of Jemison, Chilton Co.

Yellowpine limestone member (of Monte Cristo limestone).

Mississippian (middle): Southeastern Nevada (Goodsprings region).

D. F. Hewett, 1931 (U. S. G. S. P. P. 162, pp. 9, 18, etc.). *Yellowpine ls. memb.*—Several beds of dark-gray ls. that locally weather as a massive ledge; in places completely altered to dol. Thickness 60 to 120 ft. Top memb. of Monte Cristo ls. Overlies Arrowhead ls. Contains the productive ore bodies of Yellow Pine, Potosi, Ingomar, and other mines.

†Yellowstone formation.

Upper and Lower Cretaceous and Jurassic (?): Central southern Montana (Little Belt Mountains region).

G. D. Harris, 1845 (Phila. Acad. Nat. Sci. Proc., vol. 2, pp. 235–237). *No. 5 or Yellowstone series.*—Probably continues from mouth of Yellowstone River to Great Falls of Mo. Consists of sand, clay, ss., and coal alternating without regularity. Strata vary from few inches to few ft. and are of a variety of colors.

H. D. Rogers, S. G. Morton, W. R. Johnson, 1845 (Phila. Acad. Nat. Sci. Proc., vol. 2, pp. 239–240). In immediate vicinity of Fort Union, near junction of Yellowstone and Missouri Rivers, in the group of strata designated as *No. 5* in Mr. Harris' paper, occur incontestable proofs of a fresh-water fm.

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). Above the coal seam forming top bed of Cascade fm. (Lower Cret.) about E. flank of Little Belt Mtns, and resting upon the still older Ellis fm. (Juratrias) in SW. part of Little Belt quad., is a great series of clay shales and sss., 4,500 ft. thick, for convenience grouped under name of *Yellowstone fm.* Different parts of this fm. exhibit diverse characters, but the gradation from one to another makes it difficult to divide it into the distinct parts generally recognized. There is, however, an advantage in recognizing these different parts, so that one may know to what horizon the beds seen at any locality belong, even if the boundaries and precise thickness of the subdivisions cannot be given. It includes Dakota ss. at base (400 to 500 ft. thick), the Colorado sh. or Benton and Niobrara, the Pierre sh. and Fox Hills sss., and is overlain by Laramie fm.

†Yellowstone Lake group.

Pliocene: Northwestern Wyoming.

See under *South Pass group.*

†Yellville limestone.

Lower Ordovician: Northern Arkansas and southern Missouri.

G. I. Adams and E. O. Ulrich, 1904 (U. S. G. S. P. P. 24, pp. 18, 32 (fig. 1), 90, 93). *Yellville fm.*—Mag. lss. or dolomites of Ord. age, which constitute principal lead- and zinc-bearing rocks of northern Ark. Of wide occurrence in lead and zinc dist., especially in Marion and Baxter Counties. Oldest rocks exposed in northern Ark. Base not exposed, and total thickness can only be estimated from record of deep well at Cushman, near Batesville, which passed through 1,505 ft. of strata without reaching pre-Camb. crystallines. Lower rocks in this well may be Camb. Name *Yellville fm.* intended to include only Ord. rocks. Natural exposures of fm. along White River approx. 500 ft. The lss. vary from massive to thin-bedded, with intercalations of shaly material and well-defined sh. beds. Underlies Key ss.

H. F. Bain and E. O. Ulrich, 1905 (U. S. G. S. Bull. 267, p. 12), applied *Potosi or Yellville group* to all rocks btw. top of Elvins fm. of Mo. and base of St. Peter ss. (St. Peter ss. as then used by Ulrich included most of Everton ls.—see 1907 entry under *Everton ls.*). These rocks include Powell, Cotter, Jefferson City, Roubidoux, and Gasconade fms. The Roubidoux has long been classified as of Beekmantown age and the Gasconade also is now classified by U. S. Geol. Survey as of Beekmantown age.

E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22, p. 667 and pl. 27). *Yellville ls.*—Provisionally regarded as embracing all rocks in northern Ark. and southern Mo. btw. top of Jefferson City dol. and base of Everton ls. This is in fact a restriction, but I take it a permissible one, since Adams, author of the term (P. P. 24, p. 18) had a very inadequate and in certain respects an erroneous conception of the series of rocks to which he proposed to apply the name. As here limited the fm. is bounded both above and below by an important uncon. and comprises all Canadian [Beekmantown] deposits on flanks of Ozarkia.

R. S. Bassler, 1915 (U. S. Nat. Mus. Bull. 92, vol. 2, pl. 2). *Yellville* uncon. overlies Gasconade ls. and includes (descending) Powell ls., Cotter ls., Jefferson City ls., and Roubidoux ss.

A. H. Purdue and H. D. Miser, 1916 (U. S. G. S. Eureka Springs-Harrison folio, No. 202, p. 5). *Yellville* of E. O. Ulrich, 1911 (Geol. Soc. Am. Bull., vol. 22) included only Powell ls.

E. T. McKnight, 1935 (U. S. G. S. Bull. 853, on Yellville quad., Ark.). *Yellville fm.* of Adams included (descending): Everton fm. (400 ft. thick, and of Chazy or older age); Powell dol. (85 to 170 ft. thick, and of Beekmantown age); Cotter dol. (400+ ft. thick, and of Beekmantown age); and Jefferson City dol. (of Beekmantown age).

Named for exposures at Yellville, Marion Co., Ark.

†Yellville group.

See 1905 entry under †*Yellville ls.*

†Yentna beds.

Tertiary: Southern Alaska.

J. E. Spurr, 1900 (U. S. G. S. 20th Ann. Rept., pt. 7, pp. 172, 183). *Yentna beds* is name applied to rocks of which only a single outcrop was examined, and this opp. Sushitna trading post, on Sushitna River below mouth of the Yentna. Is coarse-grained cgl. containing quartz pebbles. Provisionally referred to Kenai series.

Further explorations showed this is not a useful name.

Yeso member (of Chupadera formation).

Permian: New Mexico (northern, central, and southern).

W. T. Lee, 1909 (U. S. G. S. Bull. 389). *Yeso fm.*—Consists of 1,000 to 2,000 ft. of ss., sh., earthy ls., and gyp. The ss. varies in color from gray to many shades of pink, yellow, red, and purple and in texture from soft coarse-grained friable masses to fine-grained layers, evenly bedded and flinty. The shales, frequently gypsiferous, are soft, pink to yellow in color, and beds of massive white gyp. 100 to 200 ft. thick occur in many places. Is middle fm. of Manzano group. Underlies San Andreas ls. and lies with apparent conformity on Abo ss. [See also under *San Andres ls.*] Until further information is available San Andreas ls. cannot be definitely separated from Yeso fm. except in type loc. in San Andreas Mtns. Typically exposed on Mesa del Yeso, a small table-land 12 mi. NE. of Socorro. [In several sections the top memb. of Yeso fm. is shown as consisting of 200 to 275 ft. of pink, yellow, and white ss.]

See under *Chupadera fm.*, N. H. Darton (1922), for reasons for making it a memb. of Chupadera fm.

W. B. Lang, 1937 (A. A. P. G. Bull., vol. 21, No. 7), abandoned *Picacho ls.* of Pecos Valley region for *San Andres ls. memb. of Chupadera fm.*, and replaced *Nogal fm.* of that area with *Hondo ss. memb. of Chupadera fm.* (above) and *Yeso memb. of Chupadera fm.* (below). The recognition of Hondo ss. involves a slight redefinition of both San Andres and Yeso as heretofore used.

Yoder formation.

Oligocene (early): Southeastern Wyoming (Goshen County).

E. M. Schlaikjer, 1935 (Harvard Coll. Mus. Comp. Zool., vol. 76, No. 3, pp. 71–75). *Yoder fm.*—A series of fluviatile deposits, lying uncon. on Lance fm. (upper Cret.) and grading upward into Chadron fm. (lower Olig.), occurring in certain parts of Goshen Hole area. The fauna is distinctly transitional btw. uppermost Eo., or Duchesne, and lowermost Olig., or lower Chadron. It seems too progressive to be assigned to Eo., and too primitive to be assigned to Chadron. The beds represent a strat. level quite apart from upper Eo. and easily distinguished from Chadron. The Eo. and Paleocene are absent in Goshen Hole area. Considering faunal relationships and strat. position the fm. should be regarded as Olig. rather than Eo. Named for town of Yoder, which is 1½ mi. SE. of type loc., which is SE¼ sec. 29, T. 23 N., R. 62 W., Goshen Co., where the fm. consists of (descending): (1) Reddish-green clays, with channels of wine-colored intricately cross-bedded coarse to fine ss., 20± ft.; (2) red to greenish sandy clays, mostly bedded, 18± ft.; (3) red sss. and dark to light-red rather finely bedded sandy clays, 15± ft.; base concealed.

Yogo limestone.

Upper Cambrian: Central northern Montana (Fort Benton quadrangle) and central southern Montana (Little Belt Mountains quadrangle to Helena region).

W. H. Weed, 1899 (U. S. G. S. Fort Benton folio, No. 55). The brick-red shales and lss. constituting Dry Creek sh. are overlain by 100 ft. of *Yogo ls.*

W. H. Weed, 1899 (U. S. G. S. Little Belt Mtns folio, No. 56). *Yogo ls.*—Gray or mottled ls. with a few layers of sh. Uppermost memb. of Barker fm. [a name applied to all Camb. rocks of area]. Overlies Dry Creek sh. and underlies Jefferson ls. [Derivation of name not stated, but Barker fm. is mapped at and around village of Yogo, also along Yogo Creek (both in N. part of this quad.), at both of which places it is overlain by Jefferson ls.]

W. H. Weed, 1900 (U. S. G. S. 20th Ann. Rept., pt. 3, p. 286). *Yogo ls.* of Little Belt Mtns generally consists of thin-bedded ls. flags alternating with crumbly gray or greenish sh. but grades into rather pure thick-bedded lss. Entire section is well shown at head of Sheep Creek and S. of Monarch. [On p. 328 Weed gave section exposed in Sheep Mtn, Yogo Creek Valley, N. of Yogo, which showed 10 ft. of Yogo ls. underlying Jefferson ls. and overlying Dry Creek sh. On p. 330 he gave a section at mouth of Bear Creek, Yogo Gulch, which listed 65 ft. of Yogo btw. the Jefferson ls. and Dry Creek sh. Type loc. of Dry Creek sh. is in NE. corner of Three Forks quad. See definition.]

A. Knopf, 1913 (U. S. G. S. Bull. 527, p. 91). *Yogo ls.* of Helena dist. consists of light-colored thin-bedded lss., with crinkly bands and films of jasper, in many places composed of ls. pebbles held in a glauconitic matrix. It corresponds to so-called "Pebbly" ls. of Three Forks folio [which rests on Dry Creek sh.].

C. F. Deiss, 1936 (Geol. Soc. Am. Bull., vol. 47, No. 8, pp. 1258–1342), proposed that Yogo ls. be discarded and defined Dry Creek as uncon. overlain by Dev. rocks. In upper part of his Dry Creek sh. he included a great thickness of lss.

Yogo Peak type (of granite porphyry).

A term used by L. V. Pirsson (U. S. G. S. 20th Ann. Rept., pt. 3, p. 502, 1900) for a mass of granite porphyry on divide running E. from Yogo Peak, Little Belt Mtns, central southern Mont.

Yonkers granite.

Pre-Cambrian: Southeastern New York.

F. J. H. Merrill, 1890 (Am. Jour. Sci., 3d, vol. 39, p. 388). *Yonkers gneiss.*—Lowest stratum yet recognized in Westchester Co. is a reddish gneiss which forms central mass of some of hills in Yonkers, where it is well exposed, and consists of small grains of detrital quartz with fragments of reddish orthoclase and a few crystals of biotite which have developed during process of metamorphism. From macroscopical characters it would be called a gneiss; from microscopic characters it would be called a metamorphosed ss. or arkose. It is proposed to designate it an arkose gneiss. Thickness not determined. Base not seen, but believed it rests on the stratified granulites at top of the pre-Camb. Underlies Fordham gneiss. Included in Manhattan group.

W J McGee, 1894 (Geol. map of N. Y., prepared under direction of James Hall). [Among "ancient crystalline rocks" *Yonkers granite* is shown below Cortlandt series and above Laurentian granite.]

F. J. H. Merrill, 1898 (N. Y. State Mus. 15th Ann. Rept., vol. 1, pp. 21–31). *Yonkers gneiss* is technically a gneissoid granite, is plainly *intrusive* into Fordham gneiss, and is younger than Manhattan schist.

C. P. Berkey, 1907 (N. Y. State Mus. Bull. 107, pp. 361–378). *Yonkers gneiss* appears to have been a great granite sill that can now be traced along axis of southern ridges for distance of 15 mi. Is intrusive into Fordham gneiss.

C. P. Berkey and M. Rice, 1921 (N. Y. State Mus. Bull. 225, 226, p. 140). [*Yonkers gneissoid granite* is placed in column as much younger than injection gneiss part of Fordham gneiss, which is much younger than paragneiss parts of Fordham gneiss.]

E. B. Knopf and A. I. Jonas, 1929 (U. S. G. S. Bull. 799, table opp. p. 68), classified this fm. as post-Glenarm Algonkian.

Yonkers gneiss.

See under *Yonkers granite.*

†York limestone.

Ordovician and Cambrian: Southeastern Pennsylvania.

P. Frazer, Jr., 1876 (2d Pa. Geol. Surv. Rept. C, pp. 130 et seq). [Throughout his description of York Co. Frazer frequently used *York ls.* and stated that it is same as Auroral ls.]

P. Frazer, Jr., 1880 (2d Pa. Geol. Surv. Rept. C_3, btw pp. 1 and 31). *York ls.* is a slender offshoot of Lancaster ls.

Same as ls. later named Shenandoah ls. and now divided into several fms., as shown on Pa. chart II.

†York schist.

Lower Cambrian: Southeastern Pennsylvania.

P. Frazer, Jr., 1876 (2d Pa. Geol. Surv. Rept. C, pp. 130–143), in describing the rocks of York Co., stated that hydromica slates and schists overlie the qtzite of Chiques rock and uncon. underlie York (Auroral) ls. On p. 135 he called the schists *York schists.*

P. Frazer, Jr., 1880 (2d Pa. Geol. Surv. Rept. C_3, pp. 3–6). *York schists.*—Hydromica schists. Named for locality where first studied in this [Lancaster Co.] dist. Overlie Chikis [Chickies] qtzite. Compose greater part of Chikis ridge and Chestnut Hill.

The schist overlying Chickies ("Chiques") qtzite in York Co. is now called *Harpers schist.*

†York shale.

Lower Cambrian: Southeastern Pennsylvania (York County).

C. D. Walcott, 1896 (U. S. G. S. Bull. 134, pp. 14–15, 26, 36–37). *York shales* is proposed for the band of shales resting upon the qtzites surrounding Hellam Hills. Well developed in York Co. Is subjacent to Lancaster ls. and underlain by Chickies qtzite.

Same as Harpers schist, mapped over large areas to SW. of York Co.

York zone.

Archean: Northern South Carolina.

See *Abbeville-York zone.*

Named for exposures in York Co.

†York County hydromica slates.

Lower Cambrian: Southeastern Pennsylvania.

J. P. Lesley, 1892 (2d Pa. Geol. Surv. Summ. Final Rept., vol. 1, p. 203). *York Co. hydromica schists* overlie Chiques ss. and underlie Great Valley ls.

Same as York schist of Frazer, which is now replaced by *Harpers schist.*

York Harbor biotite granite.

Devonian (?): Southwestern Maine.

A. Wandke, 1922 (Am. Jour. Sci., 5th, vol. 4, pp. 148, 149). *York Harbor biotite granite* (Dev. ?) is exposed along S. side of York Harbor, York Co.

Yorkian period.

Yorkic period.

Names introduced by C. [R.] Keyes (Pan-Am. Geol., vol. 37, pp. 234, 243–244, 1922) to include Dev. and Sil. of present commonly accepted nomenclature, "in commemoration of what is perhaps its most complete terranal representation in the world—the New York section of these rocks."

C. [R.] Keyes, 1931 (Pan-Am. Geol., vol. 56, pp. 88, 89), restricted his *Yorkic* to the time btw. Carbf. and Sil., or to Dev. period of current terminology.

C. [R.] Keyes, 1933 (Pan-Am. Geol., vol. 59, p. 57). *Yorkic* is of course a modern abbreviation of Ebenezer Emmons' early term of *New York system*, "a name which turns out to be as justly regarded as ranking with Murchison's Silurian system, and Sedgwick's Cambrian system, in date of birth, formal and precise stratigraphic characterization, exact faunal definition, just accreditation to the astute American pioneer in modern geological definition and nomenclature, useful terminal application, and in every way peer of any of our geological periodic time divisions." [†New York system of Emmons extended from top of Chemung (Upper Dev.) to base of Potsdam ss. (Upper Camb.).]

York-Petro limestone.

A name applied by R. N. Hunt, also by O. P. Peterson, 1924, Am. Inst. Min. and Met. Engrs. Trans., vol. 70, pp. 859–883 (Hunt) and pp. 908–926 (Peterson) to a ls., 1 to 10 ft. thick, in upper part of Bingham qtzite (Penn.) of Bingham dist., Utah. Lies 300 ft. above Parnell ls.

York River sandstone.

Devonian: Quebec (Gaspe Peninsula).

H. S. Williams, 1910 (Geol. Soc. Am. Bull., vol. 20, p. 690). *York River beds*, assigned to Dev.

C. H. Kindle, 1936 (Eastern geol., No. 1, April, 1936, pp. 3, 4, 6). Fossils found at various horizons in *York River ss.* of Williams, 7,000 ft. thick and lower memb. of Gaspe ss., are probably Middle Dev. This ss. underlies Malbaie cgl., upper memb. of Gaspe ss.

†Yorktown epoch.

Miocene: Atlantic coast.

J. D. Dana, 1863 (Man. geol., pp. 506, 510, 521, 522). *Yorktown epoch*, or that of the beds of Yorktown, Va., in which 15 to 30 percent of the species are living—usually called Miocene. *Yorktown beds* cover a large part of Atlantic Tert. border, occurring at Gay Head on Martha's Vineyard; in N. J.; in Md., on both sides of the Chesapeake for a great distance; and in Va., at Yorktown, Suffolk, Smithfield, and through larger part of Tert. region.

Corresponds to Chesapeake group, or all of Mio. of region described, of which Yorktown fm. of present nomenclature is upper part.

Yorktown formation. (In Chesapeake group.)

Miocene (upper): Eastern Virginia and North Carolina.

W. B. Clark and B. L. Miller, 1906 (Va. Geol. Surv. Bull. 2, pt. 1, p. 19). *Yorktown fm.*—Sands and clays crowded with remains of calc. shells, chiefly marine Mollusca. At Yorktown and on James River afford the most highly fossiliferous beds of Chesapeake Bay region. Fossils differ from those of underlying Mio. fms. and evidently represent a distinct faunal aggregate. Thickness 100+ ft. Rests conformably on St. Marys fm. Is top fm. of Chesapeake group.

W. C. Mansfield, 1935 (Fla. Geol. Surv. Bull. 12, p. 9). *Yorktown fm.* of Va. and N. C. is divisible into 2 major zones. Zone 2 (the upper) includes: (1) The uppermost Yorktown beds, which are exposed at Suffolk, Va., and which are correlated with upper part of *Cancellaria* zone of Fla.; (2) the beds at Yorktown, Va., which are correlated with lower part of *Cancellaria* zone of Fla.; and (3) the *Chama*-bearing bed, which is correlated with the aluminous clay of Fla. Zone 1 (at base) corresponds to the beds exposed at Raysor Bridge, S. C. [Raysor marl of C. W. Cooke], which are=*Ecphora* zone of Fla.

Yorkville granite.

Late Carboniferous (?): Northwestern South Carolina and southern North Carolina.

A. Keith, 1931 (U. S. G. S. Gaffney-Kings Mtn folio, No. 222). *Yorkville granite.*—Dark-gray coarse-grained granite. Intrusive into Roan gneiss. Believed to be younger than Whiteside granite.

Named for exposures at Yorkville (also called York), York Co., S. C.

Yosemite glacial epoch.

Name applied by E. Blackwelder (Geol. Soc. Am. Bull., vol. 41, pp. 91–92, 1930) to time during which the glacial deposits of Wisconsin age were laid down on slopes of Sierra Nevada, Calif. He later (G. S. A. Bull., vol. 42, pp. 865–922, 1931) replaced this name with *Tioga glacial stage*.

Young Peak dolomite.

Middle Cambrian: Western Utah (Gold Hill district).

T. B. Nolan, 1930 (Wash. Acad. Sci. Jour., vol. 20, No. 17, Oct. 19, pp. 421–432). *Young Peak dol.*—Massive dark-gray to black crystalline dol. spangled with short rods of dol. To N. the dol. interfingers with shaly lss. similar to those in underlying Abercrombie fm. Less than 5 mi. to N. only a few ft. of dol. can be found, and the strat. interval of the fm. is occupied by portions of Abercrombie fm. Top bed is a dark-gray dol. containing abundant nodules of dark-gray chert which may reach several ft. in diam. It is overlain by a cream-colored, finely laminated dol. which forms basal bed of Trippe ls. Thickness 600 ft. No fossils, but unquestionably is Middle Camb. Is well exposed on Young Peak, on S. side of Dry Canyon.

See also U. S. G. S. P. P. 177, 1934.

Young's Bluff bed.

Eocene (Jackson): Northwestern Louisiana (Grant County).

T. L. Casey, 1902 (Sci., n. s., vol. 15, p. 716). *Young's Bluff bed.*—Blackish and red clays characterized by profusion of a large *Pinna* and of *Venericardia planicosta*, *Volutilithes*, and *Pseudoliva*. Outcrops about 3 mi. below Kimbrel beds, and limits the estate of John Young. Is still higher than Kimbrel bed. Must be very nearly synchronous with Kimbrel bed but is a sufficiently distinct horizon to have developed another characteristic species of *Lucina*. Included in Jackson stage. Named for outcrops on estate of John Young, S. of Montgomery, Grant Co.

Youngstown sand.

A subsurface sand, of early Penn. (Cherokee) age, in eastern Okla., which has been said to be=Dutcher sand series, the upper or first Youngstown sand corresponding to upper Dutcher sand, and the lower or second Youngstown sand corresponding to lower Dutcher sand; but according to pp. 177–178 of Okla. Geol. Surv. Bull. 40Q, 1928, the Youngstown sand in its type area (Youngstown pool, Okmulgee Co.) lies at 2,250 ft. depth, the Dutcher sand at 2,400 ft. depth, and the Booch sand at 1,994 ft.

Younkin formation. (Buried.)

Devonian or Silurian (?): North-central Kansas.

J. S. Barwick, 1928 (A. A. P. G. Bull., vol. 12, No. 2, p. 184). *Younkin fm.*—Unit No. 3 encountered in wells in Salina Basin, Kans. Not exposed. Thickness 0 to 400 ft.; is 400 or more ft. thick in Clay and Riley Counties. Consists of white to gray dolomitic ls. locally interbedded with thick bodies of rounded quartz sand in lime matrix. Underlies Skelton sh. (unit No. 2) and overlies Engle sh. (unit No. 4). Lithology and position suggest fossiliferous Sil. and Dev. of SE. Nebr., SW. Iowa, and NW. Mo., which does not correspond to Hunton ls. of Okla. Named for Boggess et al. Younkin No. 1 well, sec. 21, T. 9 S., R. 4 E., Clay Co., Kans., where encountered at 2,194 to 2,520 ft. depth.

Ysidro shale.

Pre-Cambrian: Central northern New Mexico (Sandia and Manzano Mountains).

C. [R.] Keyes, 1915 (Iowa Acad. Sci. Proc., vol. 22, pp. 257–259; Conspectus of geol. fms. of N. Mex., pp. 4, 12). *Ysidro shales.*—The thick argill. memb. of Proterozoic sediments lying above the great qtzite, which is best exposed in sharp truncated arch in Tijeras Canyon btw. Sandia and Manzano Ranges. Thickness 1,500 ft. [Derivation of name not given.]

Yucca bed.

Lower Cretaceous (Comanche series): Western Texas (El Paso County).

J. A. Taff, 1891 (Tex. Geol. Surv. 2d Ann. Rept., pp. 725, 736). *Yucca bed.*—Consists of (descending): (1) *Caprotina* ls. (second horizon), 15 ft. of massive thick-bedded ls.; (2) alternating sands, grits, aren. ls., cgl., and flaggy marble;

(3) *Exogyra texana* horizon. Overlies Etholen bed and underlies Bluff bed; all included in Washita div.

C. L. Baker, 1927 (Univ. Tex. Bull. 2745, p. 21). Lower part of *Yucca bed* belongs to Cox ss. and upper part to Finlay ls.

Named for Yucca Mesa, El Paso Co.

†Yuha reefs.

Miocene (lower): Southern California (Imperial County).

G. D. Hanna, 1926 (Calif. Acad. Sci. Proc., 4th ser., vol. 14, p. 435). Above these [Coyote Mtn] clays, and interbedded with them near top to some extent, are extensive deposits of oyster shells for which the name "*Yuha Reefs*" has been selected. Type loc. has been chosen as prominent hill made up of the material, thoroughly cemented and partially metamorphosed, located on E. end of Coyote Mtn uplift. The same reefs are found on Yuha Buttes. Overlain by Coahuila silt. Assigned to Plio., probably middle or upper Plio. [Seems to form uppermost part of †Carrizo Creek beds. See under *Imperial fm.*]

See W. P. Woodring, 1931, under *Imperial fm.* Are interbedded at different horizons in upper part of Imperial fm.

Yukon silts.

Pleistocene: Northeastern Alaska (Yukon River region).

J. E. Spurr, 1898 (U. S. G. S. 18th Ann. Rept., pt. 3, pp. 200–220). *Yukon silts.*—The gravels or silts forming lower terraces of Yukon River. Contain remains of mammoth and other Pleist. mammals and land and fresh-water shells of living species. In most cases it seems certain the deposits were formed in fresh-water lakes.

A. G. Maddren, 1907. (See 1907 entry under *Kowak clay.*)

Yukon group.

Pre-Cambrian: Northeastern Alaska (Yukon River region) and Yukon Territory, Canada.

D. D. Cairnes, 1914 (Geol. Soc. Am. Bull., vol. 25, p. 184; Canada Geol. Surv. Summ. Rept. 1912, p. 11; Canada Geol. Surv. Mem. 67, p. 40).

J. B. Mertie, Jr., 1937 (U. S. G. S. Bull. 872). *Yukon group* is=Birch Creek schist (sedimentary) and associated meta-igneous schists, gneisses, and intrusives, and includes all older pre-Camb. crystalline rocks of Yukon Territory.

Yule marble.

Trade name for marble quarried from Leadville ls. (Miss.) in Gunnison Co., Colo. Also known to trade as *Colorado Yule marble* from 1908 to 1916. In 1928 the Yule Colorado Marble Co. was organized and the trade name for the product became *Yule Colorado marble*. The quarry is now (1937) owned by Vermont Marble Co. The Lincoln Memorial at Washington, D. C., is constructed of this marble.

†Yule limestone.

Ordovician: Western and central Colorado.

G. H. Eldridge, 1894 (U. S. G. S. Anthracite-Crested Butte folio, No. 9). *Yule ls.*—*Upper div.*, 60 to 90 ft. thick, consists mainly of green, yellow, red, and white shales, with more or less aren. or calc. layers which pass into thin lss. *Middle div.*, 250 to 280 ft. thick, consists of lss., often very thin-bedded, frequently siliceous, especially at base, and containing grayish-white cherts. Color generally gray with pink or purple cloudings, turning to brown on weathered surfaces. On Yule Creek the lss. are altered to marbles of white, green, yellow, and other colors, and they are fossiliferous. *Lower div.* consists of 75 to 100 ft. of qtzite, generally white, sometimes spotted by iron oxide, often calc., and containing indistinct fossils. The Yule overlies Sawatch qtzite and underlies Leadville ls. and has a total thickness of 350 to 450 ft. Named for fine development at head of Yule Creek.

In type area is now divided into Fremont ls. (Upper Ord.), Harding ss. (Middle Ord.), and Manitou ls. (Lower Ord.), and has been discarded.

Yule coal group.

A term applied to a group of strata in Ludlow lignitic memb. of Lance fm. in SW. N. Dak., including coals A to F, both inclusive. (See A. G. Leonard, 1908, N. Dak. Geol. Surv. 5th Bien. Rept.)

†Yulean series.

Cambrian to Upper Devonian: Western Colorado.

C. [R.] Keyes, 1924 (Pan-Am. Geol., vol. 41, pp. 281, 289) *Yulean series.*—Composes all of Late Ordovicic of Colo. Divided into (descending): Cement shales, 100 ft.; Fremont dolomites, 300 ft.; and Harding sss., 100 ft. "A modification of Eldridge's name" [Yule ls.].

According to E. Kirk, 1930 (Am. Jour. Sci., 5th, vol. 20, pp. 456–465), the Harding sss. of Keyes are Upper Camb. Sawatch qtzite; his Fremont includes equivalents of Manitou ls., Harding ss., and Fremont ls.; and his Cement is probably Upper Dev.

Yuma sandstone member.

Eocene (upper): Southeastern Texas.

B. C. Renick, 1936 (Univ. Tex. Bull. 3619, table opp. p. 17, and pp. 36–39). *Yuma ss. memb. of Manning fm.*—Massive and flaggy ss., locally containing fossiliferous marine beds; 3 to 25 ft. thick. Lies 25 to 40 ft. above Dilworth ss. memb. of Manning [expanded] and 0 to 25 ft. below top of Manning fm. [Above definition is from table. On p. 36 is statement:] Along Missouri Pacific R. R. track about 300 ft. N. of station at Yuma and about 6,000 ft. W. and 3,300 ft. S. of NE. corner of Walter Sutherland survey, there are strata consisting mostly of flags of medium-hard ss. interbedded with soft sand and sandy sh., and in basal part of this section there is an earthy ss. The entire section at Yuma is about 25 ft. thick and name *Yuma ss.* is here applied to this memb., though it is recognized that it is possible these strata may be equiv. of Dilworth ss. of Gonzales Co. [At bottom of p. 37 is statement that Yuma ss. is 25 to 40 ft. above Dilworth ss., and a long list of places where the Yuma is exposed.]

Yumuri limestone.

Miocene or Oligocene: Cuba.

E. L. DeGolyer, 1918 (A. A. P. G. Bull., vol. 2, p. 143). [Assigned to Olig., but C. Schuchert, 1935 (Hist. geol. Antillean-Caribbean region, p. 507), assigned it to middle Mio.]

Zaleski flint. (In Allegheny formation.)

Pennsylvanian: Southeastern Ohio (Vinton County).

W. Stout, 1927 (Ohio Geol. Surv., 4th ser., Bull. 31, p. 181). *Zaleski flint.*—A gray to black calc. bed, 1½ in. thick, underlying Winters clay in Vinton Co.

Zandia clay.

See *Sandia clay.*

Zanzibar limestone.

Ordovician(?): Central Nevada (Manhattan district).

H. G. Ferguson, 1924 (U. S. G. S. Bull. 723). *Zanzibar ls.*—Blue-gray ls. with black jasper; a little black sl. near top. Thickness 800 ft. Underlies Toquima fm. and overlies Mayflower schist. Prominently developed on Zanzibar claim, about 1½ mi. E. of Manhattan.

Zapata formation.

Pleistocene: Cuba.

J. W. W. Spencer, 1894 (Geol. Soc. Am. Bull., vol. 6, p. 129).

Zapotitlan formation.

Cretaceous: Mexico.

W. A. VerWiebe, 1924 (Am. Jour. Sci., 5th, vol. 8, p. 281).

Zebra limestone.

A descriptive term applied by the miners of Colo. to patches of dark-blue fine-grained ls. or dol. cut by closely parallel veinlets of coarser-grained white dol.

Zemorrian stage.

Tertiary: California.

R. M. Kleinpell, 1934 (A. A. P. G. Bull., vol. 18, No. 3, pp. 376–378), proposed the following 6 new stage names, for faunal subdivisions of Mio. series in Calif. (ascending order): (1) *Zemorrian stage* (type loc. Zemorra Creek, a branch of Chico Martinez Creek, Kern Co.); (2) *Saucesian stage* (type loc. Los Sauces Creek, Ventura Co.); (3) *Relizian stage* (type loc. Reliz Canyon, Monterey Co.); (4) *Luisian stage* (type loc. on Highland monocline about 4½ mi. W. of Indian Creek, San Luis Obispo Co.); (5) *Mohnian stage* [derivation of name not stated]; and (6) *Delmontian stage* (type loc. at head of Canyon Segundo, S. of Del Monte, Monterey Co.).

R. M. Kleinpell, 1935 (Geol. Soc. Am. Proc. 1934, p. 391), gave *Mohnian* type loc. as N. of Mohn Spring, Santa Monica Mtns.

H. G. Schenck and R. M. Kleinpell, 1936 (A. A. P. G. Bull., vol. 20, No. 2, p. 224, etc.). *Zemorrian stage* includes "*Turritella inezana* zone" of type Vaqueros, upper San Lorenzo fm., etc. Overlies Refugian stage and underlies Saucesian stage.

Zeuglodon beds.

A paleontologic name applied by W. H. Dall (U. S. G. S. 18th Ann. Rept., pt. 2, p. 342, 1898) to a bed in upper part of Jackson fm. (Eo.) that contains the remains of *Zeuglodon*.

Zia marl.

Eocene (?): Central northern New Mexico (Sandoval County).

A. B. Reagan, 1903 (Am. Geol., vol. 31, btw. pp. 67 and 111). *Zia marls*.—Bluish-yellow Eo. marls, 0 to 40 ft. thick, forming cap rock on one side of Rio Grande. Called Pleist. by Herrick. Rest on soft red and gray Eocene sss., and uncon. underlie Plio. calc. sss. and cgls. of white to deep-green color.

Probably named for village of Zia, near Jemez, Sandoval Co.

Zilhlejini formation.

Upper Cretaceous: Northeastern Arizona (Black Mesa).

A. B. Reagan, 1925 (Pan-Am. Geol., vol. 44, pp. 287, 291). *Zilhlejini shales* [on map].—Overlying, in apparent conformity, sss. in Black Mesa, Ariz., that appear to belong to Pictured Cliffs ss., is an important coal-bearing section, 200± ft. thick, which seems to have no very close affinities elsewhere unless it is=some part of Fruitland fm. of N. Mex. It is therefore designated *Zilhlejini coal fm.*

A. B. Reagan, 1926 (Pan-Am. Geol., vol. 46, pp. 193–194). *Zilhlejini fm.*—Several hundred ft. of fresh-water coal-bearing sss. and shales occurring on top of Black Mesa. Overlie 30 ft. of Masukian black shales, thought possibly to be southerly equiv. of typical Laramie fm. of Wyo., Colo., Utah, the Lower Laramie or Cretacic Laramie of some recent authors. Contains an impure limerock characterized by heaps of oyster shells (listed).

Apparently named for exposures on Ziltahjini Peak (as spelled on 1924 geol. map of Ariz.), in Black Mesa, where rocks of this description occur.

The 1921 ed. of decisions of U. S. Geographic Board states that *Black* is adopted as the name of the mesa in Hopi and Navajo Indian Reservations, Ariz., instead of Zilh-le-jini or Zilthe-le-Jini. On 1937 map of Indian Office of U. S. Dept. Int. this peak is spelled Zibi-dush-jhjni.

A. B. Reagan, 1932 (Kans. Acad. Sci. Trans., vol. 35, pp. 233–236), says Fruitland fm. [Bauer, 1916] is same as his Zilhlejini fm., and that latter name is "from Dzilijini (black streak) mountain (coal beds), the Navajo name for Black Mesa."

Zimmerman sand.

A subsurface sand of Chester (Miss.) age in Ind. that has been correlated with Cypress ss.

Zion Hill quartzite.

Lower Cambrian: Eastern New York (Rensselaer County) and southwestern Vermont (Rutland County).

R. Ruedemann, 1914 (N. Y. State Mus. Bull. 169, pp. 69-70). *Zion Hill qtzite.*—The Ferruginous qtzite of [T. N.] Dale. Named for Zion Hill, Hubbardtown, Vt., [in Castleton quad.], where, according to Dale, it is exposed to thickness of 70 ft. Overlies Schodack shales and lss. Is top fm. of Lower Camb.

Zoar limestone. (In Pottsville formation.)

Pennsylvanian: Eastern Ohio.

J. S. Newberry, 1874 (Ohio Geol. Surv. vol. 2, pp. 133, 134, and pl. opp. p. 81). *Zoar ls.*, 2 to 6 ft. thick, lies in Lower Coal Measures, overlying coal No. 3.

E. Orton, 1878 (Ohio Geol. Surv. vol. 3, pp. 891-892). *Zoar ls.*—Black or dark-blue highly fossiliferous shaly ls., 10 in. to 10 ft. thick, lying 90 to 135 ft. above Maxville ls. and 160 ft. below Hanging Rock ls. Often replaced by flint. To N. and E. of Hanging Rock dist. separated, by an interval of 15 to 22 ft., into two courses called *Upper Zoar ls.* and *Lower Zoar ls.*, each capped with iron ore and underlain by a coal seam, the ores continuing after the lss. fail, the lower ore becoming known as Dresden, Junction City, and Union Furnace Block, and the upper ore as Main Block or Hocking Furnace ore.

Later repts state this is Lower Mercer ls. memb. of Pottsville fm.

Named for Zoar, Tuscarawas Co.

Zuckerman limestone member (of Hoxbar formation).

Pennsylvanian: Central southern Oklahoma (Carter County).

C. W. Tomlinson, 1928 (Okla. Geol. Surv. Bull. 40Z, p. 16). [See 1928 entry under *Daube memb.*]

C. W. Tomlinson, 1929 (Okla. Geol. Surv. Bull. 46, p. 46). *Zuckerman memb.*—Chiefly white to buff coarsely crystalline calc. ss., with a finer-grained layer at top and a local development of intraformational (?) cgl. of gray ls. pebbles up to ¼ in. diam. in a calc. matrix. Thickness 30± ft. Lies 400 to 500 ft. above Daube ls. Overlain by 500± ft. of beds belonging to Hoxbar fm. Named for same coal mine that Daube memb. is named for.

†Zuni sandstone.

Upper Jurassic: Northwestern New Mexico and northeastern Arizona.

C. E. Dutton, 1885 (U. S. G. S. 6th Ann. Rept., pl. 16, p. 137). *Zuni sss.*—Sss. and sandy shales, with occasional masses of gyp.; wonderfully banded; variegated colors. Thickness 800 to 1,300 ft. Underlies Dakota ss. and overlies Wingate sss. in Zuni Plateau, N. Mex.

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr. (U. S. G. S. P. P. 183, 1936, p. 43 and chart opp. p. 43), the Zuni ss. of Dutton (1885) and N. H. Darton (U. S. G. S. Santa Fe Ry Guidebook, 1915) is same as Morrison fm., the intervening Summerville, Curtis, Entrada, Carmel, Navajo, and Kayenta fms. being absent in Zuni Plateau.

†Zuni shale.

Upper Jurassic: Western New Mexico.

C. R. Keyes, 1905 (Am. Jour. Sci., 4th, vol. 20, p. 424). *Zuni shales*, 1,200 ft. thick, underlie Dakota sss. in western N. Mex. and overlie Wingate sss. Are correlated with Pyramid shales of eastern N. Mex. [Derivation of name not given.]

The rocks btw. the ss. that has been called Dakota ss. in NW. N. Mex. and the Wingate ss. are now designated *Morrison fm.* In SE. Utah, NE. Ariz., and parts of SW. Colo. 6 fms. intervene btw. the Morrison and the underlying Wingate, named (descending) Summerville, Curtis, Entrada, Carmel, Navajo, and Kayenta. (See U. S. G. S. P. P. 183, 1936, by A. A. Baker, C. H. Dane, and J. B. Reeside, Jr.)

†Zunian series.

Jurassic and possibly Triassic: Northwestern New Mexico and northeastern Arizona.

C. R. Keyes, 1906 (Sci., n. s., vol. 23, p. 921, and Am. Jour. Sci., 4th, vol. 21, pp. 298–300). *Zunian series.*—Shales and sss., 0 to 1,200 ft. thick, underlying Morrisonian series and overlying Shinarumpian series in N. Mex.

C. [R.] Keyes, 1922 (Pan-Am. Geol., vol. 38, p. 250). *Zunian series* in Ariz. is divided into (descending) McElmo, LaPlata, Todilto, and Wingate.

Keyes also applied his name *Zunian series* in other Western States.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 65, No. 4, May 1936, pp. 303, 306). *Zunian series* of SW. Colo., NW. N. Mex., and NE. Ariz. divided into (descending) McElmo shales, Lohali ss., Montezuma shales, and Arido ss. The latter 3 fms. correspond to LaPlata ss. of Cross.

C. [R.] Keyes, 1936 (Pan-Am. Geol., vol. 66, No. 1, pp. 71–72). *Lohali* is preoccupied and is here replaced with *Tyende ss.*

According to A. A. Baker, C. H. Dane, and J. B. Reeside, Jr., 1936 (U. S. G. S. P. P. 183, table opp. p. 37), the Zunian series of Keyes in Ariz. included the following fms. of U. S. G. S. classification (descending): Morrison fm., Summerville fm., Entrada ss., and Carmel fm., all of Upper Jurassic age; and the Navajo ss., Kayenta fm., and Wingate ss., all of Jurassic (?) age; and the upper 4 fms. are included in Keyes' McElmo and the lower 3 in his LaPlata.

Zwolle marl.

Upper Cretaceous: Northwestern Louisiana (Sabine County).

H. R. Kamb, 1931 (A. A. P. G. Bull., vol. 15, No. 10, p. 1293). The oil in Zwolle field has been regarded as coming from the so-called "Zwolle marl," overlying the chalk series proper, which latter, according to E. B. Hutson (oral communication) is probably Marlbrook and Annona in age. The marl probably represents the time interval from the Midway to the Marlbrook.

Zypsie sand.

A subsurface sand, of Penn. age and 0 to 20 ft. thick, in Cotton Co., Okla. Lies 205 to 230 ft. below top of Priddy sand.
